Fasting has always been reckoned a particular duty among philosophers and religious people, some of whom have carried their abstinence to an incredible length. At Rome it was practised by kings and emperors themselves. Numa Pompilius, Julius Cæsar, Augustus, Vespasian, and others, we are told, had their stated fast-days: and Julian the apostate was so exact in this observance as to outdo the priests themselves, and even the most rigid philosophers. The Pythagoreans kept a continual lent; but with this difference, that they believed the use of fish to be equally unlawful with that of flesh. Besides their constant temperance, they also frequently fasted rigidly for a very long time. In this respect, however, they were all outdone by their master Pythagoras, who continued his fasts for no less than 40 days together. Even Apollonius Tyaneus, one of his most famous disciples, could never come up to him in the length of his fasts, though they greatly exceeded those of the ordinary Pythagoreans. The gymnosophists, or brachmans of the east, are also very remarkable for their severe fastings; and the Chinese, according to father le Comte, have also their stated fasts, with forms of prayer for preserving them from barrenness, inundations, earthquakes, &c. The Mahometans too, who possess so large a part of Asia, are very remarkable for the strict observance of their fasts; and the exactness of their services in this respect is extraordinary.

Fasting was often used by the heathens for superstitious purposes; sometimes to procure the interpretations of dreams; at others, to be an antidote against their pernicious consequences. A piece of superstition prevails to this day among the Jews; who, tho' expressly forbid to fast on Sabbath-days, think themselves at liberty to dispense with this duty when they happen to have frightful and unlucky dreams the night preceding, that threatened them with great misfortunes. On these occasions they observe a formal fast the whole day; and at night the patient, having invited three of his friends, addresses himself to them seven times in a very solemn manner, saying, "May the dream I have had prove a lucky one!" And his friends answer as many times, "Amen, may it be lucky, and God make it so!" After which, in order to encourage him, they conclude the ceremony with these words of Ecclesiastes, "Go eat thy bread with joy;" and then set themselves down to table. They have also added several fasts not commanded in the law of Moses, particularly three, in memory of sore distresses their nation has suffered at different times; and some among them have kept an anniversary fast in memory of the translation of the Septuagint, in order to expiate the base compliance of their doctors for a foreign prince, and the outrage offered to the dignity of their law, which in their opinion was only given to the Jewish nation. The abstinence of the ancient Jews commonly lasted 27 or 28 hours at a time; beginning before sunset, and not ending till some hours after sunset next day. On these days they were obliged to wear
white

Fasting.

Fasting.

white robes in token of grief and repentance; to cover themselves with sackcloth, or their worst cloaths; to lie on ashes; to sprinkle them on their head, &c. Some spent the whole night and day following in the temple or synagogue, in prayers and other devotions, barefooted, with a scourge in their hands, of which they sometimes made a good use in order to raise their zeal. Lastly, in order to complete their abstinence, at night they were to eat nothing but a little bread dipped in water with some salt for seasoning; except they chose to add to their repast some bitter herbs and pulse.

The ancients, both Jews and Pagans, had also their fasts for purifying the body, particularly the priests and such as were any way employed at the altars; for when nocturnal disorders happened to these, it was unlawful for them to approach all the next day, which they were bound to employ in purifying themselves. On this account, at great festivals, where their ministry could not be dispensed with, it was usual for them, on the eve thereof, not only to fast, but also to abstain from sleep, for the greater certainty. For this purpose the high-priest had under-officers to wake him, if overtaken with sleep; against which other preservatives were also made use of.

Many wonderful stories have been told of extraordinary fasts kept by religious people; great numbers of which, undoubtedly, must be false. Others, however, we have on very good authority, of which some are mentioned under the article ABSTINENCE. Another we have in the

FASTING Woman. Of the many instances of extraordinary fasting mentioned by different authors, this seems to be one of the best authenticated. A full account of this very uncommon case is given in the Phil. Transf. Vol. LXVII. Part I. the substance of which follows. The woman, whose name was *Janet M'Leod*, an inhabitant in the parish of Kincardine in Rosshire, continued healthy till she was 15 years of age, when she had a pretty severe epileptic fit; after this she had an interval of health for four years, and then another epileptic fit which continued a whole day and a night. A few days afterwards she was seized with a fever, which continued with violence several weeks, and from which she did not perfectly recover for some months. At this time she lost the use of her eyelids; so that she was under a necessity of keeping them open with the fingers of one hand, whenever she wanted to look about her. In other respects she continued in pretty good health; only she never had any appearance of menses, but periodically spit up blood in pretty large quantities, and at the same time it flowed from the nose. This discharge continued several years; but at last it ceased; and soon after she had a third epileptic fit, and after that a fever from which she recovered very slowly. Six weeks after the crisis, she stole out of the house unknown to her parents, who were busied in their harvest-work, and bound the sheaves of a ridge before she was observed. In the evening she took to her bed, complaining much of her heart, (most probably her stomach, according to the phraseology of that country) and her head. From that time she never rose for five years, but was occasionally lifted out of bed. She seldom spoke a word, and took so little food that it seemed scarce sufficient to support a sucking infant.

VOL. IV.

Fasting.

Even this small quantity was taken by compulsion; and at last, about Whit Sunday 1763, she totally refused every kind of food or drink. Her jaw now became so fast locked, that it was with the greatest difficulty her father was able to open her teeth a little, in order to admit a small quantity of gruel or whey; but of this so much generally run out at the corners of her mouth, that they could not be sensible any had been swallowed. About this time they got some water from a noted medicinal spring in Brae-Mar, some of which they attempted to make her swallow, but without effect. They continued their trials, however, for three mornings; rubbing her throat with the water, which run out at the corners of her mouth. On the third morning during the operation, she cried out "Give me more water;" and swallowed with ease all that remained in the bottle. She spoke no more intelligibly for a year; though she continued to mutter some words which her parents only understood, for 14 days. She continued to reject all kinds of food and drink till July 1765. At this time her sister thought, by some signs she made, that she wanted her jaws opened; and this being done, not without violence, she called intelligibly for a drink, and drank with ease about an English pint of water. Her father then asked her why she would not make some signs when she wanted a drink; to which she answered, why should she, when she had no desire. It was now supposed that she had regained the faculty of speech; and her jaws were kept open for about three weeks, by means of a wedge. But in four or five days she became totally silent, and the wedge was removed because it made her lips sore. She still, however, continued sensible; and when her eyelids were opened, knew every body, as could be guessed from the signs she made.

By continuing their attempts to force open her jaws, two of the under foreteeth were driven out; and of this opening her parents endeavoured to avail themselves by putting some thin nourishing drink into her mouth; but without effect, as it always returned by the corners. Sometimes they thought of thrusting a little dough of oatmeal through this gap of the teeth, which she would retain a few seconds, and then return with something like a straining to vomit, without one particle going down. Nor were the family sensible of any thing like swallowing for four years, excepting the small draught of Brae-Mar water, and the English pint of common water. For the last three years she had not any evacuation by stool or urine, except that once or twice a-week she passed a few drops of urine, about as much, to use the expression of her parents, as would wet the surface of a halfpenny. In this situation she was visited by Dr Mackenzie, who communicated the account of her case to the royal society. He found her not at all emaciated; her knees were bent, and the hamstrings tight, so that her heels almost touched her buttocks. She slept much, and was very quiet; but when awake, kept a constant whimpering like a newborn weakly infant. She never could remain a moment on her back, but always fell to one side or another; and her chin was clapped close to her breast, nor could it by any force be moved backwards.

The doctor paid his first visit in the month of October; and five years afterwards, viz. in October 1772, was induced to pay her a second visit, by hearing that

Fasting
||
Fat.

she was recovering, and had begun to eat and drink. The account given him was most extraordinary. Her parents one day returning from their country-labours (having left their daughter fixed to her bed as usual), were greatly surprised to find her sitting upon her hams, on the side of the house opposite to her bed-place, spinning with her mother's distaff. All the food she took at that time was only to crumble a little oat or barley cake in the palm of her hand, as if to feed a chicken. She put little crumbs of this into the gap of her teeth; rolled them about for some time in her mouth; and then sucked out of the palm of her hand a little water, whey, or milk; and this only once or twice a-day, and even that by compulsion. She never attempted to speak; her jaws were fast locked, and her eyes shut. On opening her eye-lids, the balls were found to be turned up under the edge of the os frontis; her countenance was ghastly, her complexion pale, and her whole person emaciated. She seemed sensible and tractable in every thing except in taking food. This she did with the utmost reluctance, and even cried before she yielded; and at last only took a few crumbs as if to feed a bird, and sucked half a spoonful of milk from the palm of her hand. The great change of her looks, Doctor Mackenzie attributed to her spinning flax on the distaff, which exhausted too much of the saliva; and therefore he recommended to her parents to confine her totally to the spinning of wool.—In 1775 she was visited again, and found to be greatly improved in her looks, as well as strength; her food was also considerably increased in quantity, though even then she did not take more than would be sufficient to sustain an infant of two years of age.

FASTI, in Roman antiquity, the kalendar wherein were expressed the several days of the year, with their feasts, games, and other ceremonies.

There were two sorts of fasti, the greater and less; the former being distinguished by the appellation *fasti magistralis*, and the latter by that of *fasti calendares*.

The greater fasti contained the feasts, with every thing relating to religion and the magistrates.

The lesser were again distinguished into the city and country fasti, each adapted to the people for whom they were designed. In all these fasti, the court-days, or those whereon causes might be heard and determined, were marked with the letter F; these days were called *fasti*, from *fari*, to speak or pronounce; and the other days, not marked with this letter, were called *nefasti*.

FASTOLF (Sir John), a valiant and renowned English officer, a knight-banneret and of the garter, who served in France under Henry IV. V. and VI. was descended from an ancient family in Norfolk, and was born about the year 1377. He was as much distinguished for his virtue at home, as for his valour abroad; and became no less amiable in his private, than he had been admirable in his public character. He died in 1459, upwards of 80 years of age, as we learn from his noted cotemporary William Caxton the first English printer. By an unaccountable mistake it has been asserted, that Shakespeare's Falstaff was drawn to ridicule this great man; and this has made judicious biographers more studious to preserve his reputation.

FAT, in anatomy, an oily concrete substance depo-

sited in different parts of animal bodies*.

Strong exercise, preternatural heat, an acrimonious state of the juices, and other like causes, by which the oily parts of the blood are attenuated, resolved, or evacuated, prevent the generation of fat: labours of the mind also have this effect, as well as labour or intemperature of the body. Hence rest and plentiful food are sufficient to fatten brutes; but with men it is often otherwise. It is surprising how soon some birds grow fat; ortolans in 24 hours, and larks still sooner.

Fats may be divided, from their consistence, into three kinds: (1.) The soft and thin, which grow perfectly liquid in a very small heat. (2.) The thick and consistent, which liquify less readily; and, (3.) The hard and firm, which require a still stronger heat to melt them. The first is called *Pinguedo*; the second, *Auxungia*; and the third, *Adeps*, as taken from the animal; and *Sebum*, or *Secum*, when freed from the skins, &c. This use of the names, however, is not constant, some employing them differently.

A great number of fats have been kept in the shops, for making ointments, plasters, and other medicinal compositions; as hogs-lard, the fat of the boar, the fox, the hare, dog, wild cat, Alpine mouse, beaver; that of hens, ducks, geese, storks; of the whale, pike, serpents, viper, &c. as also human fat.—In regard to all these kind of substances, however, much depends upon the manner of purifying or trying, and of keeping them.

To obtain fat pure, it must be cut into pieces, and cleaned from the interposed membranes and vessels. It must then be cleaned from its gelatinous matter by washing with water, till the water comes from it colourless and insipid; it is afterwards to be melted with a moderate heat in a proper vessel with a little water; and it is to be kept thus melted till the water be entirely evaporated, which is known by the discontinuance of the boiling, which is caused by the water only, and which lasts till not a drop of it remains: it is afterwards to be put into an earthen pot, where it fixes; then it is exceedingly white, sufficiently pure for the purposes of pharmacy or chemical examination.

Fat thus purified has very little taste, and a weak, but peculiar, smell.

Mineral acids exhibit the same phenomena with fat, as they do with the fixed sweet oils of vegetables, which contain nothing gummy or resinous, and which do not dry. Such is the oil of ben, oil of olives, and all those which chemists call *fat oils*.

Alkalis dissolve fat, as they do these oils, and form a similar soap. Fat contains no principle so volatile as to be raised with the heat of boiling water. It does not inflame, but when heated in open air so as to rise in vapours. Lastly, by age it contracts an acrid and rancid quality.

When fat is distilled with a heat superior to that of boiling water, which must therefore be done in a retort and in a naked fire, first an acid phlegm arises, and a small portion of oil which remains fluid. As the distillation continues, the acid becomes stronger, and the oil thicker, and at last it congeals in the receiver. No other principle arises during this distillation: and, lastly, when the retort is red, nothing remains but a very small quantity of that kind of coal which cannot be burnt without very great difficulty. See **COAL**.

Fat.

* See *Anatom.*
temy, 1082.

Fat.

If the congealed oil which is found in the receiver be again distilled, more acid is obtained, and an oil which does not congeal; and thus, by repeating the distillations, the oil is more and more attenuated. While it is thus deprived of its acid, it acquires a more and more penetrating smell; and thus, by distillation alone, it may be rendered as volatile as essential oils, and capable of rising with the heat of boiling water.

Fat, and all other analogous oily matters, cannot be heated sufficiently to be raised into vapours, without suffering a considerable alteration, and even decomposition. The vapours which rise from it, when heated in open air, are the same as those which rise when distilled in close vessels. They consist of acid and attenuated oil. This acid is remarkably penetrating, acrid, and volatile; it irritates and inflames the eyes, the throat, and lungs; it makes the eyes shed tears, and excites a cough as much as volatile sulphureous acid does, although its nature be very different.

When fat is in its natural state, and has not yet suffered any alteration, its acid is so well combined with its oily part, that none of its properties can be perceived. Thus fat, in good condition, is very mild, and used successfully in medicine, particularly externally, for its lenient quality: but, notwithstanding its great mildness, before it has been heated sufficiently to decompose it, and while it is yet fresh, it becomes exceedingly acrid, irritating, and caustic, when its acid is partly disengaged by fire or by time.

When fat is become very rancid, not only its medicinal effects, but also many of its essential properties, are totally changed, particularly its property of resisting the action of spirit of wine: for this menstruum, which does not affect pure and unchanged fat, dissolves some portion of fat which has been strongly heated, or which has become rancid. This effect can certainly proceed from no other cause, than that the acid of the fat disengages itself in both these cases. Mr de Machy, an intelligent apothecary of Paris, and an able chemist and observer, has made a remark upon this subject which corresponds with this opinion; which is, that all the rancidity of fat may be taken from it by treating it with spirit of wine. Now, this evidently happens, because the spirit of wine dissolves all the portion of fat which is disengaged from its acid; that is, all the rancid part, while it does not touch that which is not changed. This practice may be advantageously employed for the preservation or recovery of some fats used in medicine, but which are rare, and not to be procured in their recent state.

One of the chief uses of fat probably is, to receive into its composition, to blunt and correct, a great part of the acids of the aliments, and which are more than are requisite to the composition of the nutritive juice, or which nature could not otherwise expel. This is certain, that the greater the quantity of aliments is taken by healthy animals above what is necessary for their nourishment and reproduction, the fatter they become. Hence animals which are castrated, which are not much exercised, or which are come to an age when the loss and production of the seminal fluid is less, and which at the same time consume much succulent aliment, generally become fatter, and sometimes exceedingly so.

Although fat be very different from truly animalized

substances, and appears not easily convertible into nutritive juices, it being generally difficult of digestion, and apt to become rancid, as butter does in the stomachs of many persons; yet in certain cases it serves to the nourishment and reparation of the body. Animals certainly become lean, and live upon their fat, when they have too little food, and when they have diseases which prevent digestion and the production of the nutritive juice; and in these cases the fatter animals hold out longer than the leaner. The fat appears to be then absorbed by the vessels designed for this use, and to be transformed into nutritive juice.

Fat, in the sea-language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the trussing-in or tuck of her quarter be deep.

Fat is used also for several utensils; as, 1. A great wooden vessel, employed for the measuring of malt, and containing a quarter or eight bushels. 2. A large brewing vessel, used by brewers to run their wort in. 3. A leaden pan or vessel for the making of salt at Droitwich.

Fat likewise denotes an uncertain measure of capacity. Thus a fat of singglass contains from $3\frac{1}{2}$ hundred weight to 4 hundred weight; a fat of unbound books, half a maund or four bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

FATE, *fatum*, denotes an inevitable necessity depending upon a superior cause. The word is formed a *sando*, from "speaking;" and primarily implies the same with *effatum*, viz. a word or decree pronounced by God; or a fixed sentence whereby the Deity has prescribed the order of things, and allotted to every person what shall befall him.

The Greeks called it *anagkai*, as it were a chain or necessary series of things indissolubly linked together. It is also used to express a certain unavoidable designation of things, by which all agents, both necessary and voluntary, are swayed and directed to their ends. See NECESSITY.

In this last sense, fate is distinguished into, 1. Astrological, arising from the influence and position of the heavenly bodies; which (it is supposed) give laws both to the elements and mixed bodies, and to the wills of men. 2. Stoical fate, defined by Cicero an order or series of causes, wherein, cause being linked to cause, each produces another, and thus all things flow from one prime cause. To this fate the Stoics subject even the gods.

Fate is divided by later authors into physical and divine. 1. Physical fate is an order and series of natural causes appropriated to their effects. By this fate it is that fire warms, bodies communicate motion to each other, &c. and the effects of it are all the events and phenomena of nature. See NATURE. 2. Divine fate is what is more usually called *Providence*. See PROVIDENCE.

FATES, in mythology. See PARCÆ.

FATHEMITES, FATEMITES, or FATHIMITES, the descendants of Mahomet by Fathema, or Fatima, his daughter. They never enjoyed the khalifat of Mecca or Bagdad, but reigned in Barbary and Egypt. See the history of these countries.

FATHER, a term of relation denoting a person who hath begot a child. See PARENT and CHILD.

Fat.
Father.

Father
Faunalia.

By the laws of Romulus, a father had an unlimited power over his children. Amongst the Lacedæmonians, as we learn from Aristotle's politics, the father of three children was excused from the duty of mounting guard for the security of the city; and a father of four children, was exempted from every public burden. The Poppæan law amongst the Romans, granted many valuable privileges to the fathers of three children; amongst which one was, that he should be excused from civil offices, and that the mother should have liberty, in her father's life-time, to make a will, and manage her estate without the authority of tutors.

Natural FATHER, is he who has illegitimate children. See *BASTARD*; and *LAW*, N° clxi. 33. clxxxii. 3, 4.

FATHER, in theology, is used in speaking of the First Person of the *TRINITY*.

FATHER, is also used in speaking of spiritual and moral things. Thus, Abraham is called the "*father of the faithful*."

FATHER, in church-history, is applied to ancient authors who have preserved in their writings the traditions of the church. Thus St Chrysostom, St Basil, &c. are called *Greek fathers*, and St Augustine and St Ambrose *Latin fathers*. No author who wrote later than the 12th century is dignified with the title of *Father*.

FATHER, is also a title of honour given to prelates and dignitaries of the church, to the superiors of convents, to congregations of ecclesiastics, and to persons venerable for their age or quality. Thus we say, the right reverend father in God, the father-general of the Benedicines, the fathers of the council of Nice, father of his country, &c.

FATHERLASHER, in ichthyology. See *CORPUS*.

FATHOM, a long measure containing six feet, used chiefly at sea for measuring the length of cables and cordage.

FATNESS. See *CORPULENCY*.—It is observed, that for one fat person in France or Spain, there are an hundred in England and Holland. This is supposed to be from the use of new malt liquors, more than from the difference of climates or degrees of perspiration. Indolence may cause fatness in some few constitutions; but, in general, those who are disposed to this habit will be fat in spite of every endeavour to the contrary, but that of destroying health.

FATUARI, in antiquity, were persons, who, appearing inspired, foretold things to come. The word is formed of *Fatua*, wife of the god Faunus, who was supposed to inspire women with the knowledge of futurity, as Faunus himself did the men.—*Fatua* had her name from *fari*, q. d. *vaticinari*, "to prophesy."

FATUUS IGNIS, in physiology, a meteor otherwise called *Will-with-a-wisp*. See that article.

FAVISSÆ, in antiquity, were, according to Festus and Gellius, cisterns to keep water in: but the faviæ in the Capitol at Rome were dry cisterns or subterraneous cellars, where they laid up the old statues, broken vessels, and other things used in the temple. There were much the same with what, in some of the modern churches, are called the *archives* and *treasury*.

FAUNALIA, in Roman antiquity, three annual

festivals in honour of the god Faunus; the first of which was observed on the ides of February, the second on the 16th of the calends of March, and the third on the nones of December. The principal sacrifices on this occasion were lambs and kids. Faunus was a deity of the Romans only, being wholly unknown to the Greeks.

FAUNS, a kind of rural deities, among the ancient Romans. See *FAUNUS*.

FAUNUS, in fabulous history, was king of the Aborigines, or country of the Latins, and succeeded his father Picus, about 1220 B. C. He is said to have instituted a great number of religious ceremonies, and to have kept himself almost always concealed, on which account he was confounded with the god Pan. His children called *Fauni*, or *Fauns*, were visionary beings, much like the satyrs, and were usually crowned with pine; but both Faunus and they were only worshipped in Italy, and were wholly unknown to the Greeks.

FAVORINUS, an ancient orator and philosopher of Gaul, who flourished under the emperor Adrian, and taught with high reputation both at Athens and Rome. Many works are attributed to him; among the rest, a Greek miscellaneous history often quoted by Diogenes Laertius.

FAUSTUS. See *FUST*.

FAWN, among sportsmen, a buck or doe of the first year; or the young one of the buck's breed in its first year.

FE, *fo*, or *Febi*, the name of the chief god of the Chinese, whom they adore as the sovereign of heaven. They represent him shining all in light, with his hands hid under his robes, to shew that his power does all things invisibly. He has at his right-hand the famous Confucius, and at his left Lanza or Lanza, chief of the second sect of their religion.

FEALTY, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land: by this oath the tenant holds in the freest manner, on account that all who have fee hold *per fidem et fiduciam*, that is, by fealty at the least.

This fealty, at the first creation of it, bound the tenant to fidelity, the breach of which was the loss of his fee. It has been divided into general and special: general, that which is to be performed by every subject to his prince; and special, required only of such as, in respect of their fee, are tied by oath to their lords. To all manner of tenures, except tenancy at will, and frank-almoign, fealty is incident, though it chiefly belongs to copyhold estates held in fee and for life. The form of this oath by stat. 17 Edw. II. is to run as follows. "I A. B. will be to you my lord D. true and faithful, and bear to you faith for the lands and tenements which I hold of you; and I will truly do and perform the customs and services that I ought to do to you. So help me God."

FEAR, one of the passions of the human mind. See *PASSION*.

FEAR (*Metus*, *Pavor*, or *Timor*), was deified by the Pagans. Tullus Hostilius brought the worship of this deity to Rome. The Ephori of Sparta erected a temple to Fear, near their tribunal, to strike an awe into those who approached it. Fear was likewise worshipped at Corinth. The poets did not forget this

Fauns
Fear.

Feast.
Feather.

imaginary deity. Virgil places her in the entrance of hell, in company with diseases, old age, &c. *Æn.* vi. 273.—Ovid places her in the retinue of Tisiphone one of the furies, *Mét.* iv. 483.

FEAST, or FESTIVAL, in a religious sense, is a day of feasting and thanksgiving.

Among the ancients, feasts were instituted upon various accounts, but especially in memory of some favourable interposition of Providence. Thus, the Jews had their feast of passover, pentecost, and tabernacles; the Greeks their cerialia, panathæna, &c. and the Romans their saturnalia, ambarvalia, &c. See PASSOVER, CEREALIA, &c.

In the ancient Christian church, besides the high festivals of Christmas, Easter, Pentecost, Annunciation, &c. there were others instituted in honour of the apostles and martyrs: all which are retained by the church of England. See the articles CHRISTMAS, EASTER, &c. In the church of Rome, there are double, half-double, and simple feasts almost without number. The name of *double feasts* is given to such whose service is fuller and more solemn than the rest, which likewise constitutes the difference between the others; the churches being embellished, and the altars adorned, according to the rank which each saint holds in his respective church. All high festivals have an octave, consisting of the feast itself, and the seven following days.

In Italy, certain festivals are celebrated solely by lovers. When a lover wants to give his mistress the highest testimony of his gallantry, he immediately makes her the idol of his devotion; procuring vespers, and even masses, to be said to her honour. For this purpose he makes choice of the festival of some saint whose name she bears; and though the saint has the same name, they manage matters so, that the devotion of the festival is plainly relative to the lover's mistress.

The four quarterly feasts, or stated times, whereon rent on leases is usually reserved to be paid, are Lady-day, or the annunciation of the blessed virgin Mary, or 25th of March; the nativity of St John the Baptist, held on the 24th of June; the feast of St Michael the arch-angel, on the 29th of September; and Christmas, or rather of St Thomas the apostle, on the 21st of December. See ANNUNCIATION, &c.

FEATHER, in physiology, a general name for the covering of birds; it being common to all the animals of this class to have their whole body, or at least the greatest part of it, covered with feathers or plumage.

Feathers make a considerable article of commerce. Those from Somersetshire are esteemed the best, and those from Ireland the worst.—Eider down is imported from Denmark, the ducks that supply it being inhabitants of Hudson's bay, Greenland, Ireland, and Norway. Our own Islands west of Scotland breed numbers of these birds, and might turn out a profitable branch of trade to the poor inhabitants. Hudson's bay also furnishes very fine feathers, supposed to be of the goose kind. The down of the swan is brought from Dantzic. The same place also sends us great quantities of the feathers of the cock and hen. The London poulterers sell a great quantity of the feathers of those birds, and of ducks and turkeys: those of

ducks being a weaker feather, are inferior to those of the goose; and turkeys feathers are the worst of any. The best method of curing feathers is to lay them in a room, in an exposure to the sun; and when dried, to put them in bags, and beat them well with poles to get the dirt off.

FEBRIFUGE, an appellation given to such medicines as mitigate or remove a fever.

FEBRUARY, in chronology, the second month of the year, reckoning from January, first added to the calendar of Romulus by Numa Pompilius.

February derives its name from *Februa*, a feast held by the Romans in this month, in behalf of the manes of the deceased; at which ceremony sacrifices were performed, and the last offices were paid to the shades of the deceased.

February, in a common year, consists only of 28 days; but in the bissextile year, it has 29, on account of the intercalary day added that year.

FECIALES, or FOECIALES, a college of priests instituted at Rome by Numa, consisting of 30 persons, selected out of the best families. Their business was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith. It is probable that they were ranked among the officers of religion, to procure them the more deference and authority, and to render their persons more sacred among the people. If the commonwealth had received any injury from a foreign state, they immediately dispatched these officers to demand satisfaction, who, if they could not procure it, were to attest the gods against that people and country, and to denounce war: otherwise they confirmed the alliance, or contracted a new one, which they ratified by sacrificing a hog.

FECUNDITY, the same with FERTILITY.

FEE, in law, signifies a complete feudal property. Hence, where the bare liferent of any feudal subject is meant to be conveyed to A, and the absolute property to B, that meaning is expressed thus; "to A in liferent, and to B in fee." See LAW, N° lxxix. clxiv.

Fees are commonly divided into *absolute*, otherwise called fees-simple; and *limited*, one species of which we usually call fee-tail.

I. Tenant in fee-simple (or, as he is frequently styled, *tenant in fee*) is that he hath lands, tenements, or hereditaments, to hold to him and his heirs for ever; generally, absolutely, and simply; without mentioning what heirs, but referring that to his own pleasure, or to the disposition of the law. The true meaning of the word fee (*feodum*) is the same with that of *feud* or *fief*,* and in its original sense it is taken in contradistinction to *allodium*; which latter the writers on this subject define to be every man's own land, which he possesseth merely in his own right, without owing any rent or service to any superior. This is property in its highest degree; and the owner thereof hath *absolutum et directum dominium*, and therefore is said to be seised thereof absolutely in *dominio suo*, in his own demesne. But *feodum*, or *fee*, is that which is held of some superior, on condition of rendering him service: in which superior the ultimate property of the land resides. And therefore Sir Henry Spelman defines a feud or fee to be, The right which the vassal or tenant hath in lands to use the same, and take the profits thereof to him

Fee.

Blackf.
Comment.

* See Feoda,
Syltem.

and his heirs, rendering to the lord his due services; the mere allodial property of the soil always remaining in the lord. This allodial property no subject in Britain has; it being a received and now undeniable principle in the law, that all the lands are holden mediately or immediately of the king. The king therefore only hath *absolutum et directum dominium*; but all subjects lands are in the nature of *feodum* or *fee*, whether derived to them by descent from their ancestors, or purchased for a valuable consideration: for they cannot come to any man by either of those ways, unless accompanied with those feudal clogs which were laid upon the first feudatory when it was originally granted. A subject therefore hath only the usufruct, and not the absolute property, of the soil; or, as Sir Edward Coke expresses it, he hath *dominium utile*, but not *dominium directum*. And hence it is that, in the most solemn acts of law, we express the strongest and highest estate that any subject can have, by these words, "he is seised thereof in his demesne, as of fee." It is a man's demesne, *dominium*, or property, since it belongs to him and his heirs for ever: yet this *dominium*, property, or demesne, is strictly not absolute or allodial, but qualified or feudal: it is in his demesne, *as of fee*; that is, it is not purely and simply his own, since it is held of a superior lord, in whom the ultimate property resides.

This is the primary sense and acceptation of the word *fee*. But (as Sir Martin Wright very justly observes) the doctrine, "that all lands are *holden*," having been for so many ages a fixed and undeniable axiom, the English lawyers do very rarely (of late years especially) use the word *fee* in its primary original sense, in contradistinction to *allodium* or absolute property, with which they have no concern; but generally use it to express the continuance or quantity of estate. A *fee* therefore, in general, signifies an estate of inheritance; being the highest and most extensive interest that a man can have in a feud: and, when the term is used simply, without any other adjunct, or has the adjunct of *simple* annexed to it, (as, a *fee*, or a *fee-simple*) it is used in contradistinction to a *fee conditional* at the common law, or a *fee-tail* by the statute; importing an absolute inheritance, clear of any condition, limitation, or restrictions to particular heirs, but descendible to the heirs-general, whether male or female, lineal or collateral. And in no other sense than this is the king said to be seised in *fee*, he being the feudatory of no man.

Taking therefore *fee* in its its secondary sense, as a state of inheritance, it is applicable to, and may be had in, any kind of hereditaments either corporeal or incorporeal. But there is this distinction between the two species of hereditaments; that, of a corporeal inheritance a man shall be said to be seised in his demesne, *as of fee*; of an incorporeal one he shall only be said to be seised *as of fee*, and not in his demesne. For, as incorporeal hereditaments are in their nature collateral to, and issue out of, lands and houses, their owner hath no property, *dominium*, or demesne, in the thing itself, but hath only something derived out of it; resembling the *servitudes*, or services, of the civil law. The *dominium*, or property, is frequently in one man, while the appendage or service is in another. Thus Gaius may be seised *as of fee*, of a way going over the land, of

which Titius is seised in his demesne *as of fee*.

The *fee-simple* or inheritance of lands and tenements is generally vested and resides in some person or other; though divers inferior estates may be carved out of it. As if one grants a lease for 21 years, or for one or two lives, the *fee-simple* remains vested in him and his heirs; and after the determination of those years or lives, the land reverts to the grantor or his heirs, who shall hold it again in *fee-simple*. Yet sometimes the *fee* may be in *abeyance*, that is (as the word signifies) in expectation, remembrance, and contemplation in law; there being no person *in esse*, in whom it can vest and abide: though the law considers it as always potentially existing, and ready to vest whenever a proper owner appears. Thus, in a grant to John for life, and afterwards to the heirs of Richard, the inheritance is plainly neither granted to John nor Richard, nor can it vest in the heirs of Richard till his death, *nam nemo est heres viventis*: it remains therefore in waiting, or *abeyance*, during the life of Richard. This is likewise always the case of a parson of a church, who hath only an estate therein for the term of his life; and the inheritance remains in *abeyance*. And not only the *fee*, but the freehold also, may be in *abeyance*; as, when a parson dies, the freehold of his glebe is in *abeyance* until a successor be named, and then it vests in the successor.

The word, *heirs*, is necessary in the grant or donation in order to make a *fee* or inheritance. For if land be given to a man for ever, or to him and his assigns for ever, this vests in him but an estate for life. This very great nicety about the insertion of the word *heirs* in all feoffments and grants, in order to vest a *fee*, is plainly a relic of the feudal strictness: by which it was required, that the form of the donation should be punctually pursued; or that, as Craig expresses it, in the words of Baldus, "*donationes sunt stricti juris*," "*ne quis plus donasse presumatur quam in donatione expresserit*." And therefore, as the personal abilities of the donee were originally supposed to be the only inducements to the gift, the donee's estate in the land extended only to his own person, and subsisted no longer than his life; unless the donor, by an express provision in the grant, gave it a longer continuance, and extended it also to his heirs. But this rule is now softened by many exceptions.

For, 1. It does not extend to devises by will; in which, as they were introduced at the time when the feudal rigour was apace wearing out, a more liberal construction is allowed: and therefore by a devise to a man for ever, or to one and his assigns for ever, or to one in *fee-simple*, the devisee hath an estate of inheritance; for the intention of the deviser is sufficiently plain from the words of perpetuity annexed, though he hath omitted the legal words of inheritance. But if the devise be to a man and his assigns, without annexing words of perpetuity, there the devisee shall take only an estate for life; for it does not appear that the deviser intended any more. 2. Neither does this rule extend to fines or recoveries, considered as a species of conveyance; for thereby an estate in *fee* passes by act and operation of law without the word *heirs*: as it does also, for particular reasons, by certain other methods of conveyance, which have relation to a former grant or estate, wherein the word *heirs* was expressed. 3. In crea-

FEE.

creations of nobility by writ, the peer so created hath an inheritance in his title, without expressing the word *heirs*; for they are implied in the creation, unless it be otherwise specially provided: but in creations by patent, which are *stricti juris*, the word *heirs* must be inserted, otherwise there is no inheritance: 4. In grants of lands to sole corporations and their successors, the word *successors* supplies the place of *heirs*; for as heirs take from the ancestor, so doth the successor from the predecessor. Nay, in a grant to a bishop, or other sole spiritual corporation, in *frankalmoin*; the word *frankalmoin* supplies the place of *successors* (as the word *successors* supplies the place of *heirs*) *ex vi termini*; and in all these cases a fee-simple vests in such sole corporation. But, in a grant of lands to a corporation aggregate, the word *successors* is not necessary, though usually inserted: for, albeit such simple grant be strictly only an estate for life, yet as that corporation never dies, such estate for life is perpetual, or equivalent to a fee-simple, and therefore the law allows it to be one. Lastly, in the case of the king, a fee-simple will vest in him, without the word *heirs* or *successors* in the grant; partly from prerogative royal, and partly from a reason similar to the last, because the king, in judgment of law, never dies. But the general rule is, that the word *heirs* is necessary to create an estate of inheritance.

II. We are next to consider limited fees, or such estates of inheritance as are clogged and confined with conditions or qualifications of any sort. And these we may divide into two sorts: 1. *Qualified, or base fees*; and, 2. *Fees conditional*, so called at the common law; and afterwards *fees-tail*, in consequence of the Statute *de donis*.

1. A *base*, or qualified, fee is such a one as has a qualification subjoined thereto, and which must be determined whenever the qualification annexed to it is at an end. As, in the case of a grant to A and his heirs, tenants in the manor of Dale; in this instance, whenever the heirs of A cease to be tenants of that manor, the grant is entirely defeated. So, when Henry VI. granted to John Talbot, lord of the manor of Kingston-Lisle in Berks, that he and his heirs, lords of the said manor, should be peers of the realm, by the title of *barons of Lisle*; here John Talbot had a base or qualified fee in that dignity; and the instant he or his heirs quitted the seignory of this manor, the dignity was at an end. This estate is a fee, because by possibility it may endure for ever in a man and his heirs; yet as that duration depends upon the concurrence of collateral circumstances, which qualify and debase the purity of the donation, it is therefore a qualified or base fee.

2. As to *fees-conditional*, or *fees-tail*, see the article *TAIL*.

FEE also signifies a certain allowance to physicians, barristers, attorneys, and other officers, as a reward for their pains and labour.

If a person refuse to pay an officer his due fees, the court will grant an attachment against him, to be committed till the fees are paid; and an attorney may bring an action of the case for his fees, against the client that retained him in his cause.

FEE also denotes a settle perquisite of public officers, payable by those who employ them.

Feetors

Feix.

The fees due to the officers of the custom-house, are expressly mentioned in a schedule, or table, which is hung up in public view in the said office, and in all other places where the said fees are to be paid or received. And, if any officer shall offend, by acting contrary to the regulations therein contained, he shall forfeit his office and place, and be for ever after incapable of any office in the custom-house.

The other public offices have likewise their settled fees, for the several branches of business transacted in them.

FEE-FARM, a kind of tenure without homage, fealty, or other service, except that mentioned in the feoffment; which is usually the full rent, or at least a fourth part of it.

The nature of this tenure is, that if the rent be behind, and unpaid for two years, then the feoffor and his heirs may have an action for the recovery of the lands.

FEELERS, in natural history, a name used by some for the horns of insects.

FEELING, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities. See *ANATOMY*, n° 408.

FEET. See *Foot*.

FEET, in Poetry. See *POETRY*, n° 117, 175.

FEINT, in fencing, a shew of making a thrust at one part, in order to deceive the enemy, that you may really strike him in another.

A *simple feint* is a mere motion of the wrist, without stirring the foot.

FELAPTON, in logic, one of the six first modes of the third figure of syllogisms; whereof the first proposition is an universal negative, the second an universal affirmative, and the third a particular negative.

FELIÈN (Audre), was born at Chartres in 1619, and went secretary under the marquis de Fontenay-Mareuil ambassador to the court of Rome in 1647. On his return, M. Colbert procured him the places of historiographer to the king, superintendent of his buildings, and of the arts and manufactures in France. He became afterwards deputy comptroller-general of the bridges and dykes in that kingdom; and died in 1695. He wrote several pieces relating to the fine arts, the principal of which is his "Dialogues on the lives and works of the most eminent painters."

FELICITAS, (*FELICITY*, or *HAPPINESS*), was deified by the ancient Pagans. Lucullus built a temple to her. She had another erected by Lepidus. The Greeks paid divine worship to *Macaria*, daughter of Hercules, the same with *Felicitas*. This deity is often pictured upon medals, and generally with a Cornucopia in one hand and a Caduceus in the other. The inscriptions are, *Felicitas Temporum*, *Felicitas Augusti*, *Felicitas Publica*, &c.

FELIX, proconsul, and governor of Judæa in the first century, was brother to Pallas the freedman of the emperor Claudius. He arrived in Judæa about the year 53, when he conceived a violent passion for Drusilla the daughter of Agrippa and wife of Azizæ, and married her. For this reason St Paul, on his speaking before him, discoursed of chastity and the judgment to come with such energy, that Felix trembled. Some time after, Nero recalled him on account of his ill conduct, and sent Portius Festus to succeed him.

FELIX

Felis.

Felis.

FELIX (Minutius), a father of the primitive church, who flourished about the beginning of the third century. He was an African by birth, and a lawyer by profession; and has written a very elegant dialogue in defence of the Christian religion, intitled *Octavius*, from the name of the principal speaker. This work was long attributed to Arnobius; but was ascribed to the genuine author by Balduinus, a celebrated lawyer, in his edition of 1560 printed at Heidelberg. The best edition of it is that at Cambridge, in 1712, by Dr Davis.

FELIS, the CAT, a genus of quadrupeds belonging to the order of feræ, the characters of which are these: The fore-teeth are equal; the molares or grinders have three points; the tongue is furnished with rough sharp prickles, and pointing backwards; and the claws are sheathed, and retractile. This genus comprehends seven genera, viz.

1. The *Leo*, or LION. The largest lions are from eight to nine feet in length, and from four to six feet high: those of a smaller size are generally about 5½ feet long, and about 3½ high. His head is very thick, and his face is beset on all sides with long bushy yellowish hair; this shaggy hair extends from the top of the head to below the shoulders, and hangs down to his knees: the belly and breast are likewise covered with long hair. The rest of the body is covered with very short hair, excepting a bush at the point of the tail. The ears are roundish, short, and almost entirely concealed under the hair of his front. The shagginess of the fore-part of his body makes the hinder part have a naked appearance. The tail is long and very strong; the legs are thick and fleshy; and the feet are short; the length of the claws is about an inch and a quarter, are of a whitish colour, very crooked, and can be extended or retracted into the membranous sheath at pleasure: their points are seldom blunted, as they are never extended but when he seizes his prey.

The female, or lioness, has no mane, or long hair about her head or shoulders; in her we see distinctly the whole face, head, ears, neck, shoulders, breast, &c. all these parts being in some measure concealed under the long hair of the male, give the female a very different appearance: besides, she is considerably less than the male. The hair of both male and female is of a yellowish colour, and whitish on the sides and belly.

In warm countries, quadrupeds in general are larger and stronger than in the cold or temperate climates. They are likewise more fierce and hardy; all their natural qualities seem to correspond with the ardour of the climate. The lions nourished under the scorching sun of Africa or the Indies, are the most strong, fierce, and terrible. Those of mount Atlas, whose top is sometimes covered with snow, are neither so strong nor so ferocious as those of Biledulgerid or Zaara, whose plains are covered with burning sand. It is in these hot and barren deserts, that the lion is the dread of travellers, and the scourge of the neighbouring provinces. But it is a happy circumstance that the species is not very numerous: they even appear to diminish daily. The Romans, says Mr Shaw, brought many more lions out of Libya for their public shows, than are now to be found in that country. It is likewise remarked, that the lions in Turkey, Persia, and the Indies, are less numerous than formerly. As this formi-

dable and courageous animal makes a prey of most other animals, and is himself a prey to none, this diminution in the number of the species can be owing to nothing but an increase in the number of mankind: for it must be acknowledged, that the strength of this king of animals is not a match for the dexterity and address of a negro or Hottentot, who will often dare to attack him face to face, and with very slight weapons.

The ingenuity of mankind augments with their number; that of other animals continues always the same. All the noxious animals, as the lion, are reduced to a small number, not only because mankind are become more numerous, but likewise because they have become more ingenious, and have invented weapons which nothing can resist. This superiority in the numbers and industry of mankind, at the same time that it has broke the vigour of the lion, seems likewise to have enervated his courage. This quality, though natural, is exalted or lowered according to the good or bad success with which any animal has been accustomed to employ his force. In the vast deserts of Zaara; in those which seem to separate two very different races of men, the Negroes and Moors, between Senegal and the boundaries of Mauritania; in those uninhabited regions above the country of the Hottentots; and, in general, in all the meridional parts of Africa and Asia, where mankind have disdained to dwell, lions are still as numerous and as ferocious as ever. Accustomed to measure their strength by that of all other animals which they encounter, the habit of conquering renders them haughty and intrepid. Having never experienced the strength of man, or the power of his arms, instead of discovering any signs of fear, they disdain and set him at defiance. Wounds irritate, but do not terrify them: they are not even disconcerted at the sight of numbers. A single lion of the desert has been known to attack a whole caravan; and if, after a violent and obdurate engagement, he found himself weakened, he retreats fighting, always keeping his face to the enemy. On the other hand, the lions which live near the villages or huts of the Indians or Africans, being acquainted with man and the force of his arms, are so dauntless as to fly and leave their prey at the sight of women or children.

This softening in the temper and disposition of the lion, shows that he is capable of culture, and susceptible, at least to a certain degree, of the impressions that he receives: accordingly, history informs us of lions yoked in triumphal chariots, trained to war, or the chase; and that, faithful to their masters, they never employed their strength or courage but against their enemies. It is, however, certain, that a lion taken young, and brought up among domestic animals, will easily be accustomed to live and sport with them; that he is mild and caressing to his master, especially when he is young; and that, if his natural ferocity sometimes breaks out, it is rarely turned against those who have been kind to him. But, as his passions are impetuous and vehement, it is not to be expected that the impressions of education will at all times be sufficient to balance them: for this reason it is dangerous to let him suffer hunger long, or to vex him by ill-timed teazings: bad treatment not only irritates him, but he remembers it long, and meditates revenge. On the

Felis.

the other hand, he is exceedingly grateful, and seldom forgets benefits received. He has been often observed to disdain weak or insignificant enemies, to despise their insults, and to pardon their offensive liberties. When led into captivity, he will discover symptoms of uneasiness, without anger or peevishness: on the contrary, his natural temper softens, he obeys his master, caresses the hand that gives him food, and sometimes gives life to such animals as are thrown to him alive for prey: by this act of generosity he seems to consider himself as for ever bound to protect them; he lives peaceably with them; allows them a part, and sometimes the whole, of his food; and will rather submit to the pangs of hunger, than fill his stomach with the fruit of his beneficence. We may likewise observe, that the lion is not a cruel animal: he kills rather from necessity than choice, never destroying more than he eats; and whenever his appetite is satisfied, he is mild and peaceable.

The aspect of the lion does not detract from the noble and generous qualities of his mind. His figure is respectable; his looks are determined; his gate is stately; and his voice is tremendous. In a word, the body of the lion appears to be the best model of strength joined to agility. The force of his muscles is expressed by his prodigious leaps and bounds, often 20 feet at once; by the brisk motion of his tail, a single sweep of which is sufficient to throw a man to the ground; by the ease with which he moves the skin of his face, and particularly of his forehead; and, lastly, by the faculty of erecting and agitating the hair of his mane when irritated.

Lions are very ardent in their amours: when the female is in season, she is often followed by eight or ten males, who roar incessantly, and enter into furious engagements, till one of them completely overcomes the rest, takes peaceable possession of the female, and carries her off to some secret recess. The lioness brings forth her young in the spring, and produces but once every year.

All the passions of the lion, the soft passion of love not excepted, are excessive; the love of offspring is extreme: the lioness is naturally weaker, less bold, and more gentle than the lion; but she becomes perfectly rapacious and terrible when she has young. Then she exhibits more courage than the male; she regards no danger; she attacks indifferently men and all other animals, kills them, and carries them to her young ones, whom she thus early instructs to suck their blood and tear their flesh. She generally brings forth in the most secret and inaccessible places; and, when afraid of a discovery, she endeavours to conceal the traces of her feet, by returning frequently on her steps, or rather by effacing them with her tail; and, when the danger is great, she carries off her young, and conceals them somewhere else. But, when an actual attempt is made to deprive her of her young, she becomes perfectly furious, and defends them till she be torn to pieces.

The lion seldom goes abroad in the middle of the day; he goes round in the evening and night, in quest of prey. He is afraid of fire, and never approaches the artificial fires made by the shepherds for the protection of their flocks; he does not trace other animals by the scent, but is obliged to trust to his eyes. Many historians have even misrepresented him as incapable of find-

VOL. IV.

ing on his prey; but that he is obliged to the jackal, an animal of exquisite scent, in order to provide for him, and that this animal either accompanies or goes before him for this purpose. The jackal is a native of Arabia, Libya, &c. and, like the lion, lives upon prey: perhaps sometimes he follows the lion, but it is with a view to pick up what he leaves behind, not to provide for him; for, being a small and feeble animal, he ought rather to fly from than to follow the lion.

The lion, when hungry, will attack any animal that presents itself: but he is so very formidable, that all endeavour to avoid his encounter; this circumstance often obliges him to conceal himself, and lie in wait till some animal chances to pass. He lies squat on his belly in a thicket; from which he springs with such force and velocity, that he often seizes them at the first bound. He endures hunger longer than thirst; he seldom passes water without drinking, which he does by lapping like a dog. For his ordinary subsistence, he requires about 15 pounds of raw flesh each day.

The roaring of the lion is so strong and loud, that it resembles the rumbling of distant thunder. His roaring is his ordinary voice; but when he is irritated, his cry is shorter, repeated more suddenly, and is still more terrible than the roaring: besides, he beats his sides with his tail, stamps with his feet, erects and agitates the hair of his head and mane, moves the skin of his face, shows his angry teeth, and lolls out his tongue.

The gait of the lion is stately, grave, and slow, though always in an oblique direction. His movements are not equal or measured, but consist of leaps and bounds; which prevents him from stopping suddenly, and makes him often overleap his mark. When he leaps upon his prey, he makes a bound of 12 or 15 feet, falls above it, seizes it with his fore-feet, tears the flesh with his claws, and then devours it with his teeth.

The lion, however terrible, is hunted by large dogs, well supported by men on horseback: they dislodge him, and oblige him to retire. But it is necessary that both the dogs and horses be trained before-hand; for almost every animal frets and flies as soon as he feels the very smell of a lion. His skin, although hard and firm, does not resist either a ball or a javelin: however, he is seldom killed by a single stroke; and is more frequently taken by address than force. They put a live animal above a deep pit covered with light substances, and thus decoy him into the snare.

II. The *Tigris*, or *TIGER*. The size of this animal, according to some authors, is larger, and, according to others, somewhat less, than the lion. M. de la Landemagon assures us, that he has seen a tiger in the East-Indies 15 feet long, including undoubtedly the length of the tail, which, supposing it to be four feet, makes the body of the tiger about 10 feet in length. The skeleton preserved in the cabinet of the French king, indicates that the animal was about seven feet long from the point of the muzzle to the origin of the tail; but then it must be considered that he was caught young, and lived all his days in confinement. The head of the tiger is large and roundish; and the ears are short, and at a great distance from each other. The form of the body has a great resemblance to that of the panther. The skin is of a darkish yellow colour, striped with long black streaks; the hair is short,

17 D

ex-

Felis.

Felis.

Felis.

excepting on the sides of the head, where it is about four inches long. The point of the tail is black, and the rest of it is interspersed with black rings. His legs and claws resemble those of the lion, only the legs are much shorter in proportion to the size of the animal.

The Tiger.

The tiger is more ferocious, cruel, and savage than the lion. Although gorged with carnage, his thirst for blood is not appeased; he feizes and tears in pieces a new prey with equal fury and rapacity, the very moment after devouring a former one; he lays waste the country he inhabits; he neither dreads the aspect nor the weapons of men; puts to death whole troops of domestic animals; and attacks young elephants, rhinoceros's, and sometimes even braves the lion himself. The tiger seems to have no other instinct but a constant thirst after blood, a blind fury which knows no bounds or distinction, and which often stimulates him to devour his own young, and to tear the mother in pieces for endeavouring to defend them. He lies in wait on the banks of rivers, &c. where the heat of the climate obliges other animals to repair for drink. Here he feizes his prey, or rather multiplies his massacres; for he no sooner kills one animal, than he flies with equal fury upon the next, with no other view but to plunge in his head into their bodies and drink their blood. However, when he kills a large animal, as a horse or a buffalo, he sometimes does not tear out the entrails on the spot; but, to prevent any interruption, he drags them off to the wood, which he performs with incredible swiftness. This is a sufficient specimen of the strength of this rapacious animal.

Neither force, restraint, or violence, can tame the tiger. He is equally irritated with good as with bad treatment: he tears the hand which nourishes him with equal fury as that which administers blows: he roars and is enraged at the sight of every living creature. Almost every natural historian agrees in this horrible character.

It is happy for other animals, that the species of the tiger is not numerous, and that they are confined to the warm climates. They are found in Malabar, Siam, Bengal, the interior parts of Africa, and, in general, in all the regions that are inhabited by the elephant and rhinoceros.

The tiger has always been a more rare animal than the lion; and yet brings forth an equal number of young, namely, four or five at a litter. The female is furious at all times; but, when her young are attempted to be taken from her, her rage is redoubled: she braves every danger; she pursues the ravishers, who are obliged, when hard pressed, to drop one of the young in order to retard her motion; she stops, takes it up, and carries it into some secret part of the forest; but she instantly returns and pursues the hunters into their villages or boats.

The tiger moves the skin of his face, grinds his teeth, and roars, like the lion; but the sound of his voice is different.

III. The *Pardus*, or PANTHER.—It is about the size of a large dog, and has a great resemblance to a domestic cat. The tongue is rough, and remarkably red; the teeth are strong and sharp; the skin is exceedingly beautiful, being of a yellow colour, variegated with roundish black spots, and the hair is short.

The panther inhabits Africa, from Barbary to the remotest parts of Guinea. It has a cruel and ferocious

aspect; his motions are brisk and lively; his cry resembles that of an enraged dog, but is more strong and rough. He is not so perfectly ungovernable as the tiger: but, notwithstanding all attempts to render him obedient and tractable, he may rather be said to be subdued than tamed; for he never entirely loses his natural ferocity. Accordingly, when kept with a view to the hunting of bucks, goats, or other animals, great care is necessary in training him, and still greater in conducting him. When leading out to the field, they put him in a cage and carry him on a cart. When the game is sprung, they open the door of the cage; he instantly springs towards the animal, often feizes him in a few bounds, throws him to the ground, and strangles him. But, if he happens to miss his aim, he becomes mad with rage, and sometimes falls upon his master, who, in order to prevent accidents of this kind, generally carries along with him pieces of flesh, or perhaps a lamb or a kid, which he throws to him in order to appease his fury.

The panther, according to Buffon, is no where to be found but in Africa, and the regions of the Indies.

The ancients were well acquainted with these animals. These, and the leopards, were the *Varia* and *Pardi* of the old writers: one should think that the Romans would have exhibited the desarts of Africa by the numbers they drew from thence for their public shows. Scaraus exhibited at one time 150 panthers; Pompey the Great, 410; Augustus, 420. Probably they thinned the coasts of Mauritania of these animals, but they still swarm in the southern parts of Guinea.—Oppian describes two species of panther, a large species and a small one; the first of which has a shorter tail than the lesser, and may possibly be this kind.—An animal of this species is found in Bucharia, called there *Babr*: it is seven feet long, very destructive to horses, and even camels: the skin is fine, and valued in Russia at 11. Sterling.—In China there is a most remarkable kind, called there *Louchu*, whose skins sell for 61. Sterling a-piece. It must here also be observed, that there are in the furriers shops in London, skins in most respects resembling those of the panther; which, they assure us, come from the Spanish settlements in the West Indies: These skins equal those of the old continent in beauty and size.

Though Mr Buffon denies the panther to be an inhabitant of America, yet Mr Pennant is of opinion that the same, or a variety at least, inhabits that country. 1. The figure of the species described by Faber, (*Hist. An. Nov. Hisp.* p. 498.) under the name of *Tigris Mexicana*, agrees exactly with that of the panther, as does also the description in general. 2. Every other animal of this genus, which has yet been discovered in America, is far inferior in size and strength to this; whose common height, Faber says, is four or five feet, and whose prey is wild cattle, horses, &c. *M. Condamine*, and *Le Pere Cojetan Cattaneo*, speak of the tigers (*i. e.* the panthers) of America, as equal and even superior in size to those of Africa, and the colour as bright as gold; and Ulloa describes them as big as little horses. 3. Notwithstanding the vendors of furs are not entirely to be relied on as to the countries their goods come from, yet the general opinion of the whole trade, that these skins were the product of Spanish America, is a further proof of their being common to both

The Panther.

Fells. both continents.

IV. The *Onca*, or *ONCE*, is less than the panther; the tail is longer; the hair is likewise longer, and of a whitish grey colour. The once is easily tamed; and is employed in hunting in several parts of Asia, where dogs are very scarce. He has not the delicate scent of a dog; does not trace other animals by the smell; neither can he run them down in a fair chase; but lies in wait for their approach, and then darts upon them unawares. He leaps so nimbly, that he easily clears a ditch or a wall several feet high; besides, he often climbs trees, waits till some animal passes, and instantly leaps upon them. This method of catching their prey, is practised by the panther and leopard, as well as by the once.—The once inhabits Barbary, Persia, Hyrcania, and China; from which last place the skins are brought into Russia, and sold for 20 s. a piece.

The Leopard. V. The *Pardalis*, or *LEOPARD*, differs from the panther and the once, in the beauty of his colour, which is a lively yellow, with smaller spots than those of the two latter, and disposed in groups. He is larger than the once, and less than the panther. The leopard inhabits the East Indies; one kept some years ago in the Tower, seemed a good-natured animal.—A variety called the *hunting leopard*, is about the size of a large greyhound; of a long make, narrow chest, legs very long. He inhabits India, where he is tamed and trained for the chase of antelopes: carried in a small kind of waggon, hood-winked and chained, till it approaches the herd: when first unchained, does not make its attempt, but winds along the ground, stopping and concealing itself, till it gets a proper advantage; then darts on the animals with surprising swiftness; overtakes them by the rapidity of its bounds; but if it does not succeed in its first efforts, consisting of five or six amazing leaps, misses its prey: losing its breath, and finding itself unequal in speed, it stands still, gives up the point for that time, and readily returns to its master.

The Lynx. VI. The *LYNX* is about 2½ feet long and 15 inches high. He has a great resemblance to the cat; but his ears are longer, and his tail is much shorter; his hair is streaked with yellow, white, and black colours. The lynx is an inhabitant of Muscovy, Poland, Canada, &c. His eyes are brilliant, his aspect is soft, and his air is gay and sprightly: like the cat, he covers his urine with earth; he howls something like the wolf, and is heard at a considerable distance; he does not run like the dog or wolf, but walks and leaps like a cat; he pursues his prey even to the tops of trees; neither wild cats nor squirrels can escape him; he lies in wait for stags, goats, hares, &c. and darts suddenly upon them; he seizes them by the throat and sucks their blood, then opens the head and eats the brain; after this, he frequently leaves them, and goes in quest of fresh prey. The colour of his skin changes according to the season or the climate: the winter-furs are more beautiful than those of summer. These furs are valuable for their softness and warmth: numbers are annually imported from North America, and the north of Europe and Asia; the farther north and east they are taken, the whiter they are, and the more distinct the spots. Of these the most elegant kind is called *irbyz*, whose skin sells on the spot for one pound Sterling. The ancients * celebrated the great quickness of the

lynx's sight; and feigned that its urine was converted into a precious stone.

VII. The *Catus*, or *CAT*, wild, and domestic.

1. The *wild cat* differs not specifically from the tame; the latter being originally of the same kind, but altered in colour, and in some other trifling accidents, as are common to animals reclaimed from the woods and domesticated.

The cat in its savage state is three or four times as large as the house-cat; the head larger, and the face flatter. The teeth and claws are tremendous: its muscles very strong, as being formed for rapine: the tail is of a moderate length, but very thick, marked with alternate bars of black and white, the end always black: the hips and hind part of the lower joints of the legs are always black: the fur is very soft and fine. The general colour of these animals is of a yellowish white, mixed with a deep grey: these colours, though they appear at first sight confusedly blended together, yet on a close inspection will be found to be disposed like the streaks on the skin of the tiger, pointing from the back downwards, rising from a black list that runs from the head along the middle of the back to the tail.

This animal may be called the *British tiger*; it is the fiercest and most destructive beast we have; making dreadful havoc among our poultry, lambs, and kids. It inhabits the most mountainous and woody parts of these islands, living mostly in trees, and feeding only by night. It multiplies as fast as our common cats; and often the females of the latter will quit their domestic mates, and return home pregnant by the former.

They are taken either in traps, or by shooting: in the latter case, it is very dangerous only to wound them; for they will attack the person who injured them, and have strength enough to be no despicable enemy. Wild cats were formerly reckoned among the beasts of chase; as appears by the charter of Richard II. to the abbot of Peterborough, giving him leave to hunt the hare, fox, and wild cat. The use of the fur was in lining of robes: but it was esteemed not of the most luxurious kind; for it was ordained, "that no abbess or nun should use more costly apparel than such as is made of lambs or cats skins." In much earlier times it was also the object of the sportsman's diversion.

2. The *tame or domestic cat* is so well known, that it requires no description. It is an useful, but deceitful domestic. Although when young they are playful and gay, they possess at the same time an innate malice and perverse disposition, which increases as they grow up, and which education learns them to conceal, but never to subdue. Constantly bent upon theft and rapine, though in a domestic state, they are full of cunning and dissimulation; they conceal all their designs; seize every opportunity of doing mischief, and then fly from punishment. They easily take on the habits of society, but never its manners; for they have only the appearance of friendship and attachment. This dissimulation of character is betrayed by the obliquity of their movements, and the ambiguity of their looks. In a word, the cat is totally destitute of friendship; he thinks and acts for himself alone. He loves ease, searches for the softest and warmest places to repose himself. The cat is likewise extremely amorous; and

* Plin. viii. 8. xxviii. 8.

Felis.
The Cat.

which is very singular, the female is more ardent than the male; she not only invites, but searches after and calls upon him to satisfy the fury of her desires; and, if the male disdains or flies from her, she pursues, bites, and in a manner compels him. This heat of passion in females lasts but nine or ten days, and happens twice in the year, namely, in the spring and autumn; however, in some it happens thrice or four times in the year. The female goes with young 55 or 58 days, and generally produces four or five at a litter. As the male has an inclination to destroy the young, the female takes care to conceal them from him; and, when she is apprehensive of a discovery, she takes them up in her mouth one by one, and hides them in holes or inaccessible places. When she has nursed a few weeks, she brings them mice, small birds, &c. in order to learn them to eat flesh. But it is worth notice, that these careful and tender mothers sometimes become unnaturally cruel, and devour their own offspring.

The cat is incapable of restraint, and consequently of being educated to any extent. However, we are told, that the Greeks in the island of Cyprus trained this animal to catch and devour serpents, with which that island was greatly infested. This, however, was not the effect of obedience, but of a general taste for slaughter; for he delights in watching, attacking, and destroying all kinds of weak animals indifferently. He has no delicacy of scent, like the dog; he hunts only by the eye: neither does he properly pursue; he only lies in wait, and attacks animals by surprise; and after he has caught them, he sports with and torments them a long time, and at last kills them (when his belly is full) purely to gratify his sanguinary appetite.

The eye of the cat differs greatly from that of most other animals. The pupil is capable of a great degree of contraction and dilatation; it is narrow and contracted like a line during the day, round and wide in the dark; it is from this conformation of the eye that the cat sees best in the night, which gives him a great advantage in discovering and seizing his prey.

Although cats live in our houses, they can hardly be called domestic animals; they may rather be said to enjoy full liberty; for they never act but according to their own inclination. Besides, the greatest part of them are half wild; they do not know their masters, and frequent only the barns, out-houses, &c. unless when pressed with hunger.

Cats have a natural antipathy at water, cold, and bad smells. They love to bask in the sun, and to lie in warm places. They likewise have an affection for certain aromatic smells; they are transported with the root of the valerian.

Cats take about 18 months before they come to their full growth; but they are capable of propagation in 12 months, and retain this faculty all their life, which generally extends to nine or ten years. They eat slowly, and are peculiarly fond of fish. They drink frequently; their sleep is light; and they often assume the appearance of sleeping, when in reality they are meditating mischief. They walk softly, and without making any noise. As their hair is always dry, it easily gives out an electrical fire, which becomes visible when rubbed a-crofs in the dark. Their eyes likewise sparkle in the dark like diamonds.—The cat, when pleased, purrs, and moves its tail: when angry, it spits, hisses,

and strikes with its foot. It drinks little: is fond of fish: it washes its face with its fore-foot, (Linnaeus says, at the approach of a storm:) it always lights on its feet: it is even proverbially tenacious of life.

Our ancestors seem to have had a high sense of the utility of this animal. That excellent prince *Hoeldda*, or *Howel the Good*, did not think it beneath him (among his laws relating to the prices, &c. of animals*), to include that of the cat; and to describe the qualities it ought to have. The price of a kitten before it could see was to be a penny; till it caught a mouse, two-pence; when it commenced mouser, four-pence. It was required besides, that it should be perfect in its senses of hearing and seeing, be a good mouser, have the claws whole, and be a good nurse: but if it failed in any of these qualities, the seller was to forfeit to the buyer the third part of its value. If any one stole or killed the cat that guarded the prince's granary, he was to forfeit a milch-ewe, its fleece and lamb; or as much wheat as, when poured on the cat suspended by its tail (the head touching the floor), would form a heap high enough to cover the tip of the former. This last quotation is not only curious, as being an evidence of the simplicity of ancient manners, but it almost proves to a demonstration, that cats are not aborigines of these islands, or known to the earliest inhabitants. The large prices set on them, (if we consider the high value of specie at that time†), and the great care taken of the improvement and breed of an animal that multiplies so fast, are almost certain proofs of their being little known at that period.

The cat is found in almost every country in the world; and all the varieties in their appearance may be reasonably enough attributed to the climates which produce them.

The Cat of *Angora*, is a variety with long hair, of a silvery whiteness, and silky texture; very long, especially about the neck, where it forms a fine ruff: the hair on the tail very long and spreading: it is a large variety, found about Angora, the same country which produces the fine-haired goat. It degenerates after the first generation in this climate.

See figures of the principal species of *felis*, on plates CV. CVI. CVII.

FELL (Dr John), a very learned English divine and bishop, entered a student at Christ-church, Oxford, 1636. In 1648, he was ejected by the parliamentary visitors, being then in holy orders: and from that time to the restoration lived at Oxford a retired and studious life. He was installed canon of Christ-church, July 1660; and the year following, dean of that church; in which places he did great services to the college, and reformed several abuses. He was consecrated bishop of Oxford in 1675; and had leave to hold his deanry in *commendam*, that he might continue his services to the college and university. He published several works, and died in 1686.

FELLING OF TIMBER.—Many circumstances are well known and constantly observed in the felling of timber for building, which, though to a hasty observer they might appear trifling, yet prove, on experience, to be of the utmost consequence. One thing observed by Mr De Buffon, which very greatly increases the solidity and strength of timber, is, that the trees intended to be felled for service should first be stripped

Fellowship of their bark, and suffered to stand and die upon the spot before the cutting. The sappy part or blea of the oak, becomes by this means as hard and firm as the heart; and the real strength and density of the wood has been proved, by many experiments, to be greatly increased by it: nor is this a practice of any detriment to the proprietor, since the remaining stumps of these trees send up their young shoots as vigorously as if they had been cut down in their natural condition.

When any tree is to be cut down for timber, the first thing to be taken care of is a skilful disbranching of such limbs as may endanger in its fall: many trees are utterly spoiled for want of a previous care of this kind. In arms of timber that are very great, it is always necessary to chop or sink in them close to the bole, and then, meeting it with down-right strokes, it will be severed from the tree without splitting. In felling the tree, take care always to cut it as close to the ground as possible, unless it is intended to be grubbed up: and the doing that is of advantage both to the timber, and to the wood; for timber is never so much valued, if it be known to grow out of old stocks.

FELLOWSHIP, COMPANY, or *Distributive-Portion*, in arithmetic. See ARITHMETIC, n° 15.

FELO DE SE, in law, a person that lays deliberately violent hands on himself, and is the occasion of his untimely death, whether by hanging, drowning, stabbing, shooting, or any other way.

FELON, in law, a person guilty of felony. See FELONY.

FELONY, in the general acceptance of the law, comprises every species of crime, which occasioned at common law the forfeiture of lands or goods. This most frequently happens in those crimes, for which a capital punishment either is or was to be inflicted: for those felonies that are called *clergyable*, or to which the benefit of clergy extends, were anciently punished with death in all lay, or unlearned, offenders; tho' now, by the statute-law, that punishment is for the first offence universally remitted. Trespass itself, says Sir Edward Coke, was anciently comprised under the name of *felony*: and in confirmation of this we may observe, that the statute of treasons, 25 Edw. III. c. 2. speaking of some dubious crimes, directs a reference to parliament; that it may be there adjudged, "whether they be treason or other felony." All treasons, therefore, strictly speaking, are felonies; tho' all felonies are not treason. And to this also we may add, that all offences, now capital, are in some degree or other felony: but this is likewise the case with some other offences, which are not punished with death; as suicide, where the party is already dead; homicide by chance-medley, or in self-defence; and petit-larceny, or pilfering; all which are, (strictly speaking) felonies, as they subject the committers of them to forfeitures. So that, upon the whole, the only adequate definition of felony seems to be that which is before laid down; viz. an offence which occasions a total forfeiture of either lands, or goods, or both, at the common law; and to which capital or other punishment may be superadded, according to the degree of guilt.

To explain this matter a little farther: The word *felony*, or *felonia*, is of undoubted feudal original, being frequently to be met with in the books of feuds, &c;

but the derivation of it has so much puzzled the juridical lexicographers, Præzeus, Calvinus, and the rest: some deriving it from the Greek, *φύλος*, "an impollitor or deceiver;" others from the Latin, *fallo*, *fallere*, to countenance which they would have it called *felonia*. Sir Edward Coke, as his manner is, has given us a still stranger etymology; that it is *crimen animo felleo perpetratum*, "with a bitter or gallish inclination." But all of them agree in the description, that it is such a crime as works a forfeiture of all the offender's lands or goods. And this gives great probability to Sir Henry Spelman's Teutonic or German derivation of it: in which language indeed, as the word is clearly of feudal original, we ought rather to look for its signification, than among the Greeks and Romans. *Fel-on* then, according to him, is derived from two northern words: *FEE*, which signifies (we well know) the fief, feud, or beneficiary estate; and *LOH*, which signifies price or value. Felony is therefore the same as *pretium feudi*, the consideration for which a man gives up his fief; as we say in common speech, such an act is as much as your life, or estate, is worth. In this sense it will clearly signify the feudal forfeiture, or act by which an estate is forfeited, or escheats, to the lord.

To confirm this, we may observe, that it is in this sense, of forfeiture to the lord, that the feudal writers constantly use it. For all those acts, whether of a criminal nature or not, which at this day are generally forfeitures of copyhold estates, are styled *felonia* in the feudal law: "scilicet, per quas feudum amittitur." As, "si domino deservire noluerit;—si per annum et diem cessaverit in petenda investitura;—si dominum ejuravit, i. e. negavit se a domino feudum habere;—si a domino, in jus eum vocante, ter citatus non comparuerit;"—all these, with many others, are still causes of forfeiture in our copyhold estates, and were denominated *felonies* by the feudal constitutions. So likewise injuries of a more substantial or criminal nature were denominated *felonies*, that is, forfeitures: as assaulting or beating the lord; vitiating his wife or daughter, "si dominum cucurbitaverit, i. e. cum uxore ejus concubuerit;" all these are esteemed felonies, and the latter is expressly so denominated, "si fecerit feloniam, dominum forte cucurbitando." And as these contempts, or smaller offences, were felonies or acts of forfeiture, of course greater crimes, as murder and robbery, fell under the same denomination. On the other hand, the lord might be guilty of felony, or forfeit his feignory to the vassal, by the same act as the vassal would have forfeited his feud to the lord. "Si dominus commisit feloniam, per quam vassallus amitteret feudum si eam commiserit in dominum, feudi proprietatem etiam dominus perdere debet." One instance given of this sort of felony in the law is beating the servant of his vassal, so as that he loses his service; which seems merely in the nature of a civil injury, so far as it respects the vassal. And all these felonies were to be determined, "per laudamentum suæ judicium parium suorum," in the lord's court; as with us forfeitures of copyhold lands are presentable by the homage in the court-baron.

Felony, and the act of forfeiture to the lord, being thus synonymous terms in the feudal law, we may easily trace the reason why, upon the introduction of that law into England, those crimes which induced such forfeiture or escheat of lands (and, by a small flexion from

Felony,
Female.

from the original sense, such as induced the forfeiture of goods also) were denominated *felonies*. Thus it was that suicide, robbery, and rape, were felonies; that is, the consequence of such crimes was forfeiture; till by long use we began to signify by the term of *felony* the actual crime committed, and not the penal consequence. And upon this system only can we account for the cause, why treason in ancient times was held to be a species of felony; viz. because it induced a forfeiture.

Hence it follows, that capital punishment does by no means enter into the true idea and definition of *felony*. Felony may be without inflicting capital punishment, as in the cases instanced of self-murder, excusable homicide, and petit larceny: and it is possible that capital punishments may be inflicted, and yet the offence be no felony; as in case of heresy by the common law, which, though capital, never worked any forfeiture of lands or goods, an inseparable incident to felony. And of the same nature was the punishment of standing mute, without pleading to an indictment; which at the common law was capital, but without any forfeitures, therefore such standing mute was no felony. In short, the true criterion of felony is forfeiture: for, as Sir Edward Coke justly observes, in all felonies which are punishable with death, the offender loses all his lands in fee-simple, and also his goods and chattels; in such as are not punishable, his goods and chattels only.

The idea of felony is indeed so generally connected with that of capital punishment, that we find it hard to separate them; and to this usage the interpretations of the law do now conform. And therefore, if a statute makes any new offence felony, the law implies that it shall be punished with death, viz. by hanging, as well as with forfeiture: unless the offender prays the benefit of clergy; which all felons are entitled once to have, unless the same is expressly taken away by statute.

Felonies by statute are very numerous; and as this work will not admit of a proper enumeration, we must refer to the Table of the quarto edition of the Statutes, where they are set forth in alphabetical order.

FELT, in commerce, a sort of stuff deriving all its consistence merely from being fulled, or wrought with lees and size, without either spinning or weaving.

Felt is made either of wool alone, or of wool and hair. Those of French make, $3\frac{1}{2}$ yards long, and $1\frac{1}{2}$ broad, for cloaks, pay each 2 l. 14 s. $1\frac{1}{2}$ s. d. on importation; and draw back 1 l. 12 s. 3 d. on exporting them again.

FELTRIA, (anc. geog.) a town on the borders of Rhetia towards Italy. Now *Feltri*, in the territory of Venice, on the Piava. E. Long. 12. 16. N. Lat. 46°.

FELUCCA, in sea-affairs, a little vessel armed with six oars, frequent in the Mediterranean; which has this peculiarity, that its helm may be applied either in the head or stern, as occasion requires.

FEMALE, (*FÆMINA*), a term peculiar to animals, signifying that sex which conceives and generates its young within itself. See SEX and GENERATION.

FEMALE is also applied, figuratively, to things without life, from the resemblance they bear to the females

of animals. Thus we say a

FEMALE-Screw. See SCREW.

FEMALE-Flower. See *Feminus* FLOS.

FEMALE-Plant. See *Feminea* PLANTA.

FEMME COVERT, in law, a married woman. See COVERTURE.

FEMME Sole, an unmarried woman, whose debts, contracted before marriage, become those of her husband after it.

A femme-sole merchant, is where a woman, in London, uses a trade alone, without her husband; on which account she shall be charged without him.

FEMININE, in grammar, one of the genders of nouns. See GENDER.

The feminine gender is that which denotes the noun or name to belong to a female. In the Latin, the feminine gender is formed of the masculine, by altering its termination; particularly by changing *us* into *a*. Thus, of the masculine *bonus equus*, "a good horse," is formed the feminine *bona equa*, "a good mare;" so, of *parvus homo*, "a little man," is formed *parva femina*, "a little woman," &c.

In French, the feminine gender is expressed, not by a different termination, but by a different article: thus, *le* is joined to a male, and *la* to a female.

In English, we are generally more strict, and express the difference of sex, not by different terminations, nor by different particles, but different words; as boar and sow, boy and girl, brother and sister, &c.—though sometimes the feminine is formed by varying the termination of the male into *ess*; as in abbot, abbess, &c.

FEMUR, or FEMORIS, in anatomy. See there, n° 57.

FEN, a place overflowed with water, or abounding with bogs. See Bog and DRAINING.

Fens are either made up of a congeries of bogs; or consist of a multitude of pools or lakes, with dry spots of land intermixed, like so many little islands.

Several statutes have been made for the draining of fens, chiefly in Kent, Cambridgeshire, Bedfordshire, and Lincolnshire; and by a late act, 11 Geo. II. commissioners shall be appointed for the effectually draining and preserving of the fens in the isle of Ely, who are authorized to make drains, dams, and proper works thereon; and they may charge the landholders therein with a yearly acre-tax, and, in default of payment, sell the defender's lands.

The wet grounds called *fens*, in Lincolnshire and elsewhere in England, bring many advantages to the inhabitants of those counties. Fowl and fish are very plentiful in them. The pike and eels are large and easily caught, but they are usually coarse. The duck, mallard, and teal, are in such plenty as is scarce to be conceived. They are taken in decoys by prodigious flocks at a time. They send these fowl from Lincolnshire to London, twice a week, on horseback, from Michelmass to Lady-day; and one decoy will furnish 20 dozen, or more, twice a week, for the whole season in this manner. The decoy-men contract with the people, who bring them to London at a certain rate, and they are obliged to take off their hands the whole number that is caught. Two teal are usually reckoned equal to one duck; and six ducks and 12 teal are accounted a dozen of wild-fowl; and the usual market-price is about

Femine
♀
Fem.

Fen,
Fence.

about 9s. for such a dozen. About midsummer, during the moulting season, a great number also are destroyed by the people in the neighbourhoods. The poor birds at this season are neither able to swim nor fly well; and the people going in with boats among the reeds where they lie, knock them down with long poles. A little before Michaelmas, vast flights of these birds arrive at the decoys from other places; they soon grow fat in them, and continue there a prey to the masters or owners, as long as the decoys are unfrozen; but, when they are iced over, they fly away again, and go to the neighbouring fens for food.

The fens also abound in a sort of herbage that is very nourishing to cattle. Sheep and horses always grow fat upon it. These fens are common, and the owners of cattle mark them that they may be known. It is remarkable, that, though all is open, the cattle used to one particular spot of ground seldom leave it, but the owner may always find them in or near the same place. The fens have many large and deep drains. In these the pike and eels grow to a vast size: and they are full of geese which feed on the grass; but these eat rank and muddy, and may even be smelt as soon as a person comes into the room where they are roasting. But the people have another very great advantage from these birds besides the eating of them, namely, their feathers and quills; and the produce of these is so great, that the customhouse-books in the town of Bolton shew, that there are frequently sent away in one year 300 bags of feathers, each containing a hundred and a half weight. Each pound of feathers brings in the owner twopence; and it may be thought strange by people unacquainted with these things, but it is a certain truth, that the owners pull them five or six times a-year for the feathers, and three times for the quills. Each pulling comes to about a pound, and many people have 1000 geese at a time, or more. They are kept at no charge, except in deep snowy weather, when they are obliged to feed them with corn.

Oats also grow very well in many of the fen countries, and in good seasons bring great increase and advantage to the owners. There is also another vegetable of great profit to them. This is the *rapum silvestre*; the seed of which they call *cole-feed*; and they make an oil from it of great use in trade. They grind the seed between two large stones, the one standing perpendicularly on the other. The stones are made of a sort of black marble, and are brought from Germany. They sometimes turn them by sails, and sometimes by the drains which carry off the water from the fen lands.

The fens lying low, and being of a vast extent, are very subject to be overflowed by waters from the neighbouring high countries; and though great care and expence is used to keep them dry, they are often like a sea; and the sheep are obliged to be carried off in boats, and the people to live in their upper rooms, and to be supplied with provisions all by boats.

FENCE, in gardening and husbandry, a hedge, wall, ditch, bank, or other inclosure, made round gardens, fields, woods, &c.

In hot climates, where they have not occasion for walls to ripen their fruit, their gardens lie open, where they can have a water-fence, and prospects; or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing

to the sight than a dead wall: but, in colder countries, we are obliged to have walls to shelter and ripen our fruit, although they take away much from the pleasant prospect of the garden. Brick-walls are accounted the best and warmest for fruit: and these walls, being built panelwise, with pillars at equal distances, will save a great deal of charge, in that the walls may be built thinner than if they were made plain without these panels, for then it would be necessary to build them thicker every where; and, besides, these panels make the walls look the handsomer. Stone-walls, however, on account of their durability, are to be preferred to those of brick, especially those of square hewn stones. Those that are made of rough stones, though they are very dry and warm, yet, by reason of their unevenness, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there for that purpose.

But, in large gardens, it is better to have the prospect open to the pleasure-garden; which should be surrounded with a fosse, that from the garden the adjacent country may be viewed. But this must depend on the situation of the place: for, if the prospect from the garden is not good, it had better be shut out from the sight than be open. As also, when a garden lies near a populous town, and the adjoining grounds are open to the inhabitants; if the garden is open, there will be no walking there in good weather, without being exposed to the view of all passers, which is very disagreeable.

Where the fosses are made round a garden which is situated in a park, they are extremely proper; because hereby the prospect of the park will be obtained in the garden, which renders those gardens much more agreeable than those that are confined.—In the making these fosses there have been many inventions; but, upon the whole, none seem preferable to those which have an upright wall next the garden, which (where the soil will admit of a deep trench) should be five or six feet high; and, from the foot of this wall, the ground on the outside should rise with a gradual easy slope, to the distance of 18 or 20 feet; and where it can be allowed, if it slopes much farther it will be easier, and less perceptible as a ditch, to the eye, when viewed at a distance: but, if the ground is naturally wet, so as not to admit a deep fosse, then, in order to make a fence against cattle, if the wall be four feet high, and slight posts of three feet high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it; therefore it will be a secure fence against them; and if these are painted green, they will not be discerned at a distance, and at the same time the chain will secure persons walking in the garden from tumbling over.

In places where there are no good prospects to be obtained from a garden, it is common to make the inclosure of park-paleing; which, if well performed, will last many years, and has a much better appearance than a wall: and this pale may be hid from the sight within, by plantations of shrubs and evergreens; or there may be a quick-hedge planted within the pale, which may be trained up, so as to be an excellent fence by the time the pales begin to decay.

Fences round parks, are generally of paleing; which

Fence.

Miller's
Gardener's
Dictionary.

Fence.

if well made of winter-fallen oak, will last many years. But a principal thing to be observed, in making these pales, is not to make them too heavy; for, when they are so, their own weight will cause them to decay: therefore the pales should be cleft thin; and the rails should be cut triangular, to prevent the wet lodging upon them; and the posts should be good, and not placed too far asunder. If these things are observed, one of these pales will last, with a little care, upwards of 40 years very well. The common way of making these fences is, to have every other pale nine or ten inches above the intermediate ones; so that the fence may be six feet and a half high, which is enough for fallow deer; but, where there are red deer, the fence should be one foot higher, otherwise they will leap over.

Some inclose their parks with brick walls; and, in countries where stone is cheap, the walls are built with this material; some with, and others without, mortar.

A kitchen-garden, if rightly contrived, will contain walling enough to afford a supply of such fruits as require the assistance of walls, for any family; and this garden, being situated on one side, and quite out of sight of the house, may be surrounded with walls, which will screen the kitchen-garden from the sight of persons in the pleasure-garden; and, being locked up, the fruit will be much better preserved than it can be in the public garden; and the having too great a quantity of walling is often the occasion that so many ill-managed trees are frequently to be seen in large gardens.

The height of garden walls should be 12 feet, which is a moderate proportion; and, if the soil be good, it may in time be well furnished with bearing-wood in every part, especially that part planted with pears, notwithstanding of the branches being trained horizontally from the bottom of the walls.

With regard to the more common kinds of fences, Mr Anderson gives the following directions, in his *Essays on Agriculture*, &c. "The fences that are most universally employed, are either stone-dikes or hedges (A). Dikes, if well built, as effectually preserve a field from the intrusion of domestic animals, as any other kind of fence whatever; but they afford little warmth or shelter to the field: whereas hedges, if good, answer both these purposes equally well. But the most material distinction between dikes and hedges is, that dikes are in their highest degree of perfection as soon as they are reared, and from that moment begin to tend towards decay; so that the person who builds this kind of fence immediately receives the full benefit thereof; whereas hedges, being at first weak and tender, stand in need of attention and care, and do not become a fence for several years after they are planted; and, as they continue to increase in strength, and gradually acquire a higher and higher degree of perfection, it is long before they begin to fall towards decay; so that they are, in general, infinitely more durable than dikes, altho' they are longer of becoming of use to the person who

plants them. Which of these two kinds of fences may, upon the whole, be most eligible, must, in general, be determined by the circumstances and views of the possessor of the ground to be inclosed. If he is a tenant who has a short lease, without a prospect of getting it renewed; or, if he has immediate occasion for a complete fence; it will be, in general, most prudent in him to make choice of dikes, if the materials for rearing these are at hand: but, if there is any probability that his posterity may reap any advantage from these inclosures, it will be almost always more for his advantage to make choice of hedges.

"A dike built of freestone and lime will be almost as durable as a hedge; although, in general, it will neither be so cheap nor agreeable. But dry-stone dikes, unless built of the finest quarried stone, are of such a perishable nature, as to be hardly ever worth the expense of rearing; and never, excepting where the field that you would wish to inclose has plenty of stones upon its surface, which you are under a necessity of carrying away before the field can be improved. In this situation a man may, in some measure, be excused, if he should be tempted to put them into dikes; because the carriage of these stones may be said to cost him nothing; and he may, perhaps, be at some loss how to dispose of them in any other manner. But, in all other circumstances, it is very bad economy to rear fences of this kind, as seal (B) dikes can always be built at one fourth of the expense that these would cost—will answer all purposes equally well; and, if carefully built, will be kept in repair for any number of years at as small an expense as they could be.

"The want of durability generally complained of in these dikes is owing to their bad construction. The greatest part of them are made of a considerable thickness, with a ditch on each side; the heart of the dike being made up with the earth that is taken from these ditches; and only a thin wall, on each side, is built of solid seal from top to bottom: the consequence of which is, that as the loose earth that is thrown into the middle of the dike subsides much more than the seal on each side, the top of the dike sinks down; and, of course, the two side-walls are pressed too much upon the inside, so as to bilge (swell) out about the middle, and quickly crumble down to dust. To avoid this inconvenience, I have always chosen to build my dikes of this sort thinner than usual: they being only three feet and a half thick at the bottom; one foot, or a very little more, at top; and five feet high; taking care to have them built in such a manner, as that every sod (seal), from top to bottom binds the joinings of the others below it, with as much accuracy as the bricks in a well-built wall. The uppermost course of seal is cut a little longer than those that are immediately below it, and placed with the grassy side uppermost, so as to project a little on each side; which not only helps to throw the water a little off the dike, but also to prevent sheep or cattle from attempting to jump over it so readily.

(A) *Dike* is a term employed to denote any kind of wall reared for the purpose of inclosing a field and nothing else.

(B) *Seal* is a provincial word, which may perhaps have many synonyms. It here means any kind of sod dug by the spade from the surface of grass-ground, consisting of the upper mould rendered tough and coherent by the matted roots of the grass thickly interwoven with it. If only a very thin bit of the upper surface is pared off with a paring spade, the pieces are here called *divots*. These being of a firmer consistence, are more durable when built into dikes than seal, but much more expensive also.

Fence.

dily as they otherwise might do. At the foot of the dike, on each side, is dug a small ditch, about a foot and a half or two feet deep; leaving a ledge of a few inches broad, on each side, that the dike may not be undermined by the crumbling down of the loose earth into the ditch. These ditches not only help to give the dike an additional height, and keep its foundation dry; but are also of use to prevent cattle from coming close to it and rubbing upon it, or tearing it down with their horns, which they are very apt to do if this precaution be omitted. The earth that is taken out of the ditches may be thrown outwards into the place that was occupied by the seal that has been taken to build the dike; and, if the field is in grass, a few seeds may be sowed upon it, and it will soon be covered as well as the rest of the field.

"By having the joints bound in every direction, the fabric is rendered much firmer than it could be by any irregular manner of working, while it is at the same time more easily reared. If the ground is soft, and the seal rise well, I get a fence of this kind done for one penny halfpenny *per* yard; but, if it is not good to work, a little more than that must be allowed. As to the time that a fence of this kind may stand without needing any repair, I cannot speak with certainty, as it is not long since I fell into this method of building them. The oldest has just now stood ten years, and seems to be nearly as firm as when first built. I have seen some walls of poor cottages which have been built somewhat after this manner, that have been good after standing 40 or 50 years: but their durability depends greatly upon the nature of the seal of which they are formed. The best is that which is taken from poor ground of a spongy quality, which is generally covered with a strong sward of coarse bent grass. And, in situations where this can be had, I would have no hesitation in recommending this as the cheapest and best temporary fence that could be reared.

"The greatest inconvenience that attends this species of fence, is the danger it runs of being torn down by the horns, or wasted away by the rubbing, of cattle upon it; which they will sometimes do notwithstanding of the ditches. This may be effectually prevented by planting a row of sweet-briar (*oglantine*) plants between the first and second course of seal when the dike is built, which will not fail to grow with luxuriance, and in a short time defend the dike from every attack of this kind. But, if sheep are to be kept in the inclosures, this plant ought not, on any account, to be employed; for, as that animal naturally flies to the fences for shelter in stormy weather, the prickles of the straggling branches of the briar will catch hold of the wool, and tear it off in great quantities, to the great detriment of the flock and loss of the proprietor. In these cases, if the possessor of the ground is not afraid of the bad consequences that may be dreaded from the spreading of whins (*surze*), it would be much better to scatter a few of the seeds of this plant along the ledge at the foot of the dike, which would quickly become a preservative for it, and be otherwise of use as a green food for his sheep during the winter season. But, before he ventures to sow this plant, let him remember, that where it is once established, it will hardly fail to spread through the adjoining fields, and can hardly be ever afterwards thoroughly rooted out.

VOL. IV.

"I have often imagined that this kind of fence might be greatly improved both in beauty and strength, by planting a row of ivy plants beneath the first course of seal in building the dike; which would, in a short time, climb up the sides of the dike and cover the whole with a close and beautiful network of woody fibres, covered with leaves of the most beautiful verdure; which would tend to preserve the dike from being eat away by frost, and other vicissitudes of weather. And when it is arrived at the top, it would there send out a number of strong woody branches, forming a sort of hedge, that would afford some shelter to the fields, and break the force of the wind considerably; but, as I never have yet had an opportunity of trying the experiment, I only here offer it as a probable conjecture. I have seen a garden-wall that had been built of stone and clay, ornamented and strengthened in this way. I have had the experience of ivy growing well upon a dry-stone dike: and have likewise seen it growing up the walls, and covering whole cottages built of seal; which have by this means been preserved entire, long after the walls that had been naked have fallen to decay. But, not having had plants of this kind at hand, I have not had an opportunity of trying it in the manner proposed; although, I think, there is the greatest reason to hope for success.

"Whins (*surze*) have been often employed as a fence when sowed upon the top of a bank. They are attended with the convenience of coming very quickly to their perfection, and of growing upon a soil on which few other plants could be made to thrive: but, in the way that they are commonly employed, they are neither a strong nor a lasting fence. The first of these defects may, in some measure, be removed, by making the bank upon which they are sowed (for they never should be transplanted) of a considerable breadth; in order that the largeness of the aggregate body, considered as one mass, may in some measure make up for the want of strength in each individual plant. With this view, a bank may be raised of five or six feet in breadth at the top, with a large ditch on each side of it; raising the bank as high as the earth taken from the ditches will permit; the surface of which should be sowed pretty thick with whin-seeds. These will come up very quickly; and in two or three years will form a barrier that few animals will attempt to break thro', and will continue in that state of perfection for some years. But the greatest objection to this plant as a fence is, that, as it advances in size, the old prickles always die away; there being never more of these alive at any time upon the plant, than those that have been the produce of the year immediately preceding: and these thus gradually falling away, leave the stems naked below as they advance in height; so that it very soon becomes an exceeding poor and unsightly fence; the stems being entirely bare, and so slender withal as not to be able to make a sufficient resistance to almost any animal whatever. To remedy this great defect, either of the two following methods may be adopted. The first is, to take care to keep the bank always stored with young plants; never allowing them to grow to such a height as to become bare below: and it was principally to admit of this, without losing at any time the use of the fence, that I have advised the bank to be made of such an unusual breadth. For, if one side

17 E

* See Agriculture,
no 46.

fide of the hedge be cut quite close to the bank, when it is only two or three years old, the other half will remain as a fence till that side become strong again; and then the opposite side may be cut down in its turn; and so on alternately as long as you may incline: by which means the bank will always have a strong hedge upon it without ever becoming naked at the root. And as this plant, when bruised, is one of the most valuable kinds of winter-food yet known for all kinds of domestic animals*, the young tops may be carried home and employed for that purpose by the farmer; which will abundantly compensate for the trouble of cutting, and the waste of ground that is occasioned by the breadth of the bank.

“ The other method of preserving a hedge of whins from turning open below, can only be practised where sheep are kept; but may be there employed with great propriety. In this case it will be proper to sow the seeds upon a conical bank of earth, shovelled up from the surface of the ground on each side without any ditches. If this is preserved from the sheep for two or three years at first, they may then be allowed free access to it; and, as they can get up close to the foot of the bank upon each side, if they have been accustomed to this kind of food, they will eat up all the young shoots that are within their reach, which will occasion them to send out a great many lateral shoots; and these being continually browsed upon, soon become as close as could be desired, and are then in no sort of danger of becoming naked at the root, although the middle part should advance to a considerable height.

“ The fences hitherto mentioned are only intended to preserve fields from the intrusion of cattle; but, on some occasions, it is necessary to have a fence that would even resist the efforts of men to break through it: as around bleaching-fields, orchards, &c.; the want of which often subjects the proprietor of such fields to very disagreeable accidents. And, as such a fence might, on some occasions, be procured at no great expense or trouble, it were to be wished that the method of doing this were more generally known than it is at present.—To effectuate this, it is necessary to begin by trenching up or ploughing a large belt all around the field you mean to inclose, of 40 or 50 feet or more in breadth, if you find it convenient: the outer edge of which should be inclosed by a good dike, or a ditch and hedge. This belt should be kept in culture one year, and well manured, if your situation will admit of it; and laid up before winter in such a manner that no water may be allowed to lodge upon it; and planted in the winter-time all over with plants of eglantine so thick as not to be above two feet from one another; and between these put a good number of young birch plants not above two years old, interspersed with hazels, oak, ash, rown (wild service), and other trees that you think will thrive upon your soil; together with thorns, hollies, brambles, and wood-bine (honeysuckle); and having then fenced it from cattle, and kept down the weeds that may rise upon its surface by the hoe, as long as you can conveniently get access into it, leave it afterwards to nature. If this is done, and your soil be not extremely bad, the belt in a very few years will be entirely filled with a close bush of trees, so intermixed with the bending branches of the eglantine, and bound together by the trailing shoots of the

bramble and woodbine, that no animal above the size of a cat could penetrate; especially when it is of such a depth as I have recommended.

“ The first hint that I got for a fence of this kind was from a small thicket of brushwood that I had planted for ornament, pretty much in the manner above described; which in a short time became so much interwoven with the sweet-briar, that it was impossible to find any access into it. But as all kinds of trees and shrubs, if planted very close upon one another, become naked at the root when they arrive at any considerable size, care should be taken to prevent it from ever coming to that state, by cutting it down whenever it becomes in danger of being open at the root. And as it would be improper ever to leave the field entirely defenceless, it is a great advantage to have the belt as broad as it conveniently may be; so that the one half of it may be a sufficient fence; by which means, we will have it in our power to cut down the inside and the outside of the belt alternately, so as still to keep the thickest young, and never to want at any time a sufficient fence; and the brush-wood that this affords at each cutting would, in almost every situation, yield such a revenue as would do much more than indemnify the proprietor for the rent of the ground that was occupied by this fence. And if the field was in such a situation as required shelter, some trees might be allowed to grow to their full size about the middle, without any inconvenience, if the belt were of a sufficient breadth.

“ There is one other species of fencing as useful as any of those already mentioned, which is in general much less understood, and more difficult to execute properly, that deserves here to be taken notice of; viz. the method of securing the banks of rivers from being washed away by the violence of the stream, and of preventing the damages that may otherwise be occasioned by the swelling of the waters.

“ It frequently happens that, when a river runs in a bed of rich vegetable mould, the least accident that may chance to divert the stream towards any particular part of the bank, causes it to sweep away large tracts of fine ground, to the very great detriment of the proprietor, as well as the public; as this fine mould is usually carried to the sea, and the place that the water leaves to occupy the new bed that it thus forms for itself is generally of a much worse quality; consisting chiefly of stones, sand and gravel. In some cases, where the whole force of the current is quite close to the bank, and the materials necessary for fencing it are not to be found, it may perhaps be impossible or very difficult totally to prevent this evil; but, for the most part, it admits of a cure that can be obtained at a pretty moderate expence.

“ These ravages are always greatest where the bank rises perpendicularly to a pretty considerable height above the ordinary surface of the water, and never at those places where the banks slope down gradually towards the water's edge: for, when the river is swelled to a great height by rains, and runs with a force and rapidity greater than usual, it strikes violently against these perpendicular banks that directly oppose its course, which being composed of earth quite bare and uncovered, are easily softened by the water, and quickly washed away; so that the upper part of the bank being

Fence.

being thus undermined, falls by its own weight into the river, and is carried off in prodigious quantities: whereas, at those parts of the bank that shelve gradually downwards to the water's edge, when the river rises to any considerable height, it gently glides along its surface; which being defended by the matted roots of the grafs with which it is covered, scarcely sustains any damage at all; and is nearly the same after the water has retired within its banks as before the inundation. These facts, which no one who has bestowed the least attention to this subject can fail to have observed, clearly point out, that the first and most necessary step towards a cure, is to level down the edge of the bank that is next to the water, so as to make it slope gradually down towards the river. If the bank is very high, and you have no other particular use for the earth that must be taken from it, the easiest method of disposing of it, will be to throw it into the river: but, in whatever manner you may dispose of the earth, the slope of the bank must be continued until the inner edge of it is as low as the surface of the water at the driest time of the year, and be made to ascend gradually upwards from the water with an easy slope, till it comes to the level of the ground, or at least rises to such a height as that the water never exceeds. This operation ought to be performed as early in summer as possible, and should be either immediately covered with turf, pared from the surface of some field that has a very strong sward upon it; taking care to lay these in such a manner as to be in as little danger as possible of being washed away by any accidental flood that might happen before they had grown together; or, if the turf of this kind cannot be easily had, it should be sowed very thick with the seeds of some small matt-rooted grafs, that should be kept in readiness for this purpose (c).

"If the stream has not been extremely rapid at the foot of the bank, some of the earth that was thrown into the water will be allowed to subside to the bottom, and will there form a bank of loose soft earth, which will be of great use afterwards in preventing the face of the bank under water from being washed away; but, in order to secure this bulwark effectually for the future, the surface of this soft earth ought to be instantly stuck full of the roots of bog-reeds, flags, water-spiderwort, rushes, and other matt-rooted aquatic plants; which, if allowed to remain till they have once struck root, will afterwards form a barrier that nothing will ever be able to destroy. But, if the stream be too rapid to admit of this, and the bank of soft earth is much deeper than the surface of the water, it will be of use to fill up the breast of the bank with loose stones carelessly thrown in, till they rise near the surface of the water; which would most effectually secure it against any future encroachments, if the bank is sloped away above.

"If it should so happen that stones cannot be easily got for this purpose, the only resource which in this case remains, is to dig the bank so low, that, at the undermost edge, it may be always below the surface of the water, and carry it out in this way for a considerable distance, and then stick the whole surface that is below the water full of matt-rooted aquatic plants; which will in a great measure, if not entirely, defend it from

any future encroachments. This bank ought to continue to shelve downwards even where it was below water, and those aquatics that will grow in the greatest depth of water be planted on the innermost brink, and the others behind them. The water-spiderwort will grow in four feet depth of water, and the roots of the common yellow-flowered water-iris forms such a strong and compact covering upon the surface of the soil on which it grows, as would defend it from being affected by the water almost as well as if it were a rock: it is likewise an advantage attending this plant, that it grows upon a firm bottom, and chiefly delights in running water.

"If the stratum of soft earth is not so deep as to reach to the surface of the water, and lies upon a stratum of rock or hard gravel, there will be no occasion for throwing in stones of any kind. But, as it is difficult to unite the vegetable mould to any of these strata, there will always be some danger of its separating from these in violent inundations; and if the water once get an entry, it will not fail to grow larger and larger by every future inundation. To prevent this inconvenience, it will be necessary, after you have sloped the earth away till you reach the gravel or rock, to cover the place where the edge of the earth joins the inferior stratum, with a good many small stones, if they can be found; sowing between them the seeds of any kind of plants that you think are most likely to thrive, which have strong matted roots with small and flexible tops as possible. You will easily observe, that from the impossibility of ever making earth adhere firmly to stone of any kind, it must always be an improper practice to face the banks of a river to a certain height with stone, which is coped at top with earth."

For the most proper methods of raising hedges of different kinds, see HEDGE.

FENCE-Month, the month wherein deer begin to fawn, during which it is unlawful to hunt in the forest.

It commences 15 days before mid-summer, and ends 15 days, after it. This month, by ancient foresters, is called *defence-month*.

FENCING, the art of making a proper use of the sword, as well for attacking an enemy as for defending one's self.

This art is acquired by practising with foils, called in Latin *rudex*; whence fencing is also denominated *gladiatura rudiaria*.—It is one of the exercises learnt in the academies, (see EXERCISE and ACADEMY); and is an accomplishment both agreeable and useful:—Agreeable, as it affords gentlemen a noble and distinguished amusement:—Useful, as it forms their body; and furnishes them with the faculty of defence, whether it be of their honour or their life, when the one or the other is attacked by those turbulent and dangerous persons whose correction is of service to society in general.

Pyrard assures us, that the art of fencing is so highly esteemed in the East-Indies, that none but princes and noblemen are allowed to teach it. They wear a badge or cognizance on their right arms, called in their language *asaru*; which is put on with great ceremony, like the badges of our orders of knighthood, by the kings themselves.

Fence,
Fencing.

Fenelon

Fenton.

Fencing is divided into two parts, *simple* and *compound*.

Simple is that performed directly and nimbly, on the same line; and is either offensive or defensive.—The principal object of the first, is whatever may be attempted, in pushing or making passes, from this or that point, to the most uncovered part of the enemy. The second consists in parrying and repelling the thrusts aimed by the enemy.

The *compound* includes all the possible arts and inventions to deceive the enemy, and make him leave that part we have a design on bare and unguarded, upon finding we cannot come at it by force, nor by the agility of the simple play. The principal means hereof are, on the offensive side, feints, appeals, clashings, and entanglings of swords, half-thrusts, &c.; and, on the defensive, to push in parrying. Of all which a detail would be here useless, as they are only to be understood and acquired from personal instructions conjoined with practice.

FENELON (Francis de Salignac de la Motte), was of an ancient and illustrious family, and born at the castle of Fenelon in Perigord in 1651. In 1689, he was appointed tutor to the dukes of Burgundy and Anjou; and in 1695 was consecrated archbishop of Cambray. After this preferment, a storm rose against him, that obliged him to leave the court for ever, occasioned by his performance intitled, *An explication of the maxims of the saints concerning the interior life*; in which he was supposed to favour the extravagant notions of Madam Guyon, and the principles of Quietism. A controversy on this occasion was for some time carried on between him and M. Bossuet, bishop of Meux; which terminated in an appeal to the pope; when his holiness condemned the archbishop's book, by a brief dated March 12th, 1699. Some friends indeed pretend, that there was more of court-policy than religious zeal in this affair: but be this as it may, the archbishop submitted patiently to this determination; and, retiring to his diocese of Cambray, acquitted himself punctually in all the duties of his station, and led a most exemplary life. The work that gained him the greatest reputation, and which will render his memory immortal, is his *Adventures of Telemachus*; the style of which is natural, the fictions well contrived, the moral sublime, and the political maxims tending all to the happiness of mankind. Hence it is thought, as the printing of this work was stopped at Paris, that the prelate's heresy was in politics instead of religion; and though his disgrace was prior to this work, he had, while he was tutor to the young princes, taught them the same principles asserted and exemplified in *Telemachus*. Fenelon died in 1715; and a collection of all his religious works was afterwards printed at Rotterdam, under the care of the marquis de Fenelon his grand-nephew, when ambassador to the States-General.

FENNEL, in botany. See ANETHUM.

FENTON (Sir Geoffrey), privy-counsellor and secretary in Ireland during the reigns of queen Elizabeth and king James I. is well known for his translation of

Guicciardini's History of the Wars of Italy, dedicated to queen Elizabeth in 1579. He died at Dublin in 1608; after having married his daughter to Mr Boyle, afterward the great earl of Corke.

FENTON (Elijah), descended from an ancient family, was born at Shelton near Newcastle, but in what year is uncertain. He was the youngest of 12 children, and was intended for the ministry; but embracing principles contrary to the government, while at Cambridge, he became disqualified for entering into holy orders. After he quitted the university, he was secretary to the earl of Orrery; but seems to have spent the most of his life amongst his friends and relations, and used to pay an annual visit to his elder brother, who enjoyed an estate of 1000l. a-year. He was a man of great tenderness and humanity, enjoyed the fairest reputation, and was much esteemed by Mr Pope; who, when he died in 1730, paid him the tribute of a very elegant epitaph. He published a volume of poems in the year 1717; and, in 1723, was acted his tragedy of *Marianne*, built upon her story collected from Josephus in the third volume of the *Spectator*.

FENUGREEK. See TRIGONELLA.

FEOD, or FEUD, is defined to be a right which a vassal hath in lands or some immoveable thing of his lord's, to use the same, and take the profits thereof hereditarily, rendering unto the lord such feudal duties and services as belong to military tenure, &c. and the property of the soil always remaining to the lord.

FEODAL, or of belonging to a FEUD or FEE.

FEODAL System, the constitution of FIEFS or FEUDS.

This remarkable system, so universally received throughout Europe upwards of 12 centuries ago, that Sir Henry Spelman does not scruple to call it the law of nations in our western world, forms a subject that merits particular attention; as, without a general knowledge of the nature and doctrine of feuds, it is impossible to understand, with any degree of accuracy, either the civil constitution of this kingdom, or the laws which regulate its landed property.

The constitution of feuds had its original from ¹Origin of the military policy of the northern or Celtic nations, ²feuds.

the Goths, the Huns, the Franks, the Vandals, and the Lombards; who, all migrating from the same *officina gentium*, or "storehouse of nations," as it has been justly called, poured themselves in vast multitudes into all the regions of Europe at the declension of the Roman empire. It was brought by them from their own countries, and continued in their respective colonies as the most likely means to secure their new acquisitions: and, to that end, large districts or parcels of land were allotted by the conquering general to the superior officers of the army, and by them dealt out again in smaller parcels and allotments to the inferior officers and most deserving soldiers. These allotments were called *feoda*, "feuds," "fiefs," or "fees;" which appellation, in the northern languages, signifies a conditional stipend or reward (A). Rewards, or stipends, they evidently were: and the condition annexed to them was, that the possessors should do service faithfully,

(A) Pontoppidan, in his history of Norway (p. 290.) observes, that, in the northern languages, *o* signifies *proprietary*, and *all totum*. Hence he derives the *ODHAL* right in those countries; and hence too, perhaps, is derived the *odal* right in Finland. (See Macdowall's Inst. part 2.) Now, the transposition of these northern syllables, *ALLODH*, will give us the true etymology of the *allodium* or *absolute property* of the feudists; as, by a similar combination of the latter syllable with the word *FEE* (which signifies, as we have seen, a conditional reward or stipend), *FEEDOH*, or *feodum*, will denote *stipendiary property*.

Feodal System.

fully, both at home and in the wars, to him by whom they were given; for which purpose, he took the *juramentum fidelitatis*, or oath of fealty: (see the article *Feodal Tenure*): and in case of the breach of this condition and oath, by not performing the stipulated service, or by deserting the lord in battle, the lands were again to revert to him who granted them.

General nature of the feudal association.

Allotments, thus acquired, naturally engaged such as accepted them to defend them: and as they all sprang from the same right of conquest, no part could subsist independent of the whole; wherefore all givers as well as receivers were mutually bound to defend each other's possessions. But as that could not effectually be done in a tumultuous irregular way, government, and to that purpose subordination, was necessary. Every receiver of lands, or feudatory, was therefore bound, when called upon by his benefactor, or immediate lord of his feud or fee, to do all in his power to defend him. Such benefactor or lord was likewise subordinate to or under the command of his immediate benefactor or superior; and so upwards to the prince or general himself. And the several lords were also reciprocally bound in their respective gradations, to protect the possessions they had given. Thus the feudal connection was established; a proper military subjection was naturally introduced; and an army of feudatories were always ready enlisted, and mutually prepared to muller, not only in defence of each man's own several property, but also in defence of the whole and of every part of this their newly acquired country: the prudence of which constitution was soon sufficiently visible in the strength and spirit with which they maintained their conquests.

Of allodiality.

But while possessions were to flow in the range of feudality, and were to uphold a regular militia, there were also estates which were to be received and to be retained under more enlarged maxims. To these every person who was free had a title. He could lay claim to his lot or partition of territory, and could dispose of it at his pleasure (B). In contradistinction to the feudal grant, which, as we have seen, was burdened with service and confined by limitation, these lands were known by the name of *allodiality*; a term which denoted their entire freedom and exemption from superiority.

(B) The curious reader may see the remote sources of the feudal laws particularly traced in the manners of the Germanic tribes before they left their woods, by the learned and spirited author of *A view of Society in Europe*, Book I. chap. ii. sect. 1. The members of a German nation, according to Tacitus, cultivated, by turns, for its use, an extent of land corresponding to their number; which was then parcelled out to individuals in proportion to their dignity. When a German tribe obtained possession of a Roman province, they continued to be governed by their ancient principles in the distribution of their possessions. The king or sovereign, as the person of greatest dignity, had the most considerable portion; which came to constitute his *domain*. Each citizen and warrior had his lot or share; which gave rise to *allodiality*. That part of the territory which was not exhausted by partitions to individuals, was considered, agreeably to the ancient ideas, as belonging to the community; and was called, in the barbaric codes, the lands of the *frife*. The situation of a German state, which had acquired a settlement, produced the necessity of drawing closer the connection of the sovereign and the chiefs, and of the chiefs and the people. The lands of the *frife* were the medium which was employed in effecting this design. The sovereign took the direction of these: hence possessions flowed to the chiefs, under the burden of presenting themselves in arms at the call of the sovereign; hence the chiefs dealt out lands to their retainers, under the like injunction of continuing to them their aid; and thus a political system was founded, which was to act in society with infinite efficacy.

"Of this system (says Dr Stuart) the intention and the spirit were national defence and domestic independence. While it called out the inhabitant and the citizen to defend his property, and to secure his tranquillity, it opposed barriers to despotism. Growing out of liberty, it was to promote the freedom of the subject. The power of the sovereign was checked by the chiefs, who were to form a regular order of nobility; and the aristocracy, or the power of the chiefs, was repressed by the retainers and vassals, who, constituting their greatness, were to attract their attention. The chief who oppressed his retainers, was to destroy his own importance. It was their number, and their attachment, which made him formidable to his prince and to his equals."

We must not, however, imagine that these allodial proprietors had no share in the defence of their country, or that the former were its only guardians. In the feudal times, the great conditions of society were liberty and servitude. To be free, was to have a title to go to the wars, and to seek renown. To be a slave, was to be doomed to toil in the house, to sweat in the field, and to know neither ease nor glory. While the subordinations of men in the arrangements of feudality were the peculiar guardians of the kingdom, there was yet, in every person who was free, an inherent obligation to defend it against uncommon and urgent dangers. The necessities of the state gave the alarm to all the ranks of the citizens; and the brave made haste to repel the enemy, and to spill their blood.—There were thus the militia of fiefs, and the militia of the nation.

Of the free, it was a characteristic, that they might possess property; and while the train of the vassalage filled up the feudal army, the militia of the nation was necessarily to consist of the proprietors of *allodiality*. But though, in general, an allodial possession is to be applied to a property in land, it was likewise to denote an estate in moveables, or in money; and proprietors of the latter class, as well as those of the former, were, in the seasons of peril, to bear arms, and to range themselves in battle.

But there was this distinction between the feudatories and the allodial proprietors, with regard to the circumstance in question, that the latter could only be called out in foreign wars, and against the enemies of the state: as they held of no superior or lord, they had no concern in private quarrels, and made no part in the feudal association. A circumstance which, if judged by modern ideas, might appear advantageous. It was in fact, however, the reverse; and operated as a cause of the conversion of *allodium* into *tenure*.

In the imperfection of government, when the magistrate could not extend his power with equal force over all the orders of men in the society; while the weak were exposed to the insults and the passions of the strong; while nobles, haughty and independent, could legally prosecute their resentments with the sword,

sword, revenge their wrongs, and gratify their avirice and cruelty, the holders of fiefs enjoyed a supreme advantage over allodial proprietors. A lord and his retainers, connected together in an intimate alliance, following the same standard, and adopting the same passions, could act with concert and efficacy. But allodial proprietors were altogether disqualified to defend themselves. Being distant and disengaged, they could form and support no continued or powerful confederacy; and the laws, in fact, did not permit them to enter into factions and hostilities. The violence of the times created an absurdity. It gave to gifts under service and reverible to the grantor, a value superior to lands which were held in full property and at the disposal of the proprietor. It made necessary the conversion of *propriety into tenure*.

Nor was this the only consideration which had weight with the possessors of property. In every monarchy, but in one more particularly that is governed by feudal ideas, rank and pre-eminence attract chiefly the attention, and excite the ambition of individuals. The king being the fountain of honour, and distinctions flowing from his favour, the ranks of men were nicely adjusted; and in proportion as they approached to his person, they exacted and received respect. From this principle it naturally proceeded, that allodial proprietors were treated with contempt. Holding by no tenure, and occupying no place in the feu-

dal arrangements, they could not draw observation. Their pride was alarmed, and they wished for the respect and security of vassals.

Princes, bent on the extension of fiefs, discouraged these proprietors. Their ambition, their abilities, and their prerogatives, furnished them with the greatest influence; and they employed it to give universality to a system, which was calculated to support the royal dignity and the national importance. Compositions for offences inferior to those which were allowed to a vassal, were deemed sufficient for the proprietors of allodality. In the courts of justice, they felt the disadvantages of their condition. Mortified with regal neglect; without sufficient protection from the laws; exposed to the capricious insolence, and the destructive ravages, of the great; disgusted with rancours, contempt, and indignity, they were driven into the circle of fiefs. They courted the privileges and protection which were enjoyed by vassals. They submitted their estates to tenure, selecting to themselves a superior the most agreeable, granting to him their lands, and receiving them back from him as a feudal donation.

In this direction of affairs, the extension of the feudal institutions was unavoidable. The landed property was every where changed into feudality. The empire of fiefs was universal (c).

While the greatness and simplicity of those maxims which

(c) It has puzzled the learned to discover the nation of the barbarians which first gave a beginning to fiefs. No inquiry, in Dr Stuart's opinion, could be more frivolous. In all of them they must have appeared about the same period. And they prevailed in all of them in consequence of the similarity of their situation on their conquests, and in consequence of their being governed by the same customs. It is not, therefore, to the principle of imitation that their universality is to be ascribed.

The annals of France make mention of fiefs in the age of Childebert. The Longobards at an early period introduced them into Italy; and the customs and laws which relate to them seem to have advanced rapidly among this people*.

In Spain, the introduction of feudal tenures preceded the devastations of the Saracens or Moors, which began in the year 710. Among the Goths, who established the monarchy of Spain, lands were granted for service and attachment; and the receiver was the retainer of the grantor. He was said to be *in patrocinio*; and if he refused his service, he forfeited his grant. It also appears, that the retainer, or vassal, swore fealty to his patron or lord. And it was on this scheme that their militia was regulated†.

In England, there is little doubt that the feudal law was known in the Saxon times, as we shall see above §.

In Scotland, the history of fiefs is still more obscure than in any other nation. This imperfection has been ascribed partly to the melancholy condition of the Scottish records, but chiefly to the want of able antiquaries of that nation. But, according to Dr Stuart, "the two great divisions of landed property, *feudality* and *allodial possession*, were coeval with its monarchy. And they must have sprung from the same peculiarity of manners, and of situation, which had given them existence in other nations. It has been conceived, indeed, that Malcom II. building upon some foreign model, introduced their customs into Scotland; and the great body of the Scottish historians and lawyers have subscribed to this notion. It has likewise been thought, that they were imported thither expressly from England; and the policy of Malcom III. has been highly extolled as the effective cause of their establishment. But it seems to Dr Stuart, that no reasons of any authority support these opinions.

"They bear either expressly, or by implication, that the feudal system was introduced into Scotland, in consequence of a principle of adoption or imitation. Now, the peculiarities of fiefs are so strong, and so contradictory to all the common maxims which govern men, that they could not possibly be carried, in any stage of their progression, from one people to another. To transplant the feudal usages, when the grants of land were precarious, or at the will of the prince, to a country where superiority and vassalage had been unknown; to alter the orders of men, from the sovereign to the peasant; and to produce the corresponding chain of customs, with respect to legislation, and the details of the higher and the lower jurisdiction, must have been an attempt infinitely wild, and altogether impracticable. To transplant fiefs in their condition of perpetuity, must have been a project, involving an equal, or rather a greater, number of absurdities.

"But, while it is to be imagined, that fiefs could not be transported with success, in any period of their progression, from one people to another; it is also obvious, that a nation so cultivated, as to have the knowledge and the practice of them in any degree, could not be inclined to make a conquest for the purpose of a settlement. The existence of fiefs implies an establishment and a fixed residence; and history has no notice of any tribe or people under this description, who ever wandered from home to fight for a tract of country which they might inhabit.

"Wherever feudality was to flourish, it was to grow from the root. The tree could not be carried to a foreign soil. Its native earth could alone preserve it in existence, and give the aliment that was to make it rise into height, and shoot into branches.

"Scotland was a feudal kingdom; and we can point pretty exactly to the time when fiefs were *hereditary* there. Now,

which the conquerors of Rome brought with them from their woods continued to animate their posterity, the feudal association was noble in its principles, and useful in its practice. It was an exercise of bounty on the part of the lord, of gratitude on that of the vassal. On the foundation of their connection, and of that of the land or fief which the former bestowed on the latter, a train of incidents was to arise, the unequivocal expressions of friendship and habitude, the tender and affectionate fruits of an intercourse the most devoted and zealous.

The feudal
incidents.

While the grants of lands were precarious, or for life, the superior chose to educate, in his hall, the expectants of his fiefs. And, when they descended to heirs, he was careful, on the death of his vassal, to take the charge of his son and his estate. He protected his person, directed his education, and watched over his concerns. He felt a pride in observing his approaches to manhood, and delivered to him, on his majority, the lands of his ancestor, which he had been studious to improve. These cares were expressed in the incident of *wardship*.

The vassal, on entering to his fief, conscious of gratitude, and won with the attention of his lord, made him a present. This acknowledgment, so natural, and so commendable, produced the incident of *relief*.

Grateful for the past, and anxious for the future favour of his chief, the vassal did not incline to ally himself with a family which was hostile to him. The chief was ambitious to add to his power and splendor, by consulting the advantageous alliance of his vassal. They joined in finding out the lady whose charms and whose connections might accord with the passions of the one and the policy of the other. This attention gave establishment to the incident of *marriage*.

When the superior was reduced to distress and captivity in the course of public or of private wars, when he was in embarrassment from prodigality or waste, when he required an augmentation of means to support his grandeur, or to advance his schemes and ambition, the vassal was forward to relieve and assist him by the communication of his wealth. On this foundation there grew the incident of *aid*.

When the vassal gave way to violence or disorder, or when by cowardice, treachery, or any striking delinquency, he rendered himself unworthy of his fief, the sacred ties which bound him to his lord were infringed. It was necessary to deprive him of his land, and give it to a more honourable holder. This was the origin of the incident of *escheat*.

Amidst the contention of friendship and the mutuality of mind which informed the lord and his vassal, there was experienced a condition of activity, liberty, and happiness. The vassals attended to the retainers who were immediately below them. In their turn, they were courted by the lords, whose strength they constituted. And the lords gave importance to the sovereign. A subordination was known, which was

regular, compact, and powerful. The constituent parts interrelated in government as well as war, were attentive, in their several departments, to the purposes of order and justice; and, in national operations, they acted with an uniformity which made them formidable. Of this association public liberty was the result. And, while this fortunate state of things continued, the people, in every country of Europe, came in arms to their national assembly, or appeared in it by their representatives.

Such, in a more particular manner, was the condition of the Anglo-Saxon period of our history; and the people, happy alike in their individual and politic capacity, as men and as citizens, were to bear more reluctantly the oppressions of the Normans.

But the original manners which the conquerors of the Romans brought from their forests, were to spend their force. The high sentiments which had resulted from the limited ideas of property, were to decay. The generous maxims of the feudal association, and the disinterested wildness of chivalry, were to suffer with time. Property was unfolded in all its relations, and in all its uses. It became a distinction more powerful than merit, and was to alter the condition of society. By separating the interests of the lord and the vassal, it was to destroy for ever the principles of their association; and the incidents, which, in a better age, had fostered their friendship, were to feed their rage, and to prolong their animosity. As their confederacy had been attended with advantages and glory, their disaffection was marked with debasement and subjection. Out of the sweets of love, a fatal bitterness was engendered. Sufferance was to succeed to enjoyment; oppression to freedom. Society and government were to be tumultuous and disorderly; and diseases and infirmities were to threaten their decay.

In the prevalence of property and of mercenary views, the *ward* of the infant-vassal, which the superior once considered as a sacred care and an honourable trust, was to be regarded in no other light than as a lucrative emolument. The acquisitions of the vassal, which, in their state of agreement and cordiality, were a strength to the lord, seemed now to detract from his domains. He committed spoil on the estate which, of old, it was his pride to improve. He neglected the education of the heir. He gave repeated insults to his person. The relations of the vassal were often to buy from the superior the custody of his person and his lands. This right was more frequently to be let out to exercise the rapacity of strangers. The treasury of princes was to increase with this traffic; and superiors were to imitate, as well from necessity as from choice, the example of princes. The heir, on his joyless majority, received the lands of his ancestor; and, while he surveyed, with a melancholy eye, his castles, which bore the marks of neglect, and his fields, which were deformed with waste, new grievances were to

TO
The perversion of its incidents.

Now, in that form, they could not be imported by any of its princes; and, it is evident, that no conquering nation, advanced to the practice of fiefs in this degree, made a conquest and establishment in Scotland. In consequence, therefore, of a *natural* progress, fiefs must have grown to this condition of refinement. And, before fiefs were hereditary, they were for a series of years; before they were for a series of years, they were for life; and, before they were for life, they had been precarious or at pleasure.

“In every feudal country, the progress from the precarious grant, to the gift in perpetuity, was experienced. In Scotland, the same progress must have been known; and the consideration of it carries us back to a remote antiquity. For fiefs, in this kingdom, being *hereditary* about the days of Malcolm II. or Malcolm III. some centuries must have passed away in the production of the previous steps of feudality.”

situation of
vassals.

to embitter his complaints, and to swell his passions.

The *relief*, which originally was no more than a present, at the pleasure of the vassal, on his entering into the fief, was consolidated into a right. An expression of gratitude was converted into a debt and a burden. The superior, before he invested the heir in his land, made an exaction from him, in which he had no rule but his rapacity. His demand was exorbitant and grievous. And, if the heir delayed too long to extinguish this sine of redemption, or was unable to pay it, the superior continued his possession of the estate. Rigours, so humiliating, and so frantic, produced clamour, discontent, and outrage. Mitigations were to be applied to them, and to prove ineffectual. Laws were to be made against them, and to be disregarded.

The *marriage* of the vassal, which could not be abused while their association was firm and their interest mutual, became a most ruinous perquisite, when their association was broken, and their interest discordant. The superior could give his vassal in marriage to whom he pleased. This right he exerted as a property. It might be purchased from him by the vassal himself, or by a stranger. The marriage of the vassal, without the consent of the superior, involved the forfeiture of the estate, or was punished with oppressive penalties. It was a rule, indeed, resulting out of their former habits, that the heir should not be married to his disparagement. But this rule was overlooked amidst the violence of the times. The superior had no check but from his humanity, the vassal no relief but in remembrance.

This right, so mortifying to the male heir, was a stretch of still wilder oppression, and more ferocious cruelty, when exercised on the *female ward*. Her hand might be tendered at the will of the superior. He might pay no attention to her affections. She was to submit, at his mandate, to indecent embraces, unfashioned with love. Her beauty was to lose its sweets, and her heart its enjoyments, to feed his avarice, and to gratify his whim. Her relations were often to buy from him a privilege so frightful; and the unfeeling tyrant was to paint the horrors of its exertion, to extort his demand.

The *aid* which, in happier times, the vassal bestowed out of benevolence to relieve the distress and to assist the grandeur of his lord, became a burden and a tax in the misery of their disaffection. It was arrogated as a duty and a tax. The lord called for an aid or contribution, when his eldest daughter was married, when his eldest son was made a knight, and when, having been taken in war, his own person was to be ransomed. These were esteemed the legal occasions when exactions could be made. But custom and practice authorised the requisition of aids on pretences the most frivolous. When the crown or the lord was disposed to be oppressive, they could find a reason for an *aid*; and wants, not his own, were to affect every moment the subsistence of the vassal.

While their confederacy was maintained, it was not on any slight foundation that the fief could be taken from the vassal. Cowardice, dishonour, treachery, or treason, were then the causes of *escheat*. The lord was not to be so offended with lesser delinquencies, as to take possession of the estate. In the times, however, of their disagreement, the causes of forfeiture were to multiply,

and he was to be active to enforce them. Trespases and trifles were to be sufficient grounds for the seizure of lands, of which the possessor was offensive. The vassal held a precarious and dangerous territory; and, with a mind disposed to be hostile to his chief, was to observe to him an attentive and punctilious demeanour. If he refused too long to attend the court of the superior, and to give his oath of fidelity; if he happened to commit the slightest infringement of his oath; if he foresaw any misfortune that was to befall his lord, and neglected to inform him of it; if, by any act, he was to affect the credit or the reputation of his superior; if he should chance to reveal any private circumstance concerning him; if he should grant an infestation in any other form than that in which he held his own; if he should make love to the wife or the daughter of his lord, or should carelessly his sister, while yet a virgin and unmarried; these, and reasons still more absurd, were to forfeit the estate to the superior, and to involve the ruin of the vassal and that of his family.

But though the cordiality of the lord and the vassal was decayed, the grant of land from the former to the latter continued its obligations. The vassal was held by a tie, which he could not renounce without forsaking his importance. His property and subsistence fastened him to an enemy. His passions and his duties were at variance. He might hate the person of his lord, but he was to bow to him as his superior. The grant of land he enjoyed, bound him to the performance of military service. With a cold heart, he was to buckle himself in his armour; and, with reluctant steps, he was to follow the march of his chief. Of old, it had been his fondest attention to carry all his strength against an enemy, that he might display his own greatness, and add to the magnificence of his superior. He now furnished unwillingly the least assistance in his power. The fervour of his former conduct was never more to advance the measures of ambition. And, in this state of things, the feudal militia was to obstruct and retard, rather than to forward, the operations of princes.

In the heart of a populous kingdom, and surrounded with subjects accustomed to arms, the feudal sovereign was thus to feel an unnatural weakness. A malady, so formidable, could not but produce an anxiety for its cure. And, what is no less certain than peculiar, in the different countries of Europe the same remedy was applied to it.

Fiefs, or the grants of land under military service, had advanced from being annual to be for life; and, from being donations for life, they were to proceed to be hereditary. It was before the establishment of this ultimate point in their progression, that the happiness of the feudal association was disturbed. And, it was the establishment of this point which was to afford the opportunity to princes of recovering, in some degree, their greatness. While the cordiality of the vassal was maintained, a general obligation of military service was sufficient to induce him to marshal all his force in the field. When this cordiality was destroyed, policy was to extort what his generosity and attachment had conferred. Lands were to be burdened with a *full* and exact proportion of soldiers. The giving them out in perpetuity was the season for annexing this burden. An expedient, natural, and not to be opposed, suggested

Feodal
System.

Consequent
degeneracy
of the feudal
militia.

13
Expedient
service was
for its recovery.

gested itself.

The tenure of knight-service was invented.

A portion of land, of which the grant, by the agreement of the giver and the receiver, entitled to the service of a soldier or a knight, was a *knight's fee*. An estate, of 200 fees, furnished, of consequence, 200 knights. Manours, baronies, and earldoms, were thus powerful, in proportion to their extensiveness. The grants from the sovereign to the nobles claimed the service of so many knights; and the sub-infeudations of the nobles enabled them to perform this service. The tenants of the crown who were not noble, had also their fees, and furnished proportionally their knights. Grants *in capite*, or from the sovereign, and the sub-infeudations of vassals, called out the force of the kingdom. The prince, the nobility, and the people, were in the capacities of a general, officers, and soldiers. A call to arms put the nation into motion. An army, numerous and powerful, could be assembled with expedition, exact in its arrangements, and in a state for defence and hostility.

Such, Dr Stuart conceives, was the origin and nature of *Knight-service*: A tenure which came to recover the feudal militia at a time when it was perishing in weakness. But though it bound more closely, in the connection of land, the superior and the vassal, by the fixedness of the service it enjoined, it could not bring back their ancient cordiality. It gave a strength and consistency to the military department of the feudal institutions; but it removed none of their civil inconveniences and burdens. These, on the contrary, were to increase during its prevalence. It was to brace, only, with a temporary vigour, a system which no prudence or art could accommodate to refining manners.

The incidents, which had grown with the progress of fiefs, still continued their operation. Every grant by the tenure of knight-service, was attended with homage and fealty, and was exposed to wardship and relief, to marriage, aid, and escheat. The superior had still his pretensions and his claims; the vassal was still to suffer and to complain. Promises of the relaxation of the feudal perquisites, were to be made by princes, and to be forgotten. Legal solemnities of restraint were to be held out, and, occasionally, to produce their Vol. IV.

(D) For the difference between the knights produced by this service and the more ancient knights or knights of honour, see the word *Knight*.

(E) Knight-service was established in Scotland before the time of Malcolm IV. anno 1153. Records of his reign instruct its existence, and do not mention it as a novelty. It even appears probable that this tenure was known in the times of David I. See *Dr Stuart's Observ. on the Law and Constit. Hist. of Scotland*, p. 16. and 156—160.

(F) The use of entails, which was not unknown in the Anglo-Saxon times, and the succession which obtained in allodial estates, must have contributed very much to the establishment of the perpetuity of the fief; *LL. Ælfredi*, ap. *Wilkins*. The general tendency of the fief to this ultimate step, and the immense power of many of the Anglo-Saxon nobles, seem also to confirm the idea, that the existence of its perpetuity might, in some cases, be known in the Anglo-Saxon times. But presumptive arguments, though of great weight, are not to be entirely relied upon in questions of this sort.

There is actual evidence that Ethelred possessed, as an hereditary fief and earldom, the territory which had constituted the kingdom of Mercland. He had this grant from king Alfred, when he married his daughter Ethelfleda; *Selden, Tit. Hon.* part 2. ch. 5. It is testified out of records, that the earldom of Leicester was an inheritance in the days of Ethelbald; and the regular succession of its earls, for a long period, is to be pointed out: *Camden's Britannia*, by *Gibson*, vol. I. p. 542. It is known from old historians of credit, that Deirland and Bernicia were Saxon earldoms, which were not only feudal, but inheritable; *Tit. Hon.* part 2. ch. 5.

The grant of Cumberland by king Edmund to Malcolm king of Scotland, was also feudal and inheritable; and this appears from the Saxon Chronicle, and from the following version of the terms employed in it. "Eadmundus Rex totam Cumberland prædavit et contrivit, et commendavit eam Malcolm Regi Scotie; hoc pacto quod in auxilio sibi fore terra et mari. *H. Huntingdon, ap. Prefat. Episc. Derrenf. ad LL. Anglo-Sax.* p. 7. The expression

effect. But, palliatives, feeble or forced, were not to controul the spirit of the system and the times. Fiefs, while they sustained, in the tenure of knight-service, the grandeur of the European states, were waiting with internal debilities. And the eye, in surveying their strength and magnificence, can trace the marks of an approaching weakness and decline.

Thus, in the history of the feudal institutions, there are two remarkable periods; the epoch which preceded the invention of knight-service (D), and the epoch during which it prevailed.

From the conquests of the barbarians till the ninth century, fiefs were in their state of fluctuation. It was about the year 877 that the perpetuity of the fief was established in France; and it was known in every country of Europe, in the commencement of the tenth.

The tenure of knight-service soon followed the perpetuity of the fief, and was connected with it. There is an instance of a knight-fee in the 880*. In the reign of Hugh Capet, who was raised to the throne in the year 987, this tenure extended itself over France; and after having appeared in other nations, it was introduced into England (E). But, in this last country, there are peculiarities, concerning the beginnings and the progress of fiefs, which have been the subject of much inquiry and conjecture. Many learned writers are positive that the Anglo-Saxons were strangers to fiefs, which they assert were introduced into England by William duke of Normandy. There are writers not less learned who affirm, that fiefs were not introduced into England by the duke of Normandy, but prevailed among the Anglo-Saxons in the condition in which they were known under William. Dr Stuart† observes, that it cannot be true, that the Saxons who settled in England should be strangers to fiefs.—The hereditary grant of land, as well as the grant in its preceding fluctuations, was known to our Saxon ancestors. Of this, the conformity of manners which must necessarily have prevailed between the Saxons and all the other tribes of the barbarians, is a most powerful and a satisfactory argument. Nor is it single and unsupported. History and law come in aid to analogy; and these things are proved by the spirit and text of the Anglo-Saxon laws, and by actual grants of hereditary estates under military service (F).

Introduc-
tion of knight-
service into
England.

But although fiefs prevailed in the Anglo-Saxon times, yet their condition was different then, from what it afterwards became. Under the Anglo-Saxon princes, no mention is made of those feudal severities which shook the throne under William and his successors. The varying spirit of the feudal association, which Dr Stuart has been careful to remark, accounts for this difference. When the connection between the superior and vassal was warm and generous, the feudal incidents were acts of cordiality and affection. When the introduction of luxury, and an acquaintance with the use of riches, had given birth to those interested passions which set the superior and vassal at variance, the same incidents became acts of oppression and severity. This was more remarkably the case under William and his immediate successors; and until the time of king John, the people of England complained loudly of the feudal severities, and to their complaints always joined the request, that the laws of Edward the Confessor should be restored. "What these laws of Edward the Confessor were (says Mr Hume), which the English, every reign, during a century and a half, desired so passionately to have restored, is much disputed by antiquarians; and our ignorance of them seems one of the greatest defects of the ancient English history." The train of thinking into which Dr Stuart † has been led, points to an explanation of this mystery. By the laws or customs of the Confessor, that condition of felicity was expressed, which had been enjoyed during the fortunate state of the feudal association. The cordiality, equality, and independence, which then prevailed among all ranks in society, continued to be remembered in less prosperous times, and occasioned an ardent desire for the revival of those laws and usages which had been the sources of so much happiness (g).

But, while the times of duke William and his successors were discriminated from those of the Confessor and the Anglo-Saxon princes, by the different states they displayed of the feudal association, there is another circumstance in the progress of fiefs, by which they were to be distinguished more obviously.

Knight-service, which, in France, and in the other kingdoms of Europe, was introduced in the gentle gradation of manners, was about to be discovered in England, after the same manner, when the battle of Hastings facilitated the advancement of William the Nor-

man to the crown of the Confessor. The situation of the Anglo-Saxons in an island, and the Danish invasions, had obstructed their refinement. In the memorable year 1066, when they lost king Edward, and acquired duke William, they knew the perpetuity of the fief; but they were altogether strangers to knight-service and a knight's fee. The duchy of Normandy, when granted to Rollo by Charles the Simple, in the year 912, had yet experienced all the vicissitudes of fiefs. And William, being the sixth prince in the duchy, was familiar with the most extended ideas of the feudal system. These he brought with him into England, and they were to govern and direct his conduct.

The followers of Harold having forfeited their estates, they reverted to the crown. An immense number of lordships and manors being thus in the disposal of William, he naturally gave them out after the forms of Normandy. Each grant, whether to a baron or a gentleman, was computed at so many fees; and each fee gave the service of a knight. To the old beneficiary tenants, he was to renew their grants under this tenure. By degrees, all the military lands of the kingdom were to submit to it. And with a view, doubtless, to this extension, the book of DOMESDAY was undertaken, which was to contain an exact state of all the landed property in the kingdom. Instead, therefore, of bringing fiefs into England, this prince was only to introduce the last step of their progress, the invention of the knight's fee, or the tenure of knight-service.

In fact, it is to be seen by his laws, that he introduced knight-service, and not fiefs. Nor let it be fancied, that this improvement was made by his single authority and the power of the sword. His laws not only express its enactment in his reign, but mention that it was sanctioned with the consent of the common-council of the nation. It was an act of parliament, and not the will of a despot, that gave it validity and establishment (h).

The measure, it is to be conceived, was even highly acceptable to all orders of men. For, a few only of the benefices of the Anglo-Saxon princes being in perpetuity, the greatest proportion of the beneficiary or feudal tenants must have enjoyed their lands during life, or to a series of heirs. Now, the advancement of such grants into hereditary fiefs, under knight-service,

was

commendare, indeed, is said by Spelman not to mean a feudal homage; (*Feuds and Tenures*, p. 35.) But the original Saxon evinces this sense; and in fact the word *commendare*, notwithstanding the authority of this learned glossographer, is used with the utmost propriety to express a feudal homage. *Commendare se alicui*, was even the marked expression for *faire l'hommage à un seigneur*. See *Du Gange*, voc. *Commendare* et *Brüssel*, *Usage general des fiefs*, p. 35, 276.

(g) There are laws which bear the name of Edward; but it is acknowledged on every hand, that their authority is not to be fully trusted. And in the question treated, they are not of any use; unless it be, perhaps, that they illustrate the existence of fiefs among the Anglo-Saxons. This compilation, however, though posterior to the age of the Confessor, deserves to be examined with more attention than has hitherto been bestowed upon it. M. Honard, a foreign lawyer, whose acquaintance with the Norman customs is more intimate than with those of the Anglo-Saxons, is the latest writer who seems to have made a study of it.

(h) The following very curious law of William the Norman makes express mention of the knight's fee and knight-service. It does more. It alludes to a prior law which actually established this tenure, and which was the act of William and his parliament. It is, of consequence, a decisive proof of the introduction of the knight's fee, or of knight-service, by this prince, and of this only. "Statuimus etiam et finiter precipimus, ut omnes comites, et barones, et milites, et servientes, et universi liberi homines totius regni nostri predicti, habeant et teneant se femper bene in armis, et in equis, ut decet et oportet, et quod finit semper prompti et bene parati ad servitium suum integram nobis explendum, et peragendum, cum semper opus adjuverit, secundum quod nobis debent de feodis, et tenementis suis de jure facere, et sicut illis statuimus per commune consilium totius regni nostri predicti, et dedimus et concessimus in feodo jure hereditario." LL. Guill. c. 38.

Feodal
System.Feodal
Ferialia.

was an important advantage and acquisition. While it operated to the convenience and the grandeur of the sovereign, it bettered the property, and secured the independence, of the subject.

When the feudal association was cordial, there existed no necessity for the knight's fee. The vassals of a chief gave with pleasure their assistance. When the association was discordant, different interests actuating the superior and the vassal, art and policy were to prescribe the exact service to be performed. Nothing was to be left to friendship and cordiality. A rule, certain and definite, pointed out the duties of the vassal. This rule was the tenure of knight-service.

A duchy, barony, or earldom, were the estates possessed by the nobles; and, being divided into fees, each of these was to supply its knight. A tenant of the crown, who was not created into nobility, but enjoyed a grant of land, furnished also his knights in proportion to his fees. The nobles and the gentry of a feudal kingdom were thus its defenders and guardians. And they granted out territory to persons inferior to them in the divisions of fees, and under the burden of knights. In proportion, therefore, to the extent of its lands, there was, in every feudal state, an army, or a body of militia, for its support and protection.

But while a force, numerous and sufficient, was in this manner created, a care was also bestowed to hold it in readiness to take the field. The knights, who were to appear in proportion to the fees of each estate, were bound to assemble at a call, in complete armour, and in a state for action. The feudal militia, of consequence, could be marched, with expedition, to defend the rights of its nation, to support its honour, or to spread its renown.

The usual arms of a knight were the shield and helmet, the coat of mail, the sword, or the lance. It was, also, his duty to have a horse. For, a growing luxury, and the passion for show, encouraged by tournaments, had brought discredit to the infantry, which had distinguished the barbarians in their original seats, and facilitated their victories over the Romans. The horsemen were called the *battle*, and the success of every engagement was supposed to depend upon them. No proprietor of a fee, no tenant by knight-service, fought on foot. The infantry consisted of men, furnished by the villages and the towns in the demesnes of the prince or the nobles. The bow and the sling were the arms of these; and tho', at first, of little consideration, they were to grow more formidable.

During the warmth of the feudal association, the military service of the vassal was every moment in the command of the superior. When their association was decayed, it was not to be depended on; and, when afforded, was without zeal, and without advantage. The invention of knight-service, which was to recover, in some degree, the vigour of this connection, while it ascertained the exact duty to be rendered, was to fix its duration. Each possessor of a fee was, at his own expense, to keep himself in the field during 40 days. To this obligation, the great vassals of the crown were bound, and inferior proprietors were to submit to it. When a single battle was commonly to decide the fate and the disputes of nations, this portion of time was considerable and important. And, if any expediency demanded a longer duty, the prince might retain his

troops, but under the condition of giving them pay for their extraordinary service.

Such was the military system, which, during a long period of time, was to uphold the power of the monarchies of Europe; a system, of which it was the admirable consequence, that those who were the proprietors of the land of a kingdom, were to defend it. They were the most interested in its welfare and tranquillity; and, while they were naturally disposed to act with union and firmness against a foreign enemy, they were induced not less strongly to guard against domestic tyranny. Their interest and happiness, their pleasure and convenience, urged them equally to oppose invasions from abroad, intestine commotions, and the stretches of prerogative. A strength, so natural, and which could never be exhausted; a strength, in which the prince was to have less authority than the nobles, and in which the power of both was checked by the numerous class of inferior proprietors; a strength, which had directly in view the preservation of civil liberty, seems, on a slight observation, the perfection of military discipline.

But, notwithstanding this advantage, the feudal militia was found incompatible with refining manners. It had been usual, from the earliest times, for the superior to levy a fine from the military tenant, who refused to take the field at his summons. As luxury increased, men became less willing to join the army. Hence the commutation of service for money, and the introduction of the tenure of *escuage*, which, instead of exacting the personal attendance of the knight, only obliged him to pay an annual sum to his superior. As the king was lord paramount of the whole kingdom, the money thus collected ultimately centered in him; and princes, instead of recruiting their armies, filled under their exchequers. In order to defend their dominions, they hired mercenaries, composed of the dregs of the people. These were disbanded at the end of every campaign; and the disturbances which such numbers of idle handitti occasioned all over Europe, shewed the necessity of standing armies. The use of mercenaries gave birth to taxations, which began to be levied in every kingdom of Europe at the will of the prince. This produced contentions between sovereigns and their subjects. In most countries of Europe the kings acquired the right of taxation, which, united to the command of the military force, forms the completion of despotism. In England, the prerogative of taxation, which the prince had assumed, was wrested from him by the great charter of liberties. He was to command his mercenaries; but he was to depend, for their support and their pay, on the generosity of his people.

FEOFFMENT, in law, is a gift or grant of any manors, messuages, lands, or tenements, to another in fee; that is, to him and his heirs for ever, by delivery of seisin, and possession of the estate granted. See **FEU**.

FERÆ, in zoology, an order of quadrupeds. See **ZOOLOGY**.

FERALIA, in antiquity, a festival observed among the Romans on February 21st, or, according to Ovid, on the 17th of that month, in honour of the manes of their deceased friends and relations. During the ceremony, which consisted in making presents at their

graves, marriages were forbidden, and the temples of the divinities shut up; because they fancied, that, during this festival, the ghosts suffered no pains in hell, but were permitted to wander about their graves, and feast upon the meats prepared for them.

FER DE FOURCHETTE, in heraldry, a cross having at each end a forked iron, like that formerly used by soldiers to rest their muskets on. It differs from the cross-fourché, the ends of which turn forked, whereas this has that sort of fork fixed upon the square end *.

* See Heraldry.

FER DE MULIN, *Milrinde*, *Inke de Moulin*, in heraldry, is a bearing supposed to represent the iron-ink, or ink of a mill, which sustains the moving mill-stone.

FERDINAND V. king of Spain, called the *Catholic*, which title was continued to his successors. He married Isabella of Castile, by which that kingdom was united to the Spanish crown. This illustrious couple, laid the foundation of the future glory and power of Spain. The conquest of Granada, and the discoveries of Christopher Columbus, make this reign a celebrated era in the history of Spain. He died in 1516, aged 63. See (*History of*) SPAIN.

FERENTARI, in Roman antiquity, were auxiliary troops, lightly armed; their weapons being a sword, bow, arrows, and a sling.

FERENTINUM, (anc. geog.), a town of the Hernici in Latium, which the Romans, after subduing that nation, allowed to be governed by its own laws. Now *Ferentino*, an episcopal city in the Campania of Rome. E. Long. 14. 5. N. Lat. 41. 45.

FERENTUM, or FORENTUM, (anc. geog.), a town of Apulia in Italy. Now *Forenza*, in the Basilicata of Naples.

FERETRUM, among the Romans, the bier used in carrying out the bodies of the dead, which duty was performed by the nearest male relations of the deceased; thus, sons carried out their parents, brothers their sisters, &c.

FERGUS, the name of three kings of Scotland. See (*History of*) SCOTLAND.

FERGUSON, (James), an eminent experimental philosopher and mechanic, was born in Scotland, of very poor parents. At the earliest age his extraordinary genius began to exert itself. He first learned to read, by overhearing his father teach his elder brother; and he had made this acquisition before any one suspected it. He soon discovered a peculiar taste for mechanics, which first arose on seeing his father use a lever. He pursued this study a considerable length, even whilst very young; and made a watch in wood-work, from having once seen one. As he had no instructor, nor any help from books, every thing he learned had all the merit of an original discovery; and such, with infinite joy, he believed it to be. As soon as his age would permit, he went to service; in which he met with hardships, which rendered his constitution feeble through life. Whilst he was servant to a farmer, (whose goodness he acknowledges in the modest and humble account of himself which he prefixed to his last publication), he frequently contemplated the stars; and began the study of astronomy; by laying down, from his own observations only, a celestial globe. His kind master, observing these marks of his ingenuity, procured him the countenance and assistance of his superiors. By their help and instructions, he went on gaining farther

knowledge, and was sent to Edinburgh. There he began to take portraits; an employment by which he supported himself and family for several years, both in Scotland and England, whilst he was pursuing more serious studies. In London he first published some curious astronomical tables and calculations; and afterwards gave public lectures in experimental philosophy, which he repeated (by subscription) in most of the principal towns in England, with the highest marks of general approbation. He was elected a Fellow of the Royal Society, without paying for admission (an honour scarcely ever conferred on a native); and had a pension of 50l. per ann. given him, unsolicited, by our gracious king, at his accession, who had heard lectures from him, and frequently sent for and conversed with him on curious topics. He also received several presents from his majesty, the patron of real merit. To what a degree of consideration Mr Ferguson mounted by the strength of his natural genius, almost every one knows. He was universally considered as at the head of astronomy and mechanics in this nation of philosophers. And he might justly be styled self-taught; or rather heaven-taught; for in his whole life he had not above half a year's instruction at school. He was a man of the clearest judgment, and the most unwearied application to study; benevolent, meek, and innocent in his manners as a child: humble, courteous, and communicative; instead of pedantry, philosophy seemed to produce in him only diffidence and urbanity,—a love for mankind and for his Maker. His whole life was an example of resignation and Christian piety. He might be said to be an enthusiast in his love of God, if religion, founded on such substantial and enlightened grounds as his was, could be styled enthusiasm. He died in 1776.

FERIÆ, in Roman antiquity, holidays, or days upon which they obtained from work.

The Romans had two kinds of feriæ: 1. the public, common to all the people in general; 2. The private, which were only kept by some private families.

The public feriæ were fourfold: 1. *Stativæ feriæ*, holidays which always fell out upon the same day of the month, and were marked in the calendar; of these the chief were the ægonalia, carnentia, and lupercalia. 2. *Comparitivæ feriæ*, holidays appointed every year upon certain or uncertain days by the magistrates or the pontiff; such were the latine, paganalia, compitalia, &c. 3. *Imperativæ feriæ*, holidays commanded or appointed by the authority of the consuls or prætors; of this kind we may reckon the ludiisæminni. 4. *Nundinæ*, the days for fairs. See NUNDINÆ, &c.

FERIÆ Latine, were instituted by Tarquinius Superbus; who, having overcome the Tuscans, made a league with the Latins, and proposed to them to build a temple in common to Jupiter Latiæ, in which both nations might meet, and offer sacrifice for their common safety. At this festival a white bull was sacrificed; and each town, both of the Latins and Romans, provided a certain quantity of meat, wine, and fruits. At first the solemnity continued but one day; after the expulsion of the kings, the senate added a third, a fourth, and so on to ten days.

FERIA, in the Romish breviary, is applied to the several days of the week; thus Monday is the *feria secunda*,

Feria,
Feria.

Fermanagh
Fermentation.

cunda, Tuesday the *feria tertia*; though these days are not working days, but holidays. The occasion of this was, that the first Christians were used to keep the easter-week holy, calling Sunday the *prima feria*, &c. whence the term *feria* was given to the days of every week. But besides these, they have extraordinary ferie, viz. the three last days of passion-week, the two following easter-day, and the second ferie of rogation.

FERMANAGH, a county of Ireland, in the province of Ulster; bounded by Cavan on the south, Tiroen on the north and north-east, by Tyrconnel on the north-west, Leitrim on the south-west, and Monaghan on the east. It is 38 miles long and 24 broad. A great part of it is taken up with bogs, and the great lake called *Lough Erne*, which is near 20 miles in length, and in some places 14 in breadth, diversified with upwards of 300 islands, most of them well wooded, inhabited, and covered with cattle. It abounds also with great variety of fish, such as huge-pike, large bream, roach, eels, trout, and salmon. The water of the lake in some places is said to have a particular softness and liminess, that bleaches linen much sooner than could be done by other water. The lake is divided into the Upper and Lower, between which it contracts itself for five or six miles to the breadth of an ordinary river. In one part of the county are marble rocks 50 or 60 feet high. This county sends four members to parliament, viz. two for the shire, and two for Inniskillen the capital. Fermanagh gives the title of viscount to earl Verney.

FERMENT, (*subst.*) any body which, being applied to another, produces fermentation.

Ferments are either matters already in the act of fermentation, or that soon run into this act. Of the first kind are the flowers of wine, yeast, fermenting beer, or fermenting wine, &c. and of the second are the new expressed vegetable juices of summer-fruit.

Among distillers, ferments are all those bodies which, when added to the liquor, only correct some fault therein, and, by removing some obstacle to fermentation, forward it by secondary means: as also such as, being added in time of fermentation, make the liquor yield a larger proportion of spirit, and give it a finer flavour.

FERMENTATION, may be defined a sensible internal motion of the constituent particles of a moist, fluid, mixed, or compound body: by the continuance of which motion, these particles are gradually removed from their former situation or combination; and again, after some visible separation is made, joined together in a different order and arrangement, so that a new compound is formed, having qualities very sensibly different from those of the original fluid.

Fermentation, properly so called, is confined to the vegetable and animal kingdoms; for the differences between acids and alkalies, however much they may resemble the fermentation of vinous liquors, are nevertheless exceedingly different. It is divided into three kinds; or rather, there are three different stages of it, viz. the vinous, the acetous, and the putrefactive. Of the first, vegetables alone are susceptible; the flesh of young animals is in some slight degree susceptible of the second; but animal substances are particularly susceptible of the third, which vegetable do

not so easily fall into without previously undergoing the first and second. The produce of the first stage is wine, or some other vinous liquor; of the second, vinegar; and of the third, volatile alkali. See BREWING, VINEGAR, &c.

Fermentation is one of the most obscure processes in nature, and no attempt has been made to solve it with any degree of probability. All that we know with regard to it is, that the liquor, however clear and transparent at first, no sooner begins to ferment, than it becomes turbid, deposits a sediment, emits a great quantity of fixed air, and throws up a scum to the top, acquiring at the same time some degree of heat. The heat of the vinous stage, however, is but moderate, seldom or never exceeding that of the human body. The heat of the acetous is considerably greater; and that of the putrefactive is the greatest of all, inasmuch that putrefying substances, when heaped together in great quantities, will sometimes break forth into actual flame.

From these phenomena, fermentation would seem to be a process ultimately tending to the entire dissolution of the fermenting substance, and depending upon the action of the internal heat, ethereal fluid, or whatever else we please to call it, which pervades, and makes an essential ingredient in, the composition of all bodies. From such experiments as have been made upon this subject, it appears, that whether fixed air is the bond of connection between the particles of terrestrial bodies or not; yet the emission of it from any substance is always attended with a dissolution of that substance. We cannot, however, in the present case, say that the emission of the fixed air is the cause of the fermentation. It is in fact otherwise. Fixed air hath no tendency to fly off from terrestrial substances with which it is united; on the contrary, it will very readily leave the atmosphere, after it hath been united with it, to join itself to such terrestrial substances as are capable of absorbing it. The emission of it, therefore, must depend upon the action of some other fluid; most probably the fire or heat, which is dispersed thro' all substances in a latent state, and in the present case begins sensibly to manifest itself. But from what cause the heat originally begins to operate in this manner, seems to be entirely unknown and inexplicable, except that it appears some how or other to depend on the air; for, if that is totally excluded, fermentation will not go on.

FERN, *FILIX*, in botany. See FILICES.

Fern is very common in dry and barren places. It is one of the worst weeds for lands, and very hard to destroy where it has any thing of a deep soil to root in. In some grounds, the roots of it are found to the depth of eight feet. One of the most effectual ways to destroy it is, often mowing the grass; and, if the field is ploughed up, plentiful dunging thereof is very good; but the most certain remedy for it is urine. However, fern, cut while the sap is in it, and left to rot upon the ground, is a very great improver of land.

In some places of the north, the inhabitants mow it green; and, burning it to ashes, make those ashes up into balls with a little water. They then dry them in the sun, and make use of them to clean their linen with; looking upon it to be near as good as soap for that purpose. In some parts of the north, that the frequent treading them down.

Fermentation,
Fern.

Fern
Fernelius.

down by sheep, while that sort of cattle feed upon them, is an infallible method of killing them.

The ancients used the root of the fern and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds arising from obstructions of the viscera, particularly in hypochondriac cases, and in obstructions of the spleen and pancreas. There are not wanting modern authors who give it as high a character in these cases as the ancients have done; but it is an ill-tasted medicine, and in no great use in the shops. The country-people esteem it as a sovereign remedy for that troublesome distemper the rickets in children; and they give it also as a powder, after drying it in an oven, to destroy worms. As aperients and anthelmintics, the roots have been in high estimation with some; and Simon Pauli tells us, that they have been the grand secret of some empirics against the broad worm, called *tania*. In the Medical Commentaries, vol. vi. p. 307. are given some instances of the success of this remedy, by Dr Duncan of Edinburgh.

Female FERN. See PTERIS.

FERNANDO, or FERNANDES, an island in the Pacific Ocean. See *JUAN Fernandez*.

FERNELIUS (John), physician to Henry II. king of France, was born in Picardy, in the latter end of the 15th or the beginning of the 16th century. Being sent to Paris to study rhetoric and philosophy, he applied himself in a most intense manner. All other pleasure was insipid to him. He cared neither for play nor for walking, nor for entertainments, nor even for conversation. He read Cicero, Plato, and Aristotle. The reading of Cicero procured him this advantage, that the lectures he read on philosophical subjects were as eloquent, as those of the other masters were barbarous at that time. He also applied himself very earnestly to the mathematics.

This continual study drew upon him a long fit of sickness, which obliged him to leave Paris. On his recovery, he returned thither with a design to study physic; but before he applied himself entirely to it, he taught philosophy in the college of St Barbara. After this he spent four years in the study of physic; and, taking a doctor's degree, confined himself to his closet, in order to read the best authors, and to improve himself in the mathematics; that is, as far as the business of his profession would suffer him. Never was a man more diligent than Fernel. He used to rise at four o'clock in the morning, and studied till it was time either to read lectures or to visit patients. He then examined the urine that was brought him; for this was the method of those times, with regard to the poor people, who did not send for the physician. Coming home to dine, he shut himself up among his books, till they called him down to table. Rising from table, he returned to his study, which he did not leave without necessary occasions. Coming home at night, he did just as at noon: he staid among his books, till they called him to supper; returned to them the moment he had supped; and did not leave them till eleven o'clock, when he went to bed.

In the course of these studies, he contrived mathematical instruments, and was at great charges in making them. But his wife murmuring at the expence, he dismissed his instrument-makers, and applied himself in good earnest to practise physic. But as visiting

patients did not employ his whole time, he read public lectures upon Hippocrates and Galen. This soon gained him a great reputation through France, and in foreign countries. His business increasing, he left off reading lectures; but as nothing could make him cease to study in private, he spent all the hours he could spare in composing a work of physic, intitled *Physiologia*, which was soon after published. He was prevailed with to read lectures upon this new work, which he did for three years; and undertaking another work, which he published, *De vena sectione*, he laid himself under a necessity of reading lectures some years longer, in order to explain this new book to the youth.

While he was thus employed, he was sent for to court, in order to try whether he could cure a lady, whose recovery was despaired of. He was so happy as to cure her; which was the first cause of that esteem which Henry II. who was then but dauphin, and was in love with that lady, conceived for him. This prince offered him, even then, the place of first physician to him; but Fernel, who infinitely preferred his studies to the hurry of a court, would not accept the employment. When Henry came to the throne, he renewed his intreaties: but Fernel represented, that the honour which was offered to him was due, for several reasons, and as an hereditary right, to the late king's physician; and that, as for himself, he wanted more time to make experiments concerning several discoveries he had made relating to physic. The king admitted this: but as soon as Francis I.'s physician died, Fernel was obliged to go and fill his place at Henry II.'s court. And here just the contrary to what he dreaded came to pass: for he enjoyed more rest and more leisure at court, than he had done at Paris; and he might have considered the court as an agreeable retirement, had it not been for the journey which the new civil war obliged the king to take. He died in 1558, leaving behind him a great many works, besides what have been mentioned; as, *De abditis rerum causis*, seven books of Pathology, a book on Remedies, &c. They have been printed several times; with his life prefixed, written by William Plantius his disciple.

FERONIA, the pagan goddess of woods and orchards. The deity took her name from the town Feronia, situated at the foot of mount Sarcote in Italy, where was a wood and temple consecrated to her. This town and wood are mentioned by Virgil, in the catalogue of Turnus's forces. Strabo relates, that those, who sacrificed to this goddess, walked barefoot upon burning coals, without being hurt. She was the guardian deity of freed-men, who received their cap of liberty in her temple.

FERRARS (George), a lawyer, poet, historian, and accomplished gentleman, was descended from an ancient family in Hertfordshire, and born about the year 1510, in a village near St Alban's. He was educated at Oxford, and thence removed to Lincoln's inn; where applying with uncommon diligence to the study of the law, he was soon distinguished for his elocution at the bar. Cromwell earl of Essex, the great minister of Henry VIII. introduced him to the king, who employed him as his menial servant, and, in 1535, gave him a grant of the manor of Flamstead in his native county. This is supposed to have been a profitable estate; nevertheless, Mr Ferrars being a gay courtier, and

Feronia,
Ferrars.

Ferrars,
Ferrara.

and probably an expensive man, about seven years after, was taken to execution by a sheriff's officer for a debt of 200 marks, and lodged in the compter. Being at this time member for Plymouth, the house of commons immediately interfered, and he soon obtained his liberty. He continued in favour with the king to the end of his reign, and in that of Edward VI. he attended the lord protector Somerset as a commissioner of the army in his expedition to Scotland in 1548. In the same reign, the young king being then at Greenwich, Mr Ferrars was proclaimed *lord of misrule*, that is, prince of sports and pastimes; which office he discharged during 12 days, in Christmas holidays, to the entire satisfaction of the court. This is all we know of Mr Ferrars; except that he died in 1579, at Flamstead in Hertfordshire, and was buried in the parish-church. He is not less celebrated for his valour in the field, than for his other accomplishments, as a gentleman and a scholar. He wrote, 1. History of the Reign of queen Mary; published in Grafton's chronicle, 1569, fol. 2. Six Tragedies, or dramatic poems; published in a book called the *Mirror for magistrates*, first printed in 1559, afterwards in 1587, and again in 1610.

FERRARS (Henry), a Warwickshire gentleman of a good family, was eminent in antiquities, genealogies, and heraldry. Mr Wood says, that out of the collections of this gentleman, Sir William Dugdale laid part of the foundation of his celebrated *Antiquities of Warwickshire*. Camden also makes honourable mention of his assistance in relation to Coventry. Some scattered poems of his were published among others in the reign of queen Elizabeth; and he died in 1633.

FERRARA, a city of Italy, in the territory of the pope, capital of a duchy of the same name. It is seated in an agreeable and fertile plain; watered by the river Po, which is a defence on one side; and on the other is encompassed by a strong wall, and deep broad ditches full of water, as well as by a good citadel, finished by pope Paul. In the middle of the city is a magnificent castle, which was formerly the palace of the dukes, and is not now the least ornament of Ferrara. It is quite surrounded with water; and the arsenal, which is near it, deserves the observation of travellers. Over-against the palace is the duke's garden; with a park, called *Belvedere* on account of its beauty. Behind the garden there is a palace, built with white marble, called the *palace of diamonds*, because all the stones are cut diamond fashion.

Ferrara had formerly a considerable trade; but it is now almost deserted, being very poor, inasmuch that there is hardly a person to be seen in the streets. This is owing to the exactions of the popes. The fortifications are now neglected, and the ancient university is dwindled into a wretched college of the Jesuits. However, in 1735, it was advanced to an archbishopric by pope Clement XII. The country about it is so marshy, that a shower or two of rain renders the roads almost impassable. It is 24 miles north-east of Bologna, 38 north-west of Ravenna, 70 north-by-west of Florence, and 190 north of Rome. E. Long. 12. 14. N. Lat. 44. 36.

FERRARA, the duchy of a province in the pope's territory, bounded on the north by the state of Venice; on the west, by the duchies of Mantua and Mirandola;

on the south, by the Boulogne, and by Romania, of which it was formerly a part; and on the east, by the Gulph of Venice. It is 50 miles in length, and 43 in breadth along the coast; but grows narrower and narrower towards the Mantuan. This country is almost surrounded by the branches of the Po, which often overflow the country, and form the great morasses of Comacchio, which has a bad effect on the air. It is thin of people, and indifferently cultivated, though fit for corn, pulse, and hemp. The Po and the lake of Comacchio yield a large quantity of fish. Ferrara is the capital town; besides which, there are Arano, Comacchio, Magnavacca, Belriguardo, Cento, Buendeno, and Ficherola. This duchy was formerly possessed by the house of Este. But the pope took possession of it in 1598, after the death of Alphonso II. duke of Ferrara, it being a fief of the church.

FERRET, in zoology. See MUSTELA.

FERRETS, among glass-makers, the iron with which the workmen try the melted metal, to see if it be fit to work.—It is also used for those irons which make the rings at the mouth of the bottles.

FERRETTO, in glass-making, a substance which serves to colour glass.

This is made by a simple calcination of copper, but it serves for several colours: there are two ways of making it. The first is this. Take thin plates of copper, and lay them on a layer of powdered brimstone, in the bottom of a crucible; over these lay more brimstone, and over that another layer of the plates, and so on alternately till the pot is full. Cover the pot, lute it well, place it in a wind-furnace, and make a strong fire about it for two hours. When it is taken out and cooled, the copper will be found so calcined, that it may be crumbled to pieces between the fingers, like a friable earth. It will be of a reddish, and, in some parts, of a blackish colour. This must be powdered and sifted fine for use.

FERRI (Cibo), a skilful painter born of a good family at Rome, in 1634. He was bred under Peter Cortona; and the works of the scholar are often mistaken for those of the master. The great duke of Tuscany nominated him chief of the Florentine school; and he was as good an architect as a painter. He died in 1689.

FERRO, (W. Long. 19°. N. Lat. 28°,) the most westerly of the Canary islands, near the African coast, where the first meridian was lately fixed in most maps; but now, the geographers of almost every kingdom make their respective capitals the first meridian, as we do London. It is a dry and barren spot, affording no water except what is supplied in a very surprising manner by a tree which grows in these islands. See FOUNTAIN-Tree.

FERRO, or *Faro, Islands*; a cluster of little islands lying in the Northern ocean, between 61° and 63° N. Lat. and between 5° and 8° W. Long. They belong to Denmark, and have about 3000 or 4000 inhabitants.

FERROL, a sea-port town of Spain, in the province of Galicia, seated on a bay of the Atlantic ocean. It has a good harbour, and is frequented by the Spanish fleet in time of war. W. Long. 8. 46. N. Lat. 43. 26.

FERRUGINOUS, any thing partaking of iron, or which contains particles of that metal.

Ferret
Ferrug-
inous.

Ferrugo

FERRUGO, RUST. See RUST.

Fest.

FERRUM, IRON. See IRON.

FERRY, a liberty by prescription, or by the king's grant, to have a boat for passage, on a frith or river, for carrying passengers, horses, &c. over the same for a reasonable toll.

FERTILITY, that quality which denominates a thing fruitful or prolific.

Nothing can produce fertility in either sex, but what promotes perfect health: nothing but good blood, spirits, and perfect animal functions, that is, high health, can beget perfect fecundity; and therefore, all means and medicines, all nostrums and specifics, to procure fertility, different from those which procure good blood and spirits, are arrant quackery. Dr Cheyne says, that water-drinking males are very rarely infertile; and that if any thing in nature can prevent infertility, and bring fine children, it is a milk and feed diet persevered in by both parents.

To increase the fertility of vegetables, says lord Bacon, we must not only increase the vigour of the earth and of the plant, but also preserve what would otherwise be lost: whence he infers, that there is much saved by setting, in comparison of sowing. It is reported, continues he, that if nitre be mixed with water to the thickness of honey, and after a vine is cut, the bud be anointed therewith, it will sprout within eight days. If the experiment be true, the cause may be in the opening of the bud, and contiguous parts, by the spirit of the nitre; for nitre is the life of vegetables.

How far this may be true, is not perhaps sufficiently shewn, notwithstanding the experiments of Sir Kenelm Digby and M. Homberg. Consult Mr Evelyn's Sylva, the Philosophical Transactions, the French Memoirs, and Dr Stahl's Philosophical Principles of Chemistry; but a proper set of accurate experiments seems still wanting in this view.

FERULA, FENNEL GIANT; a genus of the digynia order, belonging to the pentandria class of plants. There are nine species; all of them herbaceous perennials, rising from three to ten or twelve feet high, with yellow flowers. They are propagated by seeds, which should be sown in autumn; and, when planted out, ought to be four or five feet distant from each other, or from any other plants; for no other will thrive under their shade.

FESSE, in heraldry, one of the nine honourable ordinaries. See HERALDRY.

FESSE-POINT, is the exact centre of the escutcheon. See POINT.

FESSE-WAYS, or in FESSE, denotes any thing borne after the manner of a fesse; that is, in a rank across the middle of the shield.

Party per FESSE, implies a parting across the middle of the shield, from side to side, through the fesse point.

FESTI DIES, in Roman antiquity, certain days in the year, devoted to the honour of the gods.

Numa, when he distributed the year into 12 months, divided the same into the *dies festi*, *dies profesti*, and *dies interfesti*.

The *festi* were again divided into days of sacrifices, banquets, games, and feriae. See SACRIFICE, EPULÆ, LUDI, and FERIE.

The *profesti* were those days allowed to men for the administration of their affairs, whether of a public or

private nature: these were divided into *fasti*, *comitalia*, &c. See FASTI, COMITIALES, &c.

The *interfesti* were days common both to gods and men, some parts of which were allotted to the service of the one, and some to that of the other.

FESTINO, in logic, the third mood of the second figure of the syllogism, the first proposition whereof is an universal negative, the second a particular affirmative, and the third a particular negative; as in the following example:

FES No bad man can be happy,

TI Some rich men are bad men.

NO Ergo, some rich men are not happy.

FESTIVAL, the same with feast. See FEAST.

FESTOON, in architecture and sculpture, &c. an ornament in form of a garland of flowers, fruits, and leaves, intermixed or twisted together.

It is in the form of a string or collar, somewhat biggest in the middle, where it falls down in an arch; being extended by the two ends, the extremities of which hang down perpendicularly.

Festoons are now chiefly used in friezes, and other vacant places which want to be filled up and adorned; being done in imitation of the long clusters of flowers, which the ancients placed on the doors of their temples and houses on festival occasions.

FESTUCA, PESCUE; a genus of grasses of the digynia order, belonging to the triandria class of plants.

—There are 16 species; two of which, as being the most remarkably useful, are described under the article AGRICULTURE, n° 51—56. Another species, called the *fluitans*, or *floating*, from its growing in wet ditches and ponds, is remarkable for the uses that are made of its seeds. These seeds are small, but very sweet and nourishing. They are collected in several parts of Germany and Poland, under the name of *manna seeds*; and are used at the tables of the great, in soups and gruels, on account of their nutritious quality and grateful flavour. When ground to meal, they make bread very little inferior to that in common use. The bran, separated in preparing the meal, is given to horses that have worms; but they must be kept from water for some hours afterwards. Geese are also very fond of these seeds.—Mr Lightfoot recommends this as a proper grass to be sown in wet meadows.

FESTUS (Pompeius), a celebrated grammarian of antiquity, who abridged a work of Verrius Flaccus, *De Significatione Verborum*; but took such liberties in castration and criticising, as, Gerard Vossius observes, are not favourable to the reputation of his author. A complete edition of his fragments was published by M. Dacier in 1681, for the use of the Dauphin. Scaliger says, that Festus is an author of great use to those who would attain the Latin tongue with accuracy.

FETLOCK, in the manege, a tuft of hair growing behind the palken joint of many horses; for those of a low size have scarce any such tuft.

FETTI (Domenico), an eminent painter in the style of Julio Romano, was born at Rome in 1589, and educated under Ludovico Civali of Florence. He painted but little for churches, but excelled in history; his pictures are much sought after, and are scarce. He abandoned himself to disorderly courses; and put an end to his life, by excesses, in the 35th year of his age.

FEUD (*Feida*), signifies, in the German tongue, *guerram*,

Festivo

Feud.

Feud
||
Fevre

guerram, Lat. *bellum*; and, according to Lambard, *capitales inimicitias*; and *feud* used in Scotland is a combination of kindred to revenge the death of any of their blood against the kiler, and all his race, or any other great enemy.

FEUD (*Feoda*), *Food*, *Fief*, or *Fec*. See FEODAL System.

Feuds are called by various names, according to their respective natures; as, FEUDUM *Antiquum*, a feud descending to a son, &c. from his ancestors. FEUDUM *Apertum*, a feud resulting back again to the lord of the fee; where the blood of the person last seized in fee-simple is utterly extinct and gone. FEUDUM *Honorarium*, (and *Feudum individuum*), an honorary feud, or title of nobility, of an indivisible nature, and descendible to the eldest son in exclusion of all the rest. FEUDUM *Improprium*, an improper or derivative feud; and *feoda impropria*, are all such feuds as do not fall within the description of *feoda propria*. FEUDUM *Maternum*, a feud descending to the son from the mother. FEUDUM *Novum*, a feud newly acquired by the son; to which, in ancient times, only the descendants from his body could succeed, by the known maxims of the early feudal constitutions. FEUDUM *Novum*, held *ad antiquum*; descendible in the same manner as a *feudum novum*. FEUDUM *Paternum*, a feud descendible from father to son. FEUDUM *Proprium*, a proper feud distinguished from an *improper*, which are the two grand divisions.

FEUDAL, or FEODAL. See FEODAL.

FEUDATORY, or FEODATORY, a tenant who *See Feodal formerly held his estate by feudal service*. TENURE.

FEU-DUTY, in Scots law, is the annual rent or duty which a vassal, by the tenor of his right, becomes bound to pay to his superior.

FEU-Holding, in Scots law, is that particular tenure by which a vassal is taken bound to pay an annual rent or feu-duty to his superior.

FEVER. See (Index subjoined to) MEDICINE.

The ancients divided the diseases as well as the passions and affections of men. Virgil places them in the entrance into hell, *Æn. vi. 273*. Among these, *Fever* had a temple on mount Palatine, and two other parts of ancient Rome; and there is still extant an inscription to this goddess. FEBRI. DIVÆ. FEBRI. SANCTÆ. FEBRI. MAGNÆ. CAMILLA. A. MATA. PRO. FILIO. MALE. AFFECTO.

FEVER, in fariery. See there, § iv.

FEVERFEW, in botany. See MATRICARIA.

FEVERSHAM, a town of the county of Kent in England, situated on a branch of the river Thames, which is navigable for boats. It is a member of the cinque-port of Dover. Oysters, and many other articles, are sent from hence to the London market. E. Long. o. 38. N. Lat. 51. 20.

FEVRE (Tanegui le), of Caen, in Normandy, born 1615, an excellent scholar in the Greek and Roman learning. Cardinal de Richelieu gave him a pension of 2000 livres to inspect all the works published at the Louvre, and designed to have made him principal of a college he was about to erect at Richelieu. But the cardinal's death cut off his hopes; and cardinal Mazarine having no great relish for learning, his pension was ill-paid. Some time after, the Marquis de Franciere, governor of Langres, took him along with him to his Vol. IV.

government, and there he embraced the Protestant religion; after which he was invited to Saumur, where he was chosen Greek professor. He there taught with extraordinary reputation. Young men were sent to him from all the provinces in the kingdom, and even from foreign countries, while divines and professors themselves gloried in attending his lectures. He was preparing to go to Heidelberg, whither he was invited by the prince Palatine, when he died, aged 57. He wrote, 1. Notes on Anacreon, Lucretius, Longinus, Phædrus, Justin, Terence, Virgil, Horace, &c. 2. A short account of the lives of the Greek poets. 3. Two volumes of letters; and many other works.

FEVRE (Claude le), an eminent French painter, was born at Fountainbleau in 1633, and studied in the palace there, and then at Paris under Le Sueur and Le Brun; the latter of whom advised him to adhere to portraits, for which he had a particular talent, and in his style equalled the best masters of that country. He died in England in 1675, aged 42.

FEZ, the capital of a kingdom of the same name in Barbary, in Africa. It is a very large place, surrounded with high walls, within which there are hills and valleys, only the middle being level and flat. The river, which runs through the city, is divided into two streams, from which canals are cut into every part of the town; so that the mosques, colleges, palaces, and the houses of great men, are amply supplied with water. They have generally square marble basins in the middle of the court of their houses, which are supplied with water by marble pipes that pass through the walls: they constantly run over, and the stream returns back into the street, and so into the river. The houses are built with brick or stone; and are adorned on the outside with fine mosaic work, or tiles like those of Holland. The wood-work and ceilings are carved, painted, and gilt. The roofs are flat; for they sleep on the tops of the houses in summer. Most of the houses are two stories high, and some three. There are piazzas and galleries running all round the court on the inside, so that you may go under cover from one apartment to another. The pillars are of brick, covered with glazed tiles, or of marble, with arches between. The timber-work is carved and painted with gay colours, and most of the rooms have marble cisterns of water. Some of the great men build towers over their houses several stories high, and spare no expence to render them beautiful; from hence they have a fine prospect all over the city.

There are in this city 700 mosques, great and small; 50 of which are magnificent, and supported with marble pillars, and other ornaments. The floors are covered with mats, as well as the walls to the height of a man. Every mosque has a tower or minaret, like those in Turkey, with a gallery on the top, from whence they call the people to prayers. The principal mosque is near a mile and a half in circumference. The middle building is 150 yards in length, and 80 in breadth, with a tower proportionably high. Round this to the east, west, and north, there are great colonades 30 or 40 yards long. There are 900 lamps lighted every night; and in the middle of the mosque are large branches, which are capable of holding 500 lamps each. Along the walls are seven pulpits, from which the doctors of the law teach the people. The business

Fevre,
Fet.

Fewel
Ficus.

of the priest is only to read prayers, and distribute alms to the people; to support which, there are large revenues.

Besides the mosques, there are two colleges built in the Moorish manner, and adorned with marble and paintings. In one of them there are 100 rooms, besides a magnificent hall. In this there is a great marble vase full of water, adorned with marble pillars of various colours, and finely polished. The capitals are gilt, and the roof shines with gold, azure, and purple. The walls are adorned with Arabic verses in gold characters. The other colleges are not near so beautiful, or rather all are gone to ruin since the neglect of learning.

There are hospitals in the city, where formerly all strangers were maintained three days *gratis*. But the estates belonging to them are confiscated for the emperor's use. There are above 100 public baths, many of which are stately buildings. People of the same trade or business live in streets by themselves.

Though the country about Fez is pleasant and fertile, and in many places abounding with corn and cattle, yet a great part of it lies waste and uncultivated, not so much for want of inhabitants, as from the oppression of the governors; which makes the people choose to live at some distance from the high roads, where they cultivate just as much land as is necessary for their own subsistence.

Round the city there are fine marble tombs, monuments, and gardens full of all manner of fruit-trees.

Fez is situated on the river Cebu, W. Long. 4. 25. N. Lat. 33. 58.

FEWEL. See FUEL.

FIASCOE, a town of Italy in the territories of the pope, remarkable for its good wine. E. Long. 13. 12. N. Lat. 42. 20.

FIAT, in law, a short order or warrant signed by a judge, for making out and allowing certain processes.

FIBRARIÆ, a class of fossils, naturally and essentially simple, not inflammable nor soluble in water; and composed of parallel fibres, some shorter, others longer; their external appearance being bright, and in some degree transparent: add to this, that they never give fire with steel, nor ferment with or are soluble in acid menstrua.

FIBRE, in anatomy, a perfectly simple body, or at least as simple as any thing in the human structure; being fine and slender like a thread, and serving to form other parts. Hence some fibres are hard, as the bony ones; and others soft, as those destined for the formation of all the other parts.

The fibres are divided also, according to their situation, into such as are straight, oblique, transverse, annular, and spiral; being found arranged in all these directions in different parts of the body.

FIBRE is also used to denote the slender FILAMENTS which compose other bodies, whether animal, vegetable, or mineral; but more especially, the capillary roots of plants.

FIBROSE, something consisting of fibres, as the roots of plants. See ROOT.

FICINUS (Marcius), of Florence, born 1433, applied himself particularly to the study of the Greek and Latin tongues; followed the Platonic sect; and translated into Latin the works of Plato, and of several great men who maintained that philosophy, as Jam-

blichus, Plotinus, Proclus, &c. He died in 1449.

FICOIDES, a name given to several distinct plants, as the mesembryanthemum, mufa, and opuntia. See MESEMBRYANTHEMUM.

FICTION. See FABLE, and POETRY.

FICUS, the FIG-TREE; a genus of the triocia order, belonging to the polygama class of plants. There are ten species, of which the following are the most remarkable.

1. The carica, or common fig, with an upright stem branching 15 or 20 feet high, and garnished with large palmated or hand-shaped leaves. Of this there are a number of varieties; as the common fig, a large, oblong, dark purplish blue fruit; which ripens in August either on standards or walls, and the tree carries a great quantity of fruit.—The brown or chestnut fig; a large, globular, chestnut-coloured fruit, having a purplish delicious pulp, ripening in July and August.—The black ischia fig; a middle-sized, shortish, flat-crowned, blackish fruit, having a bright pulp; ripening in the middle of August.—The green ischia fig; a large, oblong, globular-headed, greenish fruit, slightly stained by the pulp to a reddish-brown colour; ripens in the end of August.—The brown ischia fig; a small, pyramidal, brownish-yellow fruit, having a purplish very rich pulp; ripening in August and September.—The Malta fig; a small flat-topped brown fruit, ripening in the middle of August or beginning of September.—The round brown Naples fig; a globular, middle-sized, light-brown fruit, and brownish pulp; ripe in the end of August.—The long, brown, Naples fig; a long dark-brown fruit, having a reddish pulp; ripe in September.—The great blue fig; a large blue fruit, having a fine red pulp.—The black Genoa fig; a large, pear-shaped, black-coloured fruit, with a bright red pulp; ripe in August.

2. The lycamorus, or lycamore of scripture. According to Mr Hasselquist, this is a huge tree, the stem being often 50 feet round. The fruit is pierced in a remarkable manner by an insect. There is an opening made in the calyx, near the time the fruit ripens, which is occasioned in two different ways. 1. When the squamæ, which cover the calyx, wither and are bent back; which, however, is more common to the carica than the lycamore. 2. A little below the scales, on the side of the flower-cup, there appears a spot before the fruit is ripe: the fruit in this place is affected with a gangrene which extends on every side, and frequently occupies a finger's-breadth. It withers; the place affected becomes black; the fleshy substance in the middle of the calyx, for the breadth of a quill, is corroded; and the male blossoms, which are nearest to the bare side, appear naked, opening a way for the insect, which makes several furrows in the inside of the fruit, but never touches the stigmata, though it frequently eats the germen. The wounded or gangrenous part is at first covered or shut up by the blossoms; but the hole is by degrees opened and enlarged of various sizes in the different fruits; the margin and sides being always gangrenous, black, hard, and turned inwardly. The same gangrenous appearance is also found near the squamæ, after the insect has made a hole in that place. The tree is very common in the plains and fields of Lower Egypt. It buds in the latter end of March, and the fruit ripens in the beginning of June.

Ficoides
Ficus.

June. It is wounded or cut by the inhabitants at the time it buds; for without this precaution, they say, it would not bear fruit.

3. The *religiosa*, or banian-tree, is a native of several parts of the East Indies. It hath a woody stem, branching 20 or 30 feet high, with heart-shaped entire leaves, ending in acute points.—It is called by the Dutch, *devil's-tree*; and by the inhabitants of Ceylon, *budaghaha*, and *budaghass*. *Budda*, according to the tradition of these countries, was the name of the prophet who first taught the Indians under the grateful shade of this tree: for this reason, they not only give this species of fig a name commemorative of their prophet, but likewise pay it a particular veneration, by celebrating all their sacrifices under its shade.

Culture. The carica is the species most frequently cultivated in this country, and the only one which does not require to be kept in a stove. It may be propagated either by suckers arising from the root, by layers, or by cuttings.—The suckers are to be taken off as low down as possible; trim off any ragged part at bottom, leaving the tops entire, especially if for standards; and plant them in nursery-lines at two or three feet distance from each other, or they may at once be planted where they are to remain; observing, that if they are designed for walls or espaliers, they may be headed to six or eight inches in March, the more effectually to force out lateral shoots near the bottom; but, if intended for standards, they must not be topped, but trained with a stem, not less than 15 or 18 inches for dwarf-standards, a yard for half-standards, and four, five, or six feet for full standards. Then they must be suffered to branch out to form a head; observing, that, whether against walls, espaliers, or standards, the branches or shoots must never be shortened unless to procure a necessary supply of wood: for the fruit is always produced on the upper parts of the young shoots; and if these are cut off, no fruit can be expected.—The best season for propagating these trees by layers is in autumn; but it may be also done any time from October to March or April. Choose the young pliable lower shoots from the fruitful branches: lay them in the usual way, covering the body of the layers three or four inches deep in the ground, keeping the top entire, and as upright as possible; and they will be rooted and fit to separate from the parent in autumn; when they may be planted either in the nursery, or where they are to remain, managing them as above directed. The time for propagating by cuttings is either in autumn at the fall of the leaf, or any time in March: choose well-ripened shoots of the preceding summer; short, and of robust growth, from about 12 to 15 inches long; having an inch or two of the two-years wood at their base, the tops left entire; and plant them six or eight inches deep, in a bed or order of good earth, in rows two feet asunder: and when planted in autumn, it will be eligible to protect their tops in time of hard frost, the first winter, with any kind of long loose litter.

Uses. Figs are a considerable article in the materia medica, chiefly employed in emollient cataplasms and pectoral decoctions. The best are those which come from Turkey. Many are also brought from the south of France, where they prepare them in the following manner. The fruit is first dipped in scalding-hot ley

made of the ashes of the fig-tree, and then dried in the sun. Hence these figs stick to the hands, and scour them like lixivial salts; and for the same reason they excite to stool, without griping. They are moderately nutritimental, grateful to the stomach, and easier to digest than any other of the sweet fruits. They have been said to produce lice, when eaten as a common food; but this seems to be entirely without foundation. The reason of this supposition seems to be, that in the countries where they grow naturally, they make the principal food of the poor people, who are generally troubled with these vermin. The wood of the sycamore is not subject to rot; and has therefore been used for making of coffins, in which embalmed bodies were put. Mr Hasselquist affirms, that he saw in Egypt, coffins made of this kind of wood, which had been preserved found for 2000 years.

FIDDLE. See VIOLIN.

FIDDES (Richard), a learned divine and polite writer, was born in 1671, and educated at Oxford. He was presented to the living of Holfham, in Yorkshire, where he was so admired for the sweetness of his voice, and the gracefulness of his delivery, that the people for several miles round flocked to his sermons. Coming to London in 1712, he was, by the favour of dean Swift, introduced to the earl of Oxford, who made him one of his chaplains, and the queen soon after appointed him chaplain to the garrison at Hull: but losing his patrons upon the change of the ministry, he lost his chaplainship; and being obliged to apply himself to writing, composed, 1. A body of Divinity; 2. The life of Cardinal Wolsey; 3. A treatise of morality, &c. He died in 1725.

FIDEI-COMMISSUM, in Roman antiquity, an estate left in trust with any person, for the use of another. See TRUSTEE.

FIDES, or FAITH, one of the virtues, deified by the Pagans. She had a temple near the Capitol, founded by Numa Pompilius; but no animals were offered, or blood spilt, in her sacrifices. During the performance of her rites, her priests appeared in white vestments, with their heads and hands covered with linen, to shew that fidelity ought to be secret.

FIDIUS, in Pagan worship, a god who presided over alliances and promises. This deity, which the Romans borrowed from the Sabines, was also called *Sanctus*, *Semon*, and *Semi-pater*.

FIELDING (Henry), a well-known writer of the present age, son of lieutenant-general Fielding who served under the duke of Marlborough, was born in 1707. He had four sisters; of whom Sarah is well known, as writer of "The adventures of David Simple." On the death of his mother, his father married again; and Sir John Fielding who succeeded him in the commission of the peace for Middlesex, is his brother by this marriage. Henry was sent to study at Leyden; but a failure in his remittances obliged him to return in two years, when his own propensity to gaiety and profusion drove him to write for the stage at 20 years of age. His first dramatic piece "Love in several masques," which was well received, appeared in 1727; and all his plays and farces, to the amount of 18, were written before the year 1737; and many of them are still acted with applause. While he was thus employed, he married a young lady with 1500*l.* fortune, and

Ficus.

inherited an estate of 200 l. a-year from his mother: all which, though on the plan of retiring into the country, he contrived to dissipate in three years; and then applied himself to the study of the law for a maintenance. In losing his fortune, he acquired the gout: which rendering it impossible for him to attend the bar, he with a shattered constitution had recourse to many extempore applications of his pen for immediate supplies; until, soon after the late rebellion, he accepted the office of acting justice for Middlesex, an employment much more profitable than honourable in the public esteem. Reduced at length by the fatigues of this office, and by a complication of disorders, he by the advice of his physicians went to Lisbon, where he died in 1754. He wrote a great number of fugitive pamphlets and periodical essays; but is chiefly distinguished by his "Adventures of Joseph Andrews," and "History of Tom Jones:" in the former he took his character of parson Adams from the reverend Mr Young, one of his most learned and esteemed friends; who was remarkable for his acquaintance with the Greek authors, and had as passionate a veneration for Æschylus as parson Adams had; the overflowings of his beneficence were as strong, and his fits of reverie and absence of mind occurred too upon the most interesting occasions. His works have been collected and published, with his life prefixed, by Mr Murphy.

FIELD, in agriculture, a piece of ground inclosed, whether for tillage or pasture.

FIELD, in heraldry, is the whole surface of the shield, or the continent, so called because it containeth those achievements anciently acquired in the field of battle. It is the ground on which the colours, bearings, metals, furs, charges, &c. are represented. Among the modern heralds, field is less frequently used in blazoning than shield or escutcheon. See the article **SHIELD**, &c.

FIELD-Book, in surveying, that wherein the angles, stations, distances, &c. are set down.

FIELD-Colours, in war, are small flags of about a foot and half square, which are carried along with the quarter-master general, for marking out the ground for the squadrons and battalions.

FIELD-Fare, in ornithology. See **TURDUS**.

FIELD-Officers, in the art of war. See **OFFICER**.

FIELD-Pieces, small cannons, from three to twelve pounders, carried along with an army in the field.

FIELD-Staff, a weapon carried by the gunners, about the length of a halbert, with a spear at the end; having on each side ears screwed on, like the cock of a match-lock, where the gunners screw in lighted matches, when they are upon command; and then the field-staffs are said to be armed.

FIELD-Works, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

Elysian Fields. See **ELYSIAN**.

FIENUS (Thomas), an ingenious and learned physician, born at Antwerp in 1566. He went into Italy to study physic under Mercualis and Aldrovandus; and on his return distinguished himself so much in the university of Louvain, that he was there chosen professor of physic, and was afterwards made physician to the duke of Bavaria. He wrote several works, among

which were, "De viribus imaginationis;" and "De formatione fetus." He died at Louvain in 1631.

FIERI FACIAS, in law, a writ that lies where a person has recovered judgment for debt or damages in the king's courts against one, by which the sheriff is commanded to levy the debt and damages on the defendant's goods and chattels.

FIFE, in music, is a sort of wind-instrument, being a small pipe. See **PIFE**.

FIFE, in geography, a county of Scotland bounded by the Frith of Tay on the north, by the German sea on the east, by the Frith of Forth on the south, and by Monteith and Stirling on the west. It is above 40 miles in length, and 17 in breadth. The face of the country is various. Towards the west it is mountainous; the middle is most proper for pasture; but the northern and southern parts are plain and fertile, producing excellent corn, full of towns, and indented with good bays and harbours. The whole coast is almost covered with fishing-towns; breed a great number of hardy seamen; and, being all royal boroughs, send many members to parliament. The inland parts of the county are adorned with plantations and woods, affording shelter to deer and all sorts of game. The hills are covered with sheep, whose wool is excellent; and the pastures feed plenty of black cattle. This county also produces quarries of excellent free-stone, coal-mines, and lead-ore in great quantity; together with variegated crystals. It is well watered by many lakes and rivers, the principal of which are the Leven and the Eden, both of which abound with salmon. On the present condition of the county of Fife Dr Campbell has the following observations*. "One would be apt to imagine, that from such an excellent situation, this country must have been distinguished by being wonderfully populous, crowded with towns, and these towns abounding with commerce. Anciently, it seems, it was so: and if it be not in this condition now, the reasons may easily be assigned; it would be well if they could be easily removed. After the accession of king James VI. to the throne of England, the court lords extended what they called the *power of the crown*; but which, resting in their hands, was, in reality, theirs beyond measure; and this was opposed, for purposes merely their own, by others, who, in right of popularity, exercised also a power more detrimental to the public peace, and not at all more directed to the public good; and thus the true principles of policy were in a manner lost. On the other hand, an unreasonable and ill-timed zeal for forms produced as unreasonable an aversion for things indifferent in themselves; and thus, while religion was all the cry, the true spirit of the Christian faith was in a manner extinguished. Party-disputes in church and state, destroying, as they ever will do, all sense of public spirit, made way for a civil war, which ruined the small remains of past prosperity. After the restoration, an oppressive government in one part of the country, which connived, for its own support, at the establishment of a more oppressive aristocracy in the other, extirpated all seeds of industry, and brought on that general decay in Agriculture, manufactures, and commerce, which, however visible, was, till very lately, rather to be lamented, even by the most disinterested patriots, than with any rational hopes of success to be put in any train of being recovered.

Figure.

However distasteful, in one light, the contemplation of its former greatness may be, it cannot but afford us satisfaction in another; for what has once been, may most certainly be again. The country and the climate, without question, are as good as ever; and though the same thing cannot be said of its ports, yet, with some labour and a little expence, even these may be made so; after which, if any method can be found to employ in manufactures, and thereby engage the youth to remain at home, there is no doubt that an indefatigable application may quickly restore what a series of unfortunate accidents, succeeded by supine neglect, have brought into so melancholy a condition."

FIRE-Rails, in a ship, are those that are placed on banisters, on each side of the top of the poop, and fo along with haunces or falls. - They reach down to the quarter-deck, and to the stair of the gang-way.

FIFTH, in music. See **INTERVAL**.

FIG, or **FIG-TREE**. See **FICUS**.

FIGWORT, a plant called by the botanists **SCROPHULARIA**.

FIGURAL, **FIGURATE**, or *Figurative*, a term applied to whatever is expressed by obscure resemblances. The word is chiefly applied to the types and mysteries of the Mosaic law; as also to any expression which is not taken in its primary and literal sense.

FIGURE, in physics, expresses the surface or terminating extremities of any body.

FIGURES, in arithmetic, are certain characters whereby we denote any number which may be expressed by any combination of the nine digits, &c. See **ARITHMETIC**.

FIGURE, among divines, is used for the mysteries represented under certain types.

FIGURE, in dancing, denotes the several steps which the dancer makes in order and cadence, considered as they mark certain figures on the floor. See **DANCING**.

FIGURE, in painting and designing, denotes the lines and colours which form the representation of any animal, but more particularly of a human personage, See **PAINTING**, n^o 61—92.

FIGURE, in logic, denotes a certain order and disposition of the middle term in any syllogism.

Figures are fourfold. 1. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure. 2. When the middle term is the predicate of both the premises, the syllogism is said to be in the second figure. 3. If the middle term is the subject of the two premises, the syllogism is in the third figure; and lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the fourth figure. Each of these figures has a determinate number of moods, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion. See **LOGIC**.

FIGURE, in composition. See **ORATORY**; also **ALLEGORY**, **APOSTROPHE**, **HYPERBOLE**, **METAPHOR**, **PERSONIFICATION**, &c.

A **FIGURE**, the means or instrument conceived to be the agent. When we survey a number of connected objects, that which makes the greatest figure employs

chiefly our attention; and the emotion it raises, if lively, prompts us even to exceed nature in the conceptions we form of it. Take the following examples.

For Ncleus' son Alcides' rage had slain.

A broken rock the force of Pirus threw.

In these instances, the rage of Hercules and the force of Pirus, being the capital circumstances, are so far exalted as to be conceived the agents that produce the effects.

In the following instances, hunger being the chief circumstance in the description, is itself imagined to be the patient.

Whose hunger has not tasted food these three days.

June Shore.

—As when the force

Of subterranean wind transports a hill.

Paradise lost.

—As when the potent rod

Of Amram's son, in Egypt's evil day

Way'd round the coast, upcall'd a pitchy cloud

Of locusts.

Paradise lost.

A **FIGURE**, which, among related objects, extends the properties of one to another. This figure is not dignified with a proper name, because it has been overlooked by writers. It merits, however, a place in this work; and must be distinguished from the others elsewhere treated, as depending on a different principle. *Giddy brink, jovial wine, daring wound*, are examples of this figure. Here are adjectives that cannot be made to signify any quality of the substantives to which they are joined: a *brink*, for example, cannot be termed *giddy* in a sense, either proper or figurative, that can signify any of its qualities or attributes. When we examine attentively the expression, we discover, that a *brink* is termed *giddy* from producing that effect in those who stand on it: in the same manner, a wound is said to be *daring*, not with respect to itself, but with respect to the boldness of the person who inflicts it: and wine is said to be *jovial*, as inspiring mirth and jollity. Thus the attributes of one subject are extended to another with which it is connected; and the expression of such a thought must be considered as a figure, because the attribute is not applicable to the subject in any proper sense.

How are we to account for this figure, which we see lies in the thought, and to what principle shall we refer it? Have poets a privilege to alter the nature of things, and at pleasure to bestow attributes upon a subject to which they do not belong? It is observed †, that the mind passeth easily and sweetly along a train of connected objects; and, where the objects are intimately connected, that it is disposed to carry part 1. §. 6. along the good or bad properties of one to another; especially when it is in any degree inflamed with these properties. From this principle is derived the figure under consideration. Language, invented for the communication of thought, would be imperfect, if it were not expressive even of the slightest propensities and more delicate feelings: but language cannot remain so imperfect among a people who have received any polish; because language is regulated by internal feeling, and is gradually improved to express whatever passes in the mind. Thus, for example, when a sword in the hand of a coward is termed a *coward sword*, the expression is significative of an internal operation; for the mind, in passing from the agent

Figure.

† Vid.
Elem. of
Criticism,
chap. II.

Figure. to its instrument, is disposed to extend to the latter the properties of the former. Governed by the same principle, we say *listening* fear, by extending the attribute *listening* of the man who listens, to the passion with which he is moved. In the expression, *bold deed*, or *audax facinus*, we extend to the effect what properly belongs to the cause. But not to waste time by making a commentary upon every expression of this kind, the best way to give a complete view of the subject, is to exhibit a table of the different relations that may give occasion to this figure. And in viewing the table, it will be observed, that the figure can never have any grace but where the relations are of the most intimate kind.

1. An attribute of the cause expressed as an attribute of the effect.

Audax facinus.

Of yonder fleet a bold discovery make.

An impious mortal gave the daring wound.

—————To my advent'rous song,

That with no middle flight intends to soar.

Paradise lost.

2. An attribute of the effect expressed as an attribute of the cause.

Quos peritiae ambos misero censebam in mari. Plautus.

No wonder, fallen such a pernicious height.

Paradise lost.

3. An effect expressed as an attribute of the cause.

Jovial wine, Giddy brink, Drowsy night, Musing midnight,
Panting height, Altonish'd thought, Mournful gloom.

Casting a dim religious light. MILTON, Comus.

And the merry bells ring round,

And the jocund rebecks found. MILTON, Allegro.

4. An attribute of a subject bestowed upon one of its parts or members.

Longing arms.

It was the nightingale, and not the lark,

That pierc'd the fearful hollow of thine ear.

Romeo and Juliet, act 3. sc. 7.

Oh, lay by

Those most ungentle looks and angry weapons;

Unless you mean my griefs and killing fears

Should stretch me out at your relentless feet

Fair Penitent, act 3.

—————And ready now

To stoop with weagled wing, and willing feet,

On the bare outside of this world. Paradise lost, b. 3.

5. A quality of the agent given to the instrument with which it operates.

Why peep you coward Swords half out their sheaths?

6. An attribute of the agent given to the subject upon which it operates.

High-climbing hill.

Milton.

7. A quality of one subject given to another.

Icci, beatis nunc Arabum invides

Gazis.

Horat. Carm. l. 1. ode 29.

When sapless age, and weak unable limbs,

Should bring thy father to his drooping chair.

Shakspear.

By art, the pilot through the boiling deep,

And howling tempest, steers the fearless ship.

Iliad xxiii. 385.

Then, nothing loath, th' enamour'd fair he led,

And sunk transport on the conscious bed.

Odyssey viii. 337.

A stupid moment motionless the flood.

Samuel, l. 1336.

8. A circumstance connected with a subject, expressed as a quality of the subject.

Breezy summit.

'Tis ours the chance of fighting fields to try.

Iliad. 301.

Oh! had I dy'd before that well-fought wall.

Odyssey v. 395.

From this table it appears, that the adorning a cause with an attribute of the effect, is not so agreeable as the opposite expression. The progress from cause to effect is natural and easy: the opposite progress resembles retrograde motion*; and therefore *panting height*, *astonish'd thought*, are strained and uncouth expressions, which a writer of taste will avoid.

It is not less strained, to apply to a subject in its present state, an epithet that may belong to it in some future state:

Submersisq; obire puppes.

Æneid i. 73.

And mighty ruins fall.

Iliad v. 411.

Impious sons their man-gled fathers wound.

Another rule regards this figure, That the property of one subject ought not to be bestowed upon another with which that property is incongruous:

K. Rich. ———How dare thy joints forget

To pay their awful duty to our presence?

Richard II. act 3. sc. 6.

The connection between an awful superior and his submissive dependent is so intimate, that an attribute may readily be transferred from the one to the other: but awfulness cannot be so transferred, because it is inconsistent with submission.

FIGURE of Speech, as peculiarly distinguished from the above and from those first referred to.] Under the article METAPHOR and Allegory, a figure of speech is defined, "The using a word in a sense different from what is proper to it;" and the new or uncommon sense of the word is termed the *figurative sense*. The figurative sense must have a relation to that which is proper; and the more intimate the relation is, the figure is the more happy. How ornamental this figure is to language, will not be readily imagined by any one who hath not given peculiar attention; and therefore we shall endeavour to unfold its capital beauties and advantages. In the first place, a word used figuratively, or in a new sense, suggests at the same time the sense it commonly bears: and thus it has the effect to present two objects; one signified by the figurative sense, which may be termed the *principal object*; and one signified by the proper sense, which may be termed *accessory*: the principal makes a part of the thought; the accessory is merely ornamental. In this respect, a figure of speech is precisely similar to concordant sounds in music, which, without contributing to the melody, make it harmonious.

To explain the matter by examples. *Youth*, by a figure of speech, is termed the *morning of life*: This expression signifies *youth*, the principal object which enters into the thought; it suggests, at the same time, the proper sense of *morning*; and this accessory object, being in itself beautiful, and connected by resemblance to the principal object, is not a little ornamental. *Impetuous ocean* is an example of a different kind, where an attribute is expressed figuratively: Together with *stormy*, the figurative meaning of the epithet *impetuous*, there is suggested its proper meaning, viz. the

Figure.

* See PERCEPTION and Ideas in a Train.

Elem. of Criticism.

Ætern

stern authority of a despotic prince; and these two are strongly connected by resemblance. Upon this figurative power of words, Vida descants with elegance, *Poet. lib. iii. 44.*

In the next place, this figure possesses a signal power of aggrandising an object, by the following means. Words, which have no original beauty but what arises from their sound, acquire an adventitious beauty from their meaning: a word signifying any thing that is agreeable, becomes by that means agreeable; for the agreeableness of the object is communicated to its name. This acquired beauty, by the force of custom adheres to the word even when used figuratively; and the beauty received from the thing it properly signifies, is communicated to the thing which it is made to signify figuratively. Consider the foregoing expression *Imperious ocean*, how much more elevated it is than *Stormy ocean*.

Thirdly, This figure hath a happy effect by preventing the familiarity of proper names. The familiarity of a proper name, is communicated to the thing it signifies by means of their intimate connection; and the thing is thereby brought down in our feeling. This bad effect is prevented by using a figurative word instead of one that is proper; as, for example, when we express the sky by terming it *the blue vault of heaven*; for though no work of art can compare with the sky in grandeur, the expression however is relished, because it prevents the object from being brought down by the familiarity of its proper name. With respect to the degrading the familiarity of proper names, Vida has the following passage.

Hinc si dura mihi passus dicendus Ulysses,
Non illum vero memorabo nomine, sed qui
E: mores hominum multorum vidit, ei urbes,
Naufragus everse post secula incendia Troje.

Poet. lib. ii. 1. 46.

Lastly, By this figure, language is enriched, and rendered more copious; in which respect, were there no other, a figure of speech is a happy invention. This property is finely touched by Vida; *Poet. lib. iii. 90.*

The beauties we have mentioned belong to every figure of speech. Several other beauties peculiar to one or other sort, we shall have occasion to remark afterwards.

Not only subjects, but qualities, actions, effects, may be expressed figuratively. Thus, as to subjects, *the gates of breath for the lips, the watery kingdom for the ocean.* As to qualities, *fierce for stormy*, in the expression *Fierce winter*; *altus for profound*, *Altus puteus, Altum mare*; *breathing for perspiring*, *Breathing plants*. Again, as to actions, *The sea rages*, Time will melt her frozen thoughts, *Time kills grief*. An effect is put for the cause, as *lux for the sun*; and a cause for the effect, as *bourn labores for corn*. The relation of resemblance is one plentiful source of figures of speech; and nothing is more common than to apply to one object the name of another that resembles it in any respect: Height, size, and worldly greatness, resemble not each other; but the emotions they produce resemble each other, and, prompted by this resemblance, we naturally express worldly greatness by height or size: One feels a certain uneasiness in seeing a great depth; and, hence depth is made to express

any thing disagreeable by excess, as *depth of grief, depth of despair*: Again, height of place, and time long past, produce similar feelings; and hence the expression, *Ut altius repetam*: Distance in past time, producing a strong feeling, is put for any strong feeling, *Nihil mihi antiquius nostra amicitia*: Shortness with relation to space, for shortness with relation to time, *Brevis esse laboro, obscurus fio*: Suffering a punishment resembles paying a debt; hence *pendere penas*. In the same manner, light may be put for glory, sunshine for prosperity, and weight for importance.

Many words, originally figurative, having, by long and constant use, lost their figurative power, are degraded to the inferior rank of proper terms. Thus the words that express the operations of the mind, have in all languages been originally figurative: the reason holds in all, that when these operations came first under consideration, there was no other way of describing them but by what they resembled: it was not practicable to give them proper names, as may be done to objects that can be ascertained by sight and touch. A *soft nature, jarring tempers, weight of wo, pompous phrase, heget compassion, assuage grief, break a vow, bend the eye downward, shower down curses, drown'd in tears, wrap in joy, warm'd with eloquence, loaded with spoils*, and a thousand other expressions of the like nature, have lost their figurative sense. Some terms there are, that cannot be said to be altogether figurative or altogether proper: originally figurative, they are tending to simplicity, without having lost altogether their figurative power. Virgil's *Regina saucia cura*, is perhaps one of these expressions: with ordinary readers, *sauca* will be considered as expressing simply the effect of grief; but one of a lively imagination will exalt the phrase into a figure.

For epitomising this subject, and at the same time for giving a clear view of it, lord Kaimes * gives a list of the several relations upon which figures of speech are commonly founded. This list he divides into two tables; one of subjects expressed figuratively, and one of attributes.

TAB. I. Subjects expressed figuratively.

1. A word proper to one subject employed figuratively to express a resembling subject.

There is no figure of speech so frequent, as what is derived from the relation of resemblance. Youth, for example, is signified figuratively by the *morning* of life. The life of a man resembles a natural day in several particulars: the morning is the beginning of a day, youth the beginning of life; the morning is cheerful, so is youth, &c. By another resemblance, a bold warrior is termed the *thunderbolt* of war; a multitude of troubles, a *sea* of troubles.

This figure, above all others, affords pleasure to the mind by variety of beauties. Besides the beauties above-mentioned, common to all sorts, it possesses in particular the beauty of a metaphor or of a simile: a figure of speech built upon resemblance, suggests always a comparison between the principal subject and the accessory; whereby every good effect of a metaphor or simile, may, in a short and lively manner, be produced by this figure of speech.

2. A word proper to the effect employed figuratively to express the cause.

Figure.

Lux for the sun; *Shadow* for cloud. A helmet is signified by the expression *glittering terror*; a tree by *shadow* or *umbrage*. Hence the expression:

Nec habet Pellion umbras. Ovid.

Where the dun umbrage hangs. Spring, l. 1023.

A wound is made to signify an arrow:

Vulnere non pedibus te confiquar. Ovid.

There is a peculiar force and beauty in this figure: the word which signifies figuratively the principal subject, denotes it to be a cause by suggesting the effect.

3. A word proper to the cause, employed figuratively to express the effect.

Bonumque labores for corn. *Sorrow* or *grief* for tears.

Again Ulysses veil'd his pensive head;

Again, unmann'd, a thow'r of sorrow shed.

Streaming Grief his faded cheek bedew'd.

Blindness for darkness:

Cæcis erramus in undis. Æneid. iii. 200.

There is a peculiar energy in this figure, similar to that in the former: the figurative name denotes the subject to be an effect, by suggesting its cause.

4. Two things being intimately connected, the proper name of the one employed figuratively to signify the other.

Day for light. *Night* for darkness; and hence, *A sudden night*. *Winter* for a storm at sea:

Interea magno misceri murmare pontum,
Emissamque Hyæmen sensit Neptunus. Æneid. i. 128.

This last figure would be too bold for a British writer, as a storm at sea is not inseparably connected with winter in this climate.

5. A word proper to an attribute, employed figuratively to denote the subject.

Youth and *beauty* for those who are young and beautiful:

Youth and beauty shall be laid in dust.

Majesty for the king:

What art thou, that usurp'st this time of night,
Together with that fair and warlike form
In which the Majesty of buried Denmark
Did sometime march? Hamlet, act 1. sc. 1.

Or have ye chosen this place

After the toils of battle, to repose

Your weary'd virtue.

Paradise lost.

Verdure for a green field. Summer, l. 301.

Speaking of cranes,

The pinyon nations wounds and death they bring,
And all the war defends upon the wing. Iliad iii. 10.

Cool age advances venerably wife. Iliad iii. 149.

The peculiar beauty of this figure arises from suggesting an attribute that embellishes the subject, or puts it in a stronger light.

6. A complex term employed figuratively to denote one of the component parts.

Funus for a dead body. *Burial* for a grave.

7. The name of one of the component parts instead of the complex term.

Tada for a marriage. The *East* for a country situated east from us. *Jovis vestigia servat*, for imitating Jupiter in general.

8. A word signifying time or place, employed figuratively to denote what is connected with it.

Figure.

Climate for a nation, or for a constitution of government: hence the expression, *Merciful climate*, *Fleecy winter* for snow, *Seculum felix*.

9. A part for the whole.

The *pole* for the earth. The *head* for the person:

Triginta minas pro capite tuo dedi. Plautus.

Tergum for the man:

Fugiens tergum. Ovid.

Vultur for the man:

Jam fulgor armorum fugaces

Terret equos, equitumque vultus. Horat.

Quis desiderio sit pudor aut modus

Tam chari capitis? Horat.

Dumque virent genua? Horat.

Thy growing virtues justify'd my cares,

And promis'd comfort to my silver hairs. Iliad ix. 616.

His mighty stature. Paradise: Lost.

The silent heart which grief affails. Parnell.

The peculiar beauty of this figure consists in marking that part which makes the greatest figure.

10. The name of the container, employed figuratively to signify what is contained.

Grove for the birds in it, *Vocal grove*. *Ships* for the seamen, *Agonizing ships*. *Mountains* for the sheep pasturing upon them, *Bleating mountains*. *Zacynthus*, *Ithaca*, &c. for the inhabitants. *Ex mæstis domibus*, Livy.

11. The name of the sustainer, employed figuratively to signify what is sustained.

Altar for the sacrifice. *Field* for the battle fought upon it, *Well-fought field*.

12. The name of the materials, employed figuratively to signify the things made of them.

Ferrum for *gladius*.

13. The names of the Heathen deities, employed figuratively to signify what they patronise.

Jove for the air, *Mars* for war, *Venus* for beauty, *Cupid* for love, *Ceres* for corn, *Neptune* for the sea, *Vulcan* for fire.

This figure bestows great elevation upon the subject; and therefore ought to be confined to the higher strains of poetry.

TAB. II. Attributes expressed figuratively.

When two attributes are connected, the name of the one may be employed figuratively to express the other.

Purity and virginity are attributes of the same person: hence the expression, *Virgin snow*, for pure snow.

2. A word signifying properly an attribute of one subject, employed figuratively to express a resembling attribute of another subject.

Tottering state. *Imperious ocean*. *Angry flood*. *Raging tempest*. *Shallow fears*.

My sure divinity shall bear the shield,
And edge thy sword to reap the glorious field.

Odyssey xx. 61.

Black omen, for an omen that portends bad fortune.

Aster odor. Virgil.

The peculiar beauty of this figure arises from suggesting a comparison.

3. A word proper to the subject, employed to express one of its attributes.

Mens for *intellectus*. *Mens* for a resolution:

Iliam,

Figure.

Istam, oro, exue mentem.

4. When two subjects have a resemblance by a common quality, the name of the one subject may be employed figuratively to denote that quality in the other:

Summer life for agreeable life.

5. The name of the instrument made to signify the power of employing it:

— Melpomene, cui liquidam pater
Vocem cum cithara dedit.

The ample field of figurative expression displayed in these tables, affords great scope for reasoning. Several of the observations relating to metaphor*, are applicable to figures of speech: these shall be slightly retouched, with some additions peculiarly adapted to the present subject.

1. As the figure under consideration is built upon relation, we find from experience, and it must be obvious from reason, that the beauty of it depends on the intimacy of the relation between the figurative and proper sense of the word. A slight resemblance, in particular, will never make this figure agreeable: the expression, for example, *Drink down a secret*, for listening to a secret with attention, is harsh and uncouth, because there is scarce any resemblance between *listening* and *drinking*. The expression *weighty crack*, used by Ben Johnson for *loud crack*, is worse if possible: a loud sound has not the slightest resemblance to a piece of matter that is weighty.

Phemius! let acts of gods, and heroes old,
What ancient bards in hall and bow'r have told,
Attemper'd to the lyre, your voice employ,
Such the pleas'd ear will drink with silent joy.

Odyssey i. 433.

Streptumque exterritus hausit.

Æneid vi. 559.

— Write, my queen,
And with mine eyes I'll drink the words you fend.

Cymbeline, act 1. sc. 2.

As thus th' effulgence tremulous I drink.

Summer, l. 1694.

Neque audit curus habenas.

Georg. i. 514.

O prince! (Lycan's valiant son reply'd),
As thine the steeds, be thine the talk to guide.
The horses practis'd to their lord's command,
Shall hear the rein, and answer to thy hand. *Iliad* v. 288.

The following figures of speech seem altogether wild and extravagant, the figurative and proper meaning having no connection whatever. *Moving* softness, *Freshness* breathes, *Breathing* prospect, *Flowing* spring, *Dewy* light, *Lucid* coolness, and many others of this false coin, may be found in Thomson's *Seasons*.

2. The proper sense of the word ought to bear some proportion to the figurative sense, and not soar much above it, nor sink much below it. This rule, as well as the foregoing, is finely illustrated by Vida, *Poet.* iii. 148.

3. In a figure of speech, every circumstance ought to be avoided that agrees with the proper sense only, not with the figurative sense; for it is the latter that expresses the thought, and the former serves for no other purpose but to make harmony:

Zacynthus green with ever-shady groves,
And Ithaca, presumptuous boud their loves;
Obtruding on my choice a second lord,
They press the Hymenean rite abhorrd.

Odyssey, xix. 152.

Zacynthus here standing figuratively for the inhabit-

VOL. IV.

tants, the description of the island is quite out of place: it puzzles the reader, by making him doubt whether the word ought to be taken in its proper or figurative sense.

— Write, my queen,
And with mine eyes I'll drink the words you fend,
Though ink be made of gall. *Cymbeline*, act 1. sc. 2.

The disgust one has to drink ink in reality, is not to the purpose where the subject is drinking ink figuratively.

4. To draw consequences from a figure of speech, as if the word were to be understood literally, is a gross absurdity; for it is confounding truth with fiction:

Be Moubray's fins so heavy in his bosom,
That they may break his foaming courier's back,
And throw the rider headlong in the lists,
A castif recreant to my cousin Hereford.

Richard II. act 1. sc. 3.

Sin may be imagined heavy in a figurative sense: but weight in a proper sense belongs to the accessory only; and therefore to describe the effects of weight, is to desert the principal subject, and to convert the accessory into a principal:

Cromwell. How does your Grace?

Wolsey. Why, well;

Never to truly happy, my good Cromwell.

I know myself now, and I feel within me

A peace above all earthly dignities,

A still and quiet conscience. The King has cur'd me,

I humbly thank his Grace; and, from these shoulders,

These ruin'd pillars, out of pity, taken

A load would sink a navy, too much honour.

Henry VIII. act 3. sc. 6.

Ulysses speaking of Hector:

I wonder now how yonder city stands,

When we have here the base and pillar by us.

Tralus and Creffida, act 4. sc. 9.

Othello. No; my heart is turn'd to stone: I strike it, and it hurts my hand. *Othello*, act 4. sc. 5.

Not less, even in this despicable now,

'Than when my name fill'd Afric with affrights,

And froze your hearts beneath your torrid zone.

Don Sebastian King of Portugal, act 1.

How long a space, since first I lov'd it, it is!

To look into a glass I fear,

And am surpris'd with wonder, when I miss,

Grey hairs and wrinkles there.

Cowley, vol. 1. p. 86.

I chose the flourishing'ft tree in all the park,

With freshest boughs, and fairest head:

I cut my love into his gentle bark,

And in three days beheld 'tis dead;

My very written flames so violent be,

They've burnt and wither'd up the tree.

Cowley, vol. 1. p. 136.

Ah, mighty Love, that it were inward heat

Which made this precious limbeck-sweat!

But what, alas! ah what does it avail

That he weeps tears so wond'rous cold,

As scarce the ass's hoof can hold,

So cold, that I admire they fall not hat?

Cowley, vol. 1. p. 132.

Such a play of words is pleasant in a ludicrous poem.

Almeria. O Alphonso, Alphonso!

Devouring seas have wash'd thee from my sight,

No time shall raise thee from my memory;

No, I will live to be thy monument:

The cruel ocean is no more thy tomb;

But in my heart thou art interr'd.

Mourning Bride, act, 1. sc. 1.

This would be very right, if there were any inconfi-

Figure.

ence, in being interred in one place really, and in another place figuratively.

From considering, that a word used in a figurative sense suggests at the same time its proper meaning, we discover a fifth rule, 'That we ought not to employ a word in a figurative sense, the proper sense of which is inconsistent or incongruous with the subject: for every inconsistency, and even incongruity, though in the expression only and not real, is unpleasant:

*Interea genitor Tyberini ad fluminis undam
Vulnere jacebat lymphis* ———— *Æneid. x. 833.*

*Tres adeo incertos cæca caligine fœles
Erramus pælogo, totidem sine fidere noctes.* *Æneid. iii. 203.*

The foregoing rule may be extended to form a sixth, 'That no epithet ought to be given to the figurative sense of a word that agrees not also with its proper sense:

————— *Dicat Opuntia
Fratr Megillæ, quo beatus
Vulnere,* *Horat. Carm. lib. 1. ode 27.*
*Parcus decorum cultor, et infrequens,
Infansiens dum sapientia
Consultus erro.* *Horat. Carm. l. 1. ode 54.*

Seventhly, The crowding into one period or thought different figures of speech, is not less faulty than crowding metaphors in that manner: the mind is distracted in the quick transition from one image to another, and is puzzled instead of being pleased:

*I am of ladies most dejected and wretched,
That suck'd the honey of his music vows.* *Hamlet.*
My bleeding bosom tickles at the sound. *Odyssey l. 439.*

————— *Ah miser,
Quanta laboras in Clarydi!
Digne puer meliore flamma.
Quæ sapa, quis te solvere Theffalls
Magus venenis, quis poterit dens?
Vix illigatum te triforimi
Pegasus expedit Chimæra.* *Horat. Carm. lib. 1. ode 27.*

Eighthly, If crowding figures be bad, it is still worse to graft one figure upon another: For instance,
While his keen falchion drinks the warriors lives.

Iliad xi. 211.

A falchion drinking the warriors blood is a figure built upon resemblance, which is passable. But then in the expression, *lives* is again put for *blood*; and by thus grafting one figure upon another, the expression is rendered obscure and unpleasant.

Ninthly, Intricate and involved figures, that can scarce be analysed, or reduced to plain language, are least of all tolerable:

Votis incendimus aras. *Æneid. iii. 279.*
*————— Onerantque canistris
Dona laboræ Cereris.* *Æneid. viii. 189.*

Vulcan to the Cyclopes:

*Arma acri faciendâ viro: nunc viribus usus,
Nunc manibus rapidis, omni nunc arte magnifra:
Precipite moras.* *Æneid. viii. 441.*

————— *Hinc gladio, perque area secuta
Per tunica squalentem auro, latus hauriat apertum.* *Æneid. x. 373.*

*Scriberis Vario fortis, et hostium
Victor, Mæonii carminis alite.* *Horat. Carm. lib. 1. ode 6.*

Else shall our fates be number'd with the dead.

Iliad v. 294.

Commuted death the fate of war confounds.

Iliad viii. 85. and xi. 117.

Speaking of Proteus.

*Instant he wears, elusive of the rape,
The mimic force of every savage shape.*

Odyssey iv. 563.

*Rolling convulsive on the floor, is seen
The piteous object of a prostrate queen.*

Ibid. iv. 651.

The mingling tempest weaves its gloom.

Autumn, 337.

A various sweetness swells the gentle race.

Ibid. 640.

A sober calm fleeces unbounded ether.

Ibid. 967.

The distant water-fall swells in the breeze.

Winter, 739.

In the tenth place, When a subject is introduced by its proper name, it is absurd to attribute to it the properties of a different subject to which the word is sometimes applied in a figurative sense:

*Hear me, oh Neptune! thou whose arms are hurl'd
From shore to shore, and gird the solid world*

Odyssey ix. 617.

Neptune is here introduced personally, and not figuratively for the ocean: the description therefore, which is only applicable to the latter, is altogether improper.

It is not sufficient, that a figure of speech be regularly constructed, and be free from blemish: it requires taste to discern when it is proper, when improper; and taste perhaps is our only guide. One, however, may gather from reflections and experience, that ornaments and graces suit not any of the dispiriting passions, nor are proper for expressing any thing grave and important. In familiar conversation, they are in some measure ridiculous: Prospero, in the *Tempest*, speaking to his daughter Miranda, says,

*The fringed curtains of thine eyes advance,
And say what thou seest yond.*

No exception can be taken to the justness of the figure; and circumstances may be imagined to make it proper: but it is certainly not proper in familiar conversation.

In the last place, Though figures of speech have a charming effect when accurately constructed and properly introduced, they ought, however, to be scattered with a sparing hand: nothing is more luscious, and nothing consequently more satiating, than redundant ornaments of any kind.

FIGURED, in general, something marked with figures.

The term *figured* is chiefly applied to stuffs, whereon the figures of flowers, and the like, are either wrought or stamped.

FIGURED, in music, is applied either to simple notes or to harmony: to simple notes, as in these words *figured bass*, to express a bass whose notes carrying chords are subdivided into many other notes of lesser value; to harmony, when, by supposition and in a diatonic procedure, other notes than those which form the chord are employed*.

To *figure* is to pass several notes for one; to form runnings or variations; to add some notes to the air, in whatever manner it be done; in short, it is to give to harmonious sounds a figure of melody, by connect-

Figure,
Figured.

* See
Supposition.

Filament. ing them with other intermediate sounds.

FILAMENT, in anatomy, natural history, &c. a term used in the same sense with fibre, for those fine threads wherof the flesh, nerves, skin, plants, roots, &c. are composed. See FIBRE.

Vegetable FILAMENTS form a substance of great use in the arts and manufactures; furnishing thread, cloth, cordage, &c.

For these purposes the filamentous parts of the *Cannabis* and *Linum*, or hemp and flax, are employed among us*. But different vegetables have been employed in different countries for the same uses. Putrefaction destroys the pulpy or fleshy matter, and leaves the tough filaments entire: By curiously putrefying the leaf of a plant in water, we obtain the fine flexible fibres, which constituted the basis of the ribs and minute veins, and which now form as it were a skeleton of the leaf. Alkaline lixivium, in some degree, produce similar effects to putrefaction.

The Sieur de Flacourt, in his history of Madagascar, relates, that different kinds of cloth are prepared in that island, from the filaments of the bark of certain trees boiled in strong ley; that some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton; that others are coarser and stronger, and last thrice as long as cotton; and that of these the sails and cordage of his vessel were made. See also the article BARK.

The same author informs us, that the stalks of nettles are used for the like purposes in his own country, France. And Sir Hans Sloane relates, in one of his letters to Mr Ray, that he has been informed by several, that muslin and callico, and most of the Indian linens, are made of nettles.

In some of the Swedish provinces, a strong kind of cloth is said to be prepared from hop-stalks: and in the transactions of the Swedish academy for the year 1750, there is an account of an experiment made in consequence of that report. Of the stalks, gathered in Autumn, about as many were taken, as equalled in bulk a quantity of flax that would have produced a pound after preparation. The stalks were put into water, and kept covered therewith during the winter. In March they were taken out, dried in a stove, and dressed as flax. The prepared filaments weighed nearly a pound, and proved fine, soft, and white: They were spun and woven into six ells of fine strong cloth. The author, Mr Shiller, observes, that hop-stalks take much longer time to rot than flax; and that, if not fully rotted, the woody part will not separate, and the cloth will neither prove white nor fine.

Hemp, flax, and all other vegetable filaments, and thread or cloth prepared from them, differ remarkably from wool, hair, silk, and other animal productions, not only in the principles into which they are resolvable by fire, but likewise in some of their more interesting properties, particularly in their disposition to imbibe colouring matters; sundry liquors, which give a beautiful and durable dye to those of the animal, giving no stain at all to those of the vegetable kingdom.

A solution of copper in aqua-fortis, which had been changed blue by an addition of volatile spirit, on being mixed with a little solution of tin, became turbid and greenish. Pieces of white silk and flannel boiled, without any previous preparation, in this mix-

ture, received a bright deep yellow dye, whilst pieces of linen, prepared and unprepared, came out as colourless as they were put in.

Fishing-nets are usually boiled with oak-bark or other like astringents, which render them more lasting. Those made of flax receive from this decoction a brownish colour, which, by the repeated alternations of water and air, is in a little time discharged, whilst the fine glossy brown, communicated by the same means to silken nets, permanently resists both the air and water, and stands as long as the animal filaments themselves. In like manner the stain of ink, or the black dye from solutions of iron, mixed with vegetable astringents, proves durable in silk and woollen; but from linen, the astringent matter is extracted by washing, and only the yellow iron-mould remains.

The red decoction of cochineal, which, heightened with a little solution of tin, gives the fiery scarlet dye to wool or silk that have been previously impregnated with solution of tartar, makes no impression upon linen or cotton prepared in the same manner. Mr du Fay informs us in the Memoirs of the French Academy for the year 1737, that having prepared a mixed cloth whose warp was of wool, and the woof of cotton, and thoroughly blended the two together by fulling, he still found the cotton to resist the action of the scarlet liquor, and the wool to receive the same colour from it as wool by itself, the stuff coming out all over marbled fiery and white.

Many other instances of this kind are known too well to the callico-printer; whose grand desideratum it is, to find means of making linen receive the same colours that wool does. The physical cause of the difference is wholly unknown; and indeed, of the theory of dyes in general, we know as yet extremely little. (See DYEING.) Are animal filaments tubular, and the colouring atoms received within them? Are vegetable filaments solid, and the colour deposited on the surface? Or does not their different susceptibility of colour depend rather on the different intrinsic properties of the two? There are many instances of a like diversity, even in the metallic kingdom, where a mechanical difference in texture can scarcely be presumed to be the cause: Thus silver receives a deep stain from sulphureous or putrid vapours, or the yolk of a boiled egg, which have no effect upon tin.

FILAMENTS, among botanists, particularly signify the stamina. See BOTANY, p. 1294.

FILANDERS, in falconry, a disease in hawks, &c. consisting of filaments or strings of blood coagulated; and occasioned by a violent rupture of some vein, by which the blood, extravasating, hardens into these figures, and incommodes the reins, hips, &c.

FILANDERS, are also worms as small as thread, and about an inch long, that lie wrapt up in a thin skin, or net, near the reins of an hawk, apart from either gut or gorge.

This malady is known by the hawk's poverty; by rustling her tail; by her straining the fist, or perch, with her pounces; and lastly, by croaking in the night, when the filanders prick her. The disease proceeds from bad food; and must be remedied in time, to prevent its spreading over the whole body, and destroying the bird. These must not be killed as other worms are, for fear of imposthumes from their corruption, be-

Filbert
||
Filigrane.

ing incapable of passing away with the hawk's meat. They must only be stupified, to prevent their being offensive; and this is done by giving the hawk a clove of garlic, after which she will feel nothing of the filanders for 40 days. It will be prudent in the falconer, when he observes the hawk poor and low, to give her a clove of garlic once a-month by way of prevention.

FILBERT, or FILBERD, the fruit of the corylus, or hazel. See CORYLUS.

FILE, among mechanics, a tool used in metal, &c. in order to smoothen, polish, or cut.

This instrument is of iron or forged steel, cut in little furrows, with chisels and a mallet, this and that way, and of this or that depth, according to the grain or touch required. After cutting the file, it must be tempered with a composition of chimney-foot, very hard and dry, diluted and wrought up with urine, vinegar, and salt; the whole being reduced to the consistence of mustard. Tempering the files consists in rubbing them over with this composition, and covering them in loam; after which they are put in a charcoal fire, and taken out by that time they have acquired a cherry colour, which is known by a small rod of the same steel put in along with them. Being taken out of the fire, they are thrown into cold spring-water; and when cold, they are cleaned with charcoal and a rag; and being clean and dry, are kept from rust by laying them up in wheat bran. Iron files require more heating than steel ones. Files are of different forms, sizes, cuts, and degrees of fineness, according to the different uses and occasions for which they are made. See FILING.

FILE, in the art of war, a row of soldiers, standing one behind another, which is the depth of the battalion or squadron. The files of a battalion of foot are generally three deep; as are sometimes those of a squadron of horse. The files must be straight and parallel one to another.

FILE, in law, a thread, string, or wire, upon which writs and other exhibits in courts and offices are fastened or filed, for the more safe keeping, and ready turning to the same. A file is a record of the court; and the filing of a process of a court makes it a record of it. An original writ may be filed after judgment given in the cause, issued forth before; declarations, &c. are to be filed, and affidavits must be filed, some before they are read in court, and some presently when read in court. Before filing a record removed by *certiorari*, the justices of B. R. may refuse to receive it, if it appears to be for delay, &c.; and remand it back for the expedition of justice: but if the *certiorari* be once filed, the proceedings below cannot be revived. An indictment, &c. cannot be amended after it is filed.

FILIAL, something belonging to the relation of son. See SON.

The divines usually distinguish between a *servile* and a *filial* fear. The most abandoned may have a servile fear of God, such as that of a slave to his master; but not a filial fear, i. e. a fear resulting from love and respect.

FILIGRANE, or FILIGREE, *Work*, any piece of gold or silver work that is curiously done with grains or drops on the filaments or threads.

Filicacia
||
Filter.

FILICACIA (Vincent), a celebrated Italian poet, was born at Florence in 1642. He was a member of the Academy della Crusca and of that of the Arcadi, and became secretary to the duke of Tuscany. He died in 1707. His poems are much esteemed for the delicacy and nobleness of their sentiments. Scipio de Filicacia, his son, had them all printed together, under the title of *Poesie Fesiano di Vincenzo da Filicacia*, in 1707, 4to.

FILICES, (from *filum* "a thread," *quasi filatim incisa*), FERNS; one of the seven tribes or families of the vegetable kingdom, according to Linnæus, by whom it is thus characterized: "having their fructification on the back side of the frondes." They constitute the first order in the class cryptogamia; and consist of 16 genera, which are divided into *fructificationes spicatae, frondosae, & radicales*. This order comprehends the entire xviith class of Tournefort, in whose system the filices make only a single genus, in the first section of the above-mentioned class.

FILICES, is also an order of plants in the *fragmenta methodi naturalis* of Linnæus. See BOTANY, p. 1317.

FILING, one of the principal operations in smithery, &c. succeeding to forging. See FILE.

The coarser cut files are always to be succeeded by finer; and in all the kinds the rule is, to lean heavy on the file in thrusting it forward, because the teeth of the file are made to cut forwards. But in drawing the file back again for a second stroke, it is to be lightly lifted just above the work, by reason it cuts not coming back.

The rough or coarse-toothed file (which, when large, is called a *rubber*) serves to take off the unevenness of the work left by the hammer in forging.

The bastard-toothed file is to take out too deep cuts, and file strokes made by the rough file. The fine-toothed file takes out the cuts or file-strokes the bastard-file made; and the smooth file those left by the fine file.

In this order, the files of several cuts are to succeed each other till the work is as smooth as it can be filed. After which it may be made yet smoother with emery, tripoli, &c. See POLISHING.

FILIPENDULA, in botany. See SPIRÆA.

FILIX, in botany. See FILICES.

FILLET, in anatomy. See FROENUM.

FILLET, or *Filet*, in architecture, a little square member, ornament, or moulding, used in divers places and upon divers occasions, but generally as a crowning over a greater moulding.

FILLET, in heraldry, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common bordure. It is supposed to be withdrawn inwards, and is of a different colour from the field. It runs quite round, near the edge, as a lace over a cloak.

FILLET, in the manege, the loins of an horse, which begin at the place where the hinder part of the saddle rests.

FILLY, a term among horse-dealers, to denote the female or mare colt.

FILM, a thin skin or pellicle. In plants, it is used for that thin, woody skin, which separates the seeds in the pods, and keeps them apart.

FILTER, or *FILTRE*, in chemistry, a strainer commonly

Filtration
||
Finch.

monly made of bibulous or filtering paper in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid.

FILTER, is also a charm, supposed to have a virtue of inspiring love. The word is derived from the Greek *φίλος*, which signifies the same thing, of *φιλος*, *amō*, "I love."

FILTRATION. See **CHEMISTRY**, n° 69.

FIMBRIÆ, denotes appendages disposed by way of fringe round the border of any thing.

FIMBRIATED, in heraldry, an ordinary with a narrow border or hem of another tincture.

FIN, in natural history, a well-known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles.

The office of the fins has commonly been supposed to be analogous to that of feathers in fowls; and to assist the fish in its progressive motion, or swimming; but the later naturalists find this a mistake.

The tail is the great instrument of swimming: the fins only serve to keep the fish upright, and prevent vacillation or wavering.

FINAL, in general, whatever terminates or concludes a thing; as final judgment, final sentence, &c.

FINAL Cause. See **CAUSE**.

FINAL Letters, among the Hebrew grammarians, five letters so called, because they have a different figure at the end of words from what they have in any other situation.

FINAL, in geography, a port-town of Italy, subject to Genoa, and situated on the Mediterranean, about 37 miles south-west of that city. It was sold to the Genoese, in 1713, by the emperor Charles VI. E. Long. 9. 12. N. Lat. 44. 30.

FINANCES, in the French policy, denote the revenues of the king and state: much the same with the treasury or exchequer of the English, and the fiscus of the Romans.—The word is derived from the German *finantz*, "scrapping, usury." Tho' du Cange chooses rather to deduce it from the barbarous Latin *financia*, *præstatio pecuniaria*.

Council of the FINANCES, corresponds to our lords-commissioners of the treasury: the comptroller-general of the *finances*, to our lord high treasurer, &c.

The French have a peculiar kind of figures, or numerical character, which they call *chiffre de finance*.

FINCH-KIND, in ornithology, an appellation given to a genus of birds known among authors by the name of **FRINGILLA**.

FINCH (Heneage), earl of Nottingham, the son of Sir Heneage Finch, some time recorder of London, and of a younger branch of the Winchelsea family, was born in 1621. By his good parts and diligence, he became a noted proficient in the municipal laws; was made solicitor-general by Charles II. on his restoration, and was very active in the prosecution of the regicides. In 1670, he was appointed attorney-general; about three years after, lord keeper of the great seal, on the removal of the earl of Shaftesbury; and lord chancellor in 1675. He was created earl of Northampton in 1681; and died the year following, being quite worn out by the fatigues of business. He published several speeches on the trials of the judges of king Charles I. with some few other things; and left

behind him Chancery Reports in MS.

FINE, in law, hath divers applications. Sometimes it is used for a formal conveyance of lands or tenements, or of any thing inheritable, being in *esse temporis finis*, in order to cut off all controversies. Others define it to be a final agreement between persons, concerning any lands or reats, &c. of which any suit or writ is depending between them in any court.

FINE, sometimes signifies a sum of money paid for entering lands or tenements let by lease; and sometimes a pecuniary mulct for an offence committed against the king and his laws, or against the lord of the manor.

FINES for Alienation, in feudal law. One of the attendants or consequences of tenure by vassalship. *Blackst. Knight-Service*, was that of fines due to the lord for every alienation, whenever the tenant had occasion to make over his land to another. This depended on the nature of the feudal connection; it not being reasonable nor allowed, that a feudatory should transfer his lord's gift to another, and substitute a new tenant to do the service in his own stead, without the consent of the lord; and, as the feudal obligation was considered as reciprocal, the lord also could not alienate his feignory without the consent of his tenant, which consent of his was called an *attornment*. This restraint upon the lord soon wore away; that upon the tenant continued longer. For, when every thing came in process of time to be bought and sold, the lords would not grant a licence to their tenants to alienate, without a fine being paid; apprehending that, if it was reasonable for the heir to pay a fine or relief on the renovation of his paternal estate, it was much more reasonable that a stranger should make the same acknowledgment on his admission to a newly purchased feud. In England, these fines seem only to have been exacted from the king's tenants in *capite*, who were never able to alienate without a licence: but, as to common persons, they were at liberty, by *magna charta*, and the statute of *quia emptores*, (if not earlier), to alienate the whole of their estate, to be holden of the same lord as they themselves held it of before. But the king's tenants in *capite*, not being included under the general words of these statutes, could not alienate without a licence: for if they did, it was in ancient strictness an absolute forfeiture of the land; tho' some have imagined otherwise. But this severity was mitigated by the statute i Edw. III. c. 12. which ordained, that in such case the lands should not be forfeited, but a reasonable fine be paid to the king. Upon which statute it was settled, that one third of the yearly value should be paid for a licence of alienation; but, if the tenant presumed to alienate without a licence, a full year's value should be paid. These fines were at last totally taken away by statute 12 Car. II. c. 24. See **KNIGHT-Service**.

FINE-Drawing, or Rentering, a dexterous sewing up or rejoining the parts of any cloth, stuff, or the like, torn or rent in the dressing, wearing, &c.

It is prohibited to *fine-draw* pieces of foreign manufacture upon those of our own, as has formerly been practised. See **RENTERING**.

FINERS of GOLD and SILVER, are those who separate these metals from coarser ores. See **REFINERS**.

FINERY, in the iron-works, one of the forges at which

Fine
||
Finery.

Flaming
Fire.

which the iron is hammered and fashioned into what they call a *bloom*, or *square bar*.

FINCAL, a Caledonian chief, the hero of Ossian, flourished about the end of the third century. Vid. *Ossian's Poems*.

FINGERS, in anatomy, the extreme part of the hand divided into five members.

FINING of LIQUORS. See CLARIFICATION.

FINISTERRA, the most westerly cape or promontory of Spain, in 10. 15. W. Long. and 43° N. Lat. This cape is likewise the most westerly part of the continent of Europe.

FINITE, something bounded or limited, in contradistinction to INFINITE.

FINLAND (the duchy of), is bounded on the west by the gulph of Bothnia, on the east by Muscovy, on the south by the gulph of Finland and Ingria, and on the north by Bothnia and Lapland. It is about 200 miles in length, and almost as much in breadth. It contains many lakes; in which are several islands, which are generally rocks or inaccessible mountains. The inhabitants are small of stature, capable of enduring hardships, and good soldiers. The Russians have for some time rendered themselves masters of a good part of this province; the rest belongs to Sweden. It is divided into seven provinces: 1. Finland; 2. Cajana; 3. Thavasthia; 4. Nyeland; 5. Savolaxia; 6. Carrelia; and, 7. Kexholmia.

Finland Proper is an agreeable country, and lies over-against the city of Stockholm, near the place where the gulphs of Bothnia and Finland meet. It is divided into South and North Finland. It is diversified with mountains, forests, lakes, meadows, and pleasant fields. The inhabitants salt the fish they do not consume themselves, and send it into foreign countries.

FIR-TREE, in botany. See ABIES.

FIRE is that subtle, invisible, fluidity, by which all bodies are expanded, or enlarged in their dimensions, and then become hot to the touch; fluid substances of every kind are carried off in vapour; solid bodies become luminous, and are likewise dissipated in vapour, or, if incapable of being evaporated, become fluid, and at last are converted into glass. It seems likewise to be the chief agent in nature, on which animal and vegetable life have an immediate dependence, and without which it doth not appear that the system of nature itself could subsist a single moment.

No question in natural philosophy seems more difficult to be resolved than that concerning the nature of fire, and none has been more agitated. One set of philosophers, amongst whom are Lord Bacon, Mr Boyle, Sir Isaac Newton, &c. assert, that fire is not any substance of itself distinct from terrestrial bodies, but that it consists only in a vehement vibratory motion of their parts. Hence, lord Bacon defines heat, by which he means fire itself, to be "an expansive undulatory motion in the minute particles of a body, whereby they tend with some rapidity towards the circumference, and at the same time tend a little upwards." From this he infers, that if in any natural body you can excite a motion whereby it shall expand or dilate itself, and can repress and direct this motion upon itself, in such a manner, that the motion shall not proceed uniformly, but obtain in some parts and be checked in

others, you will generate heat, or fire.

To the same purpose Mr Boyle argues in a treatise on the mechanical origin of heat and cold. "In the production of heat, (says he,) there appears nothing on the part either of the agent or patient, but motion, and its natural effects. When a smith briskly hammers a small piece of iron, the metal thereby becomes exceedingly hot: yet there is nothing to make it so, except the forcible motion of the hammer impressing a vehement and variously determined agitation on the small parts of the iron; which, being a cold body before, grows, by that superinduced commotion of its small parts, hot—first, in a more loose acceptance of the word, with regard to some other bodies with which it was cold before: then sensibly hot, because this agitation exceeds that of the parts of our fingers; and, in this instance, oftentimes the hammer and anvil continue cold after the operation; which shews, that the heat acquired by the iron was not communicated by either of those implements as heat; but produced in it by a motion great enough strongly to agitate the parts of so small body as the piece of iron, without being able to have an effect upon so much greater masses of metal as the hammer or anvil. Though, if the percussions were often and briskly renewed, and the hammer were small, this also might be heated. Whence it is not necessary that a body should itself be hot to give heat.

"If a large nail is driven by a hammer into a plank of wood, it will receive several strokes on its head ere it grow hot; but when it is once driven to the head, a few strokes suffice to give it a considerable heat: for while, at every blow of the hammer, the nail enters further into the wood, the motion produced is chiefly progressive, and is of the whole nail tending one way; but when that motion ceases, the impulse given by the stroke, being unable to drive it further on, or break it, must be spent in making a various, vehement, and intestine commotion of the parts among themselves, wherein the nature of heat consists."

Sir Isaac Newton conjectures, that the sun and stars are only great earths vehemently heated: for large bodies, he observes, "preserve their heat the longest, their parts heating one another; and why may not great, dense, and fixed bodies, when heated beyond a certain degree, emit light so copiously, as by the emission and reaction thereof, and the reflections and refractions of the rays within the pores, to grow continually hotter, till they arrive at such a period of heat as is that of the sun? Their parts may be further preserved from fuming away, not only by their fixity, but by the vast weight and density of the atmosphere incumbent on them, strongly compressing them, and condensing the vapours and exhalations arising from them. Thus we see, that warm water, in an exhausted receiver, shall boil as vehemently as the hottest water open to the air; the weight of the incumbent atmosphere, in this latter case, keeping down the vapours, and hindering the ebullition, till it has received its utmost degree of heat. So also a mixture of tin and lead, put on a red-hot iron in *vacuo*, emits a fume and flame; but the same mixture in the open air, by reason of the incumbent atmosphere, does not emit the least sensible flame."

Agreeable to this, Sir Isaac is of opinion, that "gross bodies may be converted into light, by the

Fire.

2
Of Mr
Boyle.

3
Of Sir Isaac
Newton.

Fire. agitation of their particles; and light, again, into gross bodies, by being fixed therein:" and he defines fire to be "a body heated so hot, as to emit light copiously; for what, (says he,) is a red-hot iron, but fire?"

Of Doctor
Grave-
ande, Boer-
haave, &c.

By others, fire is considered as a fluid *sui generis*, an original element, which "exists in all bodies, and may be separated or procured from them by rubbing them against each other, and thus putting their fire in motion. But this motion by no means generates the fire." This is the account given by Dr s Graveande; with whom Lemery agrees, and endeavours to prove, that it is equally diffused through all space, is present in all places, in the void spaces between bodies, as well as the insensible interstices between their parts: of which opinion also was Dr Boerhaave.

Objections
against the
mechanical
origin of
fire.

The first hypothesis having been adopted by such an eminent philosopher as Sir Isaac Newton, hath from thence received very considerable weight, and been generally received by the philosophers in this country. It is, nevertheless, pressed with almost insurmountable difficulties. It can by no means be explained upon the principles of mechanism, because it directly contradicts them.—It is certain, that if one body gives motion to another that resists it, the quantity of motion produced will be less than that of the first body; because as much will be taken off as the resistance of the first body was equal to. Thus, suppose a body moves in such a manner as to be able to raise 12 pounds; if it meets with an obstacle equivalent to six pounds, it will not, after driving it out of the way, be able to raise any more than six pounds. The same rule must hold equally, whether we suppose the parts of matter in motion to be large or small. In the above example, if we take ounces instead of pounds, we cannot suppose that the effect will be in the least disproportionate. If instead of ounces we take grains, or half grains, or the minutest particles, the effect must still be the same. Let us now take Mr Boyle's example of iron becoming red-hot by being hammered. The *momentum* or quantity of motion impressed on the iron, by the blows it receives from the hammer, cannot be very great; we shall suppose them all together to amount to 500 pound weight. The momentum of the small particles of fire so produced, must be something less than 500 pound, on account of the resistance of them to motion. If these particles so put in motion, are employed to put in motion the particles of other matter, the momentum of these must be still less than that of the iron, on account of the new resistance met with. Thus, on every accession of new fuel, the fire must decay, and at last be quite extinguished. For, let us suppose the quantity of motion originally communicated to be great or small: if one part of matter gives motion to another, and that to a third, and so on, there is a constant loss of motion, occasioned by the resistance of the parts to be moved; and let us suppose this resistance as small as we please, as long as it is a resistance, an increase of the fire must be impossible. The contrary to all this, however, is confirmed by daily experience; and there seems to be no limit to the increase of fire, but the want of fuel. We cannot therefore mechanically account for the origin of fire merely on those principles by which we account for the motions of gravitating bodies.

To obviate in some measure objections of this kind,

Sir Isaac Newton seems to have supposed, that every particle of matter is endowed with a sphere of attraction, and beyond that with a sphere of repulsion. Hence, as soon as two particles of matter get without the sphere of one another's attraction, they begin to repel each other very strongly; and hence, says he, "as in algebra, where affirmative quantities cease, negative ones begin; so in mechanics, where attraction ceases, there the repelling power must succeed."

Upon this principle of repulsion alone it is that the mechanical origin of heat is tenible: for if the minute particles of any body have a force impressed upon them, in such a manner as to put them without the sphere of each other's attraction, and then they begin to repel one another strongly, it may be supposed, that putting the parts of other matter in a similar situation, and these again acting upon others in a like manner, a large mass of matter might be resolved into its minutest particles, and these scattered to an immense distance by the mutual repelling power between them, and thus produce the phenomena of heat and light.

Even this will be found quite unsatisfactory, if attentively examined; for the repelling power with which these particles are supposed to be endowed, will have as great a tendency to drive them back upon the body from whence they came, as to drive them away from it. To help our conceptions in this matter, let us suppose, that the repulsive sphere round each of the minute particles is an inch in diameter. Let us also suppose, that this repulsive force is sufficiently great to throw the particle to the distance of 1000 miles, when it comes within the repulsive power of another. If, therefore, a particle is driven off from any hard substance, suppose iron, it will indeed drive another before it, which is already in the way, but will as certainly drive back upon the iron those which are shaken off from it afterwards: for re-action is always equal to action; and if we suppose a number of such particles extricated from the body, their mutual action and re-action being always equal, the motion among them must very soon cease.

Upon this principle, however, the Newtonians explain the emission of light from luminous bodies. "A ray of light (says Sir Isaac), as soon as it is cast off from the luminous body by the vibrating motion of its parts, and is got out of the sphere of its attraction, is propelled with an immense velocity."—Now, with all due submission to such a great name as that of Sir Isaac Newton, what he advances here is utterly impossible. All the parts of the sun have a mutual attraction towards one another, by which they are kept together; and it is impossible that a particle of matter can be both attracted and repelled at the same moment by one body.—It is indeed inconceivable, how the particles of matter can be endowed with two such contrary powers, and yet remain together in one mass; for though those which lie contiguous to one another may mutually attract, yet they must also repel, and be repelled by, those which lie at a greater distance; and, from such a mixture of contrary forces, it does not seem that any body could solidly cohere together.

In support of this hypothesis, we may however suppose, that the vibratory motion of the parts of the sun is so great, that the particles of light are thrown off by it an immense way beyond the orbit of Saturn. But granting this,

Fire.

this, no sooner would they come within the sphere of one another's repulsion, than some of them would be thrown back with violence towards the sun; and, in their return, would meet with others, to which they would give a like direction; and in this they would be assisted by the attractive force of the sun himself, by which means the force with which the light was emitted, must at first be resisted, and at last entirely destroyed.

But, whatever might be the case with the sun, the vibratory force of whose parts we may suppose to be inconceivably great, it is impossible that upon this principle any fire could be kindled by man: for the vibratory motion induced among the particles of any body by him, could never be greater than the force originally applied; and thus must unavoidably decay, on account of the continual resistance met with in setting the particles of other matter in the like motion.

To these objections, we may also add, that, upon this hypothesis, fire ought to burn best *in vacuo*; because there the pressure of the atmosphere is taken off, and there should be the less resistance to the vibrations of the small particles. We find, however, that fire, so far from burning best *in vacuo*, is immediately extinguished; and that a free circulation of air is absolutely necessary to preserve it.—Professor Hamilton, indeed, of the university of Dublin, endeavours to account for this, by saying, that air is necessary only to blow off the ashes, &c. which would prevent the continuance of the motion. But if there were no other occasion for air than this, fixed or phlogisticated air would answer the same purpose; and both of these are found to extinguish fire. See AIR.

6 Whether the true pabulum of fire is contained in the air.
The property, indeed, that air hath of supporting fire, has generally induced people to think that the true *pabulum* or fuel of fire is contained in the air.—Others are by no means inclined to admit this hypothesis; and no conclusive argument hath yet been brought against it. Indeed, in a case where the agents are so exceedingly subtle, it seems impossible to prove the negative in this question. We see, that fire will not burn without air; therefore air brings continually a new supply of matter which is converted into fire. Our senses here give us positive evidence. Those who take the other side of the question, ought to bring a proof equally strong against this. Dr Hamilton, indeed, *supposes* fire to be otherwise sufficiently provided with pabulum; and, therefore, that air acts upon fire otherwise than by supplying it with fuel, as we have already hinted.

7 Dr Hamilton's opinion.
“Air (says he) is not less necessary for the support of fire than of animal-life; for fire will not long continue to burn without a circulation of air. Now, *I suppose*, this happens, not from its adding any thing to the pabulum of fire, (for fire seems to be otherwise sufficiently provided with pabulum), but rather on this account, That the air immediately about a body on fire is heated, and made specifically lighter than the air at some distance from it. This hot air, therefore, must ascend, and carry with it all those minute particles of different kinds which are thrown off from the burning body, and which would otherwise rest upon its surface, and thereby clog and stop the subtle vibrations of the burning matter, in which the nature of fire partly con-

sists. If, therefore, fire be confined in a close place, where there can be no circulation of air, the air about it, being soon saturated with the particles arising from the burning matter, will not be able to take up any more of them; and therefore the fire must go out, smothered, as it were, with such particles as are no longer combustible. Hence it is that fire burns faster when air is strongly blown upon it: for then the ashes are carried off as fast as they are formed on the surface of the burning body; and thereby the particles that have just taken fire, are kept quite free from every thing that can impede or clog their vibratory motion. The air in this case also will spread the fire quickly through the fuel, by blowing the particles that are already kindled, among those that are not; and perhaps the motion of the air in this case may promote the subtle vibrations in the burning matter by which the fire is propagated through its parts. As the air contains many subtle particles of the inflammable kind, it is not improbable, that these, mixing with the gross burning matter, may help to preserve and enliven the fire; but I think it most probable, that air supports fire chiefly by carrying off such particles as are burned out, and would therefore obstruct the progress of the fire; because we find, that the strong elastic steam of water driven violently out of the pipe of an æolipile, which will carry off those particles, will also blow up and increase the fire as well as air driven from the bellows, although the steam does not contain any inflammable particles.”

8 Deception in his reasoning.
Here we have no other reason given in support of this hypothesis, than that fire may be blown up by the steam issuing violently from an æolipile; but this reason is founded on a deception. This steam only blows up the fire by occasioning a violent motion in the air through which it passes; and thus forcibly drives it on the fuel, at the same time that it enters along with it; and thus is, in some measure, similar to the blowing up of a large fire by a stream of water, which is used in some places instead of bellows. Nevertheless, if the steam of the æolipile is only admitted to the fire, and the air totally excluded from it, the fire will be as effectually extinguished as if the stream of water employed to force the air into a large furnace was itself directed on the fuel.—Besides, on the Doctor's hypothesis, fixed, and many other kinds of air ought to be equally efficacious in preserving flame, as already observed; which are yet found to extinguish it as effectually, if not more so than water.

9 Hutchinso-
nian hypo-
thesis.
Among other hypotheses, it may not be amiss to mention the almost forgotten and exploded one published by Mr Hutchinson, and by him pretended to be plainly revealed in the sacred writings.—According to this gentleman, the nature of fire, of light, and air, are all at bottom the same, being only three different modifications of the same fluid. When air is blown upon a fire, then the grosser fluid is immediately reduced to its finest parts, and attains the utmost degree of possible fluidity, by the vehement attrition of its own particles, and those of the fire already kindled, against one another. Being continually pressed upon in this state by the surrounding gross air, it is sent out on all sides in streams of light, which being detained among the particles of the atmosphere, and having their motion stopped, become part of the air itself, and are again ready

Fire.

ready to reassume their luminous and fiery appearance on proper occasions.

Setting aside the pretended authority of revelation, many people have been of opinion, that this hypothesis might be supported by very strong arguments drawn from matter of fact. The principal are the following.

10
Arguments
in favour of
this opinion

1. It is well known, that in all mixtures of different kinds of fluids; those which are rarest, and consequently less acted upon by the force of gravity than others, will rise to the top, and occupy the uppermost place in the mixture. Thus, if water and oil are mixed together, they will soon separate themselves, and the oil will swim at the top. This separation happens in consequence of their different degrees of density, by which the oil is less affected by the force of gravity than the water; not through any principle of *innate levity*, or any power of repulsion between this fluid and the bottom of the vessel. In like manner, when we see any other two fluids mixed, and one of them ascends, we ought not to conclude, that there is any unknown power of repulsion in that which ascends, more than in the other. If only one of the two fluids is visible, and that happens to be the ascending one, we ought not therefore to seek for the cause of its ascent in unknown and imaginary repulsions and vibrations, but rather to conclude that it is pressed upwards by the tendency of an invisible fluid of greater density downwards. In most cases this is allowed by all philosophers to hold good. The smoke of a fire, for instance, does not ascend from it, on account of any principle of positive levity, or on account of a repulsive power betwixt it and the fire from which it ascends, but from the greater tendency of the air downwards; in consequence of which, it is driven upwards with a force equivalent to the difference of their specific gravities. By analogy, (say they) we ought to apply this to the emission of light itself. We have, no other proof of a repulsive power between the particles of this substance, than its constant ascent from a luminous body; and invent it in order to solve this phenomenon, when the same thing may be done with a much greater degree of probability, and more agreeable to the known laws of nature in other cases, by supposing the descent of a denser, though invisible, fluid towards that body.

2. It can be proved by experiment, that the matter of fire, or light, is convertible into a denser substance, subject to the laws of gravitation, and united to terrestrial bodies in such a manner as to become a part of their composition, while yet it is capable of being afterwards expelled by a renewal of heat, and of reappearing in the form of air.—The proof here rests upon the augmentation of weight observed in metals, when calcined either in the solar beams by means of a burning glass, or in a common fire. Thus, regulus of antimony, calcined in the focus of a large burning glass, gains almost an eighth part of its whole weight; red lead, in calcination, gains a tenth part; and some of the other metals have been observed to gain much more. When these calces are suffered to cool, and are again exposed to the action of a strong fire, they discharge a large quantity of air. The fire, therefore, say the adopters of this hypothesis, has here been evidently converted into air; it being impossible that, during the continuance of a violent heat, any thing could be imbibed from the air; for the fire would as effectually

prevent any such absorption at first, as it could expel the air afterwards.

Fire.

3. The phenomena of electricity show, that there is present between the grosser parts of bodies an invisible subtle fluid, of exceeding great power, which on certain occasions becomes visible, and then discovers itself to be the real element of fire itself. It always appears to our eyes as a stream of subtle fire, emitting a very perceptible light. It will kindle inflammable substances; melt the most difficultly fused metals, platina itself not excepted; and even turn gold into glass, which hath never yet been done either by the fiercest furnace or the strongest burning mirror.

Though this hypothesis has been laid down in its most distinct and plausible form by Hutchinson, or rather some of his followers, it appears very little if at all different from that of Boerhaave and others, who maintain the impossibility of generating fire, and affirm it to be a fluid *sui generis*. A direct proof of this, however, as well as of other suppositions concerning the nature of fire, is attended with great difficulties. Were we able to convert fire by itself into air, and convert air by itself into fire, the point would indeed be gained. But, though we blow ever so much air into a fire, unless we continually add new fuel, it will soon be extinguished. But this ought not to be the case on the Hutchinsonian hypothesis: for one quantity of air being reduced to its utmost degree of fluidity, ought to reduce to the same state every succeeding quantity which mixed itself with it; and not only would fire be kept up without any gross fuel, but there might be some danger of setting the whole atmosphere in a blaze at once.

11
Difficulties
attending
this hypothesis.

Thus, while one party is at a loss to account for the usefulness of air in supporting fire, the other is no less distressed with the gross fuel, such as wood, coals, &c. which seem to be equally necessary with the air itself for the support of our fires. The Hutchinsonians, indeed, find no other use for the fuel but to keep off too great a quantity of air, which would oppress and extinguish a small fire: but this purpose might be equally well answered by pieces of brick or stone; yet these will effectually put out a fire. The use of the fuel, therefore, which is continually to be added to our common fires, cannot be explained on the Hutchinsonian hypothesis.

The discoveries of Dr Priestley, however, have put the matter beyond a doubt with respect to air. He hath made it apparent, that terrestrial substances are necessary ingredients in the composition of air much purer than what we breathe, and much more capable of sustaining flame*; so that it is now an absurdity to talk of fire, and air being convertible into one another.

12
It is totally
overturn-
ed by Dr
Priestley's
experi-
ments.

* See Air.

The great proof on the Hutchinsonian side, and which they look upon as absolutely unanswerable, is the increase of weight in metalline calces when exposed to the action of a strong fire. This increase is found to be owing to air, as we have already mentioned: and though it should by no means be found either fit for respiration, or for the purposes of supporting flame; yet it will be sufficient for their purpose to prove, that the element of fire is capable of being converted into a gravitating substance; which, when disengaged, appears in the form of a permanently ela-

13
sile

stic fluid, and thus becomes a certain species of air.—That it really doth so, however, is very dubious: for it is certain, that metals cannot be calcined without the free access of air; and therefore it cannot certainly be known whether the air in the calx comes from the fixation of the fire, or whether it is attracted from the surrounding atmosphere, especially if, as some alledge, the calx receives no increment in weight while kept hot.

M. la Voisier mentions some very fine experiments with regard to the calcination of metals, which ought to throw a considerable light on this subject.—Having put three drachms of lead in a stone crucible placed under a glass-receiver inverted in quicksilver, he exposed it to one of Tschirnhausen's great burning-glasses; keeping it, however, a full inch from the true focus, that the heat might not be much greater than was necessary to melt the metal.

At the very instant the lead melted, though it was perfectly clean and bright on every side, a pellicle was produced on its surface. In the progress of the calcination, this pellicle became of a yellow massicot colour, and wrinkled on one side. In ten or twelve minutes the calcination stopped, and no farther effect was observed; only when the heat was a little stronger, the yellow pellicle fused in some places, and formed a yellowish glass. From the portions thus vitrified fumes arose plentifully, which tarnished the top of the cucurbit. This evaporation he opposed as much as possible, by removing the lead farther and farther from the true focus of the lens.

The metal having been exposed to the action of this lens for an hour and 15 minutes, and the vessels then perfectly cooled, it was found to have gained $2\frac{1}{2}$ grains. The mercury was found to have gained $2\frac{1}{2}$ lines above its former level. The diameter of the receiver in that place was $4\frac{1}{8}$ inches, so that the whole quantity of air absorbed was $\frac{3}{4}$ cubic inches. The proportion of the increase of weight in the calx then, had been $\frac{3}{4}$ of a grain for each inch of air, which is about one fourth more than the weight of an equal quantity of atmospherical air. Having made some experiments on the air which remained in the receiver, he found that it would not precipitate lime-water, and thus seemed to be deprived of its fixed part.

To the same purpose Dr Priestley hath made experiments on metallic calcinations; and acquaints us, that if a metal is calcined over lime-water, it doth not become turbid; because, though the calcareous earth attracts the fixed air, yet the metallic calx doth it much more strongly, and consequently no precipitation can ensue. The same reason he gives why metals cannot be calcined in nitrous air; namely, that there is then no fixed air with which the metallic calx may combine, and upon which the calcination seemed to him to depend; nevertheless, the metals fused copiously, though the phlogiston was not separated.

These experiments seem totally unanswerable by the Hutchinsonsians. It is well known, that fixed air is one of the component parts of our atmosphere; and from Mr la Voisier's and Dr Priestley's experiments, it would seem impossible to deprive a metal of its phlogiston, but by allowing the calx to combine with fixed air; and as the fire, though constantly applied, is not

able to produce this fixed air, but must have the assistance of the common atmosphere, this seems a demonstration, that fire is not convertible into an elastic fluid of any kind.

The only reply which the Hutchinsonsians can give to this is, that metals will be increased in weight tho' kept over the fire in close vessels. But this may very reasonably be supposed to proceed from the small quantity of air contained in the vessels where they are put, or from some inaccuracy in closing them, so that there may be some communication between the metals and the external air. To make these experiments perfect, the glasses ought first to be well exhausted of their air, and then hermetically sealed.

It doth not appear, therefore, that ever the element of fire hath been by human art converted into a grosser fluid of any kind; and consequently the only resource left the Hutchinsonsians is in arguments drawn from the similarity of the electric fluid and the substance of light or fire. The late discoveries in electricity, indeed, have thrown so much light upon that subject, that there are now but few who deny the existence of fire as a distinct element. It doth not, however, appear, that this element can ever be converted into any other fluid of a grosser nature, as the Hutchinsonsians affirm. The electric fluid seems to be equally subtle, and equally penetrating, with fire or light; and though it should remain ever so long at rest, it doth not appear that its fluidity is thereby lost in the smallest degree. But for a full account of the experiments most likely to ascertain the identity of elementary and electric fire, see the articles ELECTRICITY, HEAT, IGNITION, LIGHT, &c.

Wild Fire, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it.

It is composed of sulphur, naphtha, pitch, gum, and bitumen; and is only extinguishable by vinegar mixed with sand and urine, or by raw hides.

Its motion or tendency is said to be contrary to that of natural fire, and always follows the direction in which it is thrown; whether it be downwards, sideways, or otherwise. The French call it *Greek fire*, or *feu Gregeois*, because first used by the Greeks, about the year 660; as is observed by the Jesuit Petavius, on the authority of Nicetas, Theophanes, Cedrenus, &c.

The inventor, according to the same Jesuit, was an engineer of Heliopolis, in Syria, named *Callinicus*, who first applied it in the sea-fight commanded by Constantine Pogonates against the Saracens, near Cyzicus, in the Hellespont; and with such effect, that he burnt the whole fleet therewith, wherein were 30,000 men.

But others will have it of a much older date; and hold Marcus Gracchus the inventor: which opinion is supported by several passages, both in the Greek and Roman writers, which shew it to have been anciently used by both those nations in their wars. See *Scaliger* against *Cardan*.

Constantine's successors used it on divers occasions, with equal advantage as himself; and what is remarkable enough, is, that they were so happy as to keep the secret of the composition to themselves, so that no other nation knew it in the year 960.

Hugh, king of Burgundy, demanding ships of the emperor

Fire.

emperor Leo, for the siege of Frefne, desired likewise the Greek fire. Chorier *Hist. de Dauph.*

F. Daniel gives us a good description of the Greek fire, in his account of the siege of Damietta under St Louis. Every body, says that author, was astonished with the Greek fire, which the Turks then prepared; and the secret whereof is now lost. They threw it out of a kind of mortar; and sometimes shot it with an odd sort of cross-bow, which was strongly bent by means of a handle, or winch, of much greater force than the mere arm. That thrown with the mortar, sometimes appeared in the air of the size of a tun, with a long tail, and a noise like that of thunder. The French by degrees got the secret of extinguishing it; in which they succeeded several times.

Ann. Reg.
xviii. 117.

Machine for Preserving from FIRE. This machine, consists of a pole, a rope, and a basket. The pole is of fir, or a common scaffold pole, of any convenient length from 36 to 46 feet; the diameter at bottom, or greatest end, about five inches; and at the top, or smallest end, about three inches. At three feet from the top is a mortise through the pole, and a pulley fixed to it of nearly the same diameter with the pole in that part. The rope is about three quarters of an inch diameter, and twice the length of the pole, with a spring hook at one end, to pass through the ring in the handle of the basket when used: it is put through the mortise over the pulley, and then drawn tight on each side to near the bottom of the pole, and made fast there till wanted. The basket should be of strong wicker-work, three feet and a half long, two feet and a half wide, rounded off at the corners, and four feet deep, rounding every way at the bottom. To the top of the basket is fixed a strong iron curve or handle, with an eye or ring in the middle; and to one side of the basket, near the top, is fixed a small cord, or guide-rope, of about the length of the pole. When the pole is raised, and set against a house over the window from which any persons are to escape, the manner of using it is so plain and obvious, that it needs not be described. The most convenient distance from the house, for the foot of the pole to stand, where practicable, is about 12 or 14 feet. If two strong iron straps, about three feet long, rivetted to a bar cross, and spreading about 14 inches at the foot, were fixed at the bottom of the pole, this would prevent its turning round or slipping on the pavement. And if a strong iron hoop, or ferule, rivetted (or welded) to a semi-circular piece of iron spreading about 12 inches, and pointed at the ends, were fixed on at the top of the pole, it would prevent its sliding against the wall.

When these two last mentioned irons are fixed on, they give the pole all the steadiness of a ladder; and because it is not easy, except to persons who have been used to it, to raise and set upright a pole of 40 feet or more in length, it will be convenient to have two small poles, or spars, of about two inches diameter, fixed to the sides of the great pole at about two or three feet above the middle of it, by iron eyes rivetted to two plates, so as to turn every way; the lower end of these spars to reach within a foot of the bottom of the great pole, and to have ferules and short spikes to prevent sliding on the pavement, when used occasionally to support the great pole, like a tripod. There should be two strong ash trundles let through the pole, one at

Fire.

four feet and one at five feet from the bottom, to stand out about eight inches on each side, and to serve as handles, or to twist the rope round in lowering a very heavy weight. If a block and pulley were fixed at about the middle of the rope, above the other pulley, and the other part of the rope made to run double, it would diminish any weight in the basket nearly one half, and be very useful in drawing any person up, to the assistance of those in the chambers, or for removing any effects out of a chamber, which it might be dangerous to attempt by the stairs.

It has been proved, by repeated trials, that such a pole as we have been speaking of can be raised from the ground, and two or three persons taken out of the upper windows of an house and set down safely in the street, in the space of 35 seconds, or a little more than half a minute. Sick and infirm persons, women, children, and many others, who cannot make use of a ladder, may be safely and easily brought down from any of the windows of an house on fire by this machine, and, by putting a short pole through the handles of the basket, may be removed to any distance without being taken out of the basket. The pole must always have the rope ready fixed to it, and may be conveniently laid up upon two or three iron hooks under any shade or gate-way, and the basket should be kept at the watch-house. When the pole is laid up, the two spars should always be turned towards the head of it. The basket should be made of peeled rods, and the pole and spars painted of a light stone-colour, to render it more visible when used in the night.

Godfrey's Machines for Extinguishing FIRE. Of these the following account is given by Mr Ambrose Godfrey, grandson to the inventor. "The machine to be employed, consists of a small portion of gun-powder closely confined; which, when animated by fire, acts by its elastic force, upon a proper medium, and not only divideth it into the minutest atoms, but disperseth it also in every direction, so as immediately to extinguish any fire within a certain distance. This medium is a liquor strongly impregnated with a preparation of antiplogistic principles, which, by their action upon burning materials, extinguish the flames, and reduce them in general to a state of a black coal; and, by its opposite nature to fire, hinders the remaining sparks, notwithstanding the admission of the air, from kindling the flames afresh. By this means, the great point is obtained, in giving sufficient time for totally extinguishing any remains of fire.

"They who presume that water only will perform this, will find themselves greatly mistaken, as the draught of air will certainly rekindle the neighbouring materials, which are very fit to receive a fresh flame, the fire not being extinguished by the quantity of water, but rather by the expansion and rarefaction of its particles. There are several sizes of these machines, from five to fifty pounds weight, in a portable and rather small compass, and may generally be carried to any place where a man can go himself.

"But tho' these machines will prevent great fires by a timely application, they will not extinguish them after they have reached a frightful height, and several houses, perhaps near a whole street, are in flames. The floors must be standing, and access to the building safe, otherwise no person can be supposed to approach

Fire.

near enough to apply them in a proper manner. Every fire has its beginning, for the most part, in some apartment; and as soon as discovered, the family, instead of losing all presence of mind, should immediately apply one or more of these machines, which will then fully answer the intention. The proper time of applying them, supposes that they are ready at hand. It will be in vain to think of fetching them from any considerable distance, as it will then be too late for them to perform any important service; except indeed being the probable means of saving some adjacent house, by extinguishing the flames as often as they break out, till the building first on fire is totally consumed, and, by falling into ruins, leaves the other in perfect safety."

On the 19th of May 1761, at noon, Mr Godfrey's experiment for extinguishing fire, was tried in an house erected for that purpose, near Mary-le-bone. Their royal highnesses the duke of York, prince William Henry, prince Henry Frederick, a great number of persons of rank and distinction, and many of the learned world, gave their attendance on this singular occasion. The house, which is of brick, consists of three rooms, one above another, a stair-case, chimney, lath-and-plaster ceilings, and a kind of wainscoting round the rooms, of rough deal. Exactly at 12 o'clock the ground-room, and that up one pair of stairs, were set on fire, by lighting the faggots and shavings laid in there for that purpose: in about 15 minutes the wain-foot of the under room was thought to be sufficiently in flames, and three of the machines were thrown in; which, by almost immediate and sudden explosions, instantaneously extinguished the flames, and the very smoke in that apartment in a few minutes totally disappeared. By this time, the firemen, &c. who had the care of throwing in the machines, gave an alarm that the stair-case had taken fire, and that it was necessary directly to go to work upon the next room; which was accordingly done, and with the same effect. The experiment, however, hitherto did not universally satisfy: in the last instance especially it was thought to be too hastily put in execution; and the populace, without side the pangs, who were supposed to amount to near 20,000, and whose curiosity, from the very nature of their situation, remained much dissatisfied, began to grow rather riotous, and talked of a second bottle-conjuror. For the sake of the experiment, therefore, and to remove all manner of doubt, Mr Godfrey consented to a third experiment in the upper room, which was entirely of wood. The flames were now suffered to get to a considerable height, and even the window-frames destroyed, before the machines were thrown in: which, however, answered exactly as the former had done; and, being quite in sight of the out-landers, met with universal approbation.

In the year 1734, the states of Sweden offered a premium of 20,000 crowns for the best method of stopping the progress of accidental fires; when one Mr Fuches, a German physician, made a preparation for that end, and the experiment was made on a house built on purpose, of dry fir, at Legard island. In the buildings were placed several tubs of tar and pitch, and a great quantity of chips, all which were set on fire; flames issuing through the top of the house, windows, &c. when he threw in one of the barrels containing the preparation, which immediately quenched the flames;

Fire.

a second barrel entirely cleared the smoke away; and the whole was executed to the satisfaction of the spectators, and to the no small satisfaction of the inventor, who was about to return home, when unexpectedly the flames broke out again, supposed to be occasioned by a small quantity of combustible matter being introduced and set on fire secretly by some malicious person. Upon this the wrong-headed mob fell upon Mr Fuches, and beat him most unmercifully, so that he narrowly escaped with his life. He soon after left the country, and never could be prevailed on (tho' strongly persuaded by some of the most eminent citizens) to return. It is said, another experiment of the same kind was tried in the year 1761 in Holland; but rendered abortive through the perverseness of the populace.

These machines of Mr Godfrey's, it is evident, would be of great use in extinguishing fires on shipboard; and might be considered as a no less necessary part of a ship's lading, than her stores or ammunition.

The hint of these machines is said to have been taken by Dr Godfrey from the invention of one Zachary Grey, who exhibited machines similar to those of Dr Godfrey, before persons of the first rank, but without meeting with any encouragement. His machines were made of wood, and the liquor employed was only water, and consequently inferior to Dr Godfrey's in its power of extinguishing fire. The latter is said to have mixed his water with a certain quantity of oil of vitriol, or with sal ammoniac. These machines, however, are found to be only serviceable in the beginning of a fire. When the roof had fallen in, they had no effect.

Water-Engine for Extinguishing FIRE. See HYDROSTATICS, n^o 33.

In using this machine we have the following improvement by Dr Hoffman, which promises to be of great efficacy. As soon as the engine is in readiness to work, stir into the water that immediately is to be discharged, seven or eight pounds of pearl-ashes in powder, and continue to add it in this manner as occasion requires; taking care that it be directed against the timber or wainscot, &c. just beginning to burn, and not waited against the brickwork; or, where time will admit, dissolve any quantity of pearl-ashes in a copper with water, and as fast as it dissolves, which will be in a few minutes, mix a pailful with the water in the engine, pretty often; and whatever burning wood it is played upon, will be extinguished as if it was dipped in water, and will not burn afresh in the part extinguished.

Use of Gun-powder for Extinguishing FIRES. It is well known, that the inner parts of chimneys easily take fire; the foot that kindles therein emits a greater flame, according as the tunnel is more elevated, because the inferior air feeds the fire. If this air could therefore be suppressed, the fire would soon be extinguished. In order to this, some discharge a pistol into the chimney, which produces no effect: others lay under the chimney a copper full of water; but the vapours that rise from it, far from extinguishing the fire, seem to give it new force. Water thrown into the chimney at top is equally of no effect, because it comes down through the middle of the tunnel, and not along the sides. It would be more advisable to stop with dung the upper orifices of the tunnel for quenching

Fire.

ing the fire. But the surest and readiest method is, to take a little gunpowder, and, having humected it with spittle for binding it, to form it into small masses, and so throw it into the hearth of the chimney. When it is burnt, and has produced a considerable vapour, a second, afterwards a third, are thrown, and so on, as much as is necessary. In a little time the fire is extinguished, and, as it were, choaked by this vapour; and cakes of inflamed foot are seen to fall from the tunnel, till at last not the least vestige of fire appears.

FIRE, in theology. See **HELL**.

We read of the sacred fire in the first temple of Jerusalem, concerning which the Jews have a tradition that it came down from heaven: it was kept with the utmost care, and they were forbidden to carry any strange fire into the temple. This fire is one of the five things which the Jews confels were wanting in the second temple.

The pagans had their sacred fires, which they kept in their temples with the most religious care, and which were never to be extinguished. Numa was the first who built a temple to Fire as a goddess, at Rome, and instituted an order of priestesses for the preservation of it. See **VESTALS**.

Fire was the supreme god of the Chaldeans; the Magi were worshippers of fire; and the Greeks and Armenians still keep up a ceremony called the *holy fire*, upon a persuasion that every Easter-day a miraculous fire descends from heaven into the holy sepulchre, and kindles all the lamps and candles there.

FIRE kindled spontaneously in the Human Body. See *Extraordinary Cases of BURNING*.

FIRE-BARREL. See **FIRE-SHIP**, Note (B.)

FIRE-BRIM. Ibid. Note (D.)

FIRE-ARROW, in naval artillery, is a small iron dart furnished with springs and bars, together with a match impregnated with sulphur and powder, which is wound about its shaft. It is intended to fire the sails of the enemy, and is for this purpose discharged from a musketoon or swivel-gun. The match being kindled by the explosion, communicates the flame to the sail against which it is directed, where the arrow is fastened by means of its bars and springs. This weapon is peculiar to hot climates, particularly the West Indies, where the sails being extremely dry by reason of the great heats, they instantly take fire, and of course set fire to the masts and rigging, and lastly to the vessel itself.

FIRE-BALL, a composition of meal-powder, sulphur, salt-petre, pitch, &c. about the bigness of a hand-grenade, coated over with flax, and primed with the slow composition of a fuse. This is to be thrown into the enemy's works in the night-time, to discover where they are; or to fire houses, galleries, or blinds of the besiegers; but they are then armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are desired to have any effect.

FIRE-COCKS. Churchwardens in London and within the bills of mortality, are to fix firecocks at proper distances in streets, and keep a large engine and hand-engine for extinguishing fire, under the penalty of 10*l*. stat. 6 Ann. c. 31.

On the breaking out of any fire in London or Westminster, the constables and headles of parishes shall repair to the place with their slaves, and assist in ex-

tinguishing it, and cause the people to work for that end, &c.

FIRE-ENGINE. See **STEAM-ENGINE**.

FIRE-FLAIRE, in ichthyology. See **RAJA**.

FIRE-FLIES, a species of flies common in Guiana, of which there are two species. The largest is more than an inch in length, having a very large head connected with the body by a joint of a particular structure, with which at sometimes it makes a loud knock, particularly when laid on its back. The fly has two feelers or horns, two wings, and six legs. Under its belly is a circular patch, which, in the dark, shines like a candle; and on each side of the head near the eyes, is a prominent, globular, luminous body, in size about one third larger than a mustard-seed. Each of these bodies is like a living star, emitting a bright, and not small, light; since two or three of these animals, put into a glass-vessel, afford light sufficient to read without difficulty, if placed close to the book. When the fly is dead, these bodies will still afford considerable light, though it is less vivid than before; and if bruised, and rubbed over the hands or face, they become luminous in the dark, like a board smeared over with English phosphorus. They have a reddish-brown or chestnut colour; and live in rotten trees in the day, but are always abroad in the night. The other kind is not more than half as large as the former: their light proceeds from under their wings, and is seen only when they are elevated, like sparks of fire appearing or disappearing at every second. Of these the air is full in the night, tho' they are never seen in the day. They are common not only in the southern, but in the northern parts of America, during the summer.

FIRE-LOCK, or *Fusil*, a small gun which fires with a flint. It is distinguished from an old musquet, or match-lock, which was fired with a match. The firelock is now in common use in the European armies.

FIRE-POTS, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered; then the pot is covered with a piece of parchment, and two pieces of match across lighted: this pot being thrown by a handle of matches where it is desired, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, to the end its operations may be the quicker.

FIRE-REDS. See the next article, Note (c.)

FIRE-SHIP, an old vessel filled with combustible materials, and fitted with grappling irons to hook, and set fire to, the enemies ships in battle, &c.

As there is nothing particular in the construction of this ship, except the apparatus by which the fire is instantly conveyed from one part to another, and from thence to the enemy, it will be sufficient to describe the fire-room, where these combustibles are enclosed, together with the instruments necessary to grapple the ship intended to be destroyed.

The fire-room is built between decks, and limited on the after-part by a *bulk-head*, L, behind the main-mast, from which it extends quite forward, as represented in fig. 1. Plate CXIV. The train inclosed in this apartment is contained in a variety of wooden troughs, D, G, which intersect each other in different parts of the ship's length; being supported at proper distances

by

Fire.

by cross-pieces and flanchions. On each side of the ship are six or seven ports, H₃, about 18 inches broad, and 15 inches high; and having their lids to open downward, contrary to the usual method.

Against every port is placed an iron chamber (A), which, at the time of firing the ship, blows out the port-lid, and opens a passage for the flame. Immediately under the main and fore-shrouds is fixed a wooden funnel M; whose lower end communicates with a fire-barrel (a), by which the flame passing through the funnel is conducted to the shrouds. Between the funnels, which are likewise called *fire trunks*, are two scuttles, or small holes in the upper deck, serving also to let out the flames. Both funnels must be flopped with plugs, and have fail-cloth or canvas nailed close over them, to prevent any accident happening from above to the combustibles laid below.

The ports, funnels, and scuttles, not only communicate the flames to the outside and upper-works of the ship and her rigging; but likewise open a passage for the inward air, confined in the fire-room, which, is thereby expanded so as to force impetuously thro' those out-lets, and prevent the blowing up of the decks, which must of necessity happen from such a sudden and violent rarefaction of the air as will then be produced.

On each side of the bulk-head behind is cut a hole L, of sufficient size to admit a trough of the same dimensions as the others. A leading trough, L I, whose foremost-end communicates with another trough within the fire-room, is laid close to this opening, from whence it extends obliquely to a fally-port I, cut thro' the ship's side. The decks and troughs are well covered with melted rosin. At the time of the firing either of the leading troughs, the flame is immediately

conveyed to the opposite side of the ship, whereby both sides burn together.

The spaces N, O, behind the fire-room, represent the cabins of the lieutenant and master, one of which is on the starboard, and the other on the larboard side. The captain's cabin, which is separated from these by a bulk-head, is exhibited also by P.

Four of the eight fire-barrels are placed under the four fire-trunks; and the other four between them, two on each side the fire-scuttles, where they are securely cleated to the deck. The longest reeds (c) are put into the fore and aft troughs, and tied down: the shortest reeds are laid in the troughs athwart, and tied down also. The bavins (d), dipped at one end, are tied fast to the troughs over the reeds, and the curtains are nailed up to the beams, in equal quantities, on each side of the fire-room.

The remainder of the reeds are placed in a position nearly upright, at all the angles of every square in the fire-room, and there tied down. If any reeds are left, they are to be put round the fire-barrels, and other vacant places, and there tied fast.

Instructions to prime.

TAKE up all your reeds, one after another, and strow a little composition at the bottom of all the troughs under the reeds, and then tie them gently down against next strow composition upon the upper part of the reeds throughout the fire-room; and upon the said composition lay double quick-match upon all the reeds, in all the troughs: the remainder of the composition strow over all the fire-room, and then lay your bavins loose.

Cast off all the covers of the fire-barrels, and hang the quick-match loose over their sides, and place leaders

(A) The iron-chambers are ten inches long, and 3.5 in diameter. They are breeched against a piece of wood fixed across the ports, and let into another a little higher. When loaded, they are almost filled with corn-powder, and have a wooden tomion well driven into their muzzles. They are primed with a small piece of quick-match thrust through their vents into the powder, with a part of it hanging out. When the ports are blown open by means of the iron-chambers, the port-lids either fall downward, or are carried away by the explosion.

(B) The fire-barrels ought to be of a cylindrical form, as most suitable to contain the reeds with which they are filled, and more convenient for stowing them between the troughs in the fire-room. Their inside chambers should not be less than 27 inches, and 30 inches is sufficient for their length. The bottom parts are first well fored with short double-dipped reeds placed upright; and the remaining vacancy is filled with fire-barrel composition, well mixed and melted, and then poured over them. The composition used for this purpose is a mass of sulphur, pitch, tar, and tallow.

There are five holes, of three-fourths inch in diameter, and three inches deep, formed in the top of the composition while it is yet warm; one being in the centre, and the other four at equal distances round the sides of the barrel. When the composition is cold and hard, the barrel is primed by filling those holes with fuse-composition, which is firmly driven into them, so as to leave a little vacancy at the top to admit a strand of quick-match twice doubled. The centre-hole contains two strands at their whole length, and every strand must be driven home with mealed powder. The loose ends of the quick-match being then laid within the barrel, the whole is covered with a dipped curtain, fastened on with a hoop that slips over the head of the barrel, to which it is nailed.

The barrels should be made very strong, not only to support the weight of the composition before firing, when they are moved or carried from place to place, but to keep them together whilst burning: for if the flaves are too light and thin, so as to burn very soon, the remaining composition will tumble out and be dissipated, and the intention of the barrels, to carry the flame aloft, will accordingly be frustrated.

The curtain is a piece of coarse canvas, nearly a yard in breadth and length, thickened with melted composition, and covered with saw-dust on both sides.

(C) The reeds are made up in small bundles of about a foot in circumference, cut even at both ends, and tied together in two places. They are distinguished into two kinds, viz. the long and short: the former of which are four feet, and the latter two feet five inches in length. One part of them are singly dipped, i. e. at one end: the rest are dipped at both ends in a Kettle of melted composition. After being immersed about seven or eight inches in this preparation, and then drained, they are sprinkled over with pulverised sulphur upon a tanned hide.

(D) The bavins are made of birch, heath, or other brush-wood, which is tough and readily kindled. They are usually two or three feet in length, and have all their bush-ends lying one way, the other ends being tied together with small cords. They are dipped in composition at the bush-ends, whose branches are afterwards confined by the hand, to prevent them from breaking off by moving about; and also to make them burn more fiercely. After being dipped in the same manner as the reeds, they also are sprinkled with sulphur.

Fire.

ers of quick-match from the reeds into the barrels, and from thence into the vent of the chambers, in such a manner as to be certain of their blowing open the ports, and setting fire to the barrels. Two troughs of communication from each door of the fire-room to the fall-ports, must be laid with a strong leader of quick-match, four or five times double: also a cross-piece to go from the fall-port, when the ship is fired, to the communication trough, laid with leaders of quick-match, that the fire may be communicated in both sides at once.

What quick-match is left place so that the fire may be communicated to all parts of the room at once, especially about the ports and fire-barrels, and see that the chambers are well and fresh primed. [N.B. The port-fire used for firing the ship, burns about 12 minutes. Great care must be taken to have no powder on board when the ship is fired.]

The sheer-hooks (represented by fig. 2.) are fitted so as to fasten on the yard-arms of the fire-ship, where they hook the enemy's rigging. The fire-grapplings, (fig. 3.) are either fixed on the yard-arms, or thrown by hand, having a chain to confine the ships together, or fasten those instruments wherever necessary.

When the commanding officer of a fleet displays the signal to prepare for action, the fire-ships fix their sheer-hooks, and dispose their grapplings in readiness. The battle being begun, they proceed immediately to prime, and prepare their fire-works. When they are ready for grappling, they inform the admiral thereof by a particular signal.

To avoid being disabled by the enemy's cannon during a general engagement, the fire-ships continue sufficiently distant from their line of battle, either to windward or to leeward.

They cautiously shun the openings or intervals of the line, where they would be directly exposed to the enemy's fire, from which they are covered by lying on the opposite side of their own ships. They are attentively to observe the signals of the admiral, or his seconds, in order to put their designs immediately in execution.

Although no ship of the line should be previously appointed to protect any fire-ship, except a few of the smallest particularly declined to this service, yet the ship before whom the passes in order to approach the enemy, should escort her thither, and assist her with an armed boat, or whatever succour may be necessary in her situation.

The captain of the fire-ship should himself be particularly attentive that the above instructions are punctually executed, and that the yards may be so braced when he falls along-side of the ship intended to be destroyed, that the sheer-hooks and grapplings fastened to the yard-arms, &c. may effectually hook the enemy. He is expected to be the last person who quits the vessel; and being furnished with every necessary assistance and support, his reputation will greatly depend on the success of his enterprise.

Fire from Cold Liquors. See CHEMISTRY, n° 219.

Lambent Fires, as the shining of meat at certain seasons, the luminousness of the sea, of insects, vapours, &c. See the articles LIGHT, PHOLAS, MEDUSA, NEREIS, FIRE-FLIES, GLOW-WORM, &c.

Port-Fire. See PORT-Fire.

Spur-Fire. See SPUR-Fire.

FIRING-IRON, in farriery, an instrument not unlike the blade of a knife; which being made red-hot, is applied to a horse's hams, or other places standing in need of it, as in preternatural swellings, farcy, knots, &c. in order to discuss them.

FIRKIN, an English measure of capacity for things liquid, being the fourth part of the barrel: it contains eight gallons of ale, soap, or herrings; and nine gallons of beer. See MEASURE and BARREL.

FIRLOT, a dry measure used in Scotland. The oat-firLOT contains $21\frac{3}{4}$ pints of that country; the wheat-firLOT contains about 2211 cubical inches; and the barley-firLOT, 31 standard-pints. Hence it appears that the Scotch wheat-firLOT exceeds the English bushel by 33 cubical inches.

FIRMAMENT, in the Ptolemaic astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions: a diurnal motion, given to it by the primum mobile, from east to west, about the poles of the ecliptic; and another opposite motion from west to east: which last it finishes, according to Tycho, in 25412 years, according to Ptolemy in 36000, and according to Copernicus in 25800, in which time the fixed stars return to the same points in which they were at the beginning. This period is commonly called the *Platonic year*, or the *great year*.

FIRMAMENT is also used, in divers places of scripture, to denote the middle region of the air.

FIRMAN is a passport or permit granted by the great mogul to foreign vessels, to trade within the territories of his jurisdiction.

FIRMICUS MATERNUS (Julius), a famous writer, who composed in Latin, about the year 345, an excellent book in defence of Christianity, entitled *De errore profanarum religionum*, which is printed with the notes of John Wouwer. There are also attributed to him eight books of astronomy, printed by Aldus Manutius in 1501; but this last work appears to have been written by another Julius Firmicus, who lived at the same time.

FIRMNESS, denotes the consistence of a body, or that state wherein its sensible parts cohere in such a manner that the motion of one part induces a motion in the rest.

FIRMIN (Thomas), an eminent citizen of London, born in 1632, who distinguished himself by his public benefactions and extensive charities, as also by some opinions contrary to the received doctrine of the Trinity. The plague in 1665, the great conflagration in 1666, with the arrival of the French protestants in 1680 and 1681, all furnished him with great opportunities of exerting his benevolent disposition. He died in 1697; and was buried in the cloisters of Christ's hospital, where his virtues are recorded in a monumental inscription.

FIRST-FRUITS, (*primities*,) among the Hebrews, were oblations of part of the fruits of the harvest, offered to God as an acknowledgement of his sovereign dominion. The first of these fruits was offered in the name of the whole nation, being either two loaves of bread, or a sheaf of barley which was threshed in the court of the temple. Every private person was obliged to bring his first-fruits to the temple; and these

Fire
Firft.

confisted.

consisted of wheat, barley, grapes, figs, apricots, olives, and dates.

There was another sort of first-fruits which were paid to God. When bread was kneaded in a family, a portion of it was set apart, and given to the priest or Levite who dwelt in the place: if there was no priest or Levite there, it was call into the oven, and consumed by the fire. These offerings made a considerable part of the revenues of the Hebrew priesthood.

First-fruits are frequently mentioned in ancient Christian writers as one part of the church-revenue. One of the councils of Carthage enjoins, that they should consist only of grapes and corn; which shews, that this was the practice of the African church.

FIRST-Fruits, in the church of England, are the profits of every spiritual benefice for the first year, according to the valuation thereof in the king's books.

FISCUS, *FISCUS*, in the civil law, the treasury of a prince, or state; or that to which all things due to the public do fall. The word is derived from the Greek *πικτωρ*, a great basket, used when they went to market.—By the civil law, none but a sovereign prince has a right to have a fisc or public treasury.

At Rome, under the emperors, the term *erarium* was used for the revenues destined for support of the charges of the empire; and *fiscus* for those of the emperor's own family. The treasury, in effect, belonged to the people, and the *fiscus* to the prince.

FISCAL, in the civil law, something relating to the pecuniary interest of the prince or people. The officers appointed for the management of the fisc, were called *procuratores fisci*, and *advocati fisci*; and among the cases enumerated in the constitutions of the empire where it was their business to plead, one is against those who have been condemned to pay a fine to the fisc on account of their litigiousness, or frivolous appeals.

FISH, in natural history, an animal that lives in the waters as the natural place of its abode.

The most general division of fishes is into *fresh* and *salt* water ones. Some, however, are of opinion, that all fishes naturally inhabit the salt-waters, and that they have mounted up into rivers only by accident. A few species only swim up into the rivers to deposit their spawn; but by far the greatest number keep in the sea, and would soon expire in fresh water. There are about 400 species of fishes (according to Linnæus) of which we know something; but the unknown ones are supposed to be many more; and as they are thought to lie in great depths of the sea remote from land, it is probable that many species will remain for ever unknown.

Naturalists observe an exceeding great degree of wisdom in the structure of fishes, and in their conformation to the element in which they are to live. Most of them have the same external form, sharp at either end, and swelling in the middle, by which they are enabled to traverse the fluid in which they reside with greater velocity and ease. This shape is in some measure imitated by men in those vessels which they design to sail with the greatest swiftness; but the progress of the swiftest sailing ship is far inferior to that of fishes. Any of the large fishes overtake a ship in full sail with the greatest ease, play round it as though it did not move at all, and can get before it at pleasure.

The chief instruments of a fish's motion have been supposed to be the fins; which in some are much more numerous than in others. A fish completely fitted for swimming with rapidity, is generally furnished with two pair of fins on the sides, and three single ones, two above, and one below. But it does not always happen that the fish which has the greatest number of fins, is the swiftest swimmer. The shark is thought to be one of the swiftest fishes, and yet it has no fins on its belly; the haddock seems to be more completely fitted for motion, and yet does not move so swiftly. It is even observable, that some fishes which have no fins at all, such as lobsters, dart forward with prodigious rapidity, by means of their tail; and the instrument of progressive motion, in all fishes, is now found to be the tail. The great use of the fins is to keep the body in *equilibrium*; and if the fins are cut off, the fish can still swim; but will turn upon its sides or its back, without being able to keep itself in an erect posture as before. If the fish desires to turn, a blow from the tail sends it about in an instant; but if the tail strikes both ways, then the motion is progressive.

All fishes are furnished with a slimy, glutinous matter, which defends their bodies from the immediate contact of the surrounding fluid, and which likewise, in all probability, assists their motion through the water. Beneath this, in many kinds, is found a strong covering of scales; which, like a coat of mail, defends it still more powerfully; and, under that, before we come to the muscular parts of the body, lies an oily substance, which also tends to preserve the requisite warmth and vigour.

By many naturalists fishes are considered as of a nature very much inferior to land-animals, whether beasts or birds. Their sense of feeling, it is thought, must be very obscure on account of the scaly coat of mail in which they are wrapped up. The sense of smelling also, it is said, they can have only in a very small degree. All fishes, indeed, have one or more nostrils; and even those that have not the holes perceptible without, yet have the bones within, properly formed for smelling. But as the air is the only medium we know proper for the distribution of odours, it cannot be supposed that these animals which reside constantly in the water can be affected by them. As to tasting, they seem to make very little distinction. The palate of most fishes is hard and boney, and consequently incapable of the powers of relishing different substances; and accordingly these voracious animals have often been observed to swallow the fisherman's plummet instead of the bait. Hearing is generally thought to be totally deficient in fishes, notwithstanding the discoveries of some anatomists who pretend to have found out the bones designed for the organ of hearing in their heads. They have no voice, it is said, to communicate with each other, and consequently have no need of an organ for hearing. Sight seems to be that sense of which they are possessed in the greatest degree; and yet even this seems obscure, if we compare it with that of other animals. The eye, in almost all fishes, is covered with the same transparent skin which covers the rest of the head, and which probably serves to defend it in the water, as they are without eyelids. The globe is more depressed anteriorly, and is furnished behind with a muscle which serves to lengthen or flatten it.

Fish.

it as there is occasion. The crystalline humour, which in quadrupeds is flat, and of the shape of a button-mould, or like a very convex lens, in fishes is quite round, or sometimes oblong like an egg. Hence it is thought that fishes are extremely near-sighted; and that, even in the water, they can perceive objects only at a very small distance. Hence, say they, it is evident how far fishes are below terrestrial animals in their sensations, and consequently in their enjoyments. Even their brain, which is by some supposed to be of a size with every creature's understanding, shews that fishes are very much inferior to birds in this respect.

Objections
to these
arguments.

Others argue differently with regard to the nature of fishes.—With respect to the sense of feeling, say they, it cannot be justly argued that fishes are deficient, merely because they are covered with scales, as it is possible these scales may be endued with as great a power of sensation as we can imagine. The sense of feeling is not properly connected with *sensibility* in any organ, more than with *hardness* in it. A similar argument may be used with regard to smelling; for though we do not know how smells can be propagated in water, that is by no means a proof that they are not so. On the contrary, as water is found to be capable of absorbing putrid effluvia from the air*, nothing is more probable than that these putrid effluvia, when mixed with the water, would affect the olfactory organs of fishes, as well as they affect ours when mixed with the air.—With regard to taste, it certainly appears, that fishes are able to distinguish their proper food from what is improper, as well as other animals. Indeed, no voracious animal seems to be endued with much sensibility in this respect; nor would it probably be consistent with that way of promiscuously devouring every creature that comes within its reach, without which these kinds of animals could not subsist.

* See Air,
no 29.

With respect to the hearing of fishes, it is urged, that, when, they, kept in a pond may be made to answer at the call of a whistle or the ringing of a bell; and they will even be terrified at any sudden and violent noise, such as thunder, the firing of guns, &c. and shrink to the bottom of the water. Among the ancients, many were of opinion that fishes had the sense of hearing, though they were by no means satisfied about the ways or passages by which they heard. Placentini afterwards discovered some bones in the head of the pike, which had very much the appearance of being organs of hearing, though he could never discover any external passages to them. Klein affirmed, from his own experiments and observations, that all fishes have the organs of Hearing; and have also passages from without to these organs, though in many species they are difficult to be seen; and that even the most minute and obscure of these are capable of communicating a tremulous motion to those organs, from sounds issuing from without. This is likewise asserted by M. Geoffroy†, who gives a particular description of the organs of hearing belonging to several species. These organs are a set of little bones extremely hard, and white, like fine porcelain, which are to be found in the heads of all fishes: The external auditory passages are very small; being scarce sufficient to admit a hog's bristle; though with care they may be distinguished in almost all fishes. It can by no means

† Dissertation

organe de
l'ouïe, p. 97,
et seq.

Fish.

be thought that the water is an improper medium of sound, seeing daily experience shews us that sounds may be conveyed not only through water, but through the most solid bodies‡. It seems indeed very difficult to determine the matter by experiment. Mr Gouan, who kept some gold-fishes in a vase, informs us, that whatever noise he made, he could neither terrify nor disturb them; he halloo'd as loud as he could, putting a piece of paper between his mouth and the water, to prevent the vibrations from affecting the surface, and the fishes still seemed insensible: but when the paper was removed, and the sound had its full effect on the water, the case was then altered, and the fishes instantly sunk to the bottom. This experiment, however, or others similar to it, cannot prove that the fishes did not hear the sounds before the paper was removed; it only shews that they were not alarmed till a sensible vibration was introduced into the water. The call of a whistle may also be supposed to affect the water in a fish-pond with a vibratory motion: but this certainly must be very obscure; and if fishes can be assembled in this manner when no person is in sight, it amounts to a demonstration that they actually do hear.

The arguments used against the sight of fishes are the weakest of all. Many instances which daily occur, shew that fishes have a very acute sight, not only of objects in the water, but of those in the air. Their jumping out of the water in order to catch flies is an abundant proof of this; and this they will continue to do in a fine summer-evening, even after it is so dark that we cannot distinguish the insects they attempt to catch.

Though fishes are formed for living entirely in the water, yet they cannot subsist without air. On this subject Mr Hawkebee made several experiments, which are recorded in the Philosophical Transactions. The fishes he employed were gudgeons; a species that are very lively in the water, and can live a considerable time out of it. Three of them were put into a glass vessel with about three pints of fresh water, which was designed as a standard to compare the others by. Into another glass, to a like quantity of water, were put three more gudgeons, and thus the water filled the glass to the very brim. Upon this he screwed down a brass-plate with a leather below, to prevent any communication between the water and the external air; and, that it might the better resemble a pond frozen over, he suffered as little air as possible to remain on the surface of the water. A third glass had the same quantity of water put into it; which, first by boiling, and then by continuing it a whole night in *vacuo*, was purged of its air as well as possible; and into this also were put three gudgeons. In about half an hour, the fishes in the water from whence the air had been exhausted, began to discover some signs of uneasiness by a more than ordinary motion in their mouths and gills. Those who had no communication with the external air, would at this time also frequently ascend to the top, and suddenly swim down again: and in this state they continued for a considerable time, without any sensible alteration. About five hours after this observation, the fishes in the exhausted water were not so active as before, upon shaking the glass which contained them. In three hours more, the included fishes

without air.

Fish.

lay all at the bottom of the glafs with their bellies upwards; nor could they be made to shake their fins or tail by any motion given to the glafs. They had a motion with their mouths, however, which fhewed that they were not perfectly dead. On uncovering the vefel which contained them, they revived in two or three hours, and were perfectly well next morning; at which time thofe in the exhaufted water were alfo recovered. The vefel containing thefe laft being put under the receiver of an air-pump, and the air exhaufted, they all infantly died. They continued at top while the air remained exhaufted, but funk to the bottom on the admiffion of the atmofphere.

The ufe of air to fifhes is very difficult to be explained; and indeed their method of obtaining the fupply of which they ftand constantly in need, is not eafily accounted for. The motion of the gills in fifhes is certainly analogous to our breathing, and feems to be the operation by which they feparate the air from the water. Their manner of breathing is as follows. The fifh firft takes a quantity of water by the mouth, which is driven to the gills; thefe clofe, and keep the water which is fwallowed from returning by the mouth; while the bony covering of the gills prevents it from going through them till the animal has drawn the proper quantity of air from it: then the bony covers open, and give it a free paffage; by which means alfo the gills are again opened, and admit a frefh quantity of water. If the fifh is prevented from the free play of its gills, itfoon falls into convulfions, and dies. But though this is a pretty plaufible explanation of the refpiration of fifhes, it remains a difficulty not eafily folved, what is done with this air. There feems to be no receptacle for containing it, except the air-bladder, or fwim; which, by the generality of modern philofophers, is defined not to anfwer any vital purpofe, but only to enable the fifh to rife or funk at pleafure.

6
Motion of the gills of fifhes analogous to our breathing.

7
Of the ufe of the air-bladder in fifhes.

The air-bladder is a bag filled with air, compofed fometimes of one, fometimes of two, and fometimes of three divifions, fituated towards the back of the fifh, and opening into the maw or the gullet. The ufe of this in raifing or depressing the fifh, is proved by the following experiment. A carp being put into the air-pump, and the air exhaufted, the bladder is faid to burft by the expansion of the air contained in it; after which, the fifh can no more rife to the top, but ever afterwards crawls at the bottom. The fame thing alfo happens when the air-bladder is pricked or wounded in fuch a manner as to let the air out; in thefe cafes alfo the fifh continues at the bottom, without a poffibility of rifing to the top. From this it is inferred, that the ufe of the air-bladder is, by fwelling at the will of the animal, to increafe the furface of the fifh's body, and thence diminifhing its fpecific gravity, to enable it to rife to the top of the water, and to keep there at pleafure. On the contrary, when the fifh wants to defend, it is thought to contract the air-bladder; and being thus rendered fpecifically heavier, it descends to the bottom.

The ancients were of opinion, that the air-bladder in fifhes ferved for fome purpofes effentially neceffary to life; and Dr Priettley alfo conjectures, that the raifing or depressing the fifh is not the only ufe of thefe air-bladders, but that they alfo may ferve fome other

purpofes in the economy of fifhes. There are many arguments indeed to be ufed on this fide of the queftion: the moft conclufive of which is, that all the cartilaginous kind of fifhes want air-bladders, and yet they rife to the top, or funk to the bottom, of the water, without any difficulty; and though moft of the eel-kind have air-bladders, yet they cannot raife themfelves in the water without great difficulty.

Fifhes are remarkable for their longevity. "Moft of the diforders incident to mankind (fays Bacon) arife from the changes and alterations in the atmofphere; but fifhes refide in an element little fubject to change: theirs is a uniform exiftence; their movements are without effort, and their life without labour. Their bones, alfo, which are united by cartilages, admit of indefinite extension; and the different fizes of animals of the fame kind among fifhes, is very various. They ftill keep growing: their bodies, inftead of fuffering the rigidity of age, which is the caufe of the natural decay of land-animals, ftill continue increafing with frefh fupplies; and as the body grows, the conduits of life furnifh their ftores in greater abundance. How long a fifh, that feems to have fcarce any bounds put to its growth, continues to live, is not afcertained; perhaps the life of a man would be not fufficient to meafure that of the fmalleft."—There have been two methods fallen upon for determining the age of fifhes; the one is by the circles of the fcales, the other by the tranfverfe fection of the back bone. When a fifh's fcale is examined by a microfcope, it is found to confift of a number of circles one within another, in fome meafure refembling thofe which appear on the tranfverfe fection of a tree, and is fuppofed to give the fame information. For, as in trees we can tell their age by the number of their circles; fo, in fifhes, we can tell theirs by the number of circles in every fcale, reckoning one ring for every year of the animal's exiftence.—The age of fifhes that want fcales may be known by the other method, namely, by feparating the joints of the back-bone, and then minutely obferving the number of rings which the furface, where it was joined, exhibits.

8
Longevity of fifhes.

9
Methods of determining their age.

Fifhes are, in general, the moft voracious animals in nature. In moft of them, the maw is placed next the mouth; and, though poffeffed of no fenfible heat, is endowed with a very furprizing faculty of digeftion. Its digeftive power feems, in fome meafure, to increafe in proportion to the quantity of food with which the fifh is fupplied. A fingle pike has been known to devour 100 roaches in three days. Whatever is poffeffed of life, feems to be the moft defirable prey for fifhes. Some, that have very fmall mouths, feed upon worms, and the fpawn of other fifh: others, whofe mouths are larger, feek larger prey; it matters not of what kind, whether of their own fpecies, or any other. Thofe with the largeft mouths purfue almoft every thing that hath life; and often meeting each other in fierce oppofition, the fifh with the largeft fwallow comes off with the victory, and devours its antagonist.—As a counterbalance to this great voracity, however, fifhes are incredibly prolific. Some bring forth their young alive, others produce only eggs: the former are rather the leaft fruitful; yet even thefe produce in great abundance. The viviparous blenny, for inftance, brings forth 200 or 300 at a time. Thofe which produce eggs, which they are obliged to leave to chance, either

Their amazing increafe.

Fishes.

ther on the bottom where the water is shallow, or floating on the surface where it is deeper, are all much more prolific, and seem to proportion their stock to the danger there is of consumption.—Lewenhoeck assures us, that the cod spawns above nine millions in a season. The flounder commonly produces above one million, and the mackarel above 500,000. Scarce one in 100 of these eggs, however, brings forth an animal: they are devoured by all the lesser fry that frequent the shores, by water-fowl in shallow waters, and by the larger fishes in deep waters. Such a prodigious increase, if permitted to come to maturity, would overstock nature; even the ocean itself would not be able to contain, much less provide for, one half of its inhabitants. But two wise purposes are answered by this amazing increase: it preserves the species in the midst of numberless enemies, and serves to furnish the rest with a sustenance adapted to their nature.

With respect to the generation of many kinds of fishes, the common opinion is, that the female deposits her spawn or eggs, and that the male afterwards ejects his sperm or male semen upon it in the water. The want of the organs of generation in fishes, gives an apparent probability to this; but it is strenuously opposed by Linnæus. He affirms, that there can be no possibility of impregnating the eggs of any animal out of its body. To confirm this, the general course of nature, not only in birds, quadrupeds, and insects, but even in the vegetable world, has been called in to his assistance, as proving that all impregnation is performed while the egg is in the body of its parent: and he supplies the want of the organs of generation by a very strange process, affirming, that the males eject their semen always some days before the females deposit their ova or spawn; and that the females swallow this, and thus have their eggs impregnated with it. He says, that he has frequently seen, at this time, three or four females gathered about a male, and greedily snatching up into their mouths the semen he ejects. He mentions some of the eeloes, some perch, and some of the cyprini, in which he had seen this process.

Many opinions have been started in order to account how it happens that fishes are found in pools, and ditches, on high mountains, and elsewhere. But Gmelin observes, that the duck-kind swallow the eggs of fishes; and that some of these eggs go down, and come out of their bodies unhurt, and so are propagated just in the same manner as has been observed of plants.

As to the *Division of Fishes*, see ZOOLOGY, n° 10.

Breeding of Fishes may be turned to great advantage; for, besides furnishing the table, obliging one's friends, and raising money, the land will be thereby greatly improved, so as to yield more this way than by any other employment whatever. See FISH-POND, *infra*; and BREEDING of Fish.

Feeding of Fishes. When they are fed in large pools or ponds, either malt boiled, or fresh grains, is the best food; thus carps may be raised and fed like capons, and tenches will feed as well. The care of feeding them is best committed to a gardener or the butler, who should be always at hand. When fed in a stew, any sort of grain boiled, especially peas, and malt coarsely ground, are proper food; also the grains after brewing, while fresh and sweet; but one bushel

of malt not brewed, will go as far as of grains.

Fish and Fijbing, as regulated by law. No fisherman shall use any net or engine for destroying the fry of fishes; and persons using nets for that purpose, or taking salmon or trout out of season, or any fish under certain lengths, are liable to forfeit 20s. and justices of peace, and lords of leets, have power to put the acts in force. See 1 *Edw. c. 17*. 3 *Jac. I. c. 12*. 30 *Geo. II. c. 21*. & *post*. No person may fatten nets, &c. across rivers to destroy fish, and disturb the passage of vessels, on pain of 5*l.* *stat. 2. Hen. VI. c. 15*. None shall fish in any pond or moat, &c. without the owner's licence, on pain of three months imprisonment; 31 *Hen. VIII. c. 2*. And no person shall take any fish in any river, without the consent of the owner, under the penalty of 10*s.* for the use of the poor, and treble damage to the party aggrieved, leviable by distress of goods; and for want of distress, the offender is to be committed to the house of correction for a month: also nets, angles, &c. of poachers, may be seized by the owners of rivers, or by any persons by warrant from a justice of peace, &c. 22 & 23 *Car. II. c. 25*. 4 & 5 *W. & M. c. 23*. The *stat. 4 & 5 Ann. c. 21*. was made for the increase and preservation of salmon in rivers in the counties of Southampton and Wilts; requiring that no salmon be taken between the first of August and 12th of November, or under size, &c. And, by 1 *Geo. I. c. 18*. salmon taken in the rivers Severn, Dee, Wye, Were, Ouse, &c. are to be 18 inches long at least, or the persons catching them shall forfeit 5*l.* And sea-fish sold must be of the lengths following; *viz.* bret and turbot, 16 inches; brill and pearl, 14; codlin, bass, and mullet, 12; sole and plaice, 8; flounders, 7; whiting, 6 inches long, &c. on pain of forfeiting 20*s.* to the poor, and the fish. *Vide* the Statute. Persons importing any fish contrary to *stat. 1 Geo. I. c. 18*. for better preventing fresh fish taken by foreigners from being imported into this kingdom, &c. shall forfeit 100*l.* to be recovered in the court at Westminster; one moiety to informers, and the other to the poor; and masters of smacks, hoys, boats, &c. in which the fish shall be imported, or brought on shore, forfeit 50*l.* Also selling the same in England, liable to 20*l.* penalty; *Stat. 9 Geo. II. c. 33*.

By the *stat. 22 Geo. II. c. 49*. contracts for the buying fish (except fresh salmon, or soles brought by land-carriage, oysters, or salt or dried fish) to be sold by retail before the same are brought to market, and exposed to sale, are declared void; and each party contracting shall forfeit 50*l.* And fishermen not selling their fish within eight days after their arrival on the coast between North Yarmouth and Dover, shall forfeit the cargo, vessel, and tackle, &c. And sea-fish, under the dimensions prohibited by the *stat. 1 Geo. I.* may be exposed to sale, provided they are taken with a hook, and so not capable of being preserved alive. But see *stat. 35 Geo. II. c. 27*. made to regulate the sale of fish at the first hand in the fishmarkets in London and Westminster; and to prevent salemen of fish buying fish to sell again on their own account; and to allow bret, cod, turbot, brill, and pearl, although under the respective dimensions mentioned in 1 *Geo. I. c. 18*. to be imported and sold; and to punish persons who shall take or sell any spawn, brood, or fry of fish, unfizeable fish, or fish out of season, or smelts under the

Fishes.

12
Generation
of fishes.

size of five inches. By this act, every master of a vessel is to give a true account of the several sorts of fish brought alive to the *Nore* in his vessel; and if, after such arrival, he shall wilfully destroy or throw away any of the said fish, not being unwholesome or unmarketable, &c. he is liable to be committed to the house of correction, and kept to hard labour, for any time not exceeding two months, nor less than one. And see farther, 2 *Geo.* III. c. 15. for the better supplying the citizens of London and Westminster with fish, and to reduce the exorbitant price thereof, and to protect and encourage fishermen.

Preserving of Fish for Cabinets. Linnæus's method is, to expose them to the air; and when they acquire such a degree of putrefaction that the skin loses its cohesion to the body of the fish, it may be slid off almost like a glove: the two sides of this skin may then be dried upon paper like a plant, or one of the sides may be filled with plaster of Paris to give the subject a due plumpness.

A fish may be prepared, after it has acquired this degree of putrefaction, by making a longitudinal incision on the belly, and carefully dissecting the fleshy part from the skin, which are but slightly attached to it in consequence of the putrefecency. The skin is then to be filled with cotton and the antiseptic powder as directed for birds; and, lastly, to be sewed up where the incision was made. See *Methods of Preserving Birds*.

Gilding on Fish. In the posthumous papers of Mr Hooke, a method is described of gilding live craw-fish, carps, &c. without injuring the fish. The cement for this purpose is prepared, by putting some burgundy-pitch into a new earthen pot, and warming the vessel till it receives so much of the pitch as will flick round it; then strewing some finely-powdered amber over the pitch when growing cold, adding a mixture of three pounds of linseed oil and one of oil of turpentine, covering the vessel, and boiling them for an hour over a gentle fire, and grinding the mixture, as it is wanted, with so much pumice-stone in fine powder as will reduce it to the consistence of paint. The fish being wiped dry, the mixture is spread upon it; and the gold-leaf being then laid on, and gently pressed down, the fish may be immediately put into water again, without any danger of the gold coming off, for the matter quickly grows firm in water.

Fish, in a ship, a plank or piece of timber, fastened to a ship's mast or yard, to strengthen it; which is done by nailing it on with iron spikes, and winding ropes hard about them.

Fishes, in heraldry, are the emblems of silence and watchfulness; and are borne either upright, imbowed, extended, endorsed respecting each other, surmounting one another, fretted, &c.

In blazoning fishes, those borne feeding, should be termed *devouring*; all fishes borne upright and having fins, should be blazoned *auriant*; and those borne transverse the escutcheon, must be termed *naïant*.

Fish-Ponds, those made for the breeding or feeding of fish.

Fish-ponds are no small improvement of watery and boggy lands, many of which are fit for no other use. In making of a pond, its head should be at the lowest part of the ground, that the trench of the flood-gate or

sluice, having a good fall, may not be too long in emptying. The best way of making the head secure, is to drive in two or three rows of stakes above six feet long, at about four feet distance from each other, the whole length of the pond-head, whereof the first row should be rammed at least about four feet deep. If the bottom is false, the foundation may be laid with quicklime; which slaking, will make it as hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and stakes; and when these are well covered, drive in others as they see occasion, ramming in the earth as before, till the pond-head be of the height designed.

The dam should be made sloping on each side, leaving a waste to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed six feet, rising gradually in shoals towards the sides, for the fish to sun themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a fat soil with a white fat water, as the washings of hills, commons, streets, sinks, &c. is best for fattening all sorts of fish. For storing a pond, carp is to be preferred for its goodness, quick growth, and great increase, as breeding five or six times a-year. A pond of an acre, if it be a feeding and not breeding one, will every year feed 200 carps of three years old, 300 of two years old, and 400 of a year old. Carps delight in ponds that have marle or clay bottoms, with plenty of weeds and grass, whereon they feed in the hot months.

Ponds should be drained every three or four years, and the fish sorted. In breeding ones, the smaller ones are to be taken out, to store other ponds with; leaving a good stock of females, at least eight or nine years old, as they never breed before that age. In feeding ponds, it is best to keep them pretty near of a size. See *BREEDING OF FISH*.

FISHER (John), bishop of Rochester; was born at Beverly in Yorkshire, in the year 1459, and educated in the collegiate church of that place. In 1484, he removed to Michael-house in Cambridge, of which college he was elected master in the year 1495. Having applied himself to the study of divinity, he took orders; and, becoming eminent as a divine, attracted the notice of Margaret, countess of Richmond, mother of Henry VII. who made him her chaplain and confessor. In 1501, he took the degree of doctor of divinity, and the same year was elected chancellor of the university. In the year following, he was appointed Lady Margaret's first divinity-professor; and, in 1504, consecrated bishop of Rochester; which small bishopric he would never resign, though he was offered both Ely and Lincoln. It is generally allowed, that the foundation of the two colleges of Christ-church and St John's, in Cambridge, was entirely owing to bishop Fisher's persuasion, and influence with the countess of Richmond: he not only formed the design, but superintended the execution. On the promulgation of Martin Luther's doctrine, our bishop was the first to enter the lists against him. On this occasion he exerted all his influence, and is generally supposed to have written the famous book by which Henry VIII. obtained the title of *Defender of the Faith*. Hitherto he continued in favour with the king; but in 1527, opposing his dis-

Fisher,
Fishery.

voice, and denying his supremacy, the implacable Harry determined, and finally effected, his destruction. In 1534, the parliament found him guilty of misprision of treason, for concealing certain prophetic speeches of a fanatical impostor, called the *Holy Maid of Kent*, relative to the king's death; and condemned him, with five others, in loss of goods, and imprisonment during his majesty's pleasure; but he was released on paying 300 l. for the king's use.

King Henry being now married to Anne Boleyn, his obsequious parliament took an oath of allegiance proper for the occasion. This oath the bishop of Rochester steadily refused; alleging, that his conscience could not be convinced that the king's first marriage was against the law of God. For refusing this oath of succession, he was attainted by the parliament of 1534; and committed to the Tower, where he was cruelly treated, and where he would probably have died a natural death, had not the pope created him a cardinal. The king, now positively determined on his destruction, sent Rich, the solicitor-general, under a pretence of consulting the bishop on a case of conscience, but really with a design to draw him into a conversation concerning the supremacy. The honest old bishop spoke his mind without suspicion or reserve, and an indictment and conviction of high-treason was the consequence. He was beheaded on Tower-hill, on the 22d of June 1535, in the 77th year of his age. Thus died this good old prelate; who, notwithstanding his inflexible enmity to the reformation, was undoubtedly a learned, pious, and honest man. He wrote several treatises against Luther, and other works, which were printed at Wurtzburgh, in 1597, in one volume folio.

FISHERY, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring, mackrel, pilchards, &c. are along the coasts of Scotland, England, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West Indies.

FISHERY, denotes also the commerce of fish, more particularly the catching them for sale.

Were we to enter into a very minute and particular consideration of fisheries, as at present established in this kingdom, this article would swell beyond its proper bounds; because, to do justice to a subject of such concernment to the British nation, requires a very ample and distinct discussion. We shall, however, observe, that since the Divine Providence hath so eminently stored the coasts of Great Britain and Ireland with the most valuable fish; and since fisheries, if successful, become permanent nurseries for breeding expert seamen; it is not only a duty we owe to the Supreme Being, not to despise the wonderful plenty he hath afforded us, by neglecting to extend this branch of commerce to the utmost; but it is a duty we owe to our country, for its natural security, which depends upon the strength of our royal navy. No nation can have a navy, where there is not a fund of business to breed and employ seamen without any expence to the public; and no trade is so well calculated for training up these useful members of this society, as fisheries.

The situation of the British coasts is the most advantageous in the world for catching fish: the Scottish

islands, particularly those to the north and west, lie most commodious for carrying on the fishing trade to perfection; for no country in Europe can pretend to come up to Scotland in the abundance of the finest fish, with which its various creeks, bays, rivers, lakes, and coasts, are replenished. King Charles I. was so sensible of the great advantage to be derived from fisheries, that he began the experiment, together with a company of merchants; but the civil wars soon occasioned that project to be set aside. King Charles II. made a like attempt; but his pressing wants made him withdraw what money he had employed that way, whereupon the merchants that joined with him did the same. Since the union, several attempts have been made to retrieve the fisheries, and a corporation settled to that effect, entitled the *Royal British Fishery*.

In the year 1750, the parliament of Great Britain taking the state of the fisheries into consideration, an act was passed for the encouragement of the white-herring fishery, granting a charter, whereby a corporation is created, to continue 21 years, by the name of the *Society of the Free British Fishery*, to be under the direction of a governor, president, vicepresident, council, &c. who are to continue in office the space of three years, with power to make bye-laws, &c. and to raise a capital of 500,000 l. by way of subscription. And any number of persons, who, in any part of Great Britain, shall subscribe 10,000 l. into the stock of this society, under the name of the *fishing-chamber*, and carry on the said fishery on their own account of profit and loss, shall be entitled to the same bounty allowed to the society. The bounty is 30s. the tun, to be paid yearly, for 14 years, besides 3 per cent. for the money advanced by each chamber. The act contains other proper regulations, relative to the nets, marks on the herring-barrels, number of hands, and the quantity of salt that is entitled to the bounty, &c. It is, then, by the encouragement given by this act, that we now see a laudable emulation prevailing over the two kingdoms, and fishing buffes fitted out from almost every port, in order to repair to the Shetland islands, where the herring-fishery is carried on with an ardor becoming so important a branch of trade. Scotland, which suffered incredibly from the neglect of this valuable and natural produce of the seas, has not been backward to join in a scheme that tends so evidently to its own advantage; for the cities of Edinburgh, Glasgow, the towns of Montrose, Dundee, Perth, Inverness, and some other boroughs, have raised the proper sum, and chambers have been erected in each of them; the gentlemen of estates adjoining to the respective places above-mentioned, liberally contributing with merchants, towards the prosecution of an undertaking so visibly tending to the good of their country in general.

Free FISHERY, in law, or an exclusive right of fishing in a public river, is a royal franchise; and is considered as such in all countries where the feudal polity has prevailed: though the making such grants, and by that means appropriating, what it seems unnatural to restrain, the use of running water, was prohibited for the future by king John's Great Charter; and the rivers that were fenced in his time were directed to be laid open, as well as the forests to be disforested. This

Comment.

opening was extended by the second and third charters of Henry III. to those also that were fenced under Richard I.; so that a franchise of free fishery ought now to be as old at least as the reign of Henry II. This differs from a *several* of piscary, because he that has a *several* fishery must also be the owner of the soil, which in a free-fishery is not requisite. It differs also from a *common* fishery, in that the free fishery is an exclusive right, the common fishery is not so; and therefore, in a free fishery, a man has a property in the fish before they are caught; in a common piscary, not till afterwards. Some indeed have considered a *free* fishery not as a royal franchise; but merely as a private grant of a liberty to fish in the *several* fishery of the grantor. But the considering such right as originally a flower of the prerogative, till restrained by Magna Charta, and derived by royal grant (previous to the reign of Richard I.) to such as now claim it by prescription, may remove some difficulties in respect to this matter with which our law-books are embarrassed.

Cod-FISHERY. There are two kinds of cod-fish; the one green or white cod, and the other dried or cured cod: tho' it is all the same fish, differently prepared; the former being sometimes salted and barrelled, then taken out for use; and the latter, having lain some competent time in salt, dried in the sun or smoke. We shall therefore speak of each of these apart; and first of the

Green-Cod FISHERY. The chief fisheries for green cod are in the bay of Canada, on the great bank of Newfoundland, and on the isle of St Peter, and the isle of Sable; to which places vessels resort from divers parts both of Europe and America. They are from 100 to 150 tons burden, and will catch between 30,000 and 40,000 cod each. The most essential part of the fishery is, to have a master who knows how to cut up the cod, one who is skilled to take off the head properly, and above all a good salter, on which the preserving of them, and consequently the success of the voyage, depends. The best season is from the beginning of February to the end of April; the fish, which in the winter retire to the deepest water, coming then on the banks, and fattening extremely. What is caught from March to June keeps well; but those taken in July, August, and September, when it is warm on the banks, are apt to spoil soon. Every fisher takes but one at a time: the most expert will take from 350 to 400 in a day; but that is the most, the weight of the fish and the great coldness on the bank fatiguing very much. As soon as the cod are caught, the head is taken off; they are opened, gutted, and salted; and the salter flows them in the bottom of the hold, head to tail, in beds a fathom or two square; laying layers of salt and fish alternately, but never mixing fish caught on different days. When they have lain thus three or four days to drain off the water, they are replaced in another part of the ship, and salted again; where they remain till the vessel is loaded. Sometimes they are cut in thick pieces, and put in barrels for the convenience of carriage.

Dry-Cod FISHERY. The principal fishery for this article is, from Cape Rose to the Bay des Exports, along the coast of Placentia, in which compass there are divers commodious ports for the fish to be dried in. These, though of the same kind with the fresh cod, are

much smaller, and therefore fitter to keep, as the salt penetrates more easily into them. The fishery of both is much alike; only this latter is most expensive, as it takes up more time, and employs more hands, and yet scarce half so much salt is spent in this as in the other. The bait is herrings, of which great quantities are taken on the coast of Placentia. When several vessels meet and intend to fish in the same port, he whose shallop first touches ground, becomes entitled to the quality and privileges of admiral: he has the choice of his station, and the refusal of all the wood on the coast at his arrival. As salt as the masters arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts; and in the mean time the mates provide a tent on shore, covered with branches of trees, and sails over them, with a scaffold of great trunks of pines, 12, 15, 16, and often 20 feet high, commonly from 40 to 60 feet long, and about one third as much in breadth. While the scaffold is preparing, the crew are a-fishing; and as salt as they catch, they bring their fish ashore, and open and salt them upon moveable benches; but the main salting is performed on the scaffold. When the fish have taken salt, they wash and hang them to drain on rails; when drained, they are laid on kinds of stages, which are small pieces of wood laid across, and covered with branches of trees, having the leaves stripped off for the passage of the air. On these stages, they are disposed, a fish thick, head against tail, with the back uppermost, and are turned carefully four times every 24 hours. When they begin to dry, they are laid in heaps ten or twelve thick, in order to retain their warmth; and every day the heaps are enlarged, till they become double their first bulk; then two heaps are joined together, which they turn every day as before: lastly, they are salted again, beginning with those first salted; and being laid in huge piles, they remain in that situation till they are carried on board the ships, where they are laid on the branches of trees disposed for that purpose, upon the ballast, and round the ship, with mats to prevent their contracting any moisture.

There are four kinds of commodities drawn from cod, *viz.* the zounds, the tongues, the roes, and the oil extracted from the liver. The first is salted at the fishery, together with the fish, and put in barrels from 600 to 700 pound. The tongues are done in like manner, and brought in barrels from 400 to 500 pounds. The roes are also salted in barrels, and serve to cast into the sea to draw fish together, and particularly pilchards. The oil comes in barrels, from 400 to 520 pounds, and is used in dressing leather.—In Scotland, they catch a small kind of cod on the coasts of Buchan, and all along the Murray frith on both sides; as also in the frith of Forth, Clyde, &c. which is much esteemed. They salt and dry them in the sun upon rocks, and sometimes in the chimney. They also cure skait, and other smaller fish in the same manner; but most of these are for home-consumption.

Herring FISHERY. For the migrations of herrings, and the directions of their course, see the article CLUPEA. Our great stations for this fishery are off the Shetland and Western Isles, and off the coast of Norfolk; in which the Dutch also share. There are two seasons for fishing herring: the first from June to the end of August; and the second in Autumn, when the

† See
Gadus.

Fishery.

the fogs become very favourable for this kind of fishing. The Dutch begin their herring-fishing on the 24th of June, and employ a vast number of vessels therein, called *buffes*, being between 45 and 60 tons burden each, and carrying three or four small cannon. They never stir out of port without a convoy, unless there be enough together to make about 18 or 20 cannon among them, in which case they are allowed to go in company. Before they go out, they make a verbal agreement, which has the same force as if it were in writing. The regulations of the admiralty of Holland are partly followed by the French and other nations, and partly improved and augmented with new ones; as, that no fisher shall cast his net within 100 fathoms of another boat: that while the nets are cast, a light shall be kept on the hind-part of the vessel: that when a boat is by any accident obliged to leave off fishing, the light shall be cast into the sea: that when the greater part of a fleet leaves off fishing, and calls anchor, the rest shall do the same, &c.

* Hist. of
Commerce.

Mr Anderson * gives to the Scots a knowledge of great antiquity in the herring-fishery. He says that the Netherlanders resorted to these coasts as early as A.D. 836, to purchase salted fish of the natives; but, imposing on the strangers, they learned the art, and took up the trade, in after-times of such immense emolument to the Dutch.

Sir Walter Raleigh's observations on that head, extracted from the same author, are extremely worthy the attention of the curious, and excite reflections on the vast strength resulting from the wisdom of well applied industry.

In 1603, remarks that great man, the Dutch sold to different nations, as many herrings as amounted to L. 1,759,000 Sterling.

In the year 1615, they sent out once sent 2000 buffes, and employed in them 37,000 fishermen.

In the year 1618, they sent out 3000 ships, with 50,000 men to take the herrings, and 9000 more ships to transport and sell the fish; which by sea and land employed 150,000 men, besides those first mentioned. All this wealth was gotten on our coasts; while our attention was taken up in a distant whale-fishery.

The Scottish monarchs for a long time seemed to direct all their attention to the preservation of the salmon fishery; probably because their subjects were such novices in sea-affairs. At length James III. endeavoured to stimulate his great men to these patriotic undertakings; for by an act of his third parliament, he compelled "certain lords spiritual and temporal, and burrows, to make ships, buffes, and boats, with nets, and other pertinents, for fishing. That the same should be made in each burgh; in number according to the substance of each burgh, and the least of them to be of twenty tun: and that all idle men be compelled by the sheriffs in the country to go on board the same."

But his successors, by a very false policy, rendered this wise institution of little effect: for they in a manner prevented their subjects from becoming a maritime people, by directing that no white fish should be sent out of the realm, but that strangers may come and buy them; that free ports be first served; the cargoes sold to the freemen, who are to come and transport the same. The Dutch at this very time had an open trade.

Fishery.

It is well known that there have been many attempts made to secure this treasure to ourselves, but without success. In the late reign, a very strong effort was made, and bounties allowed for the encouragement of British adventurers: the first was of 30s. per ton to every bus of 70 tons and upwards. This bounty was afterwards raised to 50s. per ton, to be paid to such adventurers as were entitled to it by claiming it at the places of rendezvous. The buffes are from 20 to 90 tons burden, but the best size is 80. A vessel of 80 tons ought to take ten lasts, or 120 barrels of herrings, to clear expences, the price of the fish to be admitted to be a guinea a barrel. A ship of this size ought to have 18 men, and three boats: one of 20 tons should have six men; and every five tons above, require an additional hand.

To every ton are 280 yards of nets; so a vessel of 80 tons carries 20,000 square yards: each net is 12 yards long, and 10 deep; and every boat takes out from 20 to 30 nets, and puts them together, so as to form a long train: they are sunk at each end of the train by a stone, which weighs it down to the full extent: the top is supported by buoys, made of sheepskin, with a hollow slick at the mouth, fastened tight; through this the fish is blown up, and then stopped with a peg, to prevent the escape of the air. Sometimes these buoys are placed at the top of the nets; at other times the nets are suffered to sink deeper, by the lengthening the cords fastened to them, every cord being for that purpose 10 or 12 fathoms long. But the best fisheries are generally in more shallow water.

Of the Scots fishery in the Western Isles, the following * *Voyage to the Hebrides*, account is given by Mr Pennant *. "The fishing is always performed in the night, unless by accident. The P. 329.

buffes remain at anchor, and send out their boats a little before sun-set; which continue out, in winter and summer, till day-light; often taking up and emptying their nets, which they do 10 or 12 times in a night, in case of good success. During winter it is a most dangerous and fatiguing employ, by reason of the greatness and frequency of the gales in these seas, and in such gales are the most successful captures: but, by the Providence of heaven, the fishers are seldom lost; and, what is wonderful, few are visited with illness. They go out well prepared, with a warm great coat, boots, and skin aprons, and a good provision of beef and spirits. The same good fortune attends the buffes, which in the tempestuous season, and in the darkest nights, are continually shifting, in these narrow seas, from harbour to harbour.

"Sometimes 80 barrels of herrings are taken in a night by the boats of a single vessel. It once happened, in Loch-Slappan, in Skie, that a bus of 80 tons might have taken 200 barrels in one night, with 10,000 square yards of net; but the master was obliged to desist, for want of a sufficient number of hands to preserve the capture.

"The herrings are preserved by salting, after the entrails are taken out: an operation performed by the country people, who get three-halfpence per barrel for their trouble; and sometimes, even in the winter, can gain fifteen pence a-day. This employs both women and children; but the salting is only entrusted to the crew of the buffes. The fish are laid on their backs in the barrels, and layers of salt between them. The entrails

Fishery.

Fishery.

entrails are not loft, for they are boiled into an oil: 8000 fifh will yield ten gallons, valued at one fhilling the gallon.

"A vefel of 80 tons takes out 144 barrels of falt: a drawback of 2s. 8d. is allowed for each barrel ufed by the foreign or Irifh exportation of the fifh; but there is a duty of 1s. per barrels for the home-confumption, and the fame for thofe fent to Ireland.

"The barrels are made of oak-ftaves, chiefly from Virginia; the hoops from feveral parts of our own ifland, and are either of oak, birch, hazel, or willow: the laft from Holland, liable to a duty.

The barrels coft about 3s. each: they hold from 500 to 800 fifh, according to the fize of the fifh; and are made to contain 32 gallons. The barrels are infpected by proper officers: a cooper examines if they are ftatutable and good; if faulty, he deftroys them, and oblige the maker to ftand to the lofs.

"The herrings in general are exported to the Weft-Indies, to feed the negroes; or to Ireland, for the Irifh are not allowed to fifh in thefe feas. By having a drawback of 5d. a barrel, and by repacking the fifh in new barrels of 28 gallons, they are enabled to export them to our colonies at a cheaper rate than the Scots can do.

"The trade declines apace; the bounty, which was well paid, originally kept up the fpirit of the fifhery; but, for the laft fix years, the arrears have been very injurious to feveral adventurers, who have fold out at 30 per cent. lofs, befides that of their intereft.

"Loch-Broom has been celebrated for three or four centuries as the refort of herrings. They generally appear here in July: thofe that turn into this bay are part of the brigade that detaches itfelf from the Weft-tern column of that great army which annually deferts the vaft depths of the arctic circle, and come, heaven-directed, to the feats of population, offered as a cheap food to millions, whom wafteful luxury, or iron-hearted avarice, hath deprived, by enhancing the price, of the wonted fupports of the poor.

"The migration of thefe fifh from their Northern retreat is regular; their vifits to the Weft-tern ifles and coasts, certain; but their attachment to one particular loch, extremely precarious. All have their turns: that which fwarmed with fifh one year, is totally deferted the following; yet the next loch to it may be crowded with the fhools. Thefe changes of place give often full employ to the bufles, who are continually fhifting their harbour in queft of news refpecting thefe important wanderers.

"They commonly appear here in July; the latter end of Auguft they go into deep water, and continue there for fome time, without any apparent caufe: in November, they return to the fhallows, when a new fifhery commences, which continues till January; at that time the herrings become full of roe, and are ufelefs as articles of commerce. Some doubt, whether thefe herrings that appear in November are not part of a new migration; for they are as fat, and make the fame appearance, as thofe that compofed the firft.

"The figns of the arrival of the herrings are flocks of gulls, who catch up the fifh while they skim on the furface; and of gannets, who plunge and bring them up from confiderable depths. Both thefe birds are clofely attended to by the fifhers.

"Cod-fifh, haddocks, and dog-fifh, follow the herrings in vaft multitudes; thefe voracious fifh keep on the outfides of the columns, and may be a concurrent reafon of driving the fhools into bays and creeks. In fummer, they come into the bays generally with the warmeft weather, and with eafy gales. During winter, the hard gales from north-weft are fuppofed to afift in forcing them into fhelter. Eaft winds are very unfavourable to the fifhery.

"In a fine day, when the fifh appear near the furface, they exhibit an amazing brilliancy of colours; all the various corufcations that dart from the diamond, fapphire, and emerald, enrich their traft: but, during night, if they break, *i. e.* play on the furface, the fea appears on fire, luminous as the brighteft phofphorus."

Herrings are cured either white or pickled, or red.

1. Of the firft, thofe done by the Dutch are the moft efteemed, being diftinguifhed into four forts, according to their fizes; and the beft are thofe that are fat, flefhy, firm, and white, falted the fame day they are taken, with good falt, and well barrelled. The Britifh cured herrings are little inferior, if not equal, to the Dutch; for in fpite of all their endeavours to conceal the fecret, their method of curing, lalting, or calking the herrings, has been difcovered, and is as follows. After they have hauled in their nets, which they drag in the ftern of their veffels backwards and forwards in traverfing the coaft, they throw them upon the fhip's deck, which is cleared of every thing that for that purpofe: the crew is feparated into fundry divifions, and each divifion has a peculiar task; one part opens and guts the herrings, leaving the melts and roes; another cures and falts them, by lining or rubbing their infide with falt; the next packs them, and between each row and divifion they fpinkle handfuls of falt; laftly, the cooper puts the finifhing hand to all, by heading the calks very tight, and flowing them in the hold.

2. Red herrings muft lie 24 hours in the brine, in as much as they are to take all their falt there; and when they are taken out, they are fpitted, that is, ftrung by the head on little wooden fplits, and then hung in a chimney made for that purpofe. After which, a fire of brush-wood, which yields a deal of fmoke but no flame, being made under them, they remain there till fufficiently smoked and dried, and are afterwards barrelled up for keeping.

Pearl-Fifhery. See PEARL.

Pilchard FIFHERY. The chief-pilchard fifheries are along the coasts of Dalmatia, on the coaft of Bretagne, and along the coasts of Cornwall and Devonfhire. That of Dalmatia is very plentiful: that on the coasts of Bretagne employs annually about 300 fhips. Of the pilchard fifhery on the coaft of Cornwall the following account is given by Dr Borlase: "It employs a great number of men on the fea, training them thereby to naval affairs; employs men, women and children, at land, in falting, preffing, wafhing, and cleaning; in making boats, nets, ropes, calks, and all the trades depending on their conftruction and fale. The poor are fed with the offals of the captures, the land with the refufe of the fifh and falt; the merchant finds the gains of commiffion and honeft commerce, the fifherman the gains of the fifh. Ships are often freighted hither with falt, and into foreign coun-

countries with the fish, carrying off at the same time part of our tin. The usual produce of the great number of hogheads exported each year for ten years from 1747 to 1756 inclusive, from the four ports of Fowey, Falmouth, Penzance, and St Ives, it appears that Fowey has exported yearly 1732 hogheads; Falmouth, 14,631 hogheads and two thirds; Penzance and Mounts-Bay, 12,149 hogheads and one third; St Ives, 1282 hogheads: in all amounting to 29,795 hogheads. Every hoghead for ten years last past, together with the bounty allowed for each hoghead exported, and the oil made out of each hoghead, has amounted, one year with another at an average, to the price of one pound 13 shillings and three pence; so that the cash paid for pilchards exported has, at a medium, annually amounted to the sum of 49,532l. 10s." —The numbers that are taken at one shooting out of the nets are amazingly great. Mr Pennant says, that Dr Borlase assured him, that, on the 5th of October 1767, there were at one time inclosed in St Ives's Bay 7000 hogheads, each hoghead containing 35,000 fish, in all 245 millions.

The pilchards naturally follow the light, which contributes much to the facility of the fishery: the season is from June to September. On the coasts of France they make use of the roes of the cod-fish as a bait; which, thrown into the sea, makes them rise from the bottom, and run into the nets. On our coasts there are persons posted ashore, who, spying by the colour of the water where the shoals are, make signs to the boats to go among them to cast their nets. When taken, they are brought on shore to a warehouse, where they are laid up in broad piles, supported with backs and sides; and as they are piled, they salt them with bay-salt; in which lying to soak for 30 or 40 days, they run out a deal of blood, with dirty pickle and bitterness: then they wash them clean in sea-water; and, when dry, barrel and press them hard down to squeeze out the oil, which issues out at a hole in the bottom of the cask.

Salmon * FISHERY. The chief salmon-fisheries in Europe are in England, Scotland, and Ireland, in the rivers, and sea-coasts adjoining to the river-mouths. The most distinguished for salmon in Scotland are, the river Tweed, the Clyde, the Tay, the Dee, the Don, the Spey, the Nefs, the Bewly, &c. in most of which it is very common, about the height of summer, especially if the weather happens to be very hot, to catch four or five score salmon at a draught. The chief rivers in England for salmon are, the Tyne, the Trent, the Severn, and the Thames. The fishing is performed with nets, and sometimes with a kind of locks or weirs made on purpose, which in certain places have iron or wooden grates so disposed, in an angle, that being impelled by any force in a contrary direction to the course of the river, they may give way and open a little at the point of contact, and immediately shut again, closing the angle. The salmon, therefore, coming up into the rivers, are admitted into these grates, which open, and suffer them to pass through, but shut again, and prevent their return. The salmon is also caught with a spear, which they dart into him when they see him swimming near the surface of the water. It is customary likewise to catch them with a candle and lantern, or wisp of straw set on fire; for the fish naturally following the

light, are struck with the spear, or taken in a net spread for that purpose, and lifted with a sudden jerk from the bottom.

"The capture of salmon in the Tweed, about the month of July, (says Mr Pennant*) is prodigious. In a good fishery, often a boat-load, and sometimes near two, are taken in a tide: some few years ago there were above 700 fish taken at one haul, but from 50 to 100 is very frequent. The coopers in Berwick then begin to salt both salmon and gillies in pipes and other large vessels, and afterwards barrel them to send abroad, having then far more than the London markets can take off their hands.

"Most of the salmon taken before April, or to the setting in of the warm weather, is sent fresh to London in baskets: unless now and then the vessel is disappointed, by contrary winds, of sailing immediately; in which case the fish is brought ashore again to the coopers offices, and boiled, pickled, and kitted, and sent to the London markets by the same ship, and fresh salmon put in the baskets in lieu of the stale ones. At the beginning of the season, when a ship is on the point of sailing, a fresh clean salmon will sell from a shilling to eighteen pence a pound; and most of the time that this part of the trade is carried on, the prices are from five to nine shillings per stone; the value rising and falling according to the plenty of fish, or the prospect of a fair or foul wind. Some fish are sent in this manner to London the latter end of September, when the weather grows cool; but then the fish are full of large roes, grow very thin-bellied, and are not esteemed either palatable or wholesome.

"The season for fishing in the Tweed begins November 30th, but the fishermen work very little till after Christmas: it ends on Michaelmas-day; yet the corporation of Berwick (who are conservators of the river) indulge the fishermen with a fortnight past that time, on account of the change of the tide.

"There are on the river 41 considerable fisheries, extending upwards, about 14 miles from the mouth, (the others above being of no great value), which are rented for near 5400l. *per annum*: the expence attending the servants wages, nets, boats, &c. amount to 5000l. more; which together makes up the sum 10,400l. Now, in consequence, the produce must defray all, and no less than 20 times that sum of fish will effect it; so that 208,000 salmon must be caught there one year with another.

"Scotland possesses great numbers of fine fisheries on both sides of that kingdom. The Scotch in early times had most severe laws against the killing of this fish; for the third offence was made capital, by a law of James IV. Before that, the offender had power to redeem his life. They were thought in the time of Henry VI. a present worthy of a crowned head: for in that reign the queen of Scotland sent to the dutches of Clarence, ten casks of salted salmon; which Henry directed to pass duty-free. The salmon are cured in the same manner as at Berwick, and a great quantity is sent to London in the spring; but after that time, the adventurers begin to barrel and export them to foreign countries: but we believe that commerce is far less lucrative than it was in former times, partly owing to the great increase of the Newfoundland fishery, and partly to the general relaxation of the discipline of abstinence in the Romish church.

"Ireland (particularly the north) abounds with this fish: the most considerable fishery is at Cranna, on the river Ban, about a mile and an half from Coleraine. When I made the tour of that hospitable kingdom in 1754, it was rented by a neighbouring gentleman for 620*l.* a-year; who assured me, that the tenant, his predecessor, gave 1600*l.* *per annum*, and was a much greater gainer by the bargain, for the reasons before-mentioned, and on account of the number of poachers who destroy the fish in the fence-months.

"The mouth of this river faces the north; and is finely situated to receive the fish that roam along the coast, in search of an inlet into some fresh water, as they do all along that end of the kingdom which opposes itself to the northern ocean. We have seen near Ballinacastle, nets placed in the sea at the foot of the promontories that jut into it, which the salmon strike into as they are wandering close to shore; and numbers are taken by that method.

"In the Ban they fish with nets 18 score yards long, and are continually drawing night and day the whole season, which we think lasts about four months, two sets of 16 men each alternately relieving one another. The best drawing is when the tide is coming in: we were told, that at a single draught there were once 840 fish taken.

"A few miles higher up the river is a wear, where a considerable number of fish that escape the nets are taken. We were lately informed, that, in the year 1760, about 320 tons were taken in the Cranna fishery."

Curing Salmon. When the salmon are taken, they open them along the back, take out the guts and gills, and cut out the greatest part of the bones, endeavouring to make the inside as smooth as possible: they then salt the fish in large tubs for the purpose, where they lie a considerable time soaking in brine; and about October, they are packed close up in barrels, and sent to London, or exported up the Mediterranean. They have also in Scotland, a great deal of salmon salted in the common way, which after soaking in brine a competent time, is well pressed, and then dried in smoke: this is called *kipper*, and is chiefly made for home consumption; and, if properly cured and prepared, is reckoned very delicious.

Sturgeon † **FISHERY.** The greatest sturgeon-fishery is in the mouth of the Volga, on the Caspian sea; where the Muscovites employ a great number of hands, and catch them in a kind of inclosure formed by huge stakes representing the letter Z repeated several times. These fisheries are open on the side next the sea, and close on the other; by which means the fish ascending in its season up the river, is embarrassed in these narrow angular retreats, and so is easily killed with a harping-iron. Sturgeons, when fresh, eat deliciously; and in order to make them keep, they are salted or pickled in large pieces, and put up in cags from 30 to 50 pounds. But the great object of this fishery is the roe, of which the Muscovites are extremely fond, and of which is made the caviar, or kavia, so much esteemed by the Italians. — See **CAVEAR.**

Whale * **FISHERY.** Whales are chiefly caught in the north seas: the largest sort are found about Greenland, or Spitzbergen. At the first discovery of this country, whales not being used to be disturbed, frequently came

into the very bays, and were accordingly killed almost close to the shore; so that the blubber being cut off was immediately boiled into oil on the spot. The ships in those times took in nothing but the pure oil and the whalebone, and all the business was executed in the country; by which means a ship could bring home the product of many more whales than she can according to the present method of conducting this trade. The fishery also was then so plentiful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the situation of this trade. The ships coming in such numbers from Holland, Denmark, Hamburg, and other northern countries, all intruders upon the English, who were the first discoverers of Greenland, the whales were disturbed, and gradually, as other fish often do, forsaking the place, were not to be killed so near the shore as before; but are now found, and have been so ever since, in the openings and space among the ice, where they have deep water, and where they go sometimes a great many leagues from the shore.

The whale-fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away, and get clear of the ice, by the end of August; so that in the month of September at farthest, they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows.—Every ship is provided with six boats, to each of which belong six men for rowing the boat, and an harpooner whose business is to strike the whale with his harpoon. Two of these boats are kept constantly on the watch at some distance from the ship, fastened to pieces of ice, and are relieved by others every four hours. As soon as a whale is perceived, both the boats set out in pursuit of it, and if either of them can come up before the whale finally descends, which is known by his throwing up his tail, the harpooner discharges his harpoon at him. There is no difficulty in choosing the place where the whale is to be struck, as some have asserted; for these creatures only come up to the surface in order to spout up the water, or *blow*, as the fishermen term it, and therefore always keep the soft and vulnerable part of their bodies above water. A late improvement was made in the method of discharging the harpoon; namely, by shooting it out of kind of swivel or musquetoon: but it doth not appear, that, since this improvement was made, the whale-fishing ships have had better success than before.—As soon as the whale is struck, the men set up one of their oars in the middle of the boat as a signal to those in the ship. On perceiving this, the watchman alarms all the rest with the cry of *fall! fall!* upon which all the other boats are immediately sent out to the assistance of the first.

The whale finding himself wounded, runs off with prodigious violence. Sometimes he descends perpendicularly; at others goes off horizontally, at a small depth below the surface. The rope which is fastened to the harpoon is about 200 fathoms long, and properly coiled up, that it may freely be given out as there is a demand for it. At first, the velocity with which

† See *Asiaticus*.

* See *Asiaticus*.

Fishery.

Fishing.

which this line runs over the side of the boat is so great, that it is wetted to prevent its taking fire; but in a short time the strength of the whale begins to fail, and the fishermen, instead of letting out more rope, strive as much as possible to pull back what is given out already, though they always find themselves necessitated to yield at last to the efforts of the animal, to prevent his sinking their boat. If he runs out the 200 fathoms of line contained in one boat, that belonging to another is immediately fastened to the end of the first, and so on; and there have been instances, where all the rope belonging to the six boats has been necessary, though half that quantity is seldom required. The whale cannot stay long below water, but again comes up to blow; and being now much fatigued and wounded, stays longer above water than usual. This gives another boat time to come up with him, and he is again struck with an harpoon. He again descends, but with less force than before; and when he comes up again, is generally incapable of defending, but suffers himself to be wounded and killed with long lances which the men are provided with for the purpose. He is known to be near death when he spouts up the water deeply tinged with blood.

The whale being dead, is lashed along-side the ship. They then lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which, together with the fins, is struck off as soon as he is taken, to keep those extremities above water. On the off-side of the whale are two boats, to receive the pieces of fat, utensils, and men, that might otherwise fall into the water on that side. These precautions being taken, three or four men with irons at their feet to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick and eight long, which are hauled up at the capstain or windlafs. When the fat is all got off, they cut off the whippers of the upper jaw with an ax. Before they cut, they are all lashed to keep them firm; which also facilitates the cutting, and prevents them from falling into the sea: when on board, five or six of them are bundled together, and properly stowed; and after all is got off, the carcase is turned a-drift, and devoured by the bears, who are very fond of it. In proportion as the large pieces of fat are cut off, the rest of the crew are employed in slicing them smaller, and picking out all the lean. When this is prepared, they stow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in tubs in the hold, cramming them very full and close. Nothing now remains but to sail homewards, where the fat is to be boiled and melted down into train-oil.

It were in vain to speak in this place of the advantages that may be derived to Great Britain from the whale-fishery. We shall only remark, that the legislature think that trade of so great importance, as to grant a very considerable bounty for the encouragement of it; for every British vessel of 200 tons or upwards, bound to the Greenland seas on the whale-fishery, if found to be duly qualified according to the act, obtains a licence from the commissioners of the customs to proceed on such voyage; and on the ship's return, the master and mate making oath that they proceeded on such voyage and no other, and used all

their endeavours to take whales, &c. and that all the whale-fins, blubber, oil, &c. imported in their ship, were taken by their crew in those seas, there shall be allowed 40 s. for every ton according to the admeasurement of the ship.

Besides these fisheries, there are several others both on the coasts of Great Britain and in the North Seas, which, although not much the subject of merchandize, nevertheless employ great numbers both of ships and men; as, 1. The oyster-fishing at Colchester, Faversham, the Isle of Wight, in the Swales of the Medway, and in all the creeks between Southampton and Chichester, from whence they are carried to be fed in pits about Wevenhoe and other places. (See OSTRÆA.) 2. The lobster-fishing all along the British Channel, the Frith of Edinburgh, on the coast of Northumberland, and on the coast of Norway, from whence great quantities are brought to London. (See CANCER.) 3. and lastly, The fishing of the pot-fish, fin-fish, sea-unicorn, sea-horse, and the seal, or dog-fish: all which are found in the same seas with the whales, and yield blubber in a certain degree; besides, the horn of the unicorn is as estimable as ivory, and the skins of the seals are particularly useful to trunk-makers.

FISHING, in general, the art of catching fish, whether by means of nets, of spears, or of the line and hook.

FISHING in the great, performed by the net, spear, or harpoon, has been explained in the preceding article. That performed by the rod, line and hook, is usually termed ANGLING: See that article; and for the particular manner of angling for the different kinds of fish, see their respective names, as DACE, EEL, PERCH, &c. The following were omitted in their order.

1. The *Barbel**, (so called on account of the barb* See *Cyprinus* or beard that is under his chops), though a coarse fish, gives considerable exercise to the angler's ingenuity. They swim together in great shoals, and are at their worst in April, at which time they spawn, but come soon in season: the places whither they chiefly resort, are such as are weedy and gravelly rising grounds, in which this fish is said to dig and root with his nose like a swine. In the summer he frequents the strongest, swiftest, currents of water; as deep bridges, weirs, &c. and is apt to settle himself amongst the piles, hollow places, and moss, or weeds; and will remain there immoveable: but in the winter he retires into deep waters, and helps the female to make a hole in the sands to hide her spawn in, to hinder its being devoured by other fish. He is a very curious and cunning fish; for if his baits be not sweet, clean, well-scoured, and kept in sweet moss, he will not bite; but well-ordered and curiously kept, he will bite with great eagerness. The best bait for him is the spawn of a salmon, trout, or any other fish; and if you would have good sport with him, bait the places where you intend to fish with it a night or two before, or with large worms cut in pieces; and the earlier in the morning or the later in the evening that you fish, the better it will be. Your rod and line must be both strong and long, with a running plummet on the line; and let a little bit of lead be placed a foot or more above the hook, to keep the bullet from falling on it: so the worm will be at the bottom, where they always bite; and when

Fishing.

Sportsman.
Ditt.

the fish takes the bait, your plummet will lie and not choke him. By the bending of your rod you may know when he bites, as also with your hand you will feel him make a strong snatch; then strike, and you will rarely fail, if you play him well; but, if you manage him not dexterously, he will break your line. The best time of fishing is about nine in the morning, and the most proper season is the latter end of May, June, July, and the beginning of August.

* See
Cyprinus.

2. The *Bleak**, is an eager fish, caught with all sorts of worms bred on trees or plants; as also with flies, paste, sheep's blood, &c. They may be angled for with half a score of hooks at once, if they can be all fattened on: he will also in the evening take a natural or artificial fly. If the day be warm and clear, there is no fly so good for him as the small fly at the top of the water, which he will take at any time of the day, especially in the evening: but if the day is cold and cloudy, gentles and caddis are the best; about two feet under water. No fish yields better sport to a young angler than the bleak. It is so eager, that it will leap out of the water for a bait.

There is another way of taking bleak, which is by whipping them in a boat, or on a bank-side in fresh water in a summer's evening, with a hazel top about five or six feet long and a line twice the length of the rod. But the best method is with a drabble, thus: Tie eight or ten small hooks across a line two inches above one another; the biggest hook the lowermost, (whereby you may sometimes take a better fish), and bait them with gentles, flies, or some small red worms, by which means you may take half a dozen or more at a time.

† See
Cyprinus.

3. For the *Bream*†, observe the following directions, which will also be of use in carp-fishing.—Procure about a quart of large red worms; put them into fresh moss well washed and dried every three or four days, feeding them with fat mould and chopped fennel, and they will be thoroughly scoured in about three weeks.

Let your lines be silk and hair, but all silk is the best: let the floats be either swan-quills, or goose-quills. Let your plumb be a piece of lead in the shape of a pear, with a small ring at the little end of it: fasten the lead to the line, and the line-hook to the lead, about ten or twelve inches space between lead and hook will be enough; and take care the lead be heavy enough to sink the float. Having baited your hook well with a strong worm, the worm will draw the hook up and down in the bottom, which will provoke the bream to bite the more eagerly. It will be best to fit up three or four rods and lines in this manner, and set them as will be directed, and this will afford you much the better sport. Find the exact depth of the water if possible, that your float may swim on its surface directly over the lead; then provide the following ground-bait: take about a peck of sweet gross-ground malt; and having boiled it a very little, strain it hard through a bag, and carry it to the water-side where you have fished; and in the place where you suppose the fish frequent, there throw in the malt by handfuls squeezed hard together, that the stream may not separate it before it comes to the bottom; and be sure to throw it in at least a yard above the place where you intend the hook shall lie, otherwise the

stream will carry it down too far. Do this about nine o'clock at night, keeping some of the malt in the bag; and go to the place about three the next morning: but approach very warily, lest you should be seen by the fish; for it is certain, that they have their sentinels watching on the top of the water, while the rest are feeding below. Having baited your hook so that the worm may crawl to and fro, the better to allure the fish to bite, cast it in at the place where you find the fish to stay most, which is generally in the broadest and deepest part of the river, and so that it may rest about the midst of your bait that is on the ground. Cast in your second line so that it may rest a yard above that, and a third about a yard below it. Let your rods lie on the bank with some stones to keep them down at the great ends; and then withdraw yourself, yet not so far but that you can have your eye upon all the floats: and when you see one bitten and carried away, do not be too hasty to run in, but give time to the fish to tire himself, and then touch him gently. When you perceive the float sink, creep to the water-side, and give it as much line as you can. If it is a bream or carp, they will run to the other side; which strike gently, and hold your rod at a bent a little while; but do not pull, for then you will spoil all; but you must first tire them before they can be landed, for they are very shy. If there are any carps in the river, it is an even wager that you take one or more of them: but if there are any pike or perch, they will be sure to visit the ground-bait, though they will not touch it, being drawn thither by the great resort of the small fish; and until you remove them, it is in vain to think of taking the bream or carp. In this case, bait one of your hooks with a small bleak, roach, or gudgeon, about two foot deep from your float, with a little red worm at the point of your hook; and if a pike be there, he will be sure to snap at it. This sport is good till nine o'clock in the morning; and, in a gloomy day, till night: but do not frequent the place too much, lest the fish grow shy.

4. The *carp**. A person who angles for carp must arm himself with abundance of patience, because of its extraordinary subtilty and policy: they always choose to lie in the deepest places, either of ponds or rivers, where there is but a small running stream.

Further, observe, that they will seldom bite in cold weather; and you cannot be too early or too late at the sport in hot weather: and if he bite, you need not fear his hold; for he is one of those leather-mouthed fish that have their teeth in their throat.

Neither must you forget, in angling for him, to have a strong rod and line; and since he is so very wary, it will be proper to entice him, by baiting the ground with a coarse paste.

He seldom refuses the red worm in March, the caddis in June, nor the grasshopper in June, April, and September.

This fish does not only delight in worms, but also in sweet paste; of which there is great variety: the best is made of honey and sugar, and ought to be thrown into the water some hours before you begin to angle; neither will small pellets thrown into the water two or three days before be worse for this purpose, especially if chickens guts, garbage, or blood mixed with bran and cow-dung, be also thrown in.

Fishing.

Fishing.

But more particularly, as to a paste very proper for this use, you may make it in the manner following: Take a sufficient quantity of flour, and mingle it with veal, cut small, making it up with a compound of honey; then pound all together in a mortar till they are so tough as to hang upon the hook without washing off. In order to effect which the better, mingle whitish wool with it; and if you keep it all the year round, add some virgin wax and clarified honey.

Again, if you fish with gentles, anoint them with honey, and put them on your hook, with a deep scarlet dipped in the like, which is a good way to deceive the fish.

Honey and crumbs of white-bread, mixed together, make also a very good paste.

In taking a carp either in pond or river, if the angler intends to add profit to his pleasure, he must take a peck of ale-grains, and a good quantity of any blood to mix with the grains, baiting the ground with it where he intends to angle. This food will wonderfully attract the scale-fish, as carp, tench, roach, dace, and bream.

Let him angle in a morning, plumbing his ground, and angling for carp with a strong line: the bait must be either paste, or a knotted red worm; and by this means he will have sport enough.

5. The *chub*, or *chevin**, is a very strong, though inactive fish, yielding in a very little time after he is struck; and the larger he is, the more quietly he is taken. As for his food, he loves all sorts of worms and flies; also cheese, grain, and black worms, their bellies being split that the white may appear. He is to be angled for early in the morning with snails: but in the heat of the day make use of some other bait; and in the afternoon, fish for him at ground or with fly; of the last of which there is none he covets more than a moth with a great head, whose body is yellow, with whitish wings, which is commonly found in gardens about the evening.

Description of proper Baits for the several sorts of Fish referred to in the annexed Table.

Flies.] 1. Stone-fly, found under hollow stones at the side of rivers, is of a brown colour, with yellow streaks on the back and belly, has large wings, and is in season from April to July. 2. Green-drake, found among stones by river-sides, has a yellow body ribbed with green, is long and slender, with wings like a butterfly, his tail turns on his back, and from May to Midsummer is very good. 3. Oak-fly, found in the body of an old oak or ash, with its head downwards, is of a brown colour, and excellent from May to September. 4. Palmer-fly or worm, found on leaves of plants, is commonly called a *caterpillar*, and when it comes to a fly is excellent for trout. 5. Ant-fly, found in ant-hills from June to September. 6. The May-fly is to be found playing at the river-side, especially against rain. 7. The black-fly is to be found upon every Hawthorn, after the buds are come off.

Pastes.] 1. Take the blood of sheeps hearts, and mix it with honey and flour worked to a proper consistence. 2. Take old cheese grated, a little butter sufficient to work it, and colour it with saffron: in winter use rusty bacon instead of butter. 3. Crumbs of bread chewed or worked with honey, (or sugar), moistened with gum-ivy water. 4. Bread chewed, and worked

in the hand till stiff.

Worms.] 1. The earth-bob, found in sandy ground after ploughing; it is white, with a red head, and bigger than a gentle: another is found in heathy ground, with a blue head. Keep them in an earthen vessel well covered, and a sufficient quantity of the mould they harbour in. They are excellent from April to November. 2. Gentles, to be had from putrid flesh: let them lie in wheat-bran a few days before used. 3. Flag-worms, found in the roots of flags; they are of a pale yellow colour, are longer and thinner than a gentle, and must be scowered like them. 4. Cow-turd-bob, or clap-bait, found under a cow-turd from May to Michaelmas; it is like a gentle, but larger. Keep it in its native earth like the earth-bob. 5. Cadis-worm, or cod-bait, found under loose stones in shallow rivers; they are yellow, bigger than a gentle, with a black or blue head, and are in season from April to July. Keep them in flannel bags. 6. Lob-worm, found in gardens; it is very large, and has a red-head, a streak down the back, and a flat broad tail. 7. Marsh-worms, found in marshy ground: keep them in moss ten days before you use them: their colour is a bluish red, and are a good bait from March to Michaelmas. 8. Brandling red-worms, or blood-worms, found in rotten dung-hills and tanners bark; they are small red-worms, very good for all small fish, have sometimes a yellow tail, and are called *tag-tail*.

Fish and insects.] 1. Minnow. 2. Gudgeon. 3. Roach. 4. Dace. 5. Smelt. 6. Yellow frog. 7. Snail slit. 8. Grasshopper.

FISHING-FLY, a bait used in angling for divers kinds of fish. See *FISHING*.

The fly is either *natural* or *artificial*.

I. *Natural* flies are innumerable. The more usual for this purpose are mentioned in the preceding column.

There are two ways to fish with natural flies; either on the surface of the water, or a little underneath it.

In angling for chevin, roach, or dace, move not your natural fly swiftly, when you see the fish make at it; but rather let it glide freely towards him with the stream: but if it be in a still and slow water, draw the fly slowly sidewise by him, which will make him eagerly pursue.

II. The *artificial* fly is seldom used but in blustering weather, when the waters are so troubled by the winds, that the natural fly cannot be seen, nor rest upon them. Of this artificial fly there are reckoned no less than 12 sorts, of which the following are the principal.

1. For March, the dun-fly; made of dun-wool, and the feathers of the partridge's wing; or the body made of black wool, and the feathers of a black drake. 2. For April, the stone-fly; the body made of black wool, dyed yellow under the wings and tail. 3. For the beginning of May, the ruddy fly; made of red wool, and bound about with black silk, with the feathers of a black capon hanging dangling on his sides next his tail. 4. For June, the greenish fly; the body made of black wool, with a yellow list on either side, the wings taken off the wings of a buzzard, bound with black broken hemp. 5. The moorish fly, the body made of dusky wool, and the wings of the blackish mail of

Fishing.

An Epitome of the whole art of FISHING, wherein is shewn (at one view), the harbours, seasons, and depths, for catching all sorts of fish usually angled for; also the various baits for each, so digested as to contain the effence of all the treatises ever wrote on the subject, except from their superfluities, which tend more to perplex than instruct.

Names.	Where found.	Season.	Time to ang.	Depth from ground.	Proper Baits.				
					Fish. No.	Puffers. No.	Worms. No.	Fish and Insects. No.

Sportsm.
Dig.

a drake. 6. The tawny fly, good till the middle of June; the body made of tawny wool, the wings made contrary one against the other, of the whitish mail of a white drake. 7. For July, the wasp-fly; the body made of black wool, cast about with yellow silk, and the wings of drakes feathers. 8. The steel-fly, good in the middle of July; the body made with greenish

wool, cast about with the feathers of a peacock's tail, and the wings made of those of the buzzard. 9. For August, the drake-fly; the body made with black wool cast about with black silk; his wings of the mail of a black drake, with a black head.

The best rules for artificial fly-fishing are,

1. To fish in a river somewhat disturbed with rain;

Fishing.

or in a cloudy day, when the waters are moved by a gentle breeze: the fourth wind is best; and if the wind blow high, yet not so but that you may conveniently guard your tackle, the fish will rise in plain deeps; but if the wind be small, the best angling is in swift streams. 2. Keep as far from the water-side as may be; fish down the stream with the sun at your back, and touch not the water with your line. 3. Ever angle in clear rivers, with a small fly and slender wings; but in muddy, places use a larger. 4. When, after rain, the water becomes brownish, use an orange fly; in a clear day, a light-coloured fly; a dark fly for dark waters, &c. 5. Let the line be twice as long as the rod, unless the river be encumbered with wood. 6. For every sort of fly, have several of the same, differing in colour, to suit with the different complexions of several waters and weathers. 7. Have a nimble eye, and active hand, to strike presently with the rising of the fish; or else he will be apt to spue out the hook. 8. Let the fly fall first into the water, and not the line, which will scare the fish. 9. In slow rivers, or still places, cast the fly a-crofs the river, and let it sink a little in the water, and draw it gently back with the current.

Salmon-fishes should be made with their wings standing one behind the other, whether two or four. This fish delights in the gaudiest colours that can be; chiefly in the wings, which must be long, as well as the tail.

FISHING-Floats, are little appendages to the line, serving to keep the hook and bait suspended at the proper depth, to discover when the fish has hold of them, &c. Of these there are divers kinds; some made of Muscovy-duck quills, which are the best for slow waters; but for strong streams, sound cork, without flaws or holes, bored through with an hot iron, into which is put a quill of a fit proportion, is preferable: pare the cork to a pyramidal form, and make it smooth.

FISHING-Hook, a small instrument made of steel-wire, of a proper form to catch and retain fish.

The fishing-hook, in general, ought to be long in the shank, somewhat thick in the circumference, the point even and straight; let the bending be in the shank.

For setting the hook on, use strong, but small silk, laying the hair on the inside of your hook; for if it be on the outside, the silk will fret and cut it asunder.

There are several sizes of these fishing-hooks, some big, some little: and of these, some have peculiar names; as, 1. Single hooks. 2. Double hooks; which have two bendings, one contrary to the other. 3. Snappers, or gorgers, which are the hooks to whip the artificial fly upon, or bait with the natural fly. 4. Springers, or spring-hooks; a kind of double hooks, with a spring, which flies open upon being struck into any fish, and so keep its mouth open.

FISHING-Line, is either made of hair, twiled; or silk; or the Indian grass.—The best colours are the forrel, white, and grey; the two last for clear waters, the first for muddy ones. Nor is the pale watery green despicable; this colour is given artificially, by keeping the hair in a liquor made of alum, foot, and the juice of walnut-leaves, boiled together.

FISHING-Rod, a long slender rod or wand, to which the line is fastened, for angling.—Of these there are several sorts; as, 1. A troller, or trolling-rod, which has a ring at the end of the rod, for the line to go thro' when it runs off a reel. 2. A whipper, or whipping-

rod; a top-rod, that is weak in the middle, and top-heavy, but all slender and fine. 3. A dropper; which is a strong rod and very light. 4. A snapper, or snapper-rod; which is a strong pole, peculiarly used for the pike. 5. A bottom-rod; being the same as the dropper, but somewhat more pliable. 6. A sniggling or procking stick; a forked stick, having a short strong line, with a needle, baited with a lobe worm: this is only for eels in their holes.

FISHING-Frog, or Angler. See **LOPHIUS**.

Right of FISHING, and property of fish. It has been held, that where the lord of the manor hath the soil on both sides of the river, it is a good evidence that he hath a right of fishing; and it puts the proof upon him who claims *liberam piscariam*: but where a river ebbs and flows, and is an arm of the sea, there it is common to all, and he who claims a privilege to himself must prove it; for if the trespass is brought for fishing there, the defendant may justify, that the place where is *brachium maris, in quo unusquisque subditus domini regis habet et habere debet liberam piscariam*. In the Severn the soil belongs to the owners of the land on each side; and the soil of the river Thames is in the king, but the fishing is common to all. He who is owner of the soil of a private river, hath *separatis piscariis*; and he that hath *libera piscaria*, hath a property in the fish, and may bring a possessory action for them; but *communis piscaria* is like the case of all other commons. One that has a close pond in which there are fish, may call them *piscis suus*, in an indictment, &c. but he cannot call them *bona & catalla*, if they be not in trunks. There needs no privilege to make a fish-pond, as there doth in the case of a warren. See **FRANCHISE**.

FISURES, in the history of the earth, certain interruptions, that in an horizontal or parallel manner divide the several strata of which the body of our terrestrial globe is composed.

Fissure of the Bones, in surgery, is when they are divided either transversely or longitudinally, not quite through, but cracked after the manner of glass, by any external force. See **SURGERY**.

FISTULA, in the ancient music, an instrument of the wind-kind, resembling our flute or flageolet.

The principal wind-instruments of the ancients, were the tibia and the fistula. But how they were constituted, wherein they differed, or how they were played upon, does not appear.

FISTULA, in surgery, a deep, narrow, and callous ulcer, generally arising from abscesses.

It differs from a *sinus*, in its being callous, the latter not. See **SURGERY**.

FISTULA, in farriery. See **FARRIERY**, § xxxi.

FISTULARIA, or **TOBACCO-PIPE FISH**; a genus of fishes, belonging to the order of abdominales. Of this genus Linnæus reckons two species; but we have a description only of one, viz. the tabacaria. It is described by Mr Catelby, from the only one he ever saw. It was almost a foot in length; the fore-part from the nose to half-way the body of nearly equal bigness; from whence it grew tapering to the tail, which was forked, and from which grew a slender taper whip, four inches long, of the consistence of whale-bone; the mouth narrow, from which to the eyes was almost three inches. The whole fish was of a brown colour. They are sometimes taken on the coasts of Jamaica.

Law Dist.

FIT. See PAROXYSM.

Dr Cheyne is of opinion that fits of all kinds, whether epileptic, hysterical, or apoplectic, may be cured solely by a milk-diet, of about two quarts of cows milk a-day, without any other medicine.

FITCHY, in heraldry, (from the French *fishé*, i. e. *fixed*); a term applied to a cross when the lower branch ends in a sharp point: and the reason of it Mackenzie supposes to be, that the primitive Christians were wont to carry crosses with them wherever they went; and when they stopped on their journey at any place, they fixed those portable crosses in the ground for devotion's sake.

FITCHES, in husbandry, a sort of pulse, more generally known by the name of *chick-pea*. See CICER.

Fitches are cultivated either for feeding cattle, or improving the land. They make a wholesome and nourishing food, whether given in the straw or threshed out. When sown only to improve the soil, they are ploughed in just as they begin to blossom, by which means a tough stiff clay-soil is much enriched.

FITCHET, a name used in some places for the weasel, called also the *foumart*. See MUSTELA.

FITZ, makes part of the surname of some of the natural sons of the kings of England, as *Fitz-roy*; which is purely French, and signifies the "king's son."

FITZHERBERT (Sir Anthony), a very learned lawyer in the reign of king Henry VIII. was descended from an ancient family, and born at Norbury in Derbyshire. He was made one of the judges of the court of common-pleas in 1523; and distinguished himself by many valuable works, as well as by such an honourable discharge of the duties of his office, as made him esteemed an oracle of the law. His writings are, *The Grand Abridgment*; *The Office and Authority of Justices of Peace*; *The Office of Sheriffs, Bailiffs of Liberties, Escheators, Constables, Coroners, &c.*; *Of the Diversity of Courts*; *The New Natura Brevium*; *Of the Surveying of Lands*; and *The Book of Husbandry*. He died in 1538.

FITZ-STEPHEN (William), a learned monk of Canterbury, of Norman extraction, but born of respectable parents in the city of London. He lived in the 12th century; and being attached to the service of archbishop Becket, was present at the time of his murder. In the year 1174, he wrote in Latin, *The Life of St Thomas, archbishop and martyr*; in which, as Becket was a native of the metropolis, he introduces a description of the city of London, with a miscellaneous detail of the manners and usages of the citizens: this is deservedly considered as a great curiosity, being the earliest professed account of London extant. Fitz-Stephen died in 1191.

FIVES, or VIVES. See FARRIERY, sect. x. 10.

FIXATION, in chemistry, the rendering any volatile substance fixed, so as not to fly off upon being exposed to a great heat; hence,

FIXED BODIES, are those which bear a considerable degree of heat without evaporating, or losing any of their weight. Among the most fixed bodies are diamonds, gold, &c. See DIAMOND, GOLD, &c.

FIXED AIR. See AIR, and GAS.

FIXED STARS, are such as constantly retain the same position and distance with respect to each other*; by which they are contradistinguished from erratic or wandering stars, which are continually shifting their situa-

tion and distance. The fixed stars are what we properly and absolutely call *stars*: the rest have their peculiar denominations of *planet*, and *comet*. See ASTRONOMY, n° 40, 44, 46, &c.

FLACCUS (Caius Valerius), an ancient Latin poet, of whom we have very imperfect accounts remaining. He wrote a poem on the Argonautic expedition; of which, however, he did not live to finish the eighth book, dying at about 30 years of age. John Baptista Pius, an Italian poet, completed the eighth book of the Argonautics; and added two more, from the fourth of Apollonius; which supplement was first added to Aldus's edition in 1523.

FLAG or SLATE Stone, common in Northumberland and some of the neighbouring counties, is called by some the *Carlisle flag*. Its strata are very thick; but they sometimes separate into laminae of about half an inch thick, and the workmen seldom attempt to split it any thinner: the upper strata, however, grow gradually thinner. The bottom ones are so thick, that they cannot be made use of for slates; but are used for tanners vats, the pavements of floors, and cisterns for water.

FLAG, is also used for sedge, a kind of rush.

FLAGS, in the army, are small banners of distinction stuck in the baggage-waggons, to distinguish the baggage of one brigade from another, and of one battalion from another; that they may be marshalled by the wagon-master general according to the rank of their brigades, to avoid the confusion that might otherwise arise.

FLAG, in the marine, a certain banner or standard, by which an admiral is distinguished at sea from the inferior ships of his squadron; also the colours by which one nation is distinguished from another. See PLATE CIX.

In the British navy, flags are either red, white, or blue; and are displayed from the top of the main-mast, fore-mast, or mizen-mast, according to the rank of the admiral. When a flag is displayed from the flag-staff on the main-mast, the officer distinguished thereby is known to be an admiral; when from the fore-mast, a vice-admiral; and when from the mizen-mast, a rear-admiral.

The first flag in Great Britain is the royal standard, which is only to be hoisted when the king or queen are on board the vessel: the second is that of the anchor of hope, which characterizes the lord high admiral, or lords commissioners of the admiralty: and the third is the union-flag, in which the crosses of St George and St Andrew are blended. This last is appropriated to the admiral of the fleet, who is the first military officer under the lord high admiral.

The next flag after the union is that of the white squadron, at the main-mast head; and the last, which characterizes an admiral, is the blue, at the same mast-head.

For a vice-admiral, the first flag is the red, the second the white, the third the blue, at the flag-staff on the fore-mast.

The same order proceeds with regard to the rear-admirals, whose flags are hoisted on the top of the mizen-mast: the lowest flag in our navy is accordingly the blue on the mizen-mast.

To Lower or Strike the FLAG, in the marine, is to pull it down upon the cap, or to take it in, out of the

the respect, or submission, due from all ships or fleets inferior to those any way justly their superiors. To lower or strike the flag in an engagement is a sign of yielding.

The way of leading a ship in triumph is to tie the flags to the shrouds, or the gallery, in the hind-part of the ship, and let them hang down towards the water, and to tow the vessels by the stern. Livy relates, that this was the way the Romans used those of Carthage.

To Heave out the FLAG, is to put out or put abroad the flag.

To Hang out the White FLAG, is to ask quarter; or it shews, when a vessel is arrived on a coast, that it has no hostile intention, but comes to trade, or the like. The red flag is a sign of defiance, and battle.

Corn-FLAG. See *GLADIOLUS*.

Sweet-scented FLAG. See *ACORUS*.

FLAG-Officers, those who command the several squadrons of a fleet; such are the admirals, vice-admirals, and rear-admirals.

The flag-officers in our pay, are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue. See *ADMIRAL*, *FLAG*, and *FLEET*.

FLAG-Ship, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under the command thereof.

FLAGELLANTES, a sect of heretics, who chastised and disciplined themselves with whips, in public.

The sect of the Flagellantes had its rise at Perugia, in the year 1260. Its author was one Rainier, a hermit. It was in all probability no more than the effect of an indiscreet zeal. A great number of persons of all ages made processions, walking two by two, with their shoulders bare, which they whipped, till the blood ran down, in order to obtain mercy from God, and appease his indignation against the wickedness of the age. They were then called the *devout*: and having established a superior, he was called the *general of the devotion*.

Women did not appear in these public assemblies; though they practised the same severities; but it was in private, and in their own houses.

In the middle of the 14th century, the sect of the Flagellantes was restored, on occasion of a great mortality, and spread itself into all parts of Europe.

The bishops and magistrates at length found it necessary to put a stop to their excess. The writers and preachers disputed against it; but the Flagellantes remained unshaken against all they could say: so that of a number of, perhaps, innocent well-meaning zealots, pride, obstinacy and schism converted them into a dangerous sect. They held, that the blood thus spilt was mixed with that of Jesus Christ; and that by a flagellation of 24 days they gained the pardon of all their sins.

Clement VI. forbid all public flagellations. Gerfon wrote an express treatise against public flagellations.

FLAGEOLET, or *FLAJEOLET*, a little flute, used chiefly by shepherds and country-people. It is made of box or other hard wood, and sometimes of ivory; and has six holes besides that at the bottom, the mouth-piece, and that behind the neck.

FLAIL, an instrument for threshing corn. It consists of four VOL. IV.

fists of the following parts. 1. The hand-staff, or piece held in the threshers hand. 2. The swiple, or that part which strikes out the corn. 3. The caplins, or strong double leathers, made fast to the tops of the hand-staff and swiple. 4. The middle-band, being the leather thong, or fish skin, that ties the caplins together.

FLAMBEAU, a kind of large taper, made of hempen wicks, by pouring melted wax on their top, and letting it run down to the bottom. This done, they lay them to dry; after which they roll them on a table, and join four of them together by means of a red-hot iron; and then pour on more wax, till the flambeau is brought to the size required. Flambeaus are of different lengths, and made either of white or yellow wax. They serve to give light in the streets at night, or on occasion of illuminations.

FLAMBOROUGH-HEAD, in geography, a cape or promontory of Yorkshire, five miles east of Burlington. E. Long. 20°. N. Lat. 54. 15.

FLAME, is a general name for every kind of luminous vapour, provided the light it emits hath any considerable degree of intensity. The name *flame*, however, is most generally applied to such as are of a conical figure, like those arising from our common fires; without this, they are commonly called *luminous vapours*, or simply *lights*.

According to Sir Isaac Newton, flame is only *red-hot smoke*, or the vapour of any substance raised from it by fire and heated to such a degree as to emit light copiously. This definition seems to be the most accurate and expressive of any. It is certain, that bodies are capable of emitting flame only in proportion to the quantity of vapour that rises from them. Thus wood, coals, &c. which emit a great quantity of vapour, flame violently; while lead, tin, &c. which emit but a small fume, can scarce be perceived to flame at all.

This rule, however, is by no means to be depended upon in all cases. Some vapours *seem* to be in their own nature unflammable, and capable of extinguishing flame, as those of water, the mineral acids, sal-ammoniac, arsenic, &c. while others take fire on the slightest approach of a flaming substance, such as ether, spirit of wine, &c. These last mentioned substances also exhibit a remarkable phenomenon; namely, that they cannot be made to flame without the approach of some substance actually in flames beforehand. Thus, spirit of wine, poured on a red-hot iron, though instantly dissipated in vapour, will not flame; but if a burning candle touches its surface, the whole is set in a flame at once. The case is otherwise with oils, especially those of the grossier kind; for their vapours will readily be changed into flame by the mere increase of heat, without the approach of any flaming substance.

There is, however, no kind of vapour, perhaps, that is incapable of being converted into flame, provided it is exposed to a sufficient degree of heat. Thus the vapour of water, made to pass through burning coals, produces an exceedingly strong and bright flame.—It is remarkable, that this kind of vapour seems to be more powerful than almost any other in absorbing heat, and detaining it in a latent state. Dr Black hath shewn, that when any quantity of aqueous vapour is condensed, more heat will be separated from it than would have been sufficient to heat an equal bulk of iron

Flambeau
||
Flame.

red-hot.—It is most probably to this property which all vapours have of absorbing heat, and detaining it in a latent state, that we are to attribute the phenomena of flame, and also the exceeding great elasticity of steam. It is certain, that vapours, of water at least, have a much greater power of absorbing and retaining heat, than the water from which they are raised. In open vessels, water cannot be heated more than 212 degrees of Fahrenheit's thermometer; but in Papin's digester, where the vapour is forcibly confined, it has been heated to 400 of the same degrees; and, no doubt, might have been heated a great deal more, had the vessels been strong enough to bear the expansive force of the steam. On opening the vessels, however, the excess of heat was found to have refided entirely in the vapour; for the water in the vessel very soon sunk down to 212°, while the steam issued forth with great violence.

From these experiments it appears, that the steam of water, after it has absorbed as much heat in a latent state as it can contain, continues to absorb, or detain among its particles, an unlimited quantity of sensible heat; and if the steam could be confined till this quantity became great enough to be visible by its emission of light, there cannot be the least doubt that the vapour would then be converted into flame.

In what manner the heat is detained among the particles of steam, is perhaps impossible to be explained; but to this heat we must undoubtedly ascribe the violent expansive force of steam of every kind. It seems probable, that, when smoke is converted into flame, the latent heat with which the vapour had combined, or rather that which made an essential part of it, breaks forth, and adds to the quantity of sensible heat which is already present. This seems probable, from the sudden explosion with which all flames break out. If a vessel full of oil is set over the fire, a smoke or vapour begins to arise from it; which grows gradually thicker and thicker; and at last begins to shine in some places very near the surface of the oil, like an electric light, or sulphur just kindled. At this time the oil is very hot, as well as the steam which issues from it. But this last is continually giving off its sensible heat into the atmosphere; so that at the distance of an inch or two from the surface of the oil, the heat of the steam will not exceed 400 degrees of Fahrenheit, or perhaps may not be so much; but if a burning candle is held in the steam for a moment, the whole is immediately converted into flame, with something like an explosion; after which, the oil burns quietly until it is all consumed. The flame, as soon as it appears, is not only much hotter than the steam from whence it was produced, but even than the oil which lies below it. Whence, then, has this sudden and great increase of heat arisen? It could not be the *sensible* heat of the vapour, for that was greatly inferior; nor could it be communicated from the oil, for that could communicate no more than it had to itself. The candle, indeed, would communicate a quantity of heat to the vapour which touched its flame; but it is impossible that this quantity should extend permanently over a surface perhaps 100 times larger than the flame of the candle, in such a manner as to make every part of that surface equally hot with the flame of the candle itself; for this would be to suppose it to communicate 100 times more heat than really was in it. The heat therefore must

have originally resided in the vapour itself: and as, in the freezing of water, its latent heat is extricated and becomes sensible, and the water thereupon loses its fluidity; so, in the accension of vapour, the latent heat breaks forth with a bright flash, and the vapour is then totally decomposed, and converted into soot, ashes, or water, according to the different nature of the substances which produce it, or according to the intensity of the heat.—Several other hypotheses have been invented to solve the phenomena of burning and flaming bodies; for an account of which, see the articles IGNITION, PHLOGISTON, &c.

Flames are of different colours, according to the substances from which they are produced. Thus, the flame of sulphur and spirit of wine is blue; the flame of nitre and zinc, of a bright white; that of copper, of a greenish blue, &c.—These varieties afford an opportunity of making a number of agreeable representations in fire-works, which could not be done if the flame produced from every different substance was of the same colour. See PYROTECHNICS.

FLAMEN, in Roman antiquity, the name of an order of priests, instituted by Romulus or Numa; authors not being agreed on this head.

They were originally only three, viz. the flamen dialis, flamen martialis, and flamen quirinus. They were chosen by the people, and installed by the sovereign pontiff. Afterwards, their number was increased to 15; the three first of whom were senators, and called *flamines majores*; the other 12, taken from among the people, being denominated *flamines minores*.

The flamen dialis, or priest of Jupiter, was a considerable person at Rome; the flamen martialis, or priest of Mars, was the second in dignity; and the flamen quirinalis, was the next to him.

The greater flamen wore the robe edged with purple, like that of the great magistrates, had an ivory chair, and sat in the senate. They wore a little band of thread (*filamen*) about their head; from whence, according to Varro, they had their name. There were likewise *flaminicæ*, or priestesses, who were the wives of the *flamines diales*. These wore a flame-coloured habit, on which was painted the image of a thunderbolt; and above their head-dress they wore green oak-boughs. They are often mentioned in inscriptions.

FLAMINGO, in ornithology. See PHOENICOPTERUS.

FLAMINIUS, or FLAMINIO, (Mark Anthony), one of the best Latin poets in the 16th century, of Lomola in Italy, son and grandson of very learned men. The pope had chosen him secretary to the council in 1545; but he refused that employment, because, favouring the new opinions, he would not employ his pen in an assembly where he knew these opinions were to be condemned.—He paraphrased 30 of the psalms in Latin verse, and also wrote notes on the psalms; and some letters and poems which are esteemed. He died at Rome in 1550.

FLAMSTEED (John), an eminent English astronomer in the 17th century, born at Derby in 1646. He had early read a great deal of civil and ecclesiastical history; but happening to see John de Sacrobosco's book *de Sphæra*, this gave him a turn for astronomy, which

Flamsteed, which study he afterwards prosecuted with great vigour. His father, finding him in correspondence with several learned men, advised him to go to London, that he might be personally acquainted with them. In 1674, he wrote an ephemeris, in which he shewed the falsity of astrology; and gave a table of the moon's rising and setting, carefully calculated, together with the eclipses and appulses of the moon and planets to fixed stars. This fell into the hands of Sir Jonas More; for whom, at his request, he made a table of the moon's true southings. In 1674, Sir Jonas having informed him, that a true account of the tides would be highly acceptable to his majesty, he composed a small ephemeris for the king's use: and when Sir Jonas shewed the king and duke of York our author's telescopes and micrometer, and recommended him strongly, he procured him a warrant to be king's astronomer, with the salary of L. 100 *per annum*; on which occasion he was ordained. In 1675, the foundation of the royal observatory at Greenwich was laid, and during the building he lodged at Greenwich; his quadrant and telescopes being kept in the queen's house there.

His *Doctrine of the Sphere* was published in 1681, in a posthumous work of Sir Jonas More, intitled, *A new System of the Mathematics*. In 1684, he was presented to the living of Burfrow in Surry, which he enjoyed till he died in 1719. His *Historia celsitris Britannica*, was published at London in 1725, in 3 vols. Mr Flamsteed likewise composed the British Catalogue of the fixed stars, which contains twice the number that are in the catalogue of Hevelius; to each of which he annexed its longitude, latitude, right ascension, and distance from the pole, together with the variation of right ascension and declination, while the longitude increases a degree. This catalogue, together with most of his observations, were printed on a fine paper and character, at the expence of the late prince George of Denmark.

FLANDERS, a province of the Netherlands, bounded by the German sea and the United Provinces on the north; by the province of Brabant on the east; by Hainault and Artois on the south; and by another part of Artois and the German sea on the west; being about 60 miles long, and 50 broad, and divided between the Austrians, the French, and the Dutch.

Flanders is a perfectly champaign country, with not a rising ground or hill in it, and watered with many fine rivers and canals. Its chief commodities are fine lace, linen, and tapestry.

In this country some important arts were invented and improved. Weaving in general was greatly improved, and that of figures of all sorts in linen were invented; also the art of dying cloths and stuffs, and of oil-colours; the curing of herrings, &c. The manufactures of this country are not now in the flourishing state they were formerly; yet, silk, cotton, and woollen stuffs, brocades, camlets, tapestry, lace, and linen, are still manufactured here in great quantities. This province had counts of its own from the ninth century to the year 1369, when it went by marriage to the dukes of Burgundy; and afterwards from them, by marriage also, to the house of Austria. France, in 1667, seized the southern part, and the States-General obtained the northern, partly by the treaty of Munster,

and partly by the barrier-treaty of 1715.

FLANEL, or **FLANNEL**, a loose sort of woollen stuff, not crossed, and woven on a loom like bays.

FLATMAN (Thomas), an English poet of some repute, born at London about the year 1633. He studied at the Inner-Temple, and became a barrister, but it does not appear that he ever practised; for having a turn for the fine arts, he gave a loose to his inclination that way, and acquired reputation both as a poet and a painter. He published, in 1782, a third edition of his poems and songs, dedicated to the duke of Ormond, with a print of himself as a frontispiece: he also published a fatirical romance in prose, on Richard Cromwell, soon after the restoration; which took greatly at that turn of affairs. He died about 1688.

FLATS, in music. See **INTERVAL**.

FLATUS, **FLATULENCE**, in medicine; vapours generated in the stomach and intestines, chiefly occasioned by a weakness of these parts. They occasion distensions, uneasy sensation, and sickness, and often a considerable degree of pain. See (the *Index* subjoined to) **MEDICINE**.

FLAVEL (John), an eminent nonconformist minister, was educated at University-college, in Oxford; and became minister of Deptford, and afterwards of Dartmouth, in Devonshire, where he resided the greatest part of his life, and was admired for his preaching. Though he was generally respected at Dartmouth; yet, in 1685, several of the aldermen of that town, attended by the rabble, carried about a ridiculous effigy of him, to which were affixed the Bill of Exclusion and the Covenant. Upon this occasion, he thought it prudent to withdraw from the town; not knowing what treatment he might meet with from a riotous mob, headed by magistrates who were themselves among the lowest of mankind. Part of his Diary, printed with his Remains, must give the reader a high idea of his piety. He died in 1691, aged 61; and after his death, his works, which consisted of many pieces of practical divinity, were printed in two volumes folio. Among these, the most famous are his "Navigation spiritualized, or a new Compass for Seamen, consisting of 32 points of pleasant observations and serious reflections," of which there have been several editions in octavo; and his "Husbandry spiritualized, &c. with occasional meditations upon beasts, birds, trees, flowers, rivers, and several other objects," of which also there have been many editions in octavo.

FLAX, in botany. See **LINUM**.

The following particulars with regard to the manner of raising flax has been for some years past warmly recommended by the trustees for fisheries, manufactures, and improvements in Scotland.

Of the choice of the Soil, and preparing the Ground, for FLAX. A skilful flax-raiser always prefers a free open deep loam, and all grounds that produced the preceding year a good crop of turnip, cabbage, potatoes, barley, or broad clover; or have been formerly laid down rich, and kept for some years in pasture.

A clay soil, the second or third crop after being limed, will answer well for flax; provided, if the ground be still stiff, that it be brought to a proper mould, by tilling after harvest, to expose it to the winter frosts.

All new grounds produce a strong crop of flax, and pretty

pretty free of weeds. When a great many mole-heaps appear upon new ground, it answers the better for flax after one tilling.

Flax-feed ought never to be sown on grounds that are either too wet or dry; but on such as retain a natural moisture: and such grounds as are inclined to weeds ought to be avoided, unless prepared by a careful summer-fallow.

If the lintseed be sown early, and the flax not allowed to stand for seed, a crop of turnip may be got after the flax that very year; the second year a crop of bear or barley may be taken; and the third year, grafs-seeds are sometimes sown along with the lintseed. This is the method mostly practised in and about the counties of Lincoln and Somerset, where great quantities of flax and hemp are every year raised, and where these crops have long been capital articles. There, old ploughed grounds are never sown with lintseed, unless the soil be very rich and clean. A certain worm, called in Scotland the *coup-worm*, abounds in new-broke up grounds, which greatly hurts every crop but flax. In small inclosures surrounded with trees or high hedges, the flax, for want of free-air, is subject to fall before it be ripe, and the droppings of rain and dew from the trees prevent the flax within the reach of the trees from growing to any perfection.

Of preceding crops, potatoes and hemp are the best preparation for flax. In the fens of Lincoln, upon proper ground of old tillage, they sow hemp, dunging well the first year; the second year, hemp without dung; the third year, flax without dung; and that same year, a crop of turnip eat on the ground by sheep; the fourth year, hemp with a large coat of dung; and so on for ever.

If the ground be free and open, it should be but once ploughed; and that as shallow as possible, not deeper than 2½ inches. It should be laid flat, reduced to a fine garden-mould by much harrowing, and all stones and fods should be carried off.

Except a little pigeon's dung for cold or sour ground, no other dung should be used preparatory for flax; because it produces too many weeds, and throws up the flax thin and poor upon the stalk.

Before sowing, the bulky clods should be broken, or carried off the ground; and stones, quickenings, and every other thing that may hinder the growth of the flax, should be removed.

Of the choice of Lintseed. The brighter in colour, and heavier the seed is, so much the better; that which when bruised appears of a light or yellowish green, and fresh in the heart, oily and not dry, and smells and tastes sweet, and not stinky, may be depended upon.

Dutch seed of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than any other foreign seed. Philadelphia-feed produces fine lint and few bolls, because sown thick, and answers best in wet cold soils. Riga-feed produces coarser lint, and the greatest quantity of seed. Scots-feed, when well winned and kept, and changed from one kind of soil to another, sometimes answers pretty well; but should be sown thick, as many of its grains are bad, and fail. It springs well, and its flax is sooner ripe than any other; but its produce afterwards is generally inferior to that from fo-

reign feed.

A kind has been lately imported, called *menmel-feed*; which looks well, is short and plump, but seldom grows above eight inches, and on that account ought not to be sown.

Of Sowing Lintseed. The quantity of lintseed sown, should be proportioned to the condition of the soil; for if the ground be in good heart, and the seed sown thick, the crop will be in danger of falling before it is ready for pulling. From 11 to 12 pecks Linlithgow measure of Dutch or Riga feed, is generally sufficient for one Scots acre; and about ten pecks of Philadelphia feed, which, being the smallest grained, goes farthest. Riga lintseed, and the next year's produce of it, is preferred in Lincolnshire.

The time for sowing lintseed is from the middle of March to the end of April, as the ground and season answers; but the earlier the seed is sown, the less the crop interferes with the corn-harvest.

Late sown lintseed may grow long, but the flax upon the stalk will be thin and poor.

After sowing, the ground ought to be harrowed till the seed is well covered, and then (supposing the soil, as before mentioned, to be free and reduced to a fine mould) it ought to be rolled.

When a farmer sows a large quantity of lintseed, he may find it proper to sow a part earlier and part later, that in the future operations of weeding, pulling, watering, and grafting, the work may be the easier and more conveniently gone about.

It ought always to be sown on a dry bed.

Of Weeding FLAX. It ought to be weeded when the crop is about four inches long. If longer deferred, the weeders will so much break and crook the stalks, that they will never perhaps recover their straightness again; and when the flax grows crooked, it is more liable to be hurt in the rippling and swingling.

Quicken-grafs should not be taken up; for, being strongly rooted, the pulling of it always loosens a deal of the lint.

If there is an appearance of a settled drought, it is better to defer the weeding, than by that operation to expose the tender roots of the flax to the drought.

How soon the weeds are got out, they ought to be carried off the field, instead of being laid in the furrows, where they often take root again, and at any rate obstruct the growth of the flax in the furrows.

Of Pulling FLAX. When the crop grows so short and branchy, as to appear more valuable for seed than flax, it ought not to be pulled before it be thoroughly ripe; but if it grows long and not branchy, the seed should be disregarded, and all the attention given to the flax. In the last case it ought to be pulled after the bloom has fallen, when the stalk begins to turn yellow, and before the leaves fall, and the bolls turn hard and sharp-pointed.

When the stalk is small, and carries few bolls, the flax is fine; but the stalk of coarse flax is gros, rank, branchy, and carries many bolls.

When the flax has fallen, and lies; such as lies ought to be immediately pulled, whether it has grown enough or not, as otherwise it will rot altogether.

When parts of the same field grow unequally, so that some parts are ready for pulling before other parts; only what is ready should be pulled, and the rest should

be suffered to stand till ready.

The flax-raiser ought to be at pains to pull, and keep by itself, each different kind of lint which he finds in his field; what is both long and fine, by itself; what is both long and coarse, by itself; what is both short and fine, by itself; what is both short and coarse, by itself; and in like manner every other kind by itself that is of the same size and quality. If the different kinds be not thus kept separate, the flax must be much damaged in the watering and the other succeeding operations.

What is commonly called under-growth may be neglected as useless.

Few persons that have seen pulled flax, are ignorant of the method of laying it in handfuls across each other; which gives the flax sufficient air, and keeps the handfuls separate and ready for the rippler.

Of Stacking up FLAX during the Winter, and Winning the Seed.

If the flax be more valuable than the seed, it ought by no means to be stacked up; for its own natural juice affords it greatly in the watering; whereas, if kept long unwatered, it loses that juice, and the harle adheres so much to the boon, that it requires longer time to water, and even the quality of the flax becomes thereby harsher and coarser. Besides, the flax stacked up over year, is in great danger from vermin and other accidents; the water in spring is not so soft and warm as in harvest; and near a year is thereby lost of the use of the lint: but if the flax be so short and branchy as to appear most valuable for seed, it ought, after pulling, to be stooked and dried upon the field, as is done with corn; then stacked up for winter, rippled in spring; and after shelling, the seed should be well cleaned from bad seeds, &c.

Of Rippling FLAX. After pulling, if the flax is to be regarded more than the seed, it should be allowed to lie some hours upon the ground to dry a little, and so gain some firmness, to prevent the skin or harle, which is the flax, from rubbing off in the rippling; an operation which ought by no means to be neglected, as the bolls, if put into the water along with the flax, breed vermin there, and otherwise spoil the water. The bolls also prove very inconvenient in the grassing and breaking.

In Lincolnshire and Ireland, they think that rippling hurts the flax; and therefore, in place of rippling, they strike the bolls against a stone.

The handfuls for rippling should not be great, as that endangers the lint in the rippling comb.

After rippling, the flax-raiser will perceive, that he is able to assort each size and quality of the flax by itself more exactly than he could before.

Of Watering FLAX. A running stream wastes the lint, makes it white, and frequently carries it away. Lochs, by the great quantity and motion of the water, also waste and whiten the flax, tho' not so much as running streams. Both rivers and lochs water the flax quicker than canals.

But all flax ought to be watered in canals, which should be digged in clay ground if possible, as that soil retains the water best: but if a firm retentive soil cannot be got, the bottom or sides of the canal, or both the bottom and sides, may be lined with clay; or, instead of lining the sides with clay, which might fall down, a ditch may be dug without the canal, and

filled with clay, which will prevent both extraneous water from entering, and the water within from running off.

A canal of 40 feet long, six broad, and four deep, will generally water the growth of an acre of flax.

It ought to be filled with fresh soft water from a river or brook, if possible two or three weeks before the flax is put in, and exposed all that time to the heat of the sun. The greater way the river or brook has run, the softer, and therefore the better, will the water be. Springs, or short-runs from hills, are too cold, unless the water is allowed to stand long in the canal. Water from coal or iron, is very bad for flax. A little of the powder of galls thrown into a glass of water, will immediately discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinged in proportion to the quantity of vitriol it contains.

The canal ought not to be under shade; which, besides keeping the sun from softening the water, might make part of the canal cooler than other parts, and so water the flax unequally.

The flax-raiser will observe, when the water is brought to a proper heat, that small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising on the surface. If no such signs appear, the water must not be warm enough, or is otherwise unfit for flax.

Moss-holes, when neither too deep nor too shallow, frequently answer well for watering flax, when the water is proper, as before described.

The proper season for watering flax is, from the end of July to the end of August.

The advantage of watering flax as soon as possible after pulling, has been already mentioned.

The flax being sorted after rippling, as before mentioned, should next be put in beets, never larger than a man can grasp with both his hands, and tied very slack, with a band of a few stalks. Dried rushes answer exceedingly well for binding flax, as they do not rot in the water, and may be dried and kept for use again.

The beets should be put into the canals slope-ways, or half standing upon end, the root-end uppermost. Upon the crop-ends, when aftermolt, there frequently breeds a deal of vermin, destructive of the flax, which is effectually prevented by putting the crop-end down-molt.

The whole flax in the canal ought to be carefully covered from the sun with divots; the grassy side of which should be next the flax, to keep it clean. If it is not thus covered, the sun will discolour the flax, tho' quite covered with water. If the divots are not weighty enough to keep the flax entirely under water, a few stones may be laid above them. But the flax should not be pressed to the bottom.

When the flax is sufficiently watered, it feels soft to the grip, and the harle parts easily with the boon or straw, which last is then become brittle, and looks whitish. When these signs are found, the flax should be taken out of the water, beet after beet; each gently rinsed in the water, to cleanse it of the natins which has gathered about it in the canal; and as the lint is then very tender, and the beet slackly tied, it must be

care-

Flax.

Flax.

carefully and gently handled,

Great care ought to be taken that no part be overdone; and as the coarsest waters soonest, if different kinds be mixed together, a part will be rotted, when the rest is not sufficiently watered.

When lint taken out of the canal is not found sufficiently watered, it may be laid in a heap, for 12, 18, or 24 hours, which will have an effect like more watering; but this operation is nice, and may prove dangerous in unskilful hands.

After the flax is taken out of the canal, fresh lint should not be put a second time into it, until the former water be run off, and the canal cleaned, and supplied with fresh water.

Of Grafting FLAX. Short heath is the best field for grafting flax; as, when wet, it fastens to the heath, and is thereby prevented from being blown away by the wind. The heath also keeps it a little above the earth, and so exposes it the more equally to the weather. When such heath is not to be got, links, or clean old lea-ground is the next best. Long-grass grounds should be avoided, as the grass growing thro' the lint frequently spots, tenders, or rots it; and grounds exposed to violent winds should also be avoided.

The flax, when taken out of the water, must be spread very thin upon the ground; and being then very tender, it must be gently handled. The thinner it is spread the better, as it is then the more equally exposed to the weather. But it ought never to be spread during a heavy shower, as that would wash and waste the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blither from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better.

Follows an Estimate of the Expence, Produce, and Profit of a Scots Acre of FLAX,—supposing the season favourable, that no accidental losses happen, and that the farmer is neither unskilful nor negligent.

There

If there be little danger of high winds carrying off the flax, it will be much the better of being turned about once a-week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp, requires a deal of ground, and enriches it greatly.

The skilful flax-raiser spreads his first row of flax at the end of the field opposite to the point from whence the most violent wind commonly comes, placing the root-ends foremost; he makes the root-ends of every other row overlap the crop-ends of the former row three or four inches, and binds down the last row with a rope; by which means the wind does not easily get below the lint to blow it away: and as the crop-ends are seldom so fully watered as the root-ends, the aforesaid overlapping has an effect like giving the crop-ends more watering. Experience only can fully teach a person the signs of flax being sufficiently grafted: then it is of a clearer colour than formerly; the harle is blithered up, and easily parts with the boon, which is then become very brittle. The whole should be sufficiently grafted before any of it is lifted; for if a part be lifted sooner than the rest, that which remains is in great danger from the winds.

A dry day ought to be chosen for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grafs, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be all equally watered and grafted, and as the different qualities will best appear at lifting the flax off the grafs; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and quality.

The smaller the beets lint is made up in the better for drying, and the more convenient for flacking, housing, &c. and in making up these beets, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root-ends together, and the crop-ends together.

Flax.

There is nothing stated here as expense of the canal in which the flax is watered; because that varies much according to the conveniencies people have for making it; and a canal once made requires for after-years only to be repaired and cleansed.

It is a certain fact, that the greater the crop is, the better is the quality of the same kind of flax.

The advantage of having both a crop of flax and a crop of turnip the same year—or of sowing grafs-seeds along with the lintseed—and of reducing the ground to a fine garden mould, free of weeds, ought to be attended to.

For Cambrick and fine Laven. The ground must be a rich light soil, rather sandy, but cannot be too rich.

It ought to be ploughed in September, or the beginning of October, first putting a little hot rotten dung upon it. In January it ought to have a second ploughing, after a hard frost; and when you intend to sow it, plough it a third time, or rather hoe it, reducing the clods very fine; but make no furrows: the land must be made level like a garden; but never work the land when wet.

The seed should be sown the beginning of April, and about double the quantity that is generally sown by our farmers; if the land be very rich, it will require rather more than double.

As soon as sown (if the weather be dry) it will be necessary to roll the ground.

The lint must be weeded very clean when about three inches high; directly after which you must set forked sticks, of about one-and-half inch thick (which ought to be prepared before) every four or five feet, according to the length of the poles you are to lay upon them; they should be well fixed in the ground, the forked part to receive the poles about six or seven inches above the lint; each row of poles should be two, three, or four feet asunder, according to the length of the brushwood you are to lay upon them.

The poles ought to be from 10 to 15 feet long, and strong enough to support the brush across the poles; take the longest brushwood you can get, the more branchy the better, very thick, filling up the vacancies with smaller brush, and any of the branches that rise higher than 18 or 20 inches ought to be lopped off to make the brush lie as level as possible: any sort of brush will do except oak, as that tinges the lint.

Your lint must be pulled as soon as the seed is fully formed, which is a few days after it is out of the bloom before the lint turn yellow.

It must be pulled above the brushwood, and every handful laid upon it as soon as possible: if it is fine weather, leave it four or five hours in that manner; then carry it to a screen near a barn, to put it under cover in case of rain; there it must be spread four or five days, and always put in the barn at night, or when it appears to rain: the bundles must be opened in the barn, or made hollow, to prevent it from heating.

These operations must be performed until the lint is perfectly dry, and out of danger of heating; taking care all the time to keep the roots as even as possible, and if possible keep it from rain or wet: if you cannot prevent it from being wet, it will be better to leave it on the grafs till dry; because when once wet, the putting it under cover before dry, will make it turn black; a thing which must be prevented at all events.

Flax.

If any of the lint upon the border, or through the piece of ground, be coarser than another, it must be separated from the rest.

The utmost care must be taken to preserve the lint entire, or unbroken; for this reason they beat off the seed with a round mell or bittle.

The most proper ground is summer-fallow, or after potatoes, or lea; if possible near a wood, to prevent the expence of carrying brush.

As soon as the seed is off, if you intend to water it that season, it must be tied in bundles about as large as you can grasp with your two hands.

The water proper for it, is a very small rivulet or soft spring free of any metallic ore; taking care that no flood or foul water enters your pit; which must be at least five feet deep, about nine or ten broad at the top, and seven or eight at the bottom, the length will depend on the quantity of flax you have to water. A very small stripe of water, when clear, should always be running in and off from your pit when the lint is in it.

The pit ought to be made three or four months before it be used.

You must drive poles about four inches thick, with a hook inclining downwards, in this form 7, all along the sides of the pit, about five feet asunder. The hooks must be level with, or rather under, the surface of the water. A long pole, the whole length of the pit, must be fixed into these hooks on each side; and cross poles put under that, to keep the lint under water; but, the cross poles are not used till the lint is put in. You must order it so, that all the lint should be three or four inches under water. You next bring your lint to the sides of the pit; then put your sheaves head to head, causing each to overlap the other about one third, and take as many of these as make a bundle of two or two-and-a-half feet broad, laying the one above the other, till it is about four or four-and-a-half feet high; then you tie them together in the middle, and at each root-end: after this, you wrap your bundle in straw, and lay it in the water, putting the thin or broad side undermost, taking care that none of your lint touch the earth; after it is fully pressed under water, put in your cross poles to keep it under. The bundles ought to lie in the pit a foot separate from each other. This renders it easy to take out; for, if the bundles entangle, they will be too heavy to raise.

The time of watering depends so much upon the weather, and softness or hardness of the water, that it is impossible to fix any certain time. This must be left to the skill of the farmer. If the flax be intended for spinning yarn soft and fit for cambrick, it ought to be spread upon short grafs for four or five days before you put it into the water; but if for lawns, lace, or thread, it is best to dry it outright. In either case, avoid as much as possible to let it get rain; as much rain blanches and washes out the oil, which is necessary to preserve the strength.

The great property of this flax is to be fine and long. Thick sowing raises all plants fine and slender; and when the ground is very rich, it forces them to a great length. Pulling green prevents that coarse hardness which flax has when let stand till it be full ripe, and gives it the fine silky property. The brushwood, when the flax springs up, catches it by the middle,

Flax.

de, prevents it from lying down and rotting; infallible consequences of sowing thick upon rich ground. It likewise keeps it straight, moist, and soft at the roots; and by keeping it warm, and shaded from the sun, greatly promotes its length. The keeping it from rain, heating, taking proper care of your water, preserves the colour, and prevents those bars in cloth so much complained of by bleachers.

FLAX-DRESSING. For many ages it was the practice to separate the boon or core from the flax, which is the bark of the plant, by the following simple *hand methods*. First, for breaking the boon, the stalks in small parcels were beat with a mallet; or, more dexterously, the *break* (Plate CX. fig. 1. and 2.) was used thus: The flax being held in the left-hand a-crofs the three *under-teeth* or *swords* of the break (A, fig. 1. and a, fig. 2.), the *upper-teeth* (B, fig. 1. and b, fig. 2.) were with the right-hand quickly and often forced down upon the flax, which was artfully shifted and turned with the left-hand. Next, for clearing the flax of the broken boon: the workman with his left-hand held the flax over the *stock* (fig. 3. and 4.) while with his right-hand he struck or threshed the flax with the *scutcher* (fig. 5.).

These methods of breaking and scutching the flax being slow and very laborious, a *water-mill* was invented in Scotland about 40 years ago; which, with some late improvements, makes great dispatch, and in skilful and careful hands gives satisfaction. It has been generally constructed to break the boon by three dented rollers, placed one above the other. The middle one of which, being forced quickly round, takes the other two along with it, and one end of the handfuls of the flax being by the workman directed in between the upper and middle rollers, the flax is immediately drawn in by the rollers; a curved board or plate of tin behind the rollers directs the flax to return again between the middle and undermost rollers;—and thus the operation is repeated until the boon be sufficiently broke. Great weights of timber or stone at the ends of levers, press the upper and under rollers towards the middle one.

The scutching is next carried on by the mill in the following manner: Four arms, something like the hand-scutchers before described, project from a perpendicular axle; a box around the axle incloses these projecting scutchers; and this box is divided among the workmen, each having sufficient room to stand and handle his flax, which, through slits in the upper part and sides of the box, they hold in to the stroke of the scutchers; which, moving round horizontally, strike the flax a-crofs or at right angles, and so thresh out or clear it of the boon.

The breaking of the flax by *rollers* is scarcely subject to any objection, but that it is dangerous to workmen not sufficiently on their guard, who sometimes allow the rollers to take hold of their fingers, and thereby their whole arm is instantly drawn in: thus many have lost their arms. To avoid this danger, a break upon the general principles of the hand-break before described, has been lately adapted to water-machinery, and used in place of rollers. The horizontal stroke of the scutchers was long thought too severe, and wasteful of the flax; but very careful experiments have discovered that the waste complained

Flax.

of must be charged to the unskilfulness or negligence of the workmen, as in good hands the mill carries away nothing but what, if not so scutched off, must be taken off in the heckling with more loss both of time and flax. But to obviate this objection of the violence of the *horizontal scutchers*, an imitation of hand-scutching has lately been applied to water. The scutchers then project from an horizontal axle, and move like the arms of a check-reel, striking the flax neither across nor perpendicularly down, but sloping in upon the parcel exactly as the flax is struck by the hand-scutcher. This sloping stroke is got by raising the scutching-stock some inches higher than the centre of the axle; and by raising or lowering the stock, over which the flax is held, or screwing it nearer to or farther from the scutchers, the workman can temper or humour the stroke almost as he pleases.

A lint-mill with horizontal scutchers upon a perpendicular axle, requires a house of two stories, the rollers or break being placed in the ground story, and the scutchers in the loft above; but a mill with vertical scutchers on an horizontal axle, requires but one ground story for all the machinery.

Another method of breaking and scutching flax, more expeditious than the old hand-methods, and more gentle than water-mills, has also been lately invented in Scotland. It is much like the break and scutcher giving the sloping stroke last described, moved by the foot. The treddle is remarkably long, and the scutchers are fixed upon the rim of a fly-wheel. The foot-break is also assisted in its motion by a fly. These foot-machines are very useful where there are no water-mills, but they are far inferior to the mills in point of expedition.

The next operation that flax undergoes after scutching is heckling. The *heckle* (fig. 6.) is firmly fixed to a bench before the workman, who strikes the flax upon the teeth of the heckle, and draws it through the teeth. To persons unacquainted with that kind of work this may seem a very simple operation; but, in fact, it requires as much practice to acquire the slight of heckling well, and without wasting the flax, as any other operation in the whole manufacture of linen. They use coarser and wider toothed heckles, or finer, according to the quality of the flax; generally putting the flax thro' two heckles, a coarser one first, and next a fine one.

Flax for cambric and fine lawn, thread, and lace, is dressed in a manner somewhat different. It is not sketched so thoroughly as common flax; which from the sketch proceeds to the heckle, and from that to the spinner: whereas, this fine flax, after a rough sketching, is scraped and cleaned with a blunt knife upon the workman's knee covered with his leather-apron; from the knife it proceeds to the spinner, who, with a brush made for the purpose, straightens and dresses each parcel just before he begins to spin it.

FLAX made to resemble Cotton. In the Swedish transactions for the year 1747, a method is given of preparing flax in such a manner as to resemble cotton in whiteness and softness, as well as in coherence. For this purpose, a little sea-water is to be put into an iron pot or an untinned copper-kettle, and a mixture of equal parts of birch-ashes and quicklime strewed upon it: A small bundle of flax is to be opened

and

and spread upon the surface, and covered with more of the mixture, and the stratification continued till the vessel is sufficiently filled. The whole is then to be boiled with sea-water for ten hours, fresh quantities of water being occasionally supplied in proportion to the evaporation, that the matter may never become dry. The boiled flax is to be immediately washed in the sea by a little at a time, in a basket, with a smooth stick: When grown cold enough to be borne by the hands, it must be well rubbed, washed with soap, laid to bleach, and turned and watered every day. Repetitions of the washing with soap expedite the bleaching; after which the flax is to be beat in again well washed; when dry, it is to be worked and carded in the same manner as common cotton, and pressed betwixt two boards for 48 hours. It is now fully prepared and fit for use. It loses in this process near one half its weight, which is abundantly compensated by the improvement made in its quality.

Earth-Flax. See AMIANTHUS.

New-Zealand Flax-Plant. See PHORMIUM.

FLEA, in zoology. See PULEX,

FLEA-Bane, in botany. See CONYZA.

FLEA-Bitten, that colour of a horse, which is white or grey, spotted all over with dark reddish spots.

FLEAM, in surgery and farriery, an instrument for letting blood of a man or horse. A case of fleams, as it is called by farriers, comprehends six sorts of instruments; two hooked ones, called *drawers*, and used for cleaning wounds; a pen-knife; a sharp-pointed lancet, for making incisions; and two fleams, one sharp and the other broad pointed. These last are somewhat like the point of a lancet, fixed in a flat handle, and no longer than is just necessary to open the vein.

FLECHIER (Efpit), bishop of Nîmes, one of the most celebrated preachers of his age, and the publisher of many panegyrics and funeral orations, was born at Perne in Avignon, in 1632. He was nominated to the bishoprick of Lavaur in 1685, and translated to Nîmes in 1687. At this latter place he founded an academy, and took the presidentship upon himself: his own palace was indeed a kind of academy, where he applied himself to train up orators and writers, who might serve the church, and do honour to the nation. He published, besides his panegyrics and funeral orations, 1. An history of the emperor Theodosius, that of cardinal Ximenes, and that of cardinal Commendon. 2. Several sermons. 3. Miscellaneous works. 4. Letters, &c. He died in 1710.

FLECKNOE (Richard), an English poet in the reign of Charles II. more remarkable for Mr Dryden's satire on him, than for any works of his own. He is said to have been originally a jesuit, and to have had good English connexions in the Catholic interest. When Dryden lost the place of poet-laureat on the revolution, its being conferred on Flecknoe, for whom he had a settled aversion, gave occasion to his poem intitled *Mac Flecknoe*, one of the best-written satires in our language, and from which Pope seems to have taken the hint for his Dunciad. Flecknoe wrote some plays; but could never get more than one of them acted, and that was damned.

FLEECE, the covering of gold shorn off the bodies of sheep. See WOOL.

VOL. IV.

GOLDEN FLEECE. See GOLDEN FLEECE.

FLEET, commonly implies a company of ships of war, belonging to any prince or state: but sometimes it denotes any number of trading ships, employed in a particular branch of commerce.

The admirals of his Britannic majesty's fleet are divided into three squadrons, viz. the red, the white, and the blue. When any of these officers are invested with the command of a squadron or detachment of men of war, the particular ships are distinguished by the colours of their respective squadron: that is to say, the ships of the red squadron wear an ensign whose union is displayed on a red field; the ensigns of the white squadron have a white field; and those of the blue squadron, a blue field; the union being common to all three. The ships of war therefore are occasionally annexed to any of the three squadrons, or shifted from one to another.

Of whatsoever number a fleet of ships of war is composed, it is usually divided into three squadrons; and these, if numerous, are again separated into divisions. The admiral, or principal officer, commands the centre; the vice-admiral, or second in command, superintends the van-guard; and the operations of the rear are directed by the rear-admiral, or the officer next in rank. See the article DIVISION.

The disposition of a fleet, while proceeding on a voyage, will in some measure depend on particular circumstances; as the difficulty of the navigation; the necessity of dispatch, according to the urgency or importance of the expedition; or the expectation of an enemy in the passage. The most convenient order is probably to range it into three lines or columns, each of which is parallel to a line close-hauled according to the tack on which the line of battle is designed to be formed. This arrangement is more useful than any, because it contains the advantages of every other form, without their inconveniences. The fleet being thus more inclosed will more readily observe the signals, and with greater facility form itself into the line of battle; a circumstance which should be kept in view in every order of sailing. See NAVAL TACTICS.

FLEET, is also a noted prison in London, where persons are committed for contempt of the king and his laws, particularly of his courts of justice: or for debt, where any person will not or is unable to pay his creditors.

There are large rules and a warden belonging to the fleet prison; which had its name from the float or fleet of the river or ditch, on the side whereof it stands.

FLEETWOOD (William), a very learned English bishop in the beginning of the 18th century, of an ancient family in Lancashire. He distinguished himself during king William's reign, by his *Inscriptionum Antiquarum Sylloge*, by several sermons he preached on public occasions, and by his *Essay on Miracles*. He was designed by king William to a canonry of Windsor: the grant did not pass the seals before the king's death, but the queen gave it him, and he was installed in 1702. In 1703, he took a resolution to retire; and in 1707, published, without his name, his *Chronicon Pretiosum*. In 1708, he was nominated by the queen to the see of St Asaph. The change of the queen's ministry gave him much regret. In 1715, he published a pamphlet intitled "The 13th chapter of the Ro-

Flemish
Fleur.

Flexible
Flintshire.

mans vindicated from the abusive senses put upon it." In 1714, he was translated to the bishopric of Ely; and died in 1723, aged 67. He published several other sermons and tracts, and was a man of great learning and exemplary piety.

FLEMISH, or the **FLEMISH TONGUE**, is that which we otherwise call *low Dutch*, to distinguish it from the *German*, whereof it is a corruption and a kind of dialect. See **GERMAN**.

It differs from the *Walloon*, which is a corruption of the French language. The *Flemish* is used thro' all the provinces of the Netherlands.

FLEMISH-Bricks, a neat, strong, yellow kind of bricks, brought from Flanders, and commonly used in paving yards, stables, &c. being preferable for such purposes to the common bricks. See the article **BRICK**.

FLESH, in anatomy, a similar, fibrous part of an animal body, soft and bloody, being that whereof most of the other parts are composed, and whereby they are connected together: or more properly, it is such parts of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

FLETA, the name given to an unknown writer who lived about the end of the reign of Edward II. and beginning of Edward III. and who being a prisoner in the Fleet, wrote there an excellent treatise on the common law of England.

FLETCHER. See **BRAUMONT** and *Fletcher*.

FLETEWOOD (William), an eminent English lawyer and recorder of London, in the reign of queen Elizabeth. He was very zealous in suppressing mas-houses, and committing Popish priests: but once rushing in upon mas at the Portuguese ambassador's house, he was committed to the Fleet for breach of privilege, but soon released. Mr Wood says, "He was a learned man, and a good antiquary, but of a marvellous merriness and pleasant conceit." "He was a good popular speaker, and wrote well upon subjects of government. His principal works are, 1. *Annalium tan regum Edwardi V. Richardi III. & Henrici VII. quam Henrici VIII.* 2. A table of the reports of Edmund Plowden. 3. The office of a justice of peace. He died about the year 1593.

FLEURI (Claude), one of the best French critics and historians of his age, was born at Paris in 1640. He applied himself to the law, was made advocate for the parliament of Paris, and attended the bar nine years; he then entered into orders, and was made preceptor to the princes of Conti. In 1689, the king made him sub-preceptor to the dukes of Burgundy, Anjou, and Berry; and in 1706, when the education of these young princes was completed, the king gave him the priory of Argenteville belonging to the Benedictines in the diocese of Paris. In 1716, he was chosen counsellor to Lewis XV. and died in 1723. He was the author of a great number of esteemed French works, the principal of which are, 1. An ecclesiastical history, in 20 volumes, the last of which ends with the year 1414. 2. The manners of the Israelites and Christians. 3. Institutions of ecclesiastical law. 4. An historical catechism. 5. On the choice and method of study. 6. The duties of masters and servants, &c.

FLEURI (Andrew Hercules de), bishop of Frejus,

preceptor to Lewis XV. grand almoner to the queen, cardinal, and minister of state, was born in 1653, and died in 1743. He was an able negotiator; and distinguished himself during his ministry by his probity, his zeal for the happiness of his country, and his pacific disposition.

FLEXIBLE, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

FLEXOR, in anatomy, a name applied to several muscles, which are so called from their office, which is to bend the parts to which they belong; in opposition to the *extensor*, which open or stretch them. See **ANATOMY**, n° 83, p. o, p, q.

FLINT, in natural history, a kind of semi-transparent, or quite opaque stones; generally of a roundish form, and covered with white crust; of a smooth, uniform, shining texture; so hard, that they will strike fire with steel; calcinable by fire, after which they become white, friable, and, according to Hemckel, heavier than before, and soluble by acids; vitrifiable only by the very violent heat of the largest speculums, such as that of Villette, and not even by the focus of one of Tschirnhausen's lenses, according to an experiment of Neumann. They are found generally in beds of chalk and of sand; but never forming entire strata of rock as Jasper does. By long exposure to air and the sun, they seem to decay, to lose their lustre, their firmness of texture, and to be changed to a white calcareous earth or chalk. Hence they are almost always found covered with a white chalky crust. They are also convertible into a calcareous earth by fusion, or vitrification with so much fixed alkali, that they shall resolve into a liquid mass called the *liquamen* or *oil of flint*, and by precipitation from the fixed alkali by means of acids. See **CHEMISTRY**, n° 338.

FLINTS are of the class of earths called *vitrifiable*, because these earths are generally employed, together with fixed alkali, as materials in the making of glass. See **GLASS**.

Breaking of FLINTS. The art of cutting, or rather breaking, flint-stones into uniform figures, is by some supposed to be one of the arts now lost. That it was known formerly, appears from the ancient Bridewell at Norwich, from the gate of the Augustin friars at Canterbury, that of St John's Abbey at Colchester, and the gate near Whitehall Westminster. But that the art is not lost, and that the French know it, appears from the platform on the top of the royal observatory at Paris; which, instead of being leaded, is paved with flint cut or broke into regular figures. But we know not that this art hath been any where described.

FLINTSHIRE, a county of Wales, bounded on the north by the Irish sea and the river Dee, on the east by Cheshire, and every where else by Denbighshire and Shropshire. It is the least of all the counties of Wales, extending in length between 20 and 30 miles, and in breadth about eight. It is divided into five hundreds; and contains about 28 parishes, and 32,000 inhabitants. The air is healthful, but pretty sharp; the soil is tolerably fertile, especially in the valleys, producing plenty of wheat, barley, oats, and rye. A considerable number of cattle are reared in this county, but they are of a small size. There is plenty of honey, of which the inhabitants make mead, theglin,

Float
Floralia.

theelin, a drink much used in Wales. Here are also pit-coal, lead-ore, mill-stones, fish and fowl, but little wood or fruit.

FLOAT, a certain quantity of timber bound together with rafters athwart, and put into a river to be conveyed down the stream; and even sometimes to carry burdens down a river with the stream.

FLOAT-Boards, those boards fixed to water-wheels of under-shot mills, serving to receive the impulse of the stream, whereby the wheel is carried round. See the articles **WHEEL** and **MILL**.

It is no advantage to have too great a number of float-boards; because, when they are all struck by the water in the best manner that it can be brought to come against them, the sum of all the impulses will be but equal to the impulse made against one float-board at right angles, by all the water coming out of the penstock through the opening, so as to take place on the float-board. The best rule in this case is, to have just so many, that each of them may come out of the water as soon as possible, after it has received and acted with its full impulse. As to the length of the float-board, it may be regulated according to the breadth of the mill. See the article **MILL**.

FLOATS for Fishing. See **FISHING-Floats**.

FLOATAGES, all things floating on the surface of the sea or any water; a word much used in the commissions of water-bailiffs.

FLOATING-Bridge. See **BRIDGE**.

FLOOD. See **DELUGE**.

Deucalion's Flood. See **DEUCALION**.

FLOOKING, among miners, a term used to express a peculiarity in the load of a mine. The load, or quantity of ore is frequently intercepted in its course by the crossing of a vein of earth or stone, or some different metallic substance; in which case the load is moved to one side, and this transient part of the land is called a *flooking*.

FLORA, the goddess of flowers, was, according to the poets, the wife of Zephyrus, and was first honoured among the Sabines; but, according to Lactantius, she was a lady of pleasure, who, having gained large sums of money by prostituting herself, made the Roman people her heir, on condition that certain games, called *Floralia*, might be annually celebrated on her birth-day. Her image in the temple of Castor and Pollux was dressed in a close habit, and she held in her hands the flowers of pease and beans: but the modern poets and painters have been more lavish in setting off her charms, considering that no parts of nature offered such innocent and exquisite entertainment to the sight and smell, as the beautiful variety which adorns, and the odour which embalms, the floral creation.

FLORALIA, in Roman antiquity, a festival in honour of Flora, observed on the 29th of April, or the fifth of the calends of May, at which time games were celebrated in the Campus Martius, which were proclaimed by sound of trumpet. These games were celebrated in a very scandalous manner: and were in some sense the festival of the courtizans. To hide the shameful origin of this festival, the senate made the people believe Flora was a goddess, who presided over flowers; and that, in order to have a good crop, it was necessary to honour that goddess every year.

Floor,
Florence.

FLOOR, in architecture, the under side of a room, or that part we walk on.—Floors are of several sorts; some of earth, some of brick, some of stone, and some of wood. See **ARCHITECTURE**, n° 116. and **PAVING**.

Floor of a Ship, as much of her bottom as the keels upon which she rests on the ground.—Such ships as have long and broad floors, lie on the ground with most security; and those that are narrow in the floor cannot be grounded without danger either of being overfet, or at least of hurting their sides.

FLORENCE, one of the states of Tuscany in Italy; a most celebrated republic, to which Europe is in the highest degree indebted for the revival of the arts and sciences after they had been long lost.

The ancient history of Florence is comprehended under that of **ETRURIA** and **ROME**. Its modern history commences most properly at the time of *Alboino*, king of the Lombards, who made himself master of Tuscany, and almost all Italy. Those people continued to enjoy their dominion for 204 years, when they were driven out by Charles the Great. He was crowned and confirmed king of Italy by the pope about the year 773; after which, the governments of the several states of that country began to recover some degree of regularity and consistency. The original families of Italy, and the descendants of the various clans of barbarians who had inhabited it, were now blended into one common mass; and the feudal laws, which were of Gothic original, and then prevailed over all Italy, gave the leading men or magistrates of each state a degree of authority very little inferior to that of the king. All that Charles required, was the payment of certain tributes, or what we call *reddendos*, as marks of his sovereignty; and he left them in other respects to make the most of their situation and natural powers. Of these states, the most eminent were Florence, Pisa, Perugia, and Sienna, each of which had a particular manner of cultivating its interest. The Pisans applied themselves to maritime affairs, being the only maritime city of Tuscany that was left standing. The Perugians applied themselves to agriculture, to which they were encouraged by the fertility of their soil. The Siennese had a rich nobility, who maintained them in affluence: but the Florentines were distinguished over all the other inhabitants of Tuscany, by their industry, their knowledge of the civil arts, and their uncommon strength of genius.

For some time those states lived together in great harmony; but this was soon interrupted by the disputes between the popes and the emperors of Germany. In these contentions, Florence was subdued by the emperor Frederic II. He governed in so tyrannical a manner, that, after his death, the Florentines conceived such an insuperable aversion against monarchical government, that from thenceforth Florence became a republic. The people took the direction of affairs upon themselves; and the wisdom, spirit, and steadiness, with which they proceeded upon their new model, are almost incredible. They first recalled, and reinstated in their former honours, the noblemen whom Frederic had banished. They next made choice of 12 magistrates, whom they called *antiani*. They divided their city into six wards, from which their magistrates and all public officers were to be elected. They instituted a militia out of these wards, properly regulated; in or-

der to oppose all factious designs of their nobles at home, and to repel all attacks from abroad. Every one of the magistrates was a patriot; and Florence soon began to distinguish itself among the states of Italy, as formerly Athens did among those of Greece.

It is natural to think, that a small state, so circumstanced and regulated, would soon be involved in wars both foreign and domestic. This indeed actually happened. The Florentines were engaged in almost perpetual wars with their neighbours; and when these ceased, internal dissensions generally supplied their place. Though greatly celebrated by historians for their valour, these republicans never could make any permanent conquest over their neighbours, or extend their territories in any considerable degree. Nay, they were often in the utmost danger of being totally destroyed, had not some lucky accidents seasonably intervened. In these endless wars, they were supported by the very extensive commerce they carried on, and by which they acquired incredible wealth. But, after commerce had begun more generally to diffuse itself, the Florentines began to lose very considerably of the importance among other nations which they had till then maintained. In 1531, they were compelled to submit to the troops of the emperor Charles V. after a severe siege; and at this time ended the republican government of the city. Alexander de Medici, after marrying the natural daughter of Charles V. was by him made sovereign of Florence. He pretended to govern by the advice of a council of Florentine citizens; but, in fact, behaved so tyrannically, that he was murdered in a short time; and succeeded by Cosmo, son of John de Medici, who had become extremely popular on account of the bravery he had shown in the French and Spanish service. He first obtained the title of *Grand Duke of Tuscany*; and, as such, was crowned at Rome by pope Pius V. who bestowed the title upon him. He married Eleanora de Toledo, daughter to the duke of Naples; by which connection he established his authority so well, that the Florentines never thought of throwing off the yoke. He attached himself to the interest of the Imperialists; under whose protection he and his successors lived securely, till the time of Cosmo III. who embraced the French interest. This prince, in his youth, had paid a visit to the English court in the time of Charles II. and always professed a great deal of friendship for the family of Stuart. We do not find, however, that he was very liberal in contributing towards the efforts made for replacing king James on the throne of Britain, though often applied to for that purpose. He affected, however, to be the head and patron of all the Roman Catholics in Great Britain, and he exerted all his interest with foreign courts in their behalf. Being a complete politician, his success in this was incredible; and it was primarily owing to him, that the papists met with such indulgences as they did, even after the accession of king George I. He was a great patron of learning and learned men; and his favourite study was chemistry, nor could his friends oblige him more than by sending for medicines prepared in his laboratory by himself. He was courted by all the princes of Europe; and could be called unhappy only in the prospect of his race being extinct with his son, who had no hopes of issue, and was the last of the family. This consideration probably rendered him in-

different to all the stipulations preceding the Quadruple Alliance in 1718; by the fifth article of which, the duchies of Tuscany, Parma, and Placentia, were to be accounted for ever as male-heirs of the empire, and were to descend, in default of male-heirs, to the queen of Spain's eldest son. To alleviate, however, any chagrin which might be conceived at this article, it was also stipulated, that, during the lives of the possessors of Tuscany and Parma, no forces of any country whatsoever, whether their own or hired, should, by the emperor, the kings of France and Spain, or even by the prince appointed to the succession, be introduced into any garrison, city, port, or town, of those duchies. Yet, notwithstanding this article, it was resolved, that, for the security of the succession, 6000 Swiss were to be put into Leghorn, Porto Ferraro, Parma, and Placentia.—Cosmo did not long survive this definition of his dominions; but died, the most aged prince in Christendom, in 1723. He was succeeded by his son Gaston, whose character and manner of life greatly resembled those of his father. He presented memorials against the Quadruple Alliance at the Congress at Cambray. King George I. declined the sole mediation at this congress which was offered him; upon which the emperor, without the consent of the empire, granted the investiture of the duchies of Tuscany, Parma, and Placentia, to the queen of Spain's eldest son, in case these dukedoms should be vacant for want of heirs. These stipulations were enforced by the treaty of Seville in 1728; by which, also, great numbers of foreign troops were to be introduced into different cities within these duchies. This treaty was guaranteed by Spain, Great Britain, France, and the States-General; but was complained of by the court of Vienna as a breach of an article in the Quadruple Alliance. In the year 1731, however, the great duke, who had conceived an invincible aversion against the house of Austria, not only ratified all the stipulations with regard to the succession, but, in consequence of a new treaty, invited Don Carlos, the apparent successor, over to Florence to be educated.—In a few years, however, the emperor lost Naples and Sicily; and his son-in-law, the duke of Lorraine, was named to the succession of Tuscany, while his duchy of Lorraine was annexed to the crown of France. Duke Gaston, in the mean time, was so much decayed in person and intellects, that he took little or no concern about these proceedings; nor did he even make any remonstrances against the Imperial court, who ordered a body of troops to move towards his dominions, in order to drive out the Spaniards, which they accordingly did. He died in July 1737; and the duke of Lorraine instantly seized on his dominions. The queen of Spain could not bear the thoughts of having such a noble acquisition as the duchy of Tuscany torn from her family, and therefore endeavoured to engage the court of Great Britain to assist her in recovering it. To this end she promised, that her husband should renounce all pretensions to Gibraltar and Portmahon, and that the differences subsisting with regard to America should be adjudged. This proposal, however, was rejected; and a war ensued between Great Britain and Spain, and the duke of Lorraine (late emperor of Germany) was suffered to possess the duchy of Tuscany without opposition. Since that time the Florentines have made no figure in history, nor are they

likely

Florence
Florida.

likely to do so for a long time to come. In the year 1753 it was resolved, that the whole military force of the great duchy should consist only of three regiments of foot, and one of dragoons, of 500 men each. To support this establishment, a French company offered to farm the revenues of the duchy; but his imperial majesty rejected the proposal, and fixed upon another company composed of his own subjects, to manage the revenues under the direction of M. Richard, a gentleman of Lorraine. By this new institution, the finances of the duchy were divided into 20 shares, one half of which his imperial majesty reserved to himself. By those, and other frugal measures, the emperor was enabled to erect a college for the improvement of agriculture at Florence; a science to which the Florentines are peculiarly adapted. In the year 1755, he raised another regiment of dragoons, and regimented his militia. The duchy is now governed by a council of regency, a military board, and other officers of state; who have made a number of excellent regulations, by which, during the late war, his imperial majesty was enabled to draw many useful recruits from the grand duchy of Tuscany, who did him great service in his armies.

FLORENCE, the capital of the duchy of Tuscany, and one of the finest cities in Italy. It is divided into two by the river Arno, over which are built several magnificent bridges. It is surrounded on all sides but one with high hills, which rise insensibly, and at last join with the lofty mountains called the *Appennines*. Towards Pisa, there is a vast plain of 40 miles in length; which is so filled with villages and pleasure-houses, that they seem to be a continuation of the suburbs of the city. The circumference about the walls is near six English liatute-miles; and it contains about 9000 houses, great part of which are built uniformly of stone, and many of them surprisingly large and beautiful. According to some, the palaces of Florence are the best built of any in Italy. E. Long. 12. 24. N. Lat. 43. 34.

FLORENCE, an ancient piece of English gold coin. Every pound weight of standard-gold was to be coined into 50 Florences to be current at six shillings each; all which made in tale 15 pounds; or into a proportionate number of half-Florences or quarter-pieces, by indenture of the mint: 18 Ed. III.

FLORENTINE MARBLE. See CITADENESCA.

FLORESCENTIA, (from *floresco*, "to flourish or bloom;") the act of flowering, which Linnæus and the sexualists compare to the act of generation in animals; as the ripening of the fruit in their opinion resembles the birth. See FLOWER.

FLORID STYLE, is that too much enriched with figures and flowers of rhetoric.

FLORIDA, the most southerly province of the British empire in America, bounded on the south by the Gulf of Mexico, on the north by the Apalachian mountains, on the east by the province of Georgia, and on the west by the river Mississippi. It was first discovered, in 1497, by Sebastian Cabot, a Venetian, then in the English service; whence a right to the country was claimed by the kings of England; and this province, as well as Georgia, were included in the charter granted by Charles II. to Carolina. In 1512, however, Florida was more fully discovered by Ponce de Leon, an able Spanish navigator, but who

undertook his voyage from the most absurd motives that can be well imagined.—The Indians of the Caribbee islands had among them a tradition, that somewhere on the continent there was a fountain whose waters had the property of restoring youth to all old men who tasted them. The romantic imaginations of the Spaniards were delighted with this idea. Many embarked in voyages to find out this imaginary fountain, who were never afterwards heard of. Their superstitious countrymen never imagined that these people had perished. They concluded that they did not return, only because they had drunk of the immortalizing liquor, and had discovered a spot so delightful, that they did not choose to leave it.—Ponce de Leon set out with this extravagant view as well as others, and fully persuaded of the existence of a third world, the conquest of which was to immortalize his name. In the attempt to discover this country, he rediscovered Florida; but returned to the place from whence he came, visibly more advanced in years than when he set out.—For some time this country was neglected by the Spaniards, and some Frenchmen settled in it. But, the new colony being neglected by the ministry, and Philip II. of Spain having accustomed himself to think that he was the sole proprietor of America, fitted out a fleet at Cadiz to destroy them. His orders were executed with barbarity. The French entrenchments were forced, and most of the people killed. The prisoners were hanged on trees; with this inscription, "Not as Frenchmen, but as Heretics."

This cruelty was soon after revenged by Dominic de Gourgues, a skilful and intrepid seaman of Gascony, an enemy to the Spaniards, and passionately fond of hazardous expeditions and of glory. He held his estate; built some ships; and with a select band of adventurers like himself, embarked for Florida. He drove the Spaniards from all their posts with incredible valour and activity; defeated them in every encounter; and, by way of retaliation, hung the prisoners on trees, with this inscription, "Not as Spaniards, but as Assassins." This expedition was attended with no other consequences: Gourgues blew up the forts he had taken, and returned home, where no notice was taken of him. It was conquered in 1539, by the Spaniards under Ferdinand de Soto, not without a great deal of bloodshed; as the natives were very warlike, and made a vigorous resistance. The settlement, however, was not fully established till the year 1665; when the town of St Augustine, the capital of the colony while it remained in the hands of the Spaniards, was founded. In 1586, this place was taken and pillaged by Sir Francis Drake. It met with the same fate in 1665, being taken and plundered by Captain Davis and a body of bucaners. In 1702, an attempt was made upon it by colonel More, governor of Carolina. He set out with 500 English, and 700 Indians; and having reached St Augustine, he besieged it for three months; at the expiration of which, the Spaniards having sent some ships to the relief of the place, he was obliged to retire. In 1740, another attempt was made by general Oglethorpe: but he being outwitted by the Spanish governor, was forced to raise the siege with loss; and Florida continued in the hands of the Spaniards till the year 1763, when it was ceded by treaty to Great Britain.—The province

Florida.

Florin
Florion.

vince is now divided into two governments, the East and West Florida; but concerning these there are very few accounts which can be depended upon as authentic. According to some, the air is extremely pure and healthy; while others report, that it is to the last degree noxious. As little can be depended on what is said concerning the soil: some affirming that it is exceedingly fertile, and productive of all the necessaries of life; while others tell us that it is quite barren and sandy. It was at first thought that silk, cochineal, and wine, might have been plentifully produced in this province; but whether any of these commodities have yet been produced in any part of Florida in such abundance as to give hopes of at last supplying the demands of Great Britain from that quarter, is as yet by no means ascertained.

FLORIN, is sometimes used for a coin, and sometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding thirteen or fourteen carats, and none of them seventeen and a half. See MONEY-Table.

Florin, as a money of account, is used by the Italian, Dutch, and German merchants and bankers, but admits of different divisions in different places. *Ibid.*

FLORIST, a person well skilled in flowers, their kinds and cultivation.

FLORUS (Lucius Annæus), a Latin historian, of the same family with Seneca and Lucan. He flourished in the reigns of Trajan and Adrian; and wrote, in an elegant style, an Abridgment of the Roman History, of which there have been many editions. The best are, *Ad Usum Delphini*, 4^{to}; and, *Cum notis variorum et Dukeri*, 8vo.

FLORY, Floway, or Fleury, in heraldry, a cross that has the flowers at the end circumscribed and turning down; differing from the *potence*, in as much as the latter stretches out more like that which is called *pattee*.

FLOS, FLOWER, in botany. See FLOWER.

Femineus Flos, a female flower. By this name Linnæus and the sexualists denominate a flower which is furnished with the pointal or female organs of generation, but wants the stamina or male organ. Female flowers may be produced apart from the male, either on the same root or on distinct plants. Birch and mulberry are examples of the first case; willow and poplar of the second.

Flos, in chemistry, the most subtle part of bodies separated from the more gross parts by sublimation in a dry form.

FLOTA, or FLOTTA, *Fleet*, a name which the Spaniards give particularly to the ships that are annually sent from Cadiz to the port of Vera Cruz, to fetch thence the merchandizes gathered in Mexico for Spain. This fleet consists of the captains, admiral, and patch or pinnace, which goes on the king's account; and about 16 ships from 400 to 1000 tons belonging to particular persons. They set out from Cadiz about the month of August, and return in about 18 or 20 months.

FLOTSON, or FLOSTOM, goods that by shipwreck are lost, and floating upon the sea; which,

with jetson and lagan, are generally given to the lord admiral: but this is the case only where the owners of such goods are not known. And here it is to be observed, that *jetson* signifies any thing that is cast out of a ship when in danger, and afterwards is beat on the shore by the water, notwithstanding which the ship perishes. *Lagan* is where heavy goods are thrown overboard, before the wreck of the ship, and sink to the bottom of the sea.

FLOUNDER, FLUKE, or *Bat*, in ichthyology. See PLEURONECTES.

Flounders may be fished for all day long, either in a swift stream, or in the still deep water; but best in the stream, in the months of April, May, June, and July: the most proper baits are all sorts of worms, walps, and gentles.

FLOUR, the meal of wheat-corn, finely ground and sifted. See MEAL.

The grain itself is not only subject to be eaten by insects in that state; but, when ground into flour, it gives birth to another race of destroyers, who eat it unmercifully, and increase so fast in it, that it is not long before they wholly destroy the substance. The finest flour is most liable to breed these, especially when stale or ill prepared. In this case, if it be examined in a good light, it will be observed to be in continual motion, and on a nicer inspection there will be found in it a great number of little animals of the colour of the flour, and very nimble. If a little of this flour is laid on the plate of the double microscope, the insects are very distinctly seen in great numbers, very brisk and lively, continually crawling over one another's backs, and playing a thousand antic tricks together; whether in diversion, or in search of food, is not easy to be determined. These animals are of an oblong and slender form; their heads are furnished with a kind of trunk or hollow tube, by means of which they take in their food, and their body is composed of several rings. They do vast mischief among magazines of flour laid up for armies and other public uses. When they have once taken possession of a parcel of this valuable commodity, it is impossible to drive them out; and they increase so fast, that the only method of preventing the total loss of the parcel is to make it up into bread as soon as can be done. The way to prevent their breeding in the flour is to preserve it from damp: nothing gets more injury by being put up in damp than flour; and yet nothing is more frequently put up so. It should be always carefully and thoroughly dried before it is put up; and the barrels also dried into which it is to be put; then, if they are placed in a room tolerably warm and dry, they will keep it well. Too dry a place never does flour any hurt, though one too moist almost always spoils it.

Flour, when carefully analyzed, is found to be composed of three very different substances. The first and most abundant is pure *starch*, or white fecule, insoluble in cold but soluble in hot water, and of the nature of mucous substances; which, when dissolved, form water-glues. The second is the *gluten*, most of whose properties have been described under the article BREAD. The third is of a mild nature, perfectly soluble in cold water, of the nature of *saccharine* extractive mucous matters. It is susceptible of the spirituous

Flounder,
Flour.

rituous fermentation, and is found but in small quantity in the flour of wheat. See BREAD, GLUTEN, STARCH, and SUGAR.

FLOWER, Flos, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification,

Though no parts of plants are more generally known than their flowers, yet the definitions given by different authors of this word are very various, and necessary to be explained in order to the understanding of their works. Jungius defines it to be the most tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. But this author himself acknowledges his definition to be too limited, as there are several plants whose flowers are produced remote from their fruit. Mr Ray, says the flowers cohere for the most part with the rudiments of the fruit; which is likewise a phraseology too inaccurate to be admitted in definitions. Tournefort defines the flower to be a part of a plant very often remarkable for its peculiar colours, for the most part adhering to the young fruit, to which it seems to afford the first nourishment, in order to explicate its most tender parts: but this is still a more indeterminate definition than the former.—Poneder defines a flower to be a part of a plant, unlike the rest in form and nature. If the flower has a tube, it adheres to or is fixed very near the embryo, to the use of which it is subservient; but if the flower has no tube, then its base does not adhere to the embryo. This definition is scarce intelligible, except to expert botanists. Jussieu defines a flower to be composed of chives and a pistillum, and to be of use in the generation of the plant: but this definition is too imperfect, as there are many plants in which the pistillum are found at a great distance from the chives, many flowers which have no pistillum, and many which have no chives. Vaillant has been happier in his definition. He says, that flowers are the organs which constitute the sexes of plants, which are sometimes found naked, and without any covering; and that the petals which most of them have, are noway essential to their use, but serve, and are intended, merely as covers for them: but yet, as these coats or coverings are the most conspicuous and most beautiful parts of the flowers, these are to be called *flowers*, be they of whatever form or structure or colour; and whether they contain the organs of both sexes in each individual, or only of one, or even but of some part of one, provided they are not of the same figure and colour with the leaves of the plant. The shortest and most express definition, however, seems to be that of Martin; which is, that flowers are the organs of generation of both sexes, adhering to a common placenta, together with their common covering; or of either sex separately with its proper coverings if it have any.

The parts of flowers are, 1. The pistillum or ovary, which is the rudiment of the fruit, and is therefore properly the organ of generation. 2. The style, which is a body accompanying the ovary; either arising from the middle of it, or standing as an axis in the middle, with the embryos of the seeds round it. 3. The summits, called also *apices*, and *anthers*, which are those bodies that contain the prolific powder analogous to the male sperm of animals, and generally hung upon sen-

der threads which are called the *chives*. 4. The petals, commonly called the *flower-leaves*, which are those tender fine-coloured leaves that are generally the most conspicuous parts of a flower. 5. The empalcment or calyx, which is formed of these tender leaves that cover the outer parts of the flower. Flowers, according to the number of their leaves or petals, are called *monopetalous*, or one-leaved; *dipetalous*, or two-leaved, &c.

The structure of different flowers is very various; but Dr Grew has observed that the far greater number of them have the empalcment, foliation, chives, &c. Mr Ray accounts that every perfect flower has the petals, stamina or chives, apices or summits, and the style or pistil; and such as want any of these he calls imperfect flowers. The greater number of plants have a flower-cup; which is of a firmer structure than their leaves, and serves for their support.

Flowers, designed for medicinal use, should be plucked when they are moderately blown, and on a clear day before noon: for conserves, roses must be taken in the bud.

FLOWERS, in heraldry. They are much used in coats of arms; and in general signify hope, or denote human frailty and momentary prosperity. See ROSE, &c.

FLOWERS, in chemistry. By this name are generally understood bodies reduced into very fine parts, either spontaneously, or by some operation of art; but the term is chiefly applied to volatile solid substances, reduced into very fine parts, or into a kind of meal by sublimation.—Some flowers are nothing else than the bodies themselves, which are sublimed entire, without suffering any alteration or decomposition; and other flowers are some of the constituent parts of the body subjected to sublimation.

Colours extracted from FLOWERS. See COLOUR-Making, n^o 34, 38.

Preserving of FLOWERS. The method of preserving flowers in their natural beauty through the whole year has been much sought after by many people. Some have attempted it by gathering them when dry and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, takes off from the liveliness of their colour. Muntingius prefers the following method to all others. Gather roses, or other flowers, when they are not yet thoroughly open, in the middle of a dry day: put them into a good earthen vessel glazed within; fill the vessel up to the top with them; and when full sprinkle them over with some good French wine, with a little salt in it; then let them be in a cellar, tying down the mouths of the pot. After this they may be taken out at pleasure; and, on setting them in the sun, or within reach of the fire, they will open as if growing natural-ly.

ly; and not only the colour, but the smell also will be preserved.

The flowers of plants are by much the most difficult parts of them to preserve in any tolerable degree of perfection; of which we have instances in all the collections of dried plants, or *herbæ feci*. In these the leaves, stalks, roots, and seeds of the plants appear very well preserved; the strong texture of these parts making them always retain their natural form, and the colours in many species naturally remaining. But where these fade, the plant is little the worse for use as to the knowing the species by it. But it is very much otherwise in regard to flowers: these are naturally by much the most beautiful parts of the plants to which they belong; but they are so much injured in the common way of drying, that they not only lose, but change their colours one into another, by which means they give a handle to many errors; and they usually also wither up, so as to lose their very form and natural shape. The primrose and cowslip kinds are very eminent instances of the change of colours in the flowers of dried specimens: for those of this class of plants easily dry in their natural shape; but they lose their yellow, and, instead of it, acquire a fine green colour much superior to that of the leaves in their most perfect state. The flowers of all the violet kind lose their beautiful blue, and become of a dead white; so that in dried specimens there is no difference between the blue-flowered violet, and the white-flowered kinds.

Sir Robert Southwell has communicated to the world a method of dying plants, by which this defect is proposed to be in a great measure remedied, and all flowers preserved in their natural shape, and many in their natural colours.—For this purpose two plates of iron are to be prepared of the size of a large half-sheet of paper, or larger, for particular occasions: these plates must be made so thick as not to be apt to bend; and there must be a hole made near every corner for the receiving a screw to fasten them close together. When these plates are prepared, lay in readiness several sheets of paper, and then gather the plants with their flowers when they are quite perfect. Let this be always done in the middle of a dry day; and then lay the plant and its flower on one of the sheets of paper doubled in half, spreading out all the leaves and petals as nicely as possible. If the stalk is thick, it must be pared or cut in half, so that it may lie flat; and if it is woody, it may be peeled, and only the bark left. When the plant is thus expanded, lay round about it some loose leaves and petals of the flower, which may serve to complete any part that is deficient. When all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole between the iron plates, laying the papers smoothly on one, and laying the other evenly over them: screw them close, and put them into an oven after the bread is drawn, and let them lie there two hours. After that, make a mixture of equal parts of aquafortis and common brandy; shake these well together, and when the flowers are taken out of the pressure of the plates, rub them lightly over with a camel's-hair pencil dipped in this liquor; then lay them upon fresh brown paper, and covering them with some other sheets, press them between this and other papers with a handkerchief, till the wet of these liquors is dried wholly away. When

the plant is thus far prepared, take the bulk of a nutmeg of gum-dragon; put this into a pint of fair water cold, and let it stand 24 hours; it will in this time be wholly dissolved: then dip a fine hair-pencil in this liquor, and with it daub over the back sides of the leaves, and lay them carefully down on a half-sheet of white paper fairly expanded, and press them down with some more papers over these. When the gum-water is fixed, let the pressure and papers be removed, and the whole work is finished. The leaves retain their verdure in this case, and the flowers usually keep their natural colours. Some care, however, must be taken, that the heat of the oven be not too great. When the flowers are thick and bulky, some art may be used to pare off their backs, and dispose the petals in a due order; and after this, if any of them are wanting, their places may be supplied with some of the superfluous ones dried on purpose; and if any of them are only faded, it will be prudent to take them away, and lay down others in their stead: the leaves may be also disposed and mended in the same manner.

Another method of preserving both flowers and fruit found throughout the whole year is also given by the same author. Take salt-petre one pound; armenian bole, two pounds; clean common sand, three pounds. Mix all well together: then gather fruit of any kind that is not fully ripe, with the stalk to each; put these in, one by one, into a wide-mouthed glass, laying them in good order. Tie over the top with an oil-cloth, and carry them into a dry cellar, and set the whole upon a bed of the prepared matter of four inches thick in a box. Fill up the remainder of the box with the same preparation; and let it be four inches thick all over the top of the glass, and all round its sides. Flowers are to be preserved in the same sort of glasses, and in the same manner; and they may be taken up after a whole year as plump and fair as when they were buried.

Flower de lis, or *Flower de luce*, in heraldry, a bearing representing the lily, called the *queen of flowers*, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some *femee* or spread all over the escutcheon in great numbers.

The arms of France are, three flower de lis or, in a field azure.

FLOWERING of Bulbous PLANTS. These plants will grow and flower in water alone, without any earth, and make a very elegant appearance. We daily see this practised in single roots; but there is a method of doing it with several roots in the same vessel. Take a common small garden-pot; stop the hole at the bottom with a cork, and lute in the cork with putty, that no water can get through; then fit a board to the top of the pot, and bore six or seven holes in it at equal distances, to place the bulbs in; and as many smaller ones near them to receive sticks, which will serve to tie up the flowers. Then fill up the pot with water to the board; and place tulips, jonquils, narcissus's, and the like plants in the root upon the holes, so that the bottom of the roots may touch the water: thus will they all flower early in the season, and be much more beautiful than any pot of gathered flowers, and will last many weeks in their full perfection. After the season

Flowers,
Flowering.

Flowering. of flowering is over, the roots will gradually shrink through the holes of the board, and get loose into the water: but, instead of being spoiled there, they will soon increase in size; so that they cannot return thro' the holes, and will produce several off sets. It is natural to try from this the consequence of keeping the roots under water during the whole time of their blowing; and in this way they have been found to succeed very well, and flower even stronger and more beautifully than when in the ground. They may thus, also, with proper care in the degree of heat in the room, be kept flowering from before Christmas till March or April. It is not easy, in this last manner, to manage the keeping the boards under water; for which reason, it is better to procure some sheet-lead of about four pounds to the foot, and cut this to the size of the mouth of the pot. In this there should be bored holes for the bulbs, and other holes for the sticks: and, in order to keep the sticks quite firm, it is proper to have another plate of lead shaped to the bottom of the pot, with holes in it, answering to those of the upper plate made for the sticks. The sticks will by this means be always kept perfectly steady; and the roots, being kept under water by the upper plate of lead, will flower in the most vigorous and beautiful manner imaginable.—Some have thought of adding to the virtues of the water by putting in nitre in small quantities, and others have added earth and sand at the bottom; but it has always been found to succeed better without any addition.

It may be more agreeable to some to use glass-jars in this last method with the leads, instead of earthen pots. The bulbs succeed full as well in these; and there is this advantage, that the progress of the roots is seen all the while, and they are managed better as to the supply of water.

By repeated experiments in this way on dried bulbs, and on those taken fresh out of the ground, the former have been found to succeed the best. For those taken fresh out of the ground being full of moisture, will not so soon, upon changing their element, be nourished fully by a new one; and the fibres which they had struck in the ground, always rot when put into the water, and new ones must be formed in their places; so that it requires more time for them to come to flowering. The bulbs themselves will not rot in this manner; but they will never be so strong as those which were put into the water dry, which gradually fill themselves with moisture from it, and regularly plump up. The best method of managing the whole process is this: Place the bulbs at first only on the surface of the water; for thus they will strike out their fibres most strongly. When they have stood thus six weeks, pour in the water so high as to cover them entirely, and keep them thus till they have done flowering.

Sometimes the roots will become mouldy in several parts while they stand above the water, and the cleaning them of it is to no purpose; for it will eat and spread the farther, and frequently eat through two or three of their coats. In this case they must be immediately covered with water; when the mould will be stopped, and the roots become sound, and flower as well as those which never had any such distemper. If the roots are suffered to remain in water all the year, they will not decay; but will flower again at their proper season,

VOL. IV.

and that as vigorously as those which have been taken out and dried. The old fibres of those roots never rot till they are ready to push forth new ones. It is found by experience, that the hyacinth, and many other plants, grow to a greater degree of perfection when thus in water, than when in the ground. There is a peculiar species of hyacinth called *Keyser's jewel*; this never, or very rarely, produces seed-vessels in the common way of flowering, in the ground; but it will often produce some pods when blown in water.

Mr Miller has intimated, in the Philosophical Transactions, that bulbs set in glasses grow weaker, and should be renewed every other year: but it is found, that, when managed in this manner, and kept under water, at the time of taking them up, they are as large, and some of them larger, than when planted; and if these be dried at a proper season, they will flower, year after year, as well as fresh ones.

Ranunculus and anemone roots have been found to shoot up their stalks very well in this way; but the flowers are usually blasted, which seems to arise from want of free air. Pinks will flower very well in this manner; auriculas also may, with care, be brought to flower, but not strongly. Roses, jessamines, and honeysuckles, may also be made to flower this way, and will thrive and send out suckers; the best pieces to plant, are suckers cut off about three inches under ground, without any fibres. The succulent plants may also be raised this way; for instance, the opuntia or Indian fig. If a fragment of a leaf of this plant be cut, and laid by to dry for a month till it is an absolute skin, as soon as it is put in this manner into water, it begins to plump up, and soon sends out fibrous roots, and produces new leaves as quickly as it would do in the ground.

This is the more singular in these sort of plants, because, in their natural state in the ground, they cannot bear much water. This method of growing in water is not peculiar to the bulbous-rooted ones, but others may even be raised from seed by it. A bean, or pea, set in this manner, will grow up to its proper standard, and will flower and produce pods which will ripen their seed. The smaller seeds may be also raised in this manner, by the help of wool to support them.

No vegetable transplanted out of the earth into water will thrive kindly; but any plant, whether raised from the root or seed in water, may be transplanted to the earth, and will succeed very well. It may be possible, therefore, from this method of raising plants in water, to come at a better way than is usually practised of raising some roots in the earth which are subject to rot there; such as anemones, ranunculus's, and hyacinths. A bulb dropped by chance upon the ground, will strike out both stronger and more numerous fibres than those which are planted in the usual way in the ground. On this principle, it may be proper to take out the earth of the bed where the bulbs are to stand at the time of planting them, to such a depth as they are to be placed under it when set for flowering. The bulbs are then to be set in their places, on the surface of this low ground; and to stand there till they have shot out their fibres and their head: then the earth is to be added over them by degrees, till they are covered as high above the head as they are in the usual manner of planting them: thus they would be preserved from the danger

Flowering,
Fludd.

of rotting; and their fibres would be much stronger, and consequently they would draw more nourishment, and flower better, than in the common way. The common method of planting these roots renders them liable to be destroyed by either extreme of a wet or a dry season. In the first case, they immediately rot, by the abundant moisture they receive; and, in the second, they become dry as a stick, and mouldy; so that they are infallibly rotted by the first rain that falls afterwards.

The directions necessary to the success of the bulbs planted in water are these. When the leaden false bottoms are fixed down tight within two or three inches of the bottom of the vessel (which is only designed to hold the sticks steady which are to support the leaves and stalks), then lay on the lead upon which the bulbs are to rest, placing the notched part opposite to that in the false bottom, as near as the sticks, when placed, will suffer it; then place the bulbs one in each hole, and fill up with water to the upper lead. The bottom of the bulb will then touch the water; and as the water diminishes in quantity, keep it supplied with more up to the same height for a month or six weeks; in which time the bulbs will have shot strong fibres. Then fill up the water about half an inch above the surface of the lead; and, by degrees, as the fibres strengthen, and the plume shoots from the head, keep the water higher and higher, till at length the whole bulb is covered. The water is to be kept at this standard till the season for drying them returns.—At the time of planting the bulbs, they must be carefully cleaned from any foulness at the bottom, by scraping them with the point of a knife till the found part of the bulb appears; clear them likewise from any loose skins, and even take off their brown skin till they appear white; otherwise this brown skin will tinge the water, and the growth will not succeed so well.

The notches in the side of each lead are intended to give easy passage to the water, that, if there should be any foulness or sediment in it, on shaking it a little it may all run through, and fresh water be put in its place. But this shifting the water need not be done more than once or twice in a winter, as there may be occasion from the foulness; and when this is done, the sides of the vessel should be cleaned with a painter's brush, and rinsed out again, and the bulbs themselves washed, by pouring water on them at a little distance.

At any time when the outer skins of the bulbs dry, they are to be peeled off, that they may not occasion foulness in the water; and if any dust or foul matter be at any time observed swimming on the surface, the method is to fill up the pot or vessel to the rim, and let it run over: this will carry off that light foulness, and the water may afterwards be poured away to the proper standard.

Bulbs of equal bigness should be planted together in the same pot, that they may all have the same benefit of the water. Narcissus's and hyacinths do well together; as also tulips and jonquils, and crocuses and snow-drops.

FLUDD (Robert), a famous philosopher, born in 1447. He was fellow of the college of physicians in London, and became a most voluminous writer: he dated greatly on the wonders of chemistry; was a zealous brother of the Rosicrucian order; and his books,

which are mostly in Latin, are as dark and mysterious in their language as in their matter. He died in 1657.

FLUDDER. See **COLYMBUS**.

FLUID, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed. For the

Laws and Properties of FLUIDS. See **HYDRO-STATICS**.

There are various kinds of animalcules to be discerned in different fluids by the microscope. Of many remarkable kinds of these, a description is given under the article **ANIMALCULE**. All of these little creatures are easily destroyed by separating them from their natural element. Naturalists have even fallen upon shorter methods. A needle point, dipped in spirit of vitriol, and then immersed into a drop of pepper-water, readily kills all the animalcules; which, though before frisking about with great liveliness and activity, no sooner come within the influence of the acid particles, than they spread themselves, and tumble down to all appearance dead. The like may be done by a solution of salt; only with this difference, that, by the latter application, they seem to grow vertiginous, turning round and round, till they fall down. Tincture of salt of tartar, used in the same manner, kills them still more readily; yet not so, but there will be apparent marks of their being first sick and convulsed. Inks destroy them as fast as spirit of vitriol, and human blood produces the same effect. Urine, sack, and sugar, all destroy them, though not so fast; besides, that there is some diversity in their figures and appearances, as they receive their deaths from this poison or that. The point of a pin dipped in spittle, presently killed all the kinds of animalcules in puddle-water, as Mr Harris supposes it will other animalcules of this kind.

All who are acquainted with microscopic observations, know very well, that in water, in which the best glasses can discover no particle of animated matter, after a few grains of pepper, or a fragment of a plant of almost any kind, has been some time in it, animals full of life and motion are produced; and those in such numbers, as to equal the fluid itself in quantity.—When we see a numerous brood of young fishes in a pond, we make no doubt of their having owed their origin to the spawn, that is, to the eggs of the parents of the same species. What are we then to think of these? If we will consider the progress of nature in the insect-tribes in general, and especially in such of them as are most analogous to these, we shall find it less difficult to give an account of their origin than might have been imagined.

A small quantity of water taken from any ditch in the summer-months, is found to be full of little worms, seeming in nothing so much as in size to differ from the microscopic animalcules. Nay, water, without these, exposed in open vessels to the heat of the weather, will be always found to abound with multitudes of them, visible to the naked eye, and full of life and motion. These we know, by their future changes, are the fly-worms of the different species of gnats, and multitudes of other fly-species; and we can easily determine, that they have owed their origin only to the eggs of the parent-fly there deposited. Nay, a closer observation will at any time give ocular proof of this,

Fludder,
Fluid.

Fluid.

this; as the flies may be seen laying their eggs there, and the eggs may be followed through all their changes to the fly again. Why then are we to doubt but that the air abounds with other flies and animalcules as minute as the worms in those fluids; and that these last are only the fly-worms of the former, which, after a proper time spent in that state, will suffer changes like those of the larger kinds, and become flies like those to whose eggs they owed their origin? *Vid. Reaumur. Hist. Insect. vol. iv. p. 431.*

The differently medicated liquors made by infusions of different plants, afford a proper matter for the worms of different species of these small flies: and there is no reason to doubt, but that among these some are viviparous, others oviparous; and to this may be, in a great measure, owing the different time taken up for the production of these insects in different fluids. Those which are a proper matter for the worms of the viviparous fly, may be soonest found full of them; as, probably, the liquor is no sooner in a state to afford them proper nourishment, than their parents place them there: whereas those produced from the eggs of the little oviparous flies, must, after the liquor is in a proper state, and they are deposited in it in the form of eggs, have a proper time to be hatched, before they can appear alive.

It is easy to prove, that the animals we find in these vegetable infusions were brought thither from elsewhere. It is not less easy to prove, that they could not be in the matter infused any more than in the water in which it is infused.

Notwithstanding the fabulous accounts of salamanders, it is now well known, that no animal, large or small, can bear the force of fire for any considerable time; and, by parity of reason, we are not to believe, that any insect, or embryo insect, in any state, can bear the heat of boiling water for many minutes. To proceed to inquiries on this foundation: If several tubes filled with water, with a small quantity of vegetable matter, such as pepper, oak-bark, truffles, &c. in which, after a time, insects will be discovered by the microscope; and other like tubes be filled with simple water boiled, with water and pepper boiled together, and with water with the two other ingredients, all separately boiled in it; when all these liquors come to a proper time for the observation of the microscope, all, as well those which have been boiled, as those which have not, will be found equally to abound with insects; and those of the same kind, in infusions of the same kind, whether boiled or not boiled. Those in the infusions which had sustained a heat capable of destroying animal-life, must therefore not have subsisted either in the water, or in the matters put into it, but must have been brought thither after the boiling; and it seems by no way so probably, as by means of some little winged inhabitants of the air depositing their eggs or worms in these fluids.

On this it is natural to ask, how it comes to pass, that while we see myriads of the progeny of these winged insects in water, we never see themselves? The answer is equally easy, viz. because we can always place a drop of this water immediately before the focus of the microscope, and keep it there while we are at leisure to examine its contents; but that is not the case with regard to the air inhabited by the parent-flies of these

worms, which is an immense extent in proportion to the water proper for nourishing these worms; and consequently, while the latter are clustered together in heaps, the former may be dispersed and scattered. Nor do we want instances of this, even in insects of a larger kind. In many of our gardens, we frequently find vessels of water filled with worms of the gnat kind, as plentifully, in proportion to their size, as those of other fluids are with animalcules. Every cubic inch of water in these vessels contains many hundreds of animals; yet we see many cubic inches of air in the garden not affording one of the parent flies.

But neither are we positively to declare that the parent flies of these animalcules are in all states wholly invisible to us: if not singly to be seen, there are some strong reasons to imagine that they may in great clusters. Every one has seen in a clear day, when looking stedfastly at the sky, that the air is in many places disturbed by motious and convolutions in certain spots. These cannot be the effects of imagination, or of faults in our eyes, because they appear the same to all; and if we consider what would be the case to an eye formed in such a manner as to see nothing smaller than an ox, on viewing the air on a marsh fully peopled with gnats, we must be sensible, that the clouds of these insects, though to us distinctly enough visible, would appear to such an eye merely as the moving parcels of air in the former instance do to us: and surely it is thence no rash conclusion to infer, that the case may be the same, and that myriads of flying insects, too small to be singly the objects of our view, yet are to us what the clouds of gnats would be in the former case.

Nervous Fluid. See *NERVOUS Fluid.*

Elastic Fluids. See *AIR, GAS, VAPOUR, &c.*

FLUIDITY, is by Sir Isaac Newton defined to be, that property of bodies by which they yield to any force impressed, and which have their parts very easily moved among one another.

To this definition some have added, that the parts of a fluid are in a continual motion. This opinion is supported by the solution of salts, and the formation of tinctures. If a small bit of saffron is thrown into a vial full of water, a yellow tincture will soon be communicated to the water to a considerable height; the vial is allowed to remain at rest; which indicates a motion in those parts of the fluid which touch the saffron, by which its colouring matter is carried up.

With regard to water, this can scarce be denied; the constant exhalations from its surface shew, that there must be a perpetual motion in its parts from the ascent of the steam through it. In mercury, where insensible evaporation does not take place, it might be doubted; and accordingly the Newtonian philosophers in general have been of opinion, that there are some substances essentially fluid, from the spherical figure of their constituent particles. The congelation of mercury, however, by an extreme degree of cold*, demonstrates that fluidity is not essentially inherent in mercury more than in other bodies.

That fluids have vacuities in their substance is evident, because they may be made to dissolve certain bodies without sensibly increasing their bulk. For example, water will dissolve a certain quantity of salt; after

Fluid.
Fluidity.

* See *Cand. gelation.*

Fluidity.

Fluke
||
Fluor.

after which it will receive a little sugar, and after that a little alum, without increasing its first dimensions. Here we can scarce suppose any thing else than that the saline particles were interposed between those of the fluid; and as, by the mixture of salt and water, a considerable degree of cold is produced, we may thence easily see why the fluid receives these substances without any increase of bulk. All substances are expanded by heat, and reduced into less dimensions by cold; therefore, if any substance is added to a fluid, which tends to make it cold, the expansion by the bulk of the substance added, will not be so much perceived as if this effect had not happened; and if the quantity added be small, the fluid will contract as much, perhaps more, from the cold produced by the mixture, than it will be expanded from the bulk of the salt. This also may let us know with what these interfaces between the particles of the fluid were filled up; namely, the element of fire, or heat. The saline particles, upon their solution in the fluid, have occupied these spaces; and now the liquor, being deprived of a quantity of this element equal in bulk to the salt added, feels sensibly colder.

As, therefore, there is scarce any body to be found, but what may become solid by a sufficient degree of cold; and none but what a certain degree of heat will render fluid; the opinion naturally arises, that fire is the cause of fluidity in all bodies, and that this element is the only essentially fluid substance in nature. Hence we may conclude, that those substances which we call *fluids*, are not essentially so, but only assume that appearance in consequence of an intimate union with the element of fire; just as gums assume a fluid appearance on being dissolved in spirit of wine, or salts in water.

Upon these principles Dr Black mentions fluidity as an effect of heat. The different degrees of heat which are required to bring different bodies into a state of fluidity, he supposes to depend on some particulars in the mixture and composition of the bodies themselves: which becomes extremely probable, from considering that we change the natural state of bodies in this respect, by certain mixtures; thus, if two metals are compounded, the mixture is usually more fusible than either of them separately. See CHEMISTRY, n° 56.

It is certain, however, that water becomes warmer by being converted into ice*; which may seem contradictory to this opinion. To this, however, the Doctor replies, that fluidity does not consist in the degree of sensible heat contained in bodies, which will affect the hand, or a thermometer; but in a certain quantity which remains in a *latent state*†. This opinion he supports from the great length of time required to melt ice; and to ascertain the degree of heat requisite to keep water in a fluid state, he put 5 ounces of water into a Florence flask, and converted it into ice by means of a freezing mixture put round the flask. Into another flask of the same kind he put an equal quantity of water cooled down nearly to the freezing point, by mixing it with snow, and then pouring it off. In this he placed a very delicate thermometer; and found, that it acquired heat from the air of the room in which it was placed: seven degrees of heat were gained the first half-hour. The ice being exposed

to the same degree of heat, namely, the air of a large room without fire, it cannot be doubted that it received heat from the air as fast as the water which was not frozen: but, to prevent all possibility of deception, he put his hand under the flask containing the ice, and found a stream of cold air very sensibly descending from it, even at a considerable distance from the flask; which undeniably proved, that the ice was all that time absorbing heat from the air. Nevertheless, it was not till 11 hours, that the ice was half-melted, tho' in that time it had absorbed so much heat as ought to have raised the thermometer to 140°; and even after it was melted, the temperature of the water was found scarce above the freezing point: so that, as the heat which entered could not be found in the melted ice, he concluded that it remained concealed in the water, as an essential ingredient of its composition*.

FLUKE, or FLOUNDER, in ichthyology. See PLEURORECTES.

FLUMMERY, a wholesome sort of jelly made of oat-meal.

The manner of preparing it is as follows. Put three large handfuls of finely ground oat-meal to steep, for 24 hours, in two quarts of fair water: then pour off the clear water, and put two quarts of fresh water to it: strain it thro' a fine hair-sieve, putting in two spoonfuls of orange-flower water, and a spoonful of sugar: boil it till it is as thick as a hasty-pudding, stirring it continually while it is boiling, that it may be very smooth.

FLUOR, in physics, a fluid; or, more properly, the state of a body that was before hard or solid, but is now reduced by fusion, or fire, into a state of fluidity.

FLUOR, in mineralogy, a certain kind of stone which facilitates fusion. They are of different colours, purple, green, yellow, &c. more or less transparent, which are commonly found in veins of ores, and serve as the matrix to the minerals which they envelop. Most of them affect a cubical form, but others are found in lumps which have no determinate shape. They may be distinguished from other stones by the following properties.

1. They are not sufficiently hard to strike fire with steel. By this property they are distinguished from the coloured quartz-crystals, called *false emeralds*, *false rubies*, &c. which names have also been improperly applied to the cubical coloured fluors.

2. They are not soluble by acids, and thus are distinguishable from calcareous spars.

3. When calcined without addition, and mixed with water, they do not form plaster; and when calcined with addition of inflammable matter, they cannot be formed into the Bolognian phosphorus. Hence they may be distinguished from the gypseous phosphoric spars and stones.

4. They are fusible by fire without addition, according to M. Engestrom and M. D'Arcet.

5. They greatly facilitate the fusion of calcareous and argillaceous earths; and also of the topaz, according to Mr Pott. They are much employed in the smelting of ores, as they promote the fusion of the adhering earths.

6. When exposed to fire till they become red-hot, they emit some lucid rays in the dark: but their light

* See Congelation.

* See Evaporation.

Fluor is very weak, and afterwards they crackle and break into small pieces; whereas the pyreous phosphoric spars exposed to the same heat emit a vivid light, and then break afunder into pieces not so pulverable as those of the heated fluors.

M. Margraaf has made experiments in order to discover the nature of these stones. He ascertained the above-mentioned distinctions between them and the pyreous spars; and therefore infers, that they are not compounded of vitriolic acid with calcareous earth. He observed singular appearances on mixing them with vitriolic and other acids, and subjecting the mixtures to distillation,

Eight ounces of the powder of a green fluor, being mixed with an equal weight of pure oil of vitriol, and distilled together with a graduated heat, yielded, after the watery part of the acid had passed, a fine white sublimate, which arose and adhered to the neck of the retort, and even passed into the receiver. The first parts of this sublimate which arose, appeared like butter of antimony; and, like this butter, they melted by the heat of a live coal, brought near the neck of the retort: but the parts which arose towards the end of the operation, with the greatest degree of heat, could not be melted by that heat. The retort being broken, a residuum was found weighing 12 oz. Hence 4 oz. of oil of vitriol remained united with the spar. The bottom of the retort was observed to be pierced with holes. Lastly, the liquor, which had passed into the receiver, and the white sublimate, had very sensibly a sulphureous smell. The sublimate, triturated a long time in a mortar with hot distilled water, dissolved, and passed thro' a filter. To the filtrated liquor some fixed alkali being added, a precipitate was formed; which being well washed and dried, was readily melted by fire into a mass resembling porcelaina. The same excellent and accurate chemist produced the same effects upon this stone, by substituting, instead of the vitriolic acid, the nitrous, marine, phosphoric, or the concentrated acetic acids.

FLUOR Acid. See CHEMISTRY, n° 263.

FLUOR Albus, or Whites. See (the *Index* subjoined to) MEDICINE.

FLUSHING, an handsome, strong, and considerable town of the United Provinces, in Zeland, and in the island of Walcheren, with a very good harbour, and a great foreign trade. It was put into the hands of queen Elizabeth for a pledge of their fidelity, and as a security for the money she advanced. It is one of the three places which Charles V. advised Philip II. to preserve with care. E. Long. 3. 32. N. Lat. 51. 26.

FLUTE, an instrument of music, the simplest of all those of the wind-kind. It is played on by blowing it with the mouth; and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side.

This is a very ancient instrument. It was at first called the flute à bec, from *bec* an old Gaulish word signifying the beak of a bird or fowl, but more especially of a cock: the term *flute à bec* must therefore signify the beaked flute; which appears very proper, on comparing it with the traverse or German flute. The word *flute* is derived from *fluta*, the Latin for a lamprey or small eel taken in the Sicilian seas, having seven holes im-

mediately below the gills on each side, the precise number of those in the front of the flute.

By Merlennus this instrument is called the *flûta dulcis, seu Anglicæ*; the lowest note, according to him, for the treble flute, is *C fa ut*, and the compass of the instrument 15 notes. There is, however, a flute known by the name of the *concert-flute*, the lowest note of which is F. Indeed, ever since the introduction of the flute into concerts, the lowest note of the instrument, of what size soever it is, has been called F; when in truth its pitch is determinable only by its correspondence in respect of acuteness or gravity with one or other of the chords in the *scala maxima* or great system.

Besides the true concert-flute, others of a less size were soon introduced into concerts of violins; in which case the method was to write the flute-part in a key correspondent to its pitch. This practice was introduced in 1710 by one Woodcock, a celebrated performer on this instrument, and William Babel organist of the church of All-hallows, Bread-Street, London. They failed, however, in procuring for the flute a reception into concerts of various instruments; for which reason, one Thomas Stanesby, a very curious maker of flutes and other instruments of the like kind, about the year 1732, adverting to the scale of Merfennus, in which the lowest note was C, invented what he called the *new system*; in which, by making the flute of such a size as to be a fifth above concert-pitch, the lowest note became *C sol fa ut*. By this contrivance the necessity of transposing the flute-part was taken away; for a flute of this size, adjusted to the system above-mentioned, became an octave to the violin. To further this invention of Stanesby, one Lewis Mercier, an excellent performer on the flute, published, about the year 1735, six solos for this instrument, three of which are said to be accommodated to Mr Stanesby's new system; but the German flute was now become a favourite instrument, and Stanesby's ingenuity failed of its effect.—One great objection indeed lies against this instrument, which, however, equally affects all perforated pipes; namely, that they are never perfectly in tune, or cannot be made to play all their notes with equal exactness. The utmost that the makers of them can do is to tune them to some one key; as the hautboy to C, the German flute to D, and the English flute to F, and to effect this truly is a matter of no small difficulty. The English flutes made by the younger Stanesby come the nearest of any to perfection; but those of Bressan, though excellent in their tone, are all too flat in the upper octave. For these reasons some are induced to think, that the utmost degree of proficiency on any of those instruments is not worth the labour of attaining it.

German FLUTE, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played; but the end is stoped with a stopper or plug, and the lower lip is applied to a hole about two inches and a half or three inches distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest of which is stoped and opened by the little finger's pressing on a brass or sometimes a silver key, like those in hautboys, bassoons, &c.

Its

FLUX. Its found is exceeding sweet and agreeable; and serves as a treble in a concert.

FLUX, in metallurgy, is sometimes used synonymously with *fusion*. For instance, an ore, or other matter, is said to be in liquid flux, when it is completely fused.

But the word *flux* is generally used to signify certain saline matters, which facilitates the fusion of ores, and other matters which are difficultly fusible in effays and reductions of ores. Fixed alkalis, nitre, borax, tartar, and common salt, are the saline matters of which fluxes are generally composed. But the word *flux* is more particularly applied to mixtures of different proportions of only nitre and tartar; and these fluxes are called by particular names, according to the proportions of these ingredients, as in the following articles.

White Flux, is made with equal parts of nitre and of tartar detonated together, by which they are alkalisied. The residuum of this detonation is an alkali composed of the alkalis of the nitre and of the tartar, both which are absolutely of the same nature. As the proportion of nitre in this mixture is more than is sufficient to consume entirely all the inflammable matter of the tartar, the alkali remaining after the detonation is perfectly white, and is therefore called *white flux*; and as this alkali is made very quickly, it is also called *extemporaneous alkali*. When a small quantity only of white flux is made, as a few ounces for instance, some nitre always remains undecomposed, and a little of the inflammable principle of the tartar, which gives a red or even a black colour to some part of the flux: but this does not happen when a large quantity of white is made flux; because then the heat is much greater. This small quantity of undecomposed nitre and tartar which remains in white flux is not hurtful in most of the metallic fusions in which this flux is employed: but if the flux be required perfectly pure, it might easily be disengaged from those extraneous matters by a long and strong calcination, without fusion.

Crude Flux. By crude flux is meant the mixture of nitre and tartar in any proportions, without detonation. Thus the mixture of equal parts of the two salts used in the preparation of the white flux, or the mixture of one part of nitre and two parts of tartar for the preparation of the black flux, are each of them a *crude flux* before detonation. It has also been called *white flux*, from its colour; but this might occasion it to be confounded with the white flux above described. The name, therefore, of crude flux is more convenient.

Crude flux is detonated and alkalisied during the reductions and fusions in which it is employed; and is then changed into white or black flux, according to the proportions of which it is composed. This detonation produces good effects in these fusions and reductions, if the swelling and extravasation of the detonating matters be guarded against. Accordingly, crude flux may be employed successfully in many operations; as, for instance, in the ordinary operation for procuring the regulus of antimony.

Black Flux. Black flux is produced from the mixture of two parts of tartar and one part of nitre detonated together. As the quantity of nitre which enters into the composition of this flux is not sufficient to consume all the inflammable matter of the tartar, the alkali which remains after the detonation contains much black matter, of the nature of coal, and is therefore called *black flux*.

This flux is designedly so prepared, that it shall contain a certain quantity of inflammable matter; for it is thereby capable, not only of facilitating the fusion of metallic earths like the white flux, but also of reviving these metals by its phlogiston. From this property it is also called *reducing flux*; the black flux, therefore, or crude flux made with such proportions of the ingredients as to be convertible into black flux, ought always to be used when metallic matters are at once to be fused and reduced, or even when destructive metals are to be fused, as these require a continual supply of phlogiston to prevent their calcination.

F L U X I O N S;

A METHOD of calculation which greatly facilitates computations in the higher parts of mathematics. Sir Isaac Newton and Mr Leibnitz contended for the honour of inventing it. It is probable they had both made progress in the same discovery, unknown to each other, before there was any publication on the subject.

In this branch of mathematics, magnitudes of every kind are supposed generated by motion; a line by the motion of a point, a surface by the motion of a line, and a solid by the motion of a surface. And some part of a figure is supposed generated by an uniform motion; in consequence of which, the other parts may increase uniformly or with an accelerated or retarded motion, or may decrease in any of these ways; and the computations are made by tracing the comparative velocities with which the parts flow.

Fig. 1. If the parallelogram ABCD be generated by an uniform motion of the line AB toward CD while it moves from FE towards *fe*, while the line BF receives the increment *Ff*, and the figure will be increased

by the parallelogram *Ff*; the line FE in this case undergoes no variation.

The fluxion of any magnitude at any point is the increment that it would receive in any given time, supposing it to increase uniformly from that point; and as the measures will be the same, whatever the time be, we are at liberty to suppose it less than any assigned time.

The first letters in the alphabet are used to represent invariable quantities; the letters *x, y, z*, variable quantities; and the same letters with points over them *ẋ, ẏ, ż*, represent their fluxions.

Therefore if AB=*a*, and BF=*x*; *Ff*, the fluxion of BF, will be =*ẋ*, and *Fz*, the fluxion of AF, =*aẋ*.

If the rectangle be supposed generated by the uniform motion of FG towards CD, at the same time that HG moves uniformly towards AD, the point G keeping always on the diagonal, the lines FG HG will flow uniformly; for while Bf receives the increment *Ff*, and HB the increment HK, FG will receive the increment

ment hg , and HG the increment hg , and they will receive equal increments in equal successive times. But the parallelogram will flow with an accelerated motion; for while F flows to f , and H to K , it is increased by the gnomon KGf ; but while F and H flow through the equal spaces fm KL , it is increased by the gnomon Lgm greater than KGf ; consequently when fluxions of the sides of a parallelogram are uniform, the fluxion of the parallelogram increases continually.

The fluxion of the parallelogram $BHGF$ is the two parallelograms KG and Gf ; for though the parameter receives an increment of the gnomon KGf , while its sides flow to f and K , the part gG is owing to the additional velocity wherewith the parallelogram flows during that time; and therefore is no part of the measure of the fluxion, which must be computed by supposing the parameter to flow uniformly as it did at the beginning, without any acceleration.

Therefore if the sides of a parallelogram be x and y , their fluxions will be \dot{x} and \dot{y} ; and the fluxion of the parallelogram $xy + y\dot{x}$; and if $x=y$, that is, if the figure be a square, the fluxion of x^2 will be $2x\dot{x}$.

Fig. 2. Let the triangle ABC be described by the uniform motion of DE from A towards B , the point E moving in the line DF , so as always to touch the lines AC , CB ; while D moves from A to F , DE is uniformly increased, and the increase of the triangle is uniformly accelerated. When DE is in the position FC , it is a maximum. As D moves from F to B , the line FC decreases, and the triangle increases, but with a motion uniformly retarded.

Fig. 3. If the semicircle AFB be generated by the uniform motion of CD from A towards B , while C moves from A to G , the line CD will increase, but with a retarded motion; the circumference also increases with a retarded motion, and the circular space increases with an accelerated motion, but not uniformly, the degrees of acceleration growing less as CD approaches to the position GF . When C moves from G to B , it decreases with a motion continually accelerated, the circumference increases with a motion continually accelerated, and the area increases with a motion continually retarded, and more quickly retarded as CD approaches to B .

The fluxion of a quantity which decreases is to be considered as negative.

When a quantity does not flow uniformly, its fluxion may be represented by a variable quantity, or a line of a variable length; the fluxion of such a line is called the *second fluxion of the quantity whose fluxion that line is*: and if it be variable, a third fluxion may be deduced from it, and higher orders from these in the same manner: the second fluxion is represented by two points, as \ddot{x} .

The increment a quantity receives by flowing for any given time, contains measures of all the different orders of fluxions; for if it increases uniformly, the whole increment is the first fluxion; and it has no second fluxion. If it increases with a motion uniformly accelerated, the part of the increment occasioned by the first motion measures the first fluxion, and the part occasioned by the acceleration measures the second fluxion. If the motion be not only accelerated, but the degree of acceleration continually increased, the two first flux-

ions are measured as before; and the part of the increment occasioned by the additional degree of acceleration measures the third; and so on. These measures require to be corrected, and are only mentioned here to illustrate the subject.

DIRECT METHOD.

Any flowing quantity being given, to find its fluxion.

RULE I. To find the fluxion of any power of a quantity, multiply the fluxion of the root by the exponent of the power, and the product by a power of the same root less by unity than the given exponent.

The fluxion of x^3 is $3x^2\dot{x}$, of x^n $nx^{n-1}\dot{x}$; for the root of x^n is x , whose fluxion is \dot{x} ; which multiplied by the exponent n , and by a power of x less by unity than n , gives the above fluxion.

If x receive the increment x , it becomes $x+\dot{x}$; raise both to the power of n , and x^n becomes $x^n + nx^{n-1}\dot{x} + \frac{n(n-1)}{2}x^{n-2}\dot{x}^2 + \&c.$; but all the parts of the increment, except the first term, are owing to the accelerated increase of x^n , and form measures of the higher fluxions. The first term only measures the first fluxion; the

fluxion of $x^2 + \dot{x}^2$ is $\frac{1}{2} \times 2xz \times \dot{x} + \dot{x}^2$; for put $x = a^2 + z^2$, we have $x = zzz$; and the fluxion of x^2 , which is equal to the proposed fluent, is $\frac{1}{2} \times \dot{x}^2$; for which substituting the values of z and x , we have the above fluxion.

RULE II. To find the fluxion of the product of several variable quantities multiplied together, multiply the fluxion of each by the product of the rest of the quantities, and the sum of the products thus arising will be the fluxion sought.

Thus the fluxion of xy , is $\dot{x}y + y\dot{x}$; that of xyz , is $xy\dot{z} + xz\dot{y} + yz\dot{x}$; and that of $xyzw$, is $xyz\dot{w} + xwz\dot{y} + xwy\dot{z} + zw\dot{x}$.

RULE III. To find the fluxion of a fraction.—From the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator.

Thus, the fluxion of $\frac{x}{y}$ is $\frac{y\dot{x} - x\dot{y}}{y^2}$; that of $\frac{x}{x+y}$ is $\frac{x\dot{x} + y\dot{x} - x\dot{y} - y\dot{x}}{(x+y)^2} = \frac{y\dot{x} - x\dot{y}}{(x+y)^2}$.

RULE IV. In complex cases, let the particulars be collected from the simple rules, and combined together.

The fluxion of $\frac{x^2y^2}{z}$ is $\frac{2x\dot{x}y^2 + 2y\dot{y}xx - x^2y\dot{z}}{z^2}$; for

the fluxion of x^2 is $2x\dot{x}$, and of y^2 is $2y\dot{y}$, by Rule I. and therefore the fluxion of x^2y^2 (by Rule II.) $2x\dot{x}y^2 + 2y\dot{y}xx$; from which, multiplied by z , (by Rule III.) and subtracting from it the fluxion of the denominator z , multiplied by the numerator, and dividing the whole by the square of the denominator, gives the above fluxion.

RULE IV. The second fluxion is derived from the first.

first, in the same manner as the first from the flowing quantity.

Thus the fluxion of x^3 , $3x^2\dot{x}$; its second, $6x\dot{x}^2 + 3x^2\ddot{x}$ (by Rule II.); and so on: but if \dot{x} be invariable, $\ddot{x} = 0$, and the second fluxion of $x^3 = 6x\dot{x}^2$.

PROB. I. To determine maxima and minima.

When a quantity increases, its fluxion is positive; when it decreases, it is negative; therefore, when it is just betwixt increasing and decreasing, its fluxion is $= 0$.

RULE. Find the fluxion, make it $= 0$, whence an equation will result that will give an answer to the question.

EXAMP. To determine the dimensions of a cylindric measure ABCD, (fig. 4.) open at the top, which shall contain a given quantity (of liquor, grain, &c.) under the least internal superficies possible.

Let the diameter $AB = x$, and the altitude $AD = y$; moreover, let p (3, 14159, &c.) denote the periphery of the circle whose diameter is unity, and let c be the given content of the cylinder. Then it will be $1 : p :: x : (px)$ the circumference of the base; which, multiplied by the altitude y , gives pxy for the concave superficies of the cylinder. In like manner, the area of the base, by multiplying the same expression into $\frac{1}{4}$ of the diameter x , will be found $= \frac{px^2}{4}$; which drawn

into the altitude y , gives $\frac{px^2y}{4}$ for the solid content of the cylinder; which being made $= c$, the concave surface pxy will be found $= \frac{4c}{x}$, and consequently the whole surface $= \frac{4c}{x} + \frac{px^2}{4}$: Whereof the fluxion, which is $-\frac{4cx}{x^2} + \frac{pxx}{2}$ being put $= 0$, we shall get $-8c \times px^3 = 0$;

and therefore $x = 2\sqrt{\frac{c}{p}}$: further, because $px^3 = 8c$, and $px^2y = 4c$, it follows, that $x = 2y$; whence y is also known, and from which it appears that the diameter of the base must be just the double of the altitude.

Fig. 7. To find the longest and shortest ordinates of any curve, DEF, whose equation or the relation which the ordinates bear to the abscissas is known.

Make AC the abscissa x , and CE the ordinate y ; take a value y in terms of x , and find its fluxion; which making $= 0$, an equation will result whose roots give the value of x when y is a maximum or a minimum.

To determine when it is a maximum and when a minimum, take the value of y , when x is a little more than the root of the equation so found, and it may be perceived whether it increases or decreases.

If the equation has an even number of equal roots, y will be neither a maximum nor minimum when its fluxion is $= 0$.

PROB. II. To draw a tangent to any curve.

Fig. 5. When the abscissa CS of a curve moves uniformly from A to B, the motion of the curve will be retarded if it be concave, and accelerated if convex towards AB; for a straight line TC is described by a uniform motion, and the fluxion of the curve at any

point is the same as the fluxion of the tangent, because it would describe the tangent if it continued to move equally from that point. Now if S or Ce be the fluxion of the base, Cd will be the fluxion of the tangent, and de of the ordinate. And because the triangles TSC, Ced, are equiangular, $de : ce :: CS : ST$, wherefore,

RULE. Find a fourth proportional to the fluxion of the ordinate valued in terms of the abscissa, the fluxion of the abscissa, and the ordinate, and it determines the line ST, which is called the *semi-tangent*, and TC joined is a tangent to the curve.

EXAMP. To draw a right line CT, (fig. 6.) to touch a given circle BCA in a given point C.

Let CS be perpendicular to the diameter AB, and put $AB = a$, $BS = x$, and $SC = y$; then, by the property of the circle, y^2 (CS^2) $= BS \times AS$ ($= x \times a - x$) $= ax - x^2$; whereof the fluxion being taken, in order to determine the ratio of x and y , we get $2y\dot{y} = a\dot{x} - 2x\dot{x}$; consequently $\frac{\dot{y}}{y} = \frac{2y}{a - 2x} = \frac{\dot{y}}{\frac{1}{2}a - x}$; which multiplied by y , gives $\frac{y\dot{y}}{\frac{1}{2}a - x} =$ the subtangent ST. Whence (O being sup-

posed the centre) we have OS ($\frac{1}{2}a - x$) : CS (y) :: CS (y) : ST ; which we also know from other principles.

PROB. III. To determine points of contrary flexure in curves.

FIG. 7. Supposing C to move uniformly from A to B, the curve DEF will be convex towards AB when the celerity of E increases, and concave when it decreases; therefore at the point where it ceases to be convex and begins to be concave, or the opposite way, the celerity of E will be uniform, that is, CE will have no second fluxion. Therefore,

RULE. Find the second fluxion of the ordinate in terms of the abscissa, and make it $= 0$; and from the equation that arises you get a value of the abscissa, which determines the point of contrary flexure.

Ex. Let the nature of the curve ARS be defined by the equation $ay = a^{\frac{1}{2}}x^{\frac{1}{2}} + xx$, (the abscissa AF and the ordinate FG being, as usual, represented by x and y respectively). Then y , expressing the celerity of the

point r , in the line FH, will be equal to $\frac{\frac{1}{2}a \times \dot{x} + 2x\dot{x}}{a}$;

Whose fluxion, or that of $\frac{1}{2}a \times \dot{x}^{-\frac{1}{2}} + 2x$ (because a and \dot{x} are constant) must be equal to nothing; that is,

$-\frac{1}{4}a^{\frac{1}{2}}x^{-\frac{3}{2}} + 2\dot{x} = 0$: Whence $a^{\frac{1}{2}}x^{-\frac{3}{2}} = 8$, $\frac{a^{\frac{1}{2}}}{a^{\frac{1}{2}}x^{\frac{3}{2}}} = 8x^{\frac{1}{2}}$
 $64x^3 = a^3$, and $x = \frac{1}{4}a = AF$; therefore FG ($= \frac{a^{\frac{1}{2}}x^{\frac{1}{2}} + xx}{a}$)
 $= \frac{9}{16}a$: From which the position of the point G is given.

PROB. IV. To find the radii of curvature.

THE curvature of a circle is uniform in every point, that of every other curve continually varying: and it is measured at any point by that of a circle whose radius is of such a length as to coincide with it in curvature at that point.

All curves that have the same tangent have the same first fluxion, because the fluxion of a curve and its tangent

gent are the same. If it moved uniformly on from the point of contact, it would describe the tangent. And the deflection from the tangent is owing to the acceleration or retardation of its motion, which is measured by its second fluxion: and consequently two curves which have not only the same tangent, but the same curvature at the point of contact, will have both their first and second fluxions equal. It is easily proven from thence, that the radius of curvature is

$$= \frac{z^3}{-xy},$$
 where x, y , and z represent the abscissa, ordinate, and curve respectively.

EXAMP. Let the given curve be the common parabola, whose equation is $y = a^{\frac{1}{2}} x^{\frac{1}{2}}$. Then will $y = \frac{1}{2} a^{\frac{1}{2}} x^{-\frac{1}{2}}$ and (making x constant) $y = -\frac{1}{2} a^{\frac{1}{2}} x^{-\frac{1}{2}}$ and $\frac{a^{\frac{1}{2}} x}{2x^{\frac{3}{2}}}$: Whence $z = \sqrt{x^2 + y^2} = \frac{x}{2} \sqrt{\frac{4x+a}{x}}$, and

the radius of curvature $\left(\frac{z^3}{-xy} \right) = \frac{a+4}{2\sqrt{a}}$: Which at the vertex, where $x=0$, will be $=\frac{1}{2}a$.

INVERSE METHOD.

From a given fluxion to find a fluent.

THIS is done by tracing back the steps of the direct method. The fluxion of x is \dot{x} ; and therefore the fluent of x is x : but as there is no direct method of finding fluents, this branch of the art is imperfect. We can assign the fluxion of every fluent; but we cannot assign the fluent of a fluxion, unless it be such a one as may be produced by some rule in the direct method from a known fluent.

GENERAL RULE. Divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased.

For, dividing the fluxion $n x^{n-1} \dot{x}$ by \dot{x} (the fluxion of the root x) it becomes $n x^{n-1}$; and, adding 1 to the exponent $(n-1)$ we have $n x^n$; which, divided by n , gives x^n , the true fluent of $n x^{n-1} \dot{x}$.

Hence (by the same rule) the

Fluent of $3x^2 \dot{x}$ will be $= x^3$;

That of $8x^{\frac{3}{2}} \dot{x} = \frac{8x^{\frac{5}{2}}}{\frac{5}{2}}$;

That of $2x^{\frac{1}{2}} \dot{x} = \frac{x^{\frac{3}{2}}}{\frac{3}{2}}$;

That of $y^{\frac{1}{2}} \dot{y} = \frac{2}{3} y^{\frac{3}{2}}$.

Sometimes the fluent so found requires to be corrected. The fluxion of x is \dot{x} , and the fluxion of $a+x$ is also \dot{x} , because a is invariable, and has therefore no fluxion.

Now when the fluent of \dot{x} is required, it must be determined, from the nature of the problem, whether

any invariable part, as a , must be added to the variable part x .

When fluents cannot be exactly found, they can be approximated by infinite series.

Ex. Let it be required to approximate the fluent of

$$\frac{a^2 - x^2}{c^2 - x^2} \dot{x} \text{ in an infinite series.}$$

The value of $\frac{a^2 - x^2}{c^2 - x^2}$, expressed in a series, is $\frac{a}{c} +$

$$\frac{a}{2c^3} \frac{1}{2ac} x^2 + \frac{3a}{8c^5} \frac{1}{4ac^3} x^4 + \frac{5a}{16c^7} \frac{1}{16ac^5} x^6 + \dots$$

Which value being therefore multiplied by $x \dot{x}$, and the fluent taken (by the common method) we get $\frac{ax^{n+1}}{n+1 \times c} + \frac{a}{2c^3} \frac{1}{2ac} \times \frac{x^{n+3}}{n+3} + \frac{3a}{8c^5} \frac{1}{4ac^3} \times \frac{x^{n+5}}{n+5} + \frac{5a}{16c^7} \frac{1}{16ac^5} \times \frac{x^{n+7}}{n+7} + \dots$

PROB. I. To find the area of any curve.

RULE. Multiply the ordinate by the fluxion of the abscissa, and the product gives the fluxion of the figure, whose fluent is the area of the figure.

EXAMP. 1. Fig. 8. Let the curve ARMH, whose area you will find, be the common parabola. Let u represent the area, and \dot{u} its fluxion.

In which case the relation of $AB(x)$ and $BR(y)$ being expressed by $y^2 = ax$ where a is the parameter) we thence get $y = a^{\frac{1}{2}} x^{\frac{1}{2}}$; and therefore $\dot{u} = RmHB (= x \dot{y}) = a^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$: whence $u = \frac{2}{3} a^{\frac{1}{2}} x^{\frac{3}{2}} = \frac{2}{3} a^{\frac{1}{2}} x^{\frac{1}{2}} \times x = \frac{2}{3} xy$ (because $a^{\frac{1}{2}} x^{\frac{1}{2}} = y$) $= \frac{2}{3} \times AB \times BR$: hence a parabola is $\frac{2}{3}$ of a rectangle of the same base and altitude.

EXAMP. 2. Let the proposed curve CSDR (fig. 9.) be of such a nature, that (supposing AB unity) the sum of the areas CSTBC and CDGBC answering to any two proposed abscissas AT and AG , shall be equal to the area CRNBC, whose corresponding abscissa AN is equal to $AT \times AG$, the product of the measures of the two former abscissas.

First, in order to determine the equation of the curve, (which must be known before the area can be found), let the ordinates GD and NR move parallel to themselves towards HF ; and then having put $GD=y$, $NR=z$, $AT=a$, $AG=c$, and $AN=u$, the fluxion of the area $CDGB$ will be represented by $y \dot{y}$, and that of the area $CRNB$ by $z \dot{z}$: which two expressions must, by the nature of the problem, be equal to each other; because the latter area $CRNB$ exceeds the former $CDGB$ by the area $CSTB$, which is here considered as a constant quantity: and it is evident, that two expressions, that differ only by a constant quantity, must always have equal fluxions.

Since, therefore, $y \dot{y} = z \dot{z}$, and $u = at$, by hypothesis, it follows, that $u = az$, and that the first equation (by substituting for \dot{u}) will become $y \dot{y} = az \dot{z}$, or $y \dot{y} = az$, or lastly $y \dot{y} = za \dot{a}$, that is, $GD \times AG = NR \times AN$: there-

fore,

fore, $GD : NR :: AN : AG$; whence it appears, that every ordinate of the curve is reciprocally as its corresponding abscissa.

Now, to find the area of the curve so determined, put $AB=t$, $BC=b$, and $BG=x$; then, since $AG(1+x) : AB(1) :: BC(b) : GD(y)$ we have $y = \frac{b}{1+x}$,

consequently $\dot{u} (=y\dot{x}) = \frac{b\dot{x}}{1+x} = b \times \dot{x} - x\dot{x} + x^2\dot{x} - n^3x + x^4 - \&c.$ Whence, $BGDC$, the area itself will be $b \times x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5}$, &c. which was to be found.

Hence it appears, that as these areas have the same properties as logarithms, this series gives an easy method of computing logarithms; and the fluent may be found by means of a table of logarithms, without the trouble of an infinite series; and every fluxion whose fluent agrees with any known logarithmic expression, may be found the same way. Hence the fluents of fluxions of the following forms are deduced.

The fluent of $\frac{\dot{x}}{\sqrt{x^2 \pm a^2}} = \text{hyp. log. of } x + \sqrt{x^2 \pm a^2}$;

of $\frac{\dot{x}}{\sqrt{2ax + x^2}} = \text{hyp. log. } a\sqrt{x} + \sqrt{2ax + x^2}$;

of $\frac{2a\dot{x}}{a^2 - x^2} = \text{hyp. log. of } \frac{a+x}{a-x}$;

and of $\frac{2a\dot{x}}{x\sqrt{a^2 - x^2}} = \text{hyp. log. } \frac{a - \sqrt{a^2 - x^2}}{a + \sqrt{a^2 - x^2}}$

PROB. 2. To determine the length of curves.

Fig. 5. Because Cde is a right-angled triangle, $Cd^2 = Ce^2 + de^2$; wherefore the fluxions of the abscissa and ordinate being taken in the same terms and squared, their sum gives the square of the fluxion of the curve; whose root being extracted, and the fluent taken, gives the length of the curve.

EXAMP. To find the length of a circle from its tangent. Make the radius AO (fig. 5) $=a$, the tangent of $AC=t$, and its secant $=s$, the curve $=z$, and its fluxion $=\dot{z}$; because the triangles OTC , OCS , are similar, $OT : OC :: OC :: OS$; whence $OS = \frac{a^2}{s}$, and $SA = a - \frac{a^2}{s} = a - \frac{a^2}{\sqrt{a^2 + t^2}}$; whose

fluxion is $\frac{a^2 \dot{t}}{a^2 + t^2}$; and because the triangles OTC ,

aCt are similar, $TC (=t) : TO (= \sqrt{a^2 + t^2}) :: Ce = \left(\frac{a^2 \dot{t}}{a^2 + t^2} \right) : Cd = \frac{a^2 \dot{t}}{a^2 + t^2} = \text{fluxion of the curve.}$

Now by converting this into an infinite series, we have the

fluxion of the curve $= \dot{z} = \frac{t^2 \dot{t}}{a^2} + \frac{t^4 \dot{t}}{a^4} + \frac{t^6 \dot{t}}{a^6}$, &c. and consequently

sequently $z = -\frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8}$, &c. $= AR$.

Where, if (for example) take AR be supposed an arch of 36 degrees, and AO (to render the operation more easy) be put $=$ unity, we shall have $t = \sqrt{\frac{1}{2}} = .5773502$ (because $Ob\sqrt{\frac{1}{2}} : bR (\frac{1}{2}) :: OA(1) : AT(t) = \sqrt{\frac{1}{2}}$)

Whence,

$$t^3 (=t \times t^2 = t \times \frac{1}{2}) = .1924500$$

$$t^5 (=t^2 \times t^2 = \frac{t^3}{2}) = .0641500$$

$$t^7 (=t^5 \times t^2 = \frac{t^3}{3}) = .0213833$$

$$t^9 (=t^7 \times t^2 = \frac{t^3}{9}) = .0071277$$

$$t^{11} (=t^9 \times t^2 = \frac{t^3}{27}) = .0023759$$

$$t^{13} (=t^{11} \times t^2 = \frac{t^3}{81}) = .0007919$$

$$t^{15} (=t^{13} \times t^2 = \frac{t^3}{243}) = .0002639$$

&c.

And therefore $AR = .5773502 - \frac{.1924500}{3} + \frac{.0641500}{5} - \frac{.0213833}{7} + \frac{.0091277}{9} - \frac{.0023759}{11} + \frac{.0007919}{13} - \frac{.0002639}{15} + \frac{.0000879}{17} - \frac{.0000293}{19} + \frac{.0000097}{21} - \frac{.0000032}{23} = .5235987$; for the length of

an arch of 30 degrees, which multiplied by 6 gives 3.141592 + for the length of the semi-periphery of the circle whose radius is unity.

Other series may be deduced from the versed sine, sine and secant; and these are of use for finding fluents which cannot be expressed in finite terms.

The fluent of	$\left\{ \begin{array}{l} \frac{\dot{v}}{\sqrt{2av - v^2}} \\ \frac{\dot{v}}{\sqrt{a^2 - v^2}} \\ \frac{\dot{v}}{a^2 + v^2} \\ \frac{\dot{v}}{av\sqrt{v^2 - a^2}} \end{array} \right\}$	$\left\{ \begin{array}{l} \text{to the arch whole} \\ \text{to the right whole} \\ \text{to the tangent} \\ \text{to the secant} \end{array} \right\}$	$\left\{ \begin{array}{l} \text{Versed sine} \\ \text{Right sine} \\ \text{Tangent} \\ \text{Secant} \end{array} \right\}$	$\left\{ \begin{array}{l} \text{is } \frac{v}{a}, \text{ and} \\ \text{Radius Unity.} \end{array} \right\}$

PROB. 3. To find the contents of a solid.

LET the surface of the generating plane be multiplied by the space it passes through in any time, the product will give a solid which is the fluxion of the solid required: the surface must therefore be computed in terms of x , which represents the line or axis on which it moves, and by its motion on which the fluxion is to be measured, and the fluent found will give the contents of the solid.

EXAMP. Let it be proposed to find the content of a cone ABC , fig. 10.

Put the given altitude (AD) of the cone $=a$, and the semi-diameter (BD) of its base $=b$, the solid $=s$, its fluxion $=\dot{s}$, and the area of a circle, whose radius is unity, $=p$: then the distance (AF) of the circle EG , from the vertex A , being denoted by x , we have, by similar triangles, as $a : b :: x : EF(y)$

$= \frac{bx}{a}$. Whence in this case, $\dot{s} (=p\dot{y} \dot{x}) = \frac{pb^2 x \dot{x}}{a^2}$; and consequently $s = \frac{pb^2 x^2}{3a^2}$; which, when $x=a$ ($=AD$)

gives.

gives $\frac{p^2 a}{3}$ ($= p \times BD^2 \times \frac{1}{3} AD$) for the content of the whole cone ABC: which appears from hence to be just $\frac{1}{3}$ of a cylinder of the same base and altitude.

PROB. 4. To compute the surface of any solid body.

THE fluxion of the surface of the solid is equal to the periphery of the surface, by whose motion the solid is generated, multiplied by its velocity on the edge of the solid, and the computation is made as in the foregoing.

EXAMP. Let it be proposed to determine the convex superficies of a cone ABC, fig. 11.

Then, the semi-diameter of the base (BD, or CD) being put $= b$, the slanting line or hypotenuse AC $= c$, and FH (parallel to DC) $= y$, AG $= z$, the surface $= w$, its fluxion $= \dot{w}$, and p = the periphery of a circle whose diameter is unity, we shall, from the simi-

larity of the triangles ADC and Hmb, have $b : c :: y : mb$; whence $\dot{w} (2 p y \dot{z}) = \frac{2 p c y \dot{y}}{b}$; and consequently $\dot{w} = \frac{p c y^2}{b}$. This, when $y = b$, becomes

$\dot{w} = p c b = p \times DC \times AC$ = the convex superficies of the whole cone ABC: which therefore is equal to a rectangle under half the circumference of the base and the slanting line.

The method of fluxions is also applied to find the centres of gravities, and oscillation of different bodies; to determine the paths described by projectiles and bodies acted on by central forces, with the laws of centripetal force in different curves, the retardates given to motions performed in resisting media, the attractions of bodies under different forms, the direction of wind which has the greatest effect on an engine, and to solve many other curious and useful problems.

F L Y

Fly.

FLY, in zoology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent. By this they are distinguished from beetles, butterflies, grasshoppers, &c. See SCARABÆUS, GRYLLUS, &c.

Flies are subdivided into those which have four, and those which have two wings.

Of those with four wings there are several genera or kinds; as the ant, apis, ichneumon, &c. See ARIS, FORMICA, &c.

Of those with two wings, there are likewise several kinds, as the gad-fly, gnat, &c. See GAD-FLY, &c.

Those who desire a more particular account of the anatomy, generation, structure, and manifold subdivisions of flies, may consult Reaumur's History of Insects, tom. 4.

FLY, in mechanics, a cross with leaden weights at its ends; or rather, a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which, the force of the power, whatever it is, is not only preserved, but equally distributed in all parts of the revolution of the machine. See MECHANICS.

FLIES for Fishing. See FISHING-FLY.

Vegetable FLY, a very curious natural production chiefly found in the West Indies. "Excepting that it has no wings, it resembles the drone both in size and colour more than any other British insect. In the month of May it buries itself in the earth, and begins to vegetate. By the latter end of July the tree is arrived at its full growth, and resembles a coral branch; and is about three inches high, and bears several little pods, which dropping off become worms, and from thence flies, like the British caterpillar."

Such was the account originally given of this extraordinary production. But several boxes of these flies having been sent to Dr Hill for examination, his report was this: "There is in Martinique a fungus of the clavaria kind, different in species from those hitherto known. It produces sboles from its sides, I call it therefore *clavaria sbolesifera*. It grows on putrid animal bodies, as our fungus *ex pede equino* from the dead horse's hoof.

"The cicada is common in Martinique, and in its

F L Y

Fly.

nympha state, in which the old authors call it *tettigometra*: it buries itself under dead leaves to wait its change; and, when the season is unfavourable, many perish. The seeds of the clavaria find a proper bed on this dead insect, and grow.

"The *tettigometra* is among the cicadæ in the British museum; the clavaria is just now known.

"This is the fact, and all the fact; though the untaught inhabitants suppose a fly to vegetate, and though there is a Spanish drawing of the plant's growing into a trifoliate tree, and it has been figured with the creature flying with this tree upon its back."

The ingenious Mr Edwards has taken notice of this extraordinary production in his Gleanings of Natural History, from which the figures on Plate CV. are taken.

FLY-Boat, or Flight, a large flat-bottomed Dutch vessel, whose burden is generally from 400 to 600 tons. It is distinguished by a stern remarkably high, resembling a Gothic turret, and by very broad buttocks below.

FLY-Catcher, in zoology. See MUSCICAPA.

FLY-Trap, in botany, a newly discovered sensitive plant. See *DIONEÆ Muscipula*.

FLY-Tree, in natural history, a name given by the common people of America to a tree, whose leaves, they say, at a certain time of the year produce flies. On examining these leaves about the middle of summer, the time at which the flies use to be produced, there are found on them a sort of bags of a tough matter, of about the size of a filbert, and of a dusky greenish colour. On opening one of these bags with a knife, there is usually found a single full-grown fly, of the gnat kind, and a number of small worms, which in a day or two more have wings and flee away in the form of their parent. The tree is of the mulberry kind, and its leaves are usually very largely stocked with these insect-bags; and the generality of them are found to contain the insects in their worm-state; when they become winged, they soon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf, or injure its shape. They are of the kind of leaf-galls, and partake in all respects,

Flying. except size, of a species we have frequent on the large maple, or, as it is called, the *ycamore*.

The fly-tree is found in many parts of France, where it grows in great abundance, and is there said to bear fruit which give origin to a vast number of flies. The truth of the matter is this. The tree is a species of turpentine tree, and frequently produces or gives origin to certain tubercles, which, in the common turpentine tree, are called its *horns*. These are a sort of long bladders, of the length and thickness of a finger; which arise, not from the stalks, as fruits do, but from the surface of the leaves, and are only a kind of leaf-galls formed of an elongation of its outer membranes, occasioned by the punctures of a number of insects contained within it, which occasion a derivation of fresh juices to the part. These insects are not flies of the common kind, but are the pucerons so well known for feeding on the leaves and tender stalks of trees; and some few of these only are winged, the others being destitute of them.—The origin of these tubercles or bladders is this. The female puceron, as soon as produced from the parent, makes a way under the membrane that covers the leaf, by means of a hole bored in it with the trunk. This hole soon heals up after she is in; and the young ones, which she afterwards produces, by their wounding and sucking the sides of the lodgment in which they find themselves placed, occasion all the swelling and growth of the tubercle.

FLYING, the progressive motion of a bird, or other winged animal, in the air.

The parts of birds chiefly concerned in flying are the wings, by which they are sustained or wafted along. The tail, Messrs Willoughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air, and to obviate the vacillations of the body and wings: for, as to turning to this or that side, it is performed by the wings and inclination of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and preserves the same situation what way soever the bird turns.

In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left; so a bird, in beating the air with its right wing alone, towards the tail, will turn its fore-part to the left. Thus pigeons changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclination of their head and neck; which altering the course of gravity, the bird will proceed in a new direction.

The manner of FLYING is thus: The bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers therein, constitute one continued lamina. Being now

raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those successions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces continue to be in *equilibrium*, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

Artificial FLYING, that attempted by men, by the assistance of mechanics.

The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break the fall.

Friar Bacon, who lived near 500 years ago, not only affirms the art of flying possible, but assures us, that he himself knew how to make an engine wherein a man fitting might be able to convey himself through the air like a bird; and further adds, that there was then one who had tried it with success. The secret consisted in a couple of large thin hollow copper-globes, exhausted of air; which being much lighter than air, would sustain a chair, whereon a person might sit. Fa. Francisco Lana, in his *Prodromo*, proposes the same thing, as his own thought. He computes, that a round vessel of plate-brass, 14 foot in diameter, weighing three ounces the square foot, will only weigh 1848 ounces; whereas a quantity of air of the same bulk, will weigh 2155 ounces; so that the globe will not only be sustained in the air, but will carry with it a weight of 3733 ounces; and by increasing the bulk of the globe, without increasing the thickness of the metal, he adds, a vessel might be made to carry a much greater weight.—But the fallacy is obvious: a globe of the dimensions he describes, Dr Hook shews, would not sustain the pressure of the air, but be crushed inwards. Beside, in whatever ratio the bulk of the globe were increased, in the same must the thickness of the metal, and consequently the weight, be increased: so that there would be no advantage in such augmentation.

The same author describes an engine for flying, invented by the Sieur Besnier, a smith of Sable, in the county of Maine. *Vid. Philosoph. Collect. N° 1.*

The philosophers of king Charles the second's reign were mightily abused about this art. The famous bishop Wilkins was so confident of success in it, that he

says,

Flying
Factor.

says, he does not question but, in future ages, it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING Bridge. See BRIDGE.

FLYING Fish, a name given by the English writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of water a long time. See EXOCOETUS.

FLYING Pinion, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part.

FO, or FOE; an idol of the Chinese. He was originally worshipped in the Indies, and transported from thence into China, together with the fables with which the Indian books were filled. He is said to have performed most wonderful things, which the Chinese have described in several volumes, and represented by cuts.

Self of Fo. See CHINA, n° 61.

FOAL, or COLT and FILLY; the young of the horse kind. The word *colt*, among dealers, is understood of the male, as *filly* is of the female. See COLT.

FOCUS, in geometry and conic sections, is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves concur and meet. See CONIC SECTIONS.

FOCUS, in optics; a point in which any number of rays, after being reflected or refracted, meet.

FODDER, any kind of meat for horses or other cattle. In some places, hay and straw, mingled together, is peculiarly denominated *fodder*.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

FODDER, in mining; a measure containing 22 hundred and an half weight, though in London but 20 hundred weight.

FOENUGREEK, in botany. See TRIGONELLA.

FOENUS NAUTICUM. Where money was lent to a merchant, to be employed in a beneficial trade, with condition to be repaid, with extraordinary interest, in case such voyage was safely performed, the agreement was sometimes called *fenus nauticum*, sometimes *usura maritima*. But as this gave an opening for usurious and gaming contracts, 19 Geo. II. c. 37. enacts, that all money lent on bottomry, or at *respondentia*, on vessels bound to or from the East Indies, shall be expressly lent only upon the ship or merchandise; the lender to have the benefit of salvage, &c. Blackst. Com. II. 459. Mol. de Jur. Mar. 361.

FOESIUS (Annius), a very learned and celebrated physician of the faculty of Paris, born at Metz in 1528. He translated into Latin the whole works of Hippocrates, judiciously correcting the Greek text as he went along; and composed a kind of dictionary to him, intitled *Oeconomia Hippocratis*. He translated, besides, the Commentaries of Galen upon the second book of Hippocrates; and was the author of some other works. After practising physic a long time with great success and reputation, at Lorrain and other places, he died in 1596.

FOETOR, in medicine, stinking or foetid effluvia arising from the body or any part thereof.

Foetus,
Fog.

FOETUS, the young of all viviparous animals whilst in the womb, and of oviparous animals before being hatched: the name is transferred by botanists to the embryos of vegetables.

In the human fetus are several peculiarities not to be found in the adult; some of them are as follows.

1. The arteries of the navel-string, which are continuations of the hypogastrics, are, after the birth, shrivelled up, and form the ligamenta umbilic. infer.
2. The veins of the navel-string are formed by the union of all the venous-branches in the placenta, and passing into the abdomen become the falciform ligament of the liver.
3. The lungs, before being inflated with air, are compact and heavy; but after one inspiration they become light, and as it were spongy; and it may be noted here, that the notion of the lungs sinking in water before the child breathes, and of their swimming after the reception of air, are no certain proofs that the child had or had not breathed, much less that it was murdered: for the inflated lungs become specifically lighter than water as soon as any degree of putrefaction takes place in them; and this soon happens after the death of the child: besides, where the utmost care hath been taken to preserve the child, it hath breathed once or twice, and then died.
6. The thymus gland is very large in the fetus, but dwindles away in proportion as years advance.
7. The foramen ovale in the heart of a fetus, is generally closed in an adult.

For an account of the different opinions concerning the formation and growth of the fetus. See GENERATION.

FOG, or MIST, a meteor, consisting of gross vapours, floating near the surface of the earth.

Mists, according to lord Bacon, are imperfect condensations of the air, consisting of a large proportion of the air, and a small one of the aqueous vapour: and these happen in the winter, about the change of the weather from frost to thaw, or from thaw to frost; but in the summer, and in the spring, from the expansion of the dew.

If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous heat, do, at their first entrance into the atmosphere, meet with cold enough to condense them to a considerable degree, their specific gravity is by that means increased; and so they will be stopped from ascending, and either return back, in form of dew or of drizzling rain; or remain suspended some time in the form of a fog. Vapours may be seen on the high grounds as well as the low, but more especially about marshy places: they are easily dissipated by the wind, as also by the heat of the sun: they continue longest in the lowest grounds, because these places contain most moisture, and are least exposed to the action of the wind.

Hence we may easily conceive, that fogs are only low clouds, or clouds in the lowest region of the air; as clouds are no other than fogs raised on high. See CLOUD.

When fogs stink, then the vapours are mixed with sulphureous exhalations, which smell so. Objects viewed through fogs, appear larger and more remote than through the common air. Mr Boyle observes, that upon the coast of Coromandel, and most maritime

parts.

Fogage
Foil.

Fokien
Folcmote.

parts of the East-Indies, there are, notwithstanding the heat of the climate, annual fogs so thick, as to occasion people of other nations who reside there, and even the natives, to keep their houses close shut up.

Fogs are commonly pretty strongly electrified, as appears from Mr Cavallo's observations upon them. See ELECTRICITY, n° 69.

FOGAGE, in the forest-law, is rank grass, not eaten up in summer.

FOGLIETA (Oberto or Hubert), a Genoese priest, and one of the most learned writers of the 16th century. He had a share in the disturbances that were raised at Genoa; for which he was banished, and died at Rome in 1581, aged 63. He wrote a history of Genoa in Italian, which is highly esteemed; and many works in Latin.

FOGO, or FUEGO, a small island in the Atlantic Ocean, and one of the Cape de Verda. It is remarkable for a mountain that vomits fire and flames, like Mount Vesuvius. It sometimes throws out large stones, with a noise like thunder. The few inhabitants that are here, live at the foot of this mountain. W. Long. 24. 47. N. Lat. 15. 20.

FOHL. See FE; and CHINA, n° 7.

FOIBLE, a French term, frequently used also in our language. It literally signifies weak; and in that sense is applied to the body of animals, and the parts thereof; as, *foible reins*, *foible sight*, &c. being derived from the Italian *fiavole*, of the Latin *fibiles*, to be "lame, aged."

But it is chiefly used with us substantively, to denote a defect or flaw in a person or thing. Thus we say, Every person has his foible; and the great secret consists in hiding it artfully: Princes are gained by flattery, that is their foible: The foible of young people is pleasure; the foible of old men is avarice; the foible of the great and learned is vanity; the foible of women and girls, coquetry, or an affectation of having gallants: You should know the forte and the foible of a man, before you employ him: We should not let people perceive that we know their foible.

FOIL, among glass-grinders, a sheet of tin, with quicksilver, or the like, laid on the backside of a looking-glass, to make it reflect. See FOLIATING.

FOIL, among jewellers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give it an agreeable different colour, either deep or pale: thus, if you want a stone to be of a pale colour, put a foil of that colour under it; or, if you would have it deep, lay a dark one under it.

These foils are made either of copper, gold, or gold and silver together. The copper foils are commonly known by the name of *Nuremberg* or *German foils*; and are prepared as follows: Procure the thinnest copper-plates you can get: beat these plates gently upon a well-polished anvil, with a polished hammer, as thin as possible; and placing them between two iron plates as thin as writing-paper, heat them in the fire; then boil the foil, in a pipkin, with equal quantities of tartar and salt, constantly stirring them till by boiling they become white; after which, taking them out, and drying them, give them another hammering, till they are made fit for your purpose: however, care must be taken not to give the foils too much heat, for fear of

melting; nor must they be too long boiled, for fear of attracting too much salt.

The manner of polishing these foils is as follows. Take a plate of the best copper, one foot long and about five or six inches wide, polished to the greatest perfection; bend this to a long convex, fasten it upon a half roll, and fix it to a bench or table; then take some chalk, washed as clean as possible, and sifted through a fine linen-cloth, till it be as fine as you can make it; and, having laid some thereof on the roll, and wetted the copper all over, lay your foils on it, and with a polishing stone and the chalk, polish your foils till they are as bright as a looking-glass; after which they must be dried, and laid up secure from dust.

FOKIEN, a province of China in Asia, commodiously situated for navigation and commerce, part of it bordering on the sea, in which they catch large quantities of fish, which they send salted to other parts of the empire. Its shores are very uneven, by reason of the number and variety of its bays; and there are many forts built thereon to guard the coast. The air is hot, but pure and wholesome.

The mountains are almost every where disposed into a kind of amphitheatres, by the labour of the inhabitants, with terraces placed one above another. The fields are watered with rivers and springs, which issue out of the mountains, and which the husbandmen conduct in such a manner as to overflow the fields of rice when they please, because it thrives best in watery ground. They make use of pipes of bamboo for this purpose.

They have all commodities in common with the rest of China; but more particularly mulk, precious stones, quicksilver, silk, hempen-cloth, callico, iron, and all sorts of utensils wrought to the greatest perfection. From other countries they have cloves, cinnamon, pepper, sandal-wood, amber, coral, and many other things. The capital city is Foutcheou Fou; or, as others would have it written, Fucherosu. But as for Fokien, which most geographers make the capital, there is no such place.

FOLC-LANDS, (Sax.) copy-hold lands so called in the time of the Saxons, as charter-lands were called *hoc-lands*, Kitch. 174. *Folkland* was *terra vulgi*, or *popularis*; the land of the vulgar people, who had no certain estate therein, but held the same, under the rents and services accustomed or agreed, at the will only of their lord the thane; and it was therefore not put in writing, but accounted *prædium rusticum & ignobile*. Spelm. of Fends, c. 5.

FOLCMOTE, or FOLKMOTE, (Sax. *Folgemot*, i. e. *conventus populi*), is compounded of *folk*, *popularis*, and *mote*, or *gemote*, *convener*; and signified originally, as Somner in his Saxon Dictionary informs us, a general assembly of the people, to consider of and order matters of the commonwealth. And Sir Henry Spelman says, the *folcmote* was a sort of annual parliament, or convention of the bishops, thanes, aldermen, and freemen, upon every May-day yearly; where the laymen were sworn to defend one another and the king, and to preserve the laws of the kingdom; and then consulted of the common safety. But Dr Brady infers from the laws of the Saxon kings of England, that it was an inferior court, held before the king's *reeve* or steward, every month, to do *folk* right, or compose.

pope smaller differences, from whence there lay appeal to the superior courts; *Gloss.* p. 48. Squire seems to think the *folcmote* not distinct from the *shiremote*, or common general meeting of the county. See his *Angl. Sax. Gov.* 155. n.

Manwood mentions *folcmote* as a court holden in London, wherein all the *folk* and people of the city did complain of the mayor and aldermen, for misgovernment within the said city; and this word is still in use among the Londoners, and denotes *celebrem ex tota civitate conventum*. *Stow's Survey*. According to Kennet, the *folcmote* was a common-council of all the inhabitants of a city, town, or borough, convened often by sound of bell, to the *Mote Hall* or *House*; or it was applied to a larger congress of all the freemen within a county, called the *shire-mote*, where formerly all knights and military tenants did fealty to the king, and elected the annual sheriff on the 1st of October; till this popular election, to avoid tumults and riots, devolved to the king's nomination, *anno* 1315, 3 Edw. 1. After which the city *folcmote* was swallowed up in a select committee or common-council, and the county *folcmote* in the sheriff's tourn and assizes.

The word *folcmote* was also used for any kind of popular or public meeting; as of all the tenants at the *court-leet*, or *court-baron*, in which signification it was of a less extent. *Paroch. Antiq.* 120.

FOLENGIO (Theophilus), of Mantua, known also by the title of *Merlin Cocayne*, an Italian poet, remarkable for giving to a poem a name which has been adopted ever since for all trifling performances of the same species, consisting of buffoonry, puns, anagrams, wit without wisdom, and humour without good-sense. His poem was called *The Macaroni*, from an Italian cake of the same name, which is sweet to the taste, but has not the least alimentary virtue, on the contrary palls the appetite and clogs the stomach. These idle poems, however, became the reigning taste in Italy and in France: they gave birth to macaroni academies; and, reaching England, to macaroni clubs; till, in the end, every thing insipid, contemptible, and ridiculous, in the character, dress, or behaviour, of both men and women, is now summed up in the despicable appellation of a *macaroni*. Folengio died in 1544.

FOLIA, among botanists, particularly signify the leaves of plants; those of flowers being expressed by the word *PETALS*. See *LEAF*.

FOLIAGE, a cluster or assemblage of flowers, leaves, branches, &c.

FOLIAGE, is particularly used for the representations of such flowers, leaves, branches, rinds, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

FOLIATING OF LOOKING-GLASSES, the spreading the plates over, after they are polished, with quicksilver, &c. in order to reflect the image. It is performed thus: A thin blotting paper is spread on the table, and sprinkled with fine chalk; and then a fine lamina or leaf of tin, called *foil*, is laid over the paper; upon this is poured mercury, which is to be distributed equally over the leaf with a hare's-foot or cotton: over this is laid a clean paper, and over that the glass-plate, which is pressed down with the right-hand, and the paper drawn gently out with the left: this being done, the plate is covered with a thicker paper, and loaded

with a greater weight, that the superfluous mercury may be driven out and the tin adhere more closely to the glass. When it is dried, the weight is removed, and the looking-glass is complete.

Some add an ounce of marcasite, melted by the fire; and, lest the mercury should evaporate in smoke, they pour it into cold water; and when cooled, squeeze through a cloth, or through leather.

Some add a quarter of an ounce of tin and lead to the marcasite, that the glass may dry the sooner.

FOLIATING OF *Globe Looking-glasses*, is done as follows: Take five ounces of quicksilver, and one ounce of bismuth; of lead and tin, half an ounce each: first put the lead and tin into fusion, then put in the bismuth; and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quicksilver into it: after this, take the glass-globe, which must be very clean, and the inside free from dust: make a paper-funnel, which put into the hole of the globe, as near the glass as you can, so that the amalgam, when you pour it in, may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where: if you find the amalgam begin to be curdly and fixed, then hold it over a gentle fire, and it will easily flow again; and if you find the amalgam too thin, add a little more lead, tin, and bismuth to it. The finer and clearer your globe is, the better will the looking-glass be.

Dr Shaw observes, that this operation has considerable advantages, as being performable in the cold; and that it is not attended with the danger of poisonous fumes from arsenic, or other unwholesome matters, usually employed for this purpose: besides, how far it is applicable to the more commodious foliating of the common looking-glasses, and other speculums, he thinks, may deserve to be considered.

FOLIO, in merchants books, denotes a page, or rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See *BOOK-KEEPING*.

FOLIO, among printers and booksellers, the largest form of books, when each sheet is so printed that it may be bound up in two leaves only.

FOLIUM, or LEAF, in botany. See *LEAF*.

FOLKLAND, and FOLKMOLE. See *FOLCLAND*. FOLLICULUS, (from *folli*, a bag), a species of seed-vessel first mentioned by Linnæus in his *Delineatio plantæ*, generally consisting of one valve, which opens from bottom to top on one side, and has no future for fattening or attaching the seeds within it.

FOLLICULI are likewise defined by the same author to be small glandular vessels distended with air, which appear on the surface of some plants; as at the root of water-milfoil, and on the leaves of alderovanda. In the former, the vessels in question are roundish, and furnished with an appearance like two horns; in the latter, pot-shaped and semi-circular.

FOMAHANT, in astronomy, a star of the first magnitude in the constellation AQUARIUS.

FOMENTATION, in medicine, is a fluid externally applied, usually as warm as the patient can bear it, and in the following manner. Two flannel cloths are dipped into the heated liquor, one of which is wrung as dry as the necessary speed will admit, then immediately applied to the part affected; it lies on un-

Tont,
Fontaine.

til the heat begins to go off, and the other is in readiness to apply at the instant in which the first is removed: thus these flannels are alternately applied, so as to keep the affected part constantly supplied with them warm. This is continued 15 or 20 minutes, and repeated two or three times a-day.

Every intention of relaxing and soothing by fomentations, may be answered as well by warm water alone as when the whole tribe of emollients are boiled in it; but when discutients or antiseptics are required, such ingredients must be called in as are adapted to that end.

The degree of heat should never exceed that of producing a pleasing sensation; great heat produces effects very opposite to that intended by the use of fomentations.

FONT, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants or other persons.

FONTAINE (John), the celebrated French poet, and one of the first-rate geniuses of his age, was born at Chateau-Thierry in Champagne, the 8th of July 1621, of a good extraction. At the age of 19 he entered amongst the Oratorians, but quitted that order 18 months after. He was 22 years of age before he knew his own talents for poetry; but hearing an ode of Malherbe read, upon the assassination of Henry IV. he was so taken with admiration of it, that the poetical fire, which had before lain dormant within him, seemed to be enkindled from that of the other great poet. He applied himself to read, to meditate, to repeat, in fine, to imitate, the works of Malherbe. The first essays of his pen he confined to one of his relations, who made him read the best Latin authors, Horace, Virgil, Terence, Quintilian, &c. and then the best compositions in French and Italian. He applied himself likewise to the study of the Greek authors, particularly Plato and Plutarch. Some time afterwards his parents made him marry a daughter of a lieutenant-general, a relation of the great Racine. This young lady, besides her very great beauty, was remarkable for the delicacy of her wit, and Fontaine never composed any work without consulting her. But, as her temper was none of the best, to avoid discussion, he separated himself from her company as often as he well could. The famous duchess of Bouillon, niece to cardinal Mazarine, being exiled to Chateau-Thierry, took particular notice of Fontaine. Upon her recall he followed her to Paris; where, by the interest of one of his relations, he got a pension settled upon him. He met with great friends and protectors amongst the most distinguished persons of the court, but madame de La Sabliere was the most particular. She took him to live at her house; and it was then that Fontaine, divested of domestic concerns, led a life conformable to his disposition, and cultivated an acquaintance with all the great men of the age. It was his custom, after he was fixed at Paris, to go every year, during the month of September, to his native place of Chateau-Thierry, and pay a visit to his wife, carrying with him Racine, Despreaux, Chapelle, or some other celebrated writers. When he has sometimes gone thither alone by himself, he has come away without remembering even to call upon her; but seldom omitted selling some part of his lands, by which means he squandered away a consider-

able fortune. After the death of madame de La Sabliere, he was invited into England, particularly by madame Mazarin, and by St Evremont, who promised him all the sweets and comforts of life; but the difficulty of learning the English language, and the liberality of the duke of Burgundy, prevented his voyage.

About the end of the year 1692 he fell dangerously ill; and, as is customary upon these occasions in the Romish church, he made a general confession of his whole life to P. Pogue, an oratorian; and, before he received the sacrament, he sent for the gentlemen of the French academy, and in their presence declared his sincere compunction for having composed his Tales; a work he could not reflect upon without the greatest repentance and detestation; promising, that if it should please God to restore his health, he would employ his talents only in writing upon matters of morality or piety. He survived this illness two years, living in the most exemplary and edifying manner, and died the 13th of March 1695, being 74 years of age. When they stripped his body, they found, next his skin, a hair-shirt; which gave room for the following expression of the younger Racine:

Et l'Auteur de Jacoupe est arme d'un Cilice.

Fontaine's character is remarkable for a simplicity, candour, and probity, seldom to be met with. He was of an obliging disposition; cultivating a real friendship with his brother poets and authors; and, what is very rare, beloved and esteemed by them all. His conversation was neither gay nor brilliant, especially when he was not among his intimate friends.

One day being invited to dinner at a farmer-general's, he eat a great deal, but did not speak. Rising up from table very early, under pretext of going to the academy, one of the company represented to him that it was not yet a proper time: "Well, (says he,) if it is not, I will stay a little longer." He had one son by his wife in the year 1660. At the age of 14, he put him into the hands of M. de Harley, the first president, recommending to him his education and fortune. It is said, that having been a long time without seeing him, he happened to meet him one day visiting, without recollecting him again, and mentioned to the company that he thought that young man had a good deal of wit and understanding. When they told him it was his own son, he answered in the most tranquil manner, "Ah! then I am very well contented with him." An indifference, or rather an absence of mind, influenced his whole conduct, and rendered him often insensible to the inclemency of the weather. Madame de Bouillon going one morning to Versailles, saw him, abstracted in thought, sitting in an arbour; returning at night, she found him in the same place, and the same attitude, although it was very cold and had rained almost the whole day. He carried this simplicity so far, that he was scarce sensible of the bad effects some of his writings might occasion, particularly his Tales. In a great sickness, his confessor exhorting him to prayer and alms-deeds: "As for alms-deeds, (replied Fontaine,) I am not able, having nothing to give; but they are about publishing a new edition of my Tales, and the bookseller owes me a hundred copies; you shall have them to sell, and distribute their amount amongst the poor." Another time P. Pogue exhorting him

Fontaine.

Fontain-
bleau
Fontenelle.

him to repent of his faults, " If he has committed any, (cried the nurse), I am sure it is more from ignorance than malice, for he has as much simplicity as an infant."

One time having composed a tale, wherein he made a profane application of those words of the gospel, " Lord, five talents thou didst deliver to me," he dedicated it, by a most ingenious prologue, to the celebrated Arnould, telling him, it was to shew to posterity the great esteem he had for the learned doctor. He was not sensible of the indecency of the dedication, and the profane application of the text, till Boileau and Racine represented it to him. He addressed another, by a dedication in the same manner, to the archbishop of Paris. His Fables are an immortal work, exceeding every thing in that kind, both ancient and modern, in the opinion of the learned. People of taste, the oftener they read them, will find continually new beauties and charms, not to be met with elsewhere. The descendants of this great poet are exempted in France from all taxes and impositions, a privilege which the intendants of Soissons to this day think it an honour to confer them to.

FONTAINEBLEAU, a town in the Isle of France, and in the Gatinois, remarkable for its fine palace, which has been the place where the kings of France used to lodge when they went a-hunting. It was first embellished by Francis I. and all the successive kings have added something thereto; inasmuch that it may now be called the finest pleasure-house in the world. It stands in the middle of a forest, consisting of 26.424 arpents of land, each containing 100 square perches, and each perch 18 feet. E. Long. 2. 33. N. Lat. 40. 22.

FONTARABIA, a sea-port town of Spain in Biscay, and in the territory of Guipuscoa, seated on a peninsula on the sea-shore, and on the river Bidassoa. It is small, but well fortified, both by nature and art; and has a good harbour, tho' dry at low-water. It is built in the form of an amphitheatre, on the declivity of an hill, and surrounded on the land-side by the high Pyrenean mountains. It is a very important place, being accounted the key of Spain on that side. W. Long. 1. 43. N. Lat. 43. 23.

FONTENAY (John Baptist Blain de), a very famous painter of fruit and flowers, was born at Caen in 1654. Lewis XIV. gave him a pension, and an apartment in the galleries of the Louvre; and he was nominated counsellor of the Academy of Painting. His fruit and flowers have all the freshness and beauty of nature; the very dew seems to trickle down their stalks, with all the lustre and transparency of the diamond, while the insects upon them seem perfectly alive and animated. This ingenious painter died at Paris, in 1715.

FONTENELLE (Bernard de), a celebrated French author, was born in 1657, and died in 1756, when he was near 100 years old. He discharged the trust of perpetual secretary to the Academy of Sciences above 40 years with universal applause; and his *History of the Academy of Sciences* throws a great light upon their memoirs, which are very obscure. The eloges which he pronounced on the deceased members of the academy, have this peculiar merit, that they excite a respect for the sciences as well as for the author. In his poetical performances, and the *Dialogues of the dead*,

VOL. IV.

the spirit of Voiture was discernible, though more extended and more philosophical. His *Plurality of Worlds*, is a work singular in its kind; the design of which was to present that part of philosophy to view in a gay and pleasing dress. In his more advanced years, he published comedies, which, tho' they shewed the elegance of Fontenelle, were little fitted for the stage; and *An apology for Des Cartes's Vortices*. M. de Voltaire, who declares him to have been the most universal genius the age of Lewis XIV. produced, says, " We must excuse his comedies, on account of his great age; and his Cartesian opinions, as they were those of his youth, when they were universally received all over Europe."

FONTENOY, a town or village of the Austrian Netherlands, in the province of Hainault, and on the borders of Flanders; remarkable for a battle fought there between the allies and the French on the first of May 1745. The French were commanded by Mareschal Saxe, and the Allies by the Duke of Cumberland. The latter behaved with great bravery; but through the superiority of the numbers of the French army, and likewise the superior generalship of their commander, the Allies were defeated with great slaughter. The British troops behaved with astonishing intrepidity, as their enemies themselves avow. It is even said, that the battle was lost through the cowardice of the Dutch, who failed in their attack on the village of Fontenoy, on which the event of the day depended. E. Long. 2. 20. N. Lat. 50. 35.

FONTENOY, a village of France, in the duchy of Burgundy, remarkable for a bloody battle fought there in 841, between the Germans and the French, in which were killed above 100,000 men; and the Germans were defeated. E. Long. 3. 48. N. Lat. 47. 28.

FONTEVRAUD, or *Order of FONTEVRAUD*, a religious order instituted about the latter end of the 11th century. By the rules of this order, the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

FONTICULUS, or FONTANELLA, in surgery, an issue, seton, or small ulcer, made in various parts of the body, in order to eliminate the latent corruption out of it.

FONTALIS, WATER-MOSS; a genus of the cryptogamia musci class. There are four species, all of them natives of Britain. They grow on the brinks of rivulets, and on the trunks of trees. The most remarkable is the antipyretica, with purple stalks. The Scandinavians line the insides of their chimneys with this moss, to defend them against the fire; for, contrary to the nature of all other moss, this is scarcely capable of burning.

FOOD, in the most extensive signification of the word, implies whatever aliments are taken into the body, whether solid or fluid; but, in common language, it is generally used to signify only the solid part of our aliment.

The most remarkable distinction of foods is into those which are already assimilated into the animal nature, and such as are not. Of the first kind are animal substances in general; which if not entirely similar, are nearly so, to our nature. The second comprehends vegetables, which are much more difficultly assimilated.

Fontenoy
Font.

ted. But, as the nourishment of all animals, even those which live on other animals, can be traced originally to the vegetable kingdom, it is plain, that the principle of all nourishment is in vegetables.

Cullen on the
Mat. Med.

Though there is, perhaps, no vegetable which does not afford nourishment to some species of animals or others; yet, with regard to mankind, a very considerable distinction is to be made. Those vegetables which are of a mild, bland, agreeable taste, are proper nourishment; while those of an acrid, bitter, and nauseous nature, are improper. We use, indeed, several acrid substances as food; but the mild, the bland, and agreeable, are in the largest proportion in almost every vegetable. Such as are very acrid, and at the same time of an aromatic nature, are not used as food, but as spices or condiments, which answer the purposes of medicine rather than any thing else. Sometimes, indeed, acrid and bitter vegetables seem to be admitted as food. Thus celeri and endive are used in common food, though both are substances of considerable acrimony; but it must be observed, that, when we use them, they are previously blanched, which almost totally destroys their acrimony. Or if we employ other acrid substances, we generally, in a great measure, deprive them of their acrimony by boiling. In different countries the same plants grow with different degrees of acrimony. Thus, garlic here seldom enters our food; but in the southern countries, where the plants grow more mild, they are frequently used for that purpose. The plant which furnishes cassia, being very acrimonious, and even poisonous, in its recent state, affords an instance of the necessity of preparing acrid substances even in the hot countries: and there are other plants, such as arum-root, which are so exceedingly acrimonious in their natural state, that they cannot be swallowed with safety; yet, when deprived of that acrimony, will afford good nourishment.

The most remarkable properties of different vegetable substances as food, are taken notice of under their different names; here we shall only compare vegetable foods in general with those of the animal kind.

I. *In the Stomach*, they differ remarkably, in that the vegetables always have a tendency to acidity, while animal-food of all kinds tend rather to alkalescency and putrefaction. Some animal-foods, indeed, turn manifestly acid before they putrify; and it has been asserted, that some degree of accefency takes place in every kind of animal-food before digestion. This accefency of animal-food, however, never comes to any morbid degree, but the disease is always on the side of putrefaction. The accefency of vegetables is more frequent, and ought to be more attended to, than the alkalescency of animal food; which last, even in weak stomachs, is seldom felt; while accefency greatly affects both the stomach and system.

With regard to their difference of *solution*:—Heaviness, as it is called, is seldom felt from vegetables, except from tough farinaceous paste, or the most viscid substances; while the heaviness of animal-food is more frequently noticed, especially when in any great quantity. Difficulty of solution does not depend so much on firmness of texture, (as a man, from fish of all kinds, is more oppressed than from firmer substances), but on viscosity; and hence it is more frequent in animal-food,

especially in the younger animals.

With regard to *mixture*:—There is no instance of difficult mixture in vegetables, except in vegetable oils; while animal-foods, from both viscosity and oiliness, especially the fatter meats, are refractory in this respect. Perhaps the difference of animal and vegetable foods might be referred to this head of mixture. For vegetable food continues long in the stomach, giving little stimulus: Now the system is affected in proportion to the extent of this stimulus, which is incomparably greater from the animal viscid oily food, than from the vegetable, firmer, and more aqueous. However, there are certain applications to the stomach, which have a tendency to bring on the cold fit of fever, independent of stimulus, merely by their refrigeration: and this oftener arises from vegetables; as we see, in those hot countries where intermittents prevail, they are oftener induced from a surfeit of vegetable than of animal food. A proof of this is, that when one is recovering of an intermittent, there is nothing more apt to cause a relapse than cold food, especially if taken on those days when the fit should return, and particularly acceft, fermentable vegetables, as salad, melons, cucumbers, &c. *acido-dulces*, &c. which, according to Dr Cullen, are the most frequent causes of epidemics; therefore, when an intermittent is to be avoided, we shun vegetable diet, and give animal-foods, although their stimulus be greater.

II. *In the Intestines*. When the putrefaction of animal-food has gone too far, it produces an active stimulus, causing diarrhoea, dysentery, &c. But these effects are but rare: whereas from vegetable food and its acid, which, united with the bile, proves a pretty strong stimulus, they more frequently occur; but, luckily, are of less consequence, if the refrigeration is not very great. In the autumnal season, when there is a tendency to dysentery, if it is observed that eating of fruits brings it on, it is rather to be ascribed to their cooling than stimulating the intestines.

As to *food*—Wherever neither putrefaction, nor acidity, has gone a great length, animal-food keeps the belly more regular. Vegetable food gives a greater proportion of feculent matter, and when excreted by the stomach and intestines, is more apt to stagnate, and produce slow belly and costiveness, than animal stimulating food; which, before it comes to the great guts, where stoppage is made, has attained a putrefactive tendency, and gives a proper stimulus: and thus those who are costive from the use of vegetables, when they have recourse to animal-food are in this respect better.

III. *In the blood-vessels*. They both give a blood of the same kind, but of different quality. Animal-food gives it in greater quantity, being in great part, as the expression is, convertible in *succum et sanguinem*, and of easy digestion; whereas vegetable is more watery, and contains a portion of unconquerable saline matter, which causes it to be thrown out of the body by some excretion. Animal-food affords a more dense stimulating elastic blood than vegetable; stretching and causing a greater resistance in the solids, and again exciting their stronger action. It has been supposed, that accefency of vegetable food is carried into the blood-vessels, and there exerts its effects; but the tendency of animal-fluids is so strong to alkalescency, that the existence of an acid acrimony in animal-blood seems

very

very improbable. Animal-food alone will soon produce an alkalescent acrimony; and if a person who lives entirely on vegetables were to take no food for a few days, his acrimony would be alkalescent.

IV. We are next to take notice of the *quantity of nutriment* these different foods afford. Nutriment is of two kinds: the first repairs the waste of the solid fibres; the other supplies certain fluids, the chief of which is oil. Now, as animal-food is easier converted, and also longer retained in the system, and as it contains a greater proportion of oil, it will afford both kinds of nutriment more copiously than vegetables.

V. Lastly, *As to the different degrees of perspirability of these foods.* This is not yet properly determined. Sanctörus constantly speaks of mutton as the most perspirable of all food, and of vegetables as checking perspiration. This is a consequence of the different stimulus those foods give to the stomach, so that persons who live on vegetables have not their perspiration so suddenly excited. In time of digestion, perspiration is stopped from whatever food; much more so from cooling vegetables. Another reason why vegetables are less perspirable is, because their aquo-saline juices determine them to go off by urine, while the more perfectly mixed animal-food is more equally diffused over the system, and so goes off by perspiration. Hence Sanctörus's accounts may be underflood; for vegetable aliment is not longer retained in the body, but mostly takes the course of the kidneys. Both are equally perspirable in this respect, viz. that a person living on either, returns once a-day to his usual weight; and if we consider the little nourishment of vegetables, and the great tendency of animal food to corpulency, we must allow that vegetable is more quickly perspired than animal-food.

As to the question, Whether man was originally designed for animal or vegetable food, see the article **CARNIVOROUS.**

With regard to the effects of these foods on men, it must be observed, that there are no persons who live entirely on vegetables. The Pythagoreans themselves eat milk; and those who do so mostly, as these Pythagoreans are weakly, sickly, and meagre, labouring under a constant diarrhoea and several other diseases. None of the hardy, robust, live on these; but chiefly such as gain a livelihood by the exertion of their mental faculties, as (in the East Indies) factors and brokers; and this method of life is now confined to the hot climates, where vegetable diet, without inconvenience, may be carried to great excess. Though it be granted, therefore, that man is intended to live on these different foods promiscuously, yet the vegetable should be in very great proportion. Thus the Laplanders are said to live entirely on animal-food: but this is contradicted by the best accounts; for Linneus says, that besides milk, which they take sour, to obviate the bad effects of animal-food, they use also calla, menyanthus, and many other plants copiously. So there is no instance of any nation living entirely either on vegetable or animal food, though there are indeed some who live particularly on one or other in the greatest proportion. In the cold countries, *e. g.* the inhabitants live chiefly on animal-food, on account of the rigour of the season, their smaller perspiration, and little tendency to putrefaction.

Of more importance, however, is the following than the former question, viz. *In what proportion animal and vegetable food ought to be mixed?*

1. *Animal food* certainly gives most strength to the system. It is a known aphorism of Sanctörus, that *pondus addit robur*; which may be explained from the impletion of the blood-vessels, and giving a proper degree of tension for the performance of strong oscillations. Now animal-food not only goes a greater way in supplying fluid, but also gives the fluid more dense and elastic. The art of giving the utmost strength to the system is best understood by those who breed fighting-cocks. These people raise the cocks to a certain weight, which must bear a certain proportion to the other parts of the system, and which at the same time is so nicely proportioned, as that, on losing a few ounces of it, their strength is very considerably impaired. Dr Robinson of Dublin has observed, that the force and weight of the system ought to be determined by the largeness of the heart, and its proportion to the system: for a large heart will give large blood-vessels, while at the same time the viscera are less, particularly the liver; which last being increased in size, a greater quantity of fluid is determined into the cellular texture, and less into the sanguiferous system. Hence we see how animal-food gives strength, by filling the sanguiferous vessels. What pains we now bestow on cocks, the ancients did on the *Athlete*, by proper nourishment bringing them to a great degree of strength and agility. It is said that men were at first fed on figs, a proof of which we have from their nutritious quality: however, in this respect they were soon found to fall far short of animal-food; and thus we see, that men, in some measure, will work in proportion to the quality of their food. The English labour more than the Scots; and wherever men are exposed to hard labour, their food should be animal. Animal food, although it gives strength, yet loads the body; and Hippocrates long ago observed, that the athletic habit, by a small increase, was exposed to the greatest hazards. Hence it is only proper for bodily labours, and entirely improper for mental exercises; for whoever would keep his mind acute and penetrating, will exceed rather on the side of vegetable food. Even the body is oppressed with animal-food; a full meal always produces dulness, laziness, and yawning; and hence the feeding of gamblers, whose mind must be ready to take advantage, is always performed by avoiding a large quantity of animal-food. Farther, with regard to the strength of the body, animal-food in the first stage of life is hardly necessary to give strength: in manhood, when we are exposed to active scenes, it is more allowable; and even in the decline of life, some proportion of it is necessary to keep the body in vigour. There are some diseases which come on in the decay of life, at least are aggravated by it; among these the most remarkable is the gout. This, when it is in the system, and does not appear with inflammation in the extremities, has pernicious effects there, attacking the lungs, stomach, head, &c. Now to determine this to the extremities, a large proportion of animal-food is necessary, especially as the person is commonly incapable of much exercise.

Animal-food, although it gives strength, is yet of many hazards to the system, as it produces plethora and

all its consequences. As a stimulus to the stomach and to the whole system, it excites fever, urges the circulation, and promotes the perspiration. The system, however, by the repetition of these stimuli, is soon worn out; and a man who has early used the athletic diet, is either early carried off by inflammatory diseases, or, if he takes exercise sufficient to render that diet salutary, such an accumulation is made of putrescent fluids, as in his after-life lays a foundation for the most inveterate chronic distempers. Therefore it is to be questioned, whether we should desire this high degree of bodily strength, with all the inconveniences and dangers attending it. Those who are chiefly employed in mental researches, and not exposed to too much bodily labour, should always avoid an excess of animal-food. There is a disease which seems to require animal-food, viz. the hysteric or hypochondriac; and which appears to be very much a-kin to the gout, affecting the alimentary canal. All people affected with this disease are much disposed to acefcency; which sometimes goes so far, that no other vegetable but bread can be taken in, without occasioning the worst consequences. Here then we are obliged to prescribe an animal-diet, even to those of very weak organs; for it generally obviates the symptoms. However, several instances of scurvy in excess have been produced by a long-continued use of this diet, which it is always unlucky to be obliged to prescribe; and when it is absolutely necessary to prescribe, it should be joined with as much of the vegetable as possible, and when a cure is performed we should gradually recur to that again.

2. Next, let us consider the *vegetable* diet. The chief inconvenience of this is difficulty of assimilation; which, however, in the vigorous and exercised, will not be liable to occur. In warm climates, the assimilation of vegetable aliment is more easy, so that *there* it may be more used, and when joined to exercise gives a pretty tolerable degree of strength and vigour; and though the general rule be in favour of *animal* diet, for giving strength, yet there are many instances of their being remarkably produced from vegetable. Vegetable diet has this advantage, that it whets the appetite, and that we can hardly suffer from a full meal of it. Besides the disorders it is liable to produce in the *prima via*, and its falling short to give strength, there seem to be no bad consequences it can produce in the blood-vessels; for there is no instance where its peculiar acrimony was ever carried there, and it is certainly less putrifiable than animal food; nor, without the utmost indolence, and a sharp appetite, does it give plethora, or any of its consequences: so that we cannot here but conclude, that a large proportion of vegetable food is useful for the generality of mankind.

There is no error in this country more dangerous, or more common, than the neglect of bread: for it is the safest of vegetable aliment, and the best corrector of animal-food; and, by a large proportion of this alone, its bad consequences, when used in a hypochondriac state, have been obviated. The French apparently have as much animal-food on their tables as the Britons; and yet, by a greater use of bread and the dried acid fruits, its bad effects are prevented; and therefore bread should be particularly used by the English, as they are so voracious of animal food. Vegetable food is not only necessary to secure health, but

long life: and, as we have said, in infancy and youth we should be confined to it mostly; in manhood, and decay of life, use animal food; and, near the end, vegetable again.

There is another question much agitated, viz. *What are the effects of variety in food?* Is it necessary and allowable, or universally hurtful? Variety of a certain kind seems necessary; as vegetable and animal foods have their mutual advantages, tending to correct each other. Another variety, which is very proper, is that of liquid and solid food, which should be so managed as to temper each other; and liquid food, especially of the vegetable kind, is too ready to pass off before it is properly assimilated, while solid food makes a long stay. But this does not properly belong to the question, whether variety of the same kind is necessary or proper, as in animal-foods, beef, fish, fowl, &c. It doth not appear that there is any inconvenience arising from this mixture, or difficulty of assimilation, provided a moderate quantity be taken. When any inconvenience does arise, it probably proceeds from this, that one of the particular substances in the mixture, when taken by itself, would produce the *same effect*; and, indeed, it would appear, that this effect is not *heightened* by the mixture, but probably *obviated* by it. There are few exceptions to this, if any, e. g. taking a large proportion of acefcient substances with milk. The coldness, &c. acidity, flatulency, &c. may appear; and it is possible that the coagulium, from the acefcency of the vegetables, being somewhat stronger induced, may give occasion to too long retention in the stomach, and to acidity in too great degree. Again, the mixture of fish and milk often occasions inconveniences. The theory of this is difficult, though, from universal consent, it must certainly be just. Can we suppose that fish gives occasion to such a coagulium as runnet? If it does so, it may produce bad effects. Besides, fishes approach somewhat to vegetables, in giving little stimulus; and are accused of the same bad effects as these, viz. bringing on the cold fit of fever.

Thus much may be said for variety. But it also has its disadvantages, provoking to gluttony; this, and the art of cookery, making men take in more than they properly can digest: and hence, perhaps, very justly, physicians have universally almost preferred simplicity of diet; for, in spite of rules, man's eating will only be measured by his appetite, and satiety is sooner produced by *one* than by *many* substances. But this is so far from being an argument against variety, that it is one for it, as the only way of avoiding a full meal of animal-food, and its bad effects, is by presenting a quantity of vegetables. Another mean of preventing the bad effects of animal-food, is to take a large proportion of liquid; and hence the bad effects of animal-food are less felt in Scotland, on account of their drinking much with it, and using broths, which are at once excellent correctors of animal-food and preventives of gluttony.

WITH regard to the differences between ANIMAL FOODS, properly so called, the first regards their solubility, depending on a lax or firm texture of their different kinds.

I. SOLUBILITY of animal food seems to deserve less attention than is commonly imagined; for there are many

many instances of persons of a weak stomach incapable of breaking down the texture of vegetables, or even of dissolving a light pudding, to whom hung beef, or a piece of ham, was very grateful and easily digested. None of the theories given for the solution of animal-food in the human stomach seem to have explained that process sufficiently. Long ago has been discarded the supposition of an active corrosive menstruum there; and also the doctrine of trituration, for which, indeed, there seems no mechanism in the human body; and, till lately, physicians commonly agreed with Boerhaave in supposing nothing more to be necessary than a watery menstruum, moderate heat, and frequent agitation. This will account for solution in some cases, but not entirely. Let us try to imitate it out of the body with the same circumstances, and in ten times the time in which the food is dissolved in the stomach we shall not be able to bring about the same changes. Take the coagulated white of an egg, which almost every body can easily digest, and yet no artifice shall be able to dissolve it. Hence, then, we are led to seek another cause for solution, *viz.* fermentation; a notion, indeed, formerly embraced, but, on the introduction of mechanical philosophy, indulously banished, with every other supposition of that process taking place at all in the animal economy.

Many of the ancients imagined this fermentation to be putrefactive. But this we deny, as an acid is produced; though hence the fermentation might be reckoned the vinous, which, however, seems always to be morbid. Neither, indeed, is the fermentation purely acetous, but modified by putrescence; for Pringle has observed, that animal-matters raise and even expedite the acetous process. The fermentation, then, in the stomach is of a mixed nature, between the acetous and putrefactive, mutually modifying each other; though, indeed, in the intestines, somewhat of the putrefactive seems to take place, as may be observed from the state of the fæces broke down, and from the little disposition of such substances to be so, which are not liable to the putrefactive process, as the firmer parts of vegetables, &c. Upon this view solution seems to be extremely easy, and those substances to be most easily broke down which are most subject to putrefaction. See ANATOMY, n° 368.—and GASTRIC Juice.

But solution also depends on other circumstances, and hence requires a more particular regard.

1. There is a difference of solubility with respect to the manducation of animal-food, for which bread is extremely necessary, in order to keep the more slippery parts in the mouth till they be properly comminuted*. From want of proper manducation persons are subject to eructations; and this more frequently from the firm vegetable foods, as apples, almonds, &c. than from the animal, though, indeed, even from animal food, very tendinous, or swallowed in unbroken masses, such sometimes occur. Manducation is so much connected with solution, that some, from imperfectly performing that, are obliged to belch up their food, remanducate it, and swallow it again before the stomach can dissolve it, or proper nourishment be extracted. Another proof of our regard to solubility, is our rejecting the firmer parts of animal food, as bull-beef, and generally carnivorous animals.

2. Its effects with regard to solubility, seem also to be the foundation of our choice between *fat* and *lean*, *young* and *old* meats. In the *lean*, although, perhaps, a single fibre might be sufficiently tender, yet these, when collected in *fasciculi*, are very firm and compact, and of difficult solution; whereas in the *fat* there is a greater number of vessels, a greater quantity of juice, more interposition of cellular substance, and consequently more solubility. Again, in young animals, there is probably the same number of fibres as in the older, but these more connected: whereas, in the older, the growth depending on the separation of these, and the increase of vessels and cellular substance, the texture is less firm and more soluble; which qualities, with regard to the stomach, are at that time too increased, by the increased alkalescence of the animal. To this also may be referred our choice of castrated animals, *viz.* on account of their disposition to fatten after the operation.

3. It is with a view to the solubility, that we make a choice between meats recently killed, and those which have been kept for some time. As soon as meat is killed, the putrefactive process begins; which commonly we allow to proceed for a little, as that process is the most effectual breaker down of animal matters, and a great assistance to solution. The length of time during which meat ought to be kept, is proportioned to the meat's tendency to undergo the putrid fermentation, and the degree of those circumstances which favour it: Thus in the Torrid Zone, where meat cannot be kept above four or five hours, it is used much more recent than in these northern climates.

4. *Boiled* or *roasted* meats create a difference of solution. By boiling we extract the juices interposed between the fibres, approximate them more to each other, and render them of more difficult solubility; which is increased too by the extraction of the juices, which are much more alkalescent than the fibres: but when we want to avoid the stimulus of alkalescent food, and the quick solution, as in some cases of disease, the roasted is not to be chosen. Of roasted meat it may be asked, which are more proper, those which are most or least roasted? That which is least done is certainly the most soluble: even raw meats are more soluble than dressed, as Dr Cullen was informed by a person who from necessity was obliged, for some time, to eat such. But at the same time that meats little done are very soluble, they are very alkalescent; so that, wherever we want to avoid alkalescence in the *prima viæ*, the most roasted meats should be chosen. Those who throw away the broths of boiled meat do very improperly; for, besides their supplying a fluid, from their greater alkalescence they increase the solubility of the meat. Here we shall observe, that pure blood has been thought insoluble. Undoubtedly it is very nutritious; and though out of the body, like the white of eggs, it seems very insoluble, yet, like that too, in the body it is commonly easily digested. Moses very properly forbid it the Israelites, as, in warm countries, it is highly alkalescent; and even here, when it was used in great quantity, the scurvy was more frequent: but to a moderate use of it, in these climates, no such objection takes place.

5. Solubility is varied from another source, *viz.* viscosity

* See the article
BRAD.

cidity of the juice of aliment. Young animals, then, appear more soluble than old, not only on account of the compaction and firmness of texture in the latter, but also their greater viscosity of juice. And nothing is more common, than to be longer oppressed from a full meal of veal, than from the same quantity of beef, &c. Upon account, too, of their greater viscosity of juice, are the tendinous and ligamentous parts of animals longer retained than the purely muscular, as well as on account of their firmness of texture. Even fishes, whose muscular parts are exceedingly tender, are, on account of their gluey viscosity, longer of solution in the stomach. And eggs, too, which are exceedingly nourishing, have the same effect, and cannot be taken in great quantity: For the stomach is peculiarly sensible to gelatinous substances; and by this means has nature perhaps taught us, as it were by a sort of instinct, to limit ourselves in the quantity of such nutritive substances.

6. With regard to solution, we must take in the oils of animal-food; which, when tolerably pure, are the least putrescent part of it, and, by diminishing the cohesion of the fibres, render them more soluble. On this last account is the lean of fat meat more easily dissolved than other lean. But when the meat is exposed to much heat, this oil is separated, leaving the solid parts less easily soluble, and becoming itself empyreumatic, rancid, and of difficult mixture in the stomach. Fried meats, from the reasons now given, and baked meats, for the same, as well as for the tenacity of the paste, are preparations which diminish the solubility of the food. From what has been said, the preparation of food by fattening it, and keeping it for some time after killed, altho' it may administer to glutony, will yet, it must be confessed, increase the solution of the food.

II. The second difference of animal-food is with regard to ALKALESCENCY.

Of this we have taken a little notice already under the head of solubility.

1. From their too great alkalescency we commonly avoid the carnivorous animals, and the *feræ*; and choose rather the granivorous. Some birds, indeed, which live on insects, are admitted into our food; but no man, without *nausea*, can live upon these alone for any length of time. Fishes, too, are an exception to this rule, living almost universally on each other. But in these the alkalescency does not proceed so far; whether from the viscosity of their juice, their want of heat, or some peculiarity in their œconomy, is not easy to determine.

2. Alkalescency is determined by difference of age. The older animals are always more alkalescent than the young, from their continual progress to putrefaction. Homberg always found, in his endeavours to extract an acid from human blood, that more was obtained from the young than from the old animals.

3. A third circumstance which varies the alkalescency of the food, is the wildness or tameness of the animal; and this again seems to depend on its exercise. Dr Cullen knew a gentleman who was fond of cats for food: but he always used to feed them on vegetable food, and kept them from exercise; and in the same manner did the Romans rear up their rats, when in-

tended for food. In the same way the flesh of the partridge and the hen seems to be much the same; only, from its being more on the wing, the one is more alkalescent than the other. Again, tame animals are commonly used without their blood; whereas the wild are commonly killed in their blood, and upon that account, as well as their greater exercise, are more alkalescent.

4. The alkalescency of food may be determined from the quantity of volatile salt it affords. The older the meat is, it is found to give the greater proportion of volatile salt.

5. The alkalescency of aliment may also, in some measure, be determined from its colour, the younger animals being whiter and less alkalescent. We also take a mark from the colour of the gravy poured out, according to the redness of the juices judging of the animal's alkalescency.

6. The relief of food is found to depend much on its alkalescency, as does also the stimulus it gives and the fever it produces in the system. These effects are also complicated with the viscosity of the food, by which means it is longer detained in the stomach, and the want of alkalescency supplied.

Having mentioned animal food as differing in solubility and alkalescency, which often go together in the same subject, we come to the third difference, viz.

III. QUANTITY of Nutriment. Which is either absolute or relative: absolute with respect to the quantity it really contains, sufficient powers being given to extract it; relative, with respect to the assimilatory powers of those who use it. The absolute nutriment is of some consequence; but the relative, in the robust and healthy, and except in cases of extraordinary weakness, may, without much inconvenience, be disregarded. In another case is the quantity of nourishment relative, viz. with regard to its *perspirability*; for if the food is soon carried off by the excretions, it is the same thing as if it contained a less proportion of nourishment. For, giving more fluid, that which is longer retained affords more; and, for the repair of the solids, that retention also is of advantage. Now gelatinous substances are long retained; and are, besides, animal substances themselves, dissolved: so that, both absolutely and relatively, such substances are nutritious. Of this kind are eggs, shell-fish, &c. In adults, though it is disputed whether their solids need any repair, yet, at any rate, at this period, fluid is more required; for this purpose the alkalescent foods are most proper, being most easily dissolved. They are, at the same time, the most perspirable; on one hand that alkalescency leading to discase, while on the other their perspirability obviates it. Adults, therefore, as writers justly observe, are better nourished on the alkalescent; the young and growing, on gelatinous foods. All this leads to a comparison of young and old meats; the first being more gelatinous, and the last more alkalescent. This, however, by experience, is not yet properly ascertained. Mr Geoffroy is the only person who has been taken up with the analysis of foods. See *Mémoires de l'Académie*, l'an 1731 & 1732. His attempt was certainly laudable, and in some respects usefully performed; but, in general, his experiments were not sufficiently repeated, nor are, indeed, suf-

sufficiently accurate. He has not been on his guard against the various circumstances which affect meats; the cow kind liking a moist succulent herbage, which is not to be got in warm climates; while the sheep are fond of a dry food, and thrive best there. Again, some of his experiments seem contradictory. He says, that veal gives more solution than beef, while lamb gives less than mutton, which is much to be doubted. If both he and Sanctorius had examined English beef, the result, probably, would have been very different as to its perspirability, &c. Besides, Mr Geoffroy has only analysed beef and veal when raw; has made no proper circumstantial comparisons between quadrupeds and birds; and has examined these last along with their bones, and not their muscles, &c. by themselves, as he ought to have done, &c. If a set of experiments of this kind were properly and accurately performed, they might be of great use; but, at present, for the purpose of determining our present subject, we must have recourse to our alkalefescency, solubility &c.

IV. The fourth difference of animal foods, is, *The Nature of the Fluids they afford*. The whole of this will be understood, from what has been said on alkalefescency; the fluid produced being more or less dense and stimulating, in proportion as that prevails.

V. The fifth difference of animal-foods is with respect to their

PERSPIRABILITY. The sum of what can be said on this matter is this, that such foods as promote an accumulation of fluid in our vessels, and dispose to plethora, are the least perspirable, and commonly give most strength; that the more alkalescent foods are the most perspirable, though the viscid and less alkalescent may attain the same property by long retention in the system. The authors on perspirability have determined the perspiration of foods as imperfectly as Mr Geoffroy has done the solubility, and in a few cases only. We must not lay hold on what Sanctorius has said on the perspirability of mutton, because he has not examined, in the same way, other meats in their perfect state; far less on what Keil says of oysters, as he himself was a valetudinarian, and consequently an unfit subject for such experiments, and probably of a peculiar temperament.

As to the effects of Food on the MIND, we have already hinted at them above. It is plain, that delicacy of feeling, liveliness of imagination, quickness of apprehension, and acuteness of judgment, more frequently accompany a weak state of the body. True it is, indeed, that the same state is liable to timidity, fluctuation, and doubt; while the strong have that steadiness of judgment, and firmness of purpose, which are proper for the higher and more active scenes of life. The most valuable state of the mind, however, appears to reside in somewhat less firmness and vigour of body. Vegetable aliment, as never over-distending the vessels or loading the system, never interrupts the stronger motions of the mind; while the heat, fulness, and weight, of animal-food, are an enemy to its vigorous efforts. Temperance, then, does not so much consist in the quantity, for that always will be regulated by our appetite, as in the quality, viz. a large proportion of vegetable aliment.

Food of Plants. See AGRICULTURE, n° 1,—6. and PLANTS; also the article COMPOSTS.

FOOL, according to Mr Locke, is a person who makes false conclusions from right principles; whereas a madman, on the contrary, draws right conclusions from wrong principles.

FOOL- Stones, in botany. See ORCHIS.

FOOT, a part of the body of most animals whereon they stand, walk, &c. See ANATOMY, n° 62.

Foot, in the Latin and Greek poetry, a metre or measure, composed of a certain number of long and short syllables.

These feet are commonly reckoned 28: of which some are simple, as consisting of two or three syllables, and therefore called *disyllabic* or *trisyllabic feet*; others are compound, consisting of four syllables, and are therefore called *tetrasyllabic feet*.

The disyllabic feet are four in number, viz. the pyrrhichius, spondee, iambus, and trocheus. See PYRRHICHIVS, &c.

The trisyllabic feet are eight in number, viz. the dactylus, anapestus, tribrachys, molossus, amphibrachys, amphimacer, bacchius, and antibacchius. See DACTYL, &c.

The tetrasyllabic are in number 16, viz. the procleumaticus, dispondens, choriambus, antispastus, diiambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus secundus, epitritus tertius, epitritus quartus, pæon primus, pæon secundus, pæon tertius, and pæon quartus. See PROCLEUMATICUS, &c.

Foot, in English poetry. See POETRY, n° 117, 175.

Foot is also a long measure consisting of 12 inches. Geometricians divide the foot into 10 digits, and the digit into 10 lines.

Foot Square, is the same measure both in breadth and length, containing 144 square or superficial inches.

Cubic or Solid Foot, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

Foot of a Horse, in the menage, the extremity of the leg, from the coronet to the lower part of the hoof.

Foot-Level, among artificers, an instrument that serves as a foot-rule, a square, and a level. See LEVEL, RULE, and SQUARES.

FOOTE (Samuel, Esq;), the modern Aristophanes, was born at Truro, in Cornwall; and was descended from a very ancient family. His father was member of parliament for Tiverton, in Devonshire; and enjoyed the post of commissioner of the prize-office and fine-contract. His mother was heiress of the Dinely and Goodere families. In consequence of a fatal misunderstanding between her two brothers, Sir John Dinely Goodere, bart. and Samuel Goodere, esq; captain of his majesty's ship the Ruby, which ended in the death of both, a considerable part of the Goodere estate, which was better than 5000l. *per annum*, descended to Mr Foote.

He was educated at Worcester college, Oxford, which owed its foundation to Sir Thomas Cookes Winford, bart. a second cousin of our author's. On leaving the university, he commenced student of law in the Temple; but, as the dryness of this study did not suit the liveliness of his genius, he soon relinquished it. He married a young lady of a good family and some fortune; but, their tempers not agreeing, a perfect

harmony did not long subsist between them. He now lunched into all the fashionable foibles of the age, gaming not excepted; and in a few years spent his whole fortune. His necessities led him to the stage, and he made his first appearance in the character of Othello. He next performed Fondlewife with much more applause; and this, indeed, was ever after one of his capital parts. He attempted Lord Poppington likewise, but prudently gave it up. But, as Mr Foote was never a capital actor in the plays of others, his salary was very unequal to his gay and extravagant turn; and he contracted debts which forced him to take refuge within the verge of the court.

He relieved his necessities by a very laughable stratagem. Sir Francis D—l—l had long been his intimate friend, and had dissipated his fortune by similar extravagance. Lady N—l—l, who was likewise an intimate acquaintance of Foote's, and who was exceeding rich, was fortunately at that time bent upon a matrimonial scheme. Foote strongly recommended to her to consult upon this momentous affair the conjurer in the Old Bailey, whom he represented as a man of surprising skill and penetration. He employed an acquaintance of his own to perorate the conjurer, who depicted Sir Francis D—l—l at full length; described the time when, the place where, and the dress in which, she would see him. The lady was so struck with the coincidence of every circumstance, that she married D—l—l in a few days. For this service Sir Francis settled an annuity upon Foote; and this enabled him once more to emerge from obscurity.

In 1747 he opened the little theatre in the Haymarket, taking upon himself the double character of author and performer; and appeared in a dramatic piece of his own composing, called the *Diversions of the Morning*. This piece consisted of nothing more than the exhibition of several characters well known in real life, whose manner of conversation and expression this author very happily hit off in the diction of his drama, and still more happily represented on the stage, by an exact and most amazing imitation, not only of the manner and tone of voice, but even of the very persons, of those whom he intended to take off. In this performance, a certain physician, Dr L—n—n, well known for the oddity and singularity of his appearance and conversation, and the celebrated Chevalier Taylor, who was at that time in the height of his popularity, were made objects of Foote's ridicule; the latter, indeed, very deservedly; and, in the concluding part of his speech, under the character of a theatrical director, Mr Foote took off, with great humour and accuracy, the several styles of acting of every principal performer on the English stage.

This performance at first met with some opposition from the civil magistrates of Westminster, under the sanction of the act of parliament for limiting the number of playhouses, as well as from the jealousy of one of the managers of Drury-lane playhouse; but, the author being patronized by many of the principal nobility, and other persons of distinction, this opposition was over-ruled: and, having altered the title of his performance, Mr Foote proceeded, without further molestation, to give *Tea in a morning* to his friends, and represented it through a run of 40 mornings to crowded and splendid audiences.

The ensuing season he produced another piece of the same kind, which he called *An Audition of Pictures*. In this performance he introduced several new and popular characters; particularly Sir Thomas de Veil, then the acting justice of peace for Westminster, Mr Cook the celebrated auctioneer, and the equally famous Orator Henley. This piece also had a very great run.

His *Knights*, which was the produce of the ensuing season, was a performance of somewhat more dramatic regularity: but still, although his plot and characters seemed less immediately personal, it was apparent that he kept some particular real persons strongly in his eye in the performance; and the town took upon themselves to fix them where the resemblance appeared to be the most striking.

Thus Mr Foote continued, from time to time, to select, for the entertainment of the public, such characters, as well general as individual, as seemed most likely to engage their attention. His dramatic pieces, exclusive of the interlude called *Pity in Pattens*, are as follow: *Taite, The Knights, The Author, The Englishman in Paris, The Englishman Returned from Paris, The Mayor of Garrat, The Liar, The Patron, The Minor, The Orators, The Commissary, The Devil upon Two Sticks, The Lame Lover, The Maid of Bath, The Nabob, The Cozeners, The Capuchin, The Bankrupt, and an unfinished comedy called The Slanderer.*

All these works are only to be ranked among the *petites pieces* of the theatre. In the execution they are somewhat loose, negligent, and unfinished; the plots are often irregular, and the catastrophes not always conclusive: but, with all these deficiencies, they contain more strength of character, more strokes of keen satire, and more touches of temporary humour, than are to be found in the writings of any other modern dramatist. Even the language spoken by his characters, incorrect as it may sometimes seem, will, on a closer examination, be found entirely dramatical; as it abounds with those natural minutiae of expression which frequently form the very basis of character, and which render it the truest mirror of the conversation of the times in which he wrote.

In the year 1766, being on a party of pleasure with the late duke of York, lord Mexborough, and Sir Francis Delaval, Mr Foote had the misfortune to break his leg, by a fall from his horse; in consequence of which, he was compelled to undergo an amputation. This accident so sensibly affected the duke, that he made a point of obtaining for Mr Foote a patent for life; whereby he was allowed to perform, at the little theatre in the Haymarket, from the 15th of May to the 15th of September every year.

He now became a greater favourite of the town than ever: his very laughable pieces, with his more laughable performances, constantly filled his house; and his receipts were some seasons almost incredible. Parsimony was never a vice to be ascribed to Mr Foote; his hospitality and generosity were ever conspicuous; he was visited by the first nobility, and he was sometimes honoured even by royal guests.

The attack made upon his character by one of his domestics, whom he had dismissed for misbehaviour, is too well known to be particularized here. Suffice it to say, he was honourably acquitted of that charge: but

but it is believed by some, that the shock which he received from it accelerated his death; others pretend, that his literary altercation with a certain *then* duchess, or rather her agents, much affected him, and that from that time his health declined. It is probable, however, that his natural volatility of spirits could scarcely fail to support him against all impressions from either of these quarters.

Mr Foote, finding his health decline, entered into an agreement with Mr Colman, for his patent of the theatre; according to which, he was to receive from Mr Colman 1600*l.* *per annum*, besides a stipulated sum whenever he chose to perform. Mr Foote made his appearance two or three times last summer, in some of the most admired characters; but being suddenly affected with a paralytic stroke one night whilst upon the stage, he was compelled to retire. He was advised to bathe; and accordingly repaired to Brighthelmston, where he apparently recovered his former health and spirits, and was what is called the *fiddle of the company* who resorted to that agreeable place of amusement. A few weeks before his death, he returned to London; but, by the advice of his physicians, set out with an intention to spend the winter at Paris and in the south of France. He had got no farther than Dover, when he was suddenly attacked by another stroke of the palsy, which in a few hours terminated his existence. He died on the 21st of October 1777, in the 56th year of his age, and was privately interred in the cloisters of Westminster abbey.

FORAMEN, in anatomy, a name given to several apertures or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membrance tympani. See ANATOMY.

FORAMEN *Ovale*, an oval aperture or passage thro' the heart of a fetus, which closes up after birth. It arises above the coronal vein, near the right auricle, and passes directly into the left auricle of the heart, serving for the circulation of the blood in the fetus, till such time as the infant breathes, and the lungs are open; it being generally reckoned one of the temporary parts of the fetus, wherein it differs from an adult; although almost all anatomists, Mr Cheselden excepted, assure us, that the foramen *ovale* has sometimes been found open in adults. See FOETUS.

FORBES (Patrick), bishop of Aberdeen, was born in 1654, when the affairs of the church of Scotland were in much confusion; to the settlement of which he greatly contributed. As chancellor of the university of Aberdeen, he improved that seat of learning by repairing the fabric, augmenting the library, and reviving the professorships. He published a *Commentary on the Revelations*, at London, in 1613; and died in 1635.

FORBES (John), the son of Patrick, but of much more extensive learning than his father, was perhaps excelled by none of his age, which will be allowed by those who read his *Historical and Theological Institutes*. He was bishop of Aberdeen; but was expelled by the Covenanters, and forced to fly beyond sea. He continued in Holland two years; and, upon his return, lived private on his estate at Corke, until he died in 1648. An edition of all his works was printed in two vols folio at Amsterdam in 1703.

VOL. IV.

FORBES (William), a learned bishop of Edinburgh, born in 1585. His ill-health, and the anti-episcopal disposition of the Scots, confined him chiefly to a retired life; but when Charles I. in 1633, founded an episcopal church at Edinburgh, he thought none more worthy to fill the see than Mr Forbes; who, however, died three months after his consecration, in 1634. Though very able and learned, he published nothing; but wrote a treatise to pacify controversies, which was printed at London 24 years after his death.

FORBES (Duncan, Esq; of Culloeden), was born in the year 1685. In his early life, he was brought up in a family remarkable for hospitality; which perhaps led him afterwards to a freer indulgence in social pleasures. His natural disposition inclined him to the army; but, as he soon discovered a superior genius, by the advice of his friends he applied himself to letters. He directed his studies particularly to the civil law; in which he made a quick progress, and in 1709 was admitted an advocate. From 1722 to 1737, he represented in parliament the boroughs of Inverness, Fortrose, Nairn, and Forbes. In 1725, he was made king's advocate; and Lord President of the Court of Session, in 1737. In the troubles of 1715 and 1745, he espoused the royal cause; but with so much prudence and moderation did he conduct himself at this delicate conjuncture, that not a whisper was at any time heard to his prejudice. The glory he acquired in advancing the prosperity of his country, and in contributing to re-establish peace and order, was the only reward of his services. He had even impaired, and almost ruined, his private fortune in the cause of the public; but government did not make him the smallest recompense. The minister, with a meanness for which it is difficult to account, desired to have a state of his disbursements. He was so much shocked at the rudeness of this treatment, that he left the minister without making any reply. Throughout the whole course of his life he had a lively sense of religion, without the least taint of superstition; and his charity was extended to every sect and denomination of religionists indiscriminately. He was well versed in the Hebrew language; and wrote, in a flowing and oratorical style, concerning religion natural and revealed, some important discoveries in theology and philosophy, and concerning the sources of incredulity. He died in 1747, in the 62d year of his age; and his works have since been published in two volumes octavo.

FORCE, in mechanics, denotes the cause of the change in the state of a body when, being at rest, it begins to move, or has a motion which is either not uniform or not direct. See MECHANICS.

Central Forces. See MECHANICS.

Centrifugal Force. See CENTRIFUGAL.

FORCE, in law, signifies any unlawful violence offered to things or persons, and is divided into simple and compound. *Simple force* is what is so committed, that it has no other crime attending it; as where a person by force enters on another's possession, without committing any other unlawful act. *Compound force*, is where some other violence is committed with such an act which of itself alone is criminal; as if one enters by force into another's house, and there kills a person, or ravishes a woman. There is likewise a force implied in law, as in every trespass, rescue, or distress,

17 R and

Forceps,
Forcible.

and an actual force with weapons, number of persons, &c.—Any person may lawfully enter a tavern, inn, or victualling-house; so may a landlord his tenant's house to view repairs, &c. But if, in these cases, the person that enters commits any violence or force, the law will intend that he entered for that purpose.

FORCEPS, in surgery, &c. a pair of scissors for cutting off, or dividing, the fleshy membranous parts of the body, as occasion requires. See **SURGERY**.

FORCIBLE ENTRY, is a violent and actual entry into houses, or lands; and a forcible detainer, is where one by violence with-holds the possession of lands, &c. so that the person who has a right of entry is barred, or hindered, therefrom.

At common law, any person that had a right to enter into lands, &c. might retain possession of it by force. But this liberty being abused, to the breach of the peace, it was therefore found necessary that the same should be restrained: Though, at this day, he who is wrongfully dispossessed of goods may by force retake them. By statute, no persons shall make an entry on any lands or tenements, except where it is given by law, and in a peaceable manner, even tho' they have title of entry, on pain of imprisonment: and where a forcible entry is committed, justices of peace are authorized to view the place, and inquire of the force by a jury, summoned by the sheriff of the county; and they may cause the tenements &c. to be restored, and imprison the offenders till they pay a fine. Likewise a writ of forcible entry lies, where a person seized of freehold, is by force put out thereof.

FORCIBLE Marriage, of a woman of estate, is felony. For by the statute 3 H. 7. c. 2. it is enacted, "That if any persons shall take away any woman having lands or goods, or that is heir apparent to her ancestor, by force, and against her will, and marry or defile her; the takers, procurers, abettors and receivers of the woman taken away against her will, and knowing the same, shall be deemed principal felons; but as to procurers and accessories, they are, before the offence be committed, to be excluded the benefit of clergy, by 39 Eliz. c. 9. The indictment on the statute 3 H. 7. is expressly to set forth, that the woman taken away had lands or goods, or was heir apparent; and also that she was married or defiled, because no other case is within the statute; and it ought to allege that the taking was for lucre. It is no excuse that the woman at first was taken away with her consent: for if the afterwards refuse to continue with the offender, and be forced against her will, she may from that time properly be said to be taken against her will; and it is not material whether a woman so taken away be at last married or defiled with her own consent or not, if she were under force at the time; the offender being in both cases equally within the words of the act.

Those persons who, after the fact, receive the offender, are but accessories after the offence, according to the rules of common law; and those that are only privy to the damage, but not parties to the forcible taking away, are not within the act, *H. P. C.* 119. A man may be indicted for taking away a woman by force in another country; for the continuing of the force in any country, amounts to a forcible taking there. *Ibid.* Taking away any woman-child un-

der the age of 16 years and unmarried, out of the custody and without the consent of the father or guardian, &c. the offender shall suffer fine and imprisonment; and if the woman agrees to any contract of matrimony with such person, she shall forfeit her estate during life, to the next of kin to whom the inheritance should descend, &c. *Stat. 4 & 5. P. & M. c. 8.* This is a force against the parents: and information will lie for seducing a young man or woman from their parents, against their consents, in order to marry them, &c. See **MARRIAGE**.

FORCING, in gardening, a method of producing ripe fruits from trees before their natural season. The method of doing it is this: A wall should be erected ten feet high; a border must be marked out on the south side of it, of about four feet wide, and some stakes must be fastened into the ground all along the edge of the border; these should be four inches thick. They are intended to rest the glass lights upon, which are to slope backwards to the wall, to shelter the fruit as there shall be occasion; and there must be, at each end, a door to open either way, according as the wind blows. The frame should be made moveable along the wall, that when a tree has been forced one year, the frame may be removed to another, and so on, that the trees may each of them be forced only once in three years, at which rate they will last a long time. They must be always well-grown trees that are chosen for forcing; for young ones are soon destroyed, and the fruit that is produced from them is never so well tasted. The fruits most proper for this management are the avant or small white nutmeg, the albarle, the early newington, and the brown nutmeg peaches; Mr Fairchild's early, and the el-rugo and newington neArines; the masculine apricot, and the may-duke and may cherry. For grapes, the white and black sweet-water are the properest; and of gooseberries the Dutch white, the Dutch early green, and the walnut gooseberry; and the large Dutch white and large Dutch red currants.

The dung, before it is put to the wall, should be laid together in a heap for five or six days, that it may heat uniformly through; and when thus prepared it must be laid four feet thick at the base of the wall, and go sloping up till it is two feet thick at the top. It must be laid at least within three or four inches of the top of the wall; and when it sinks, as it will sink two or three feet, more dung must be laid on; for the first heat will do little more than just swell the blossoms. The covering the trees with glasses is of great service; but they should be taken off to admit the benefit of gentle showers to the trees, and the doors at the ends should be either left entirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and keep off the frosts.

The dung is never to be applied till towards the end of November; and three changes of it will be sufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, neArines, peaches, and plums, if the weather be milder, the glasses are to be opened to let in sunshine or gentle showers.

If a row or two of scarlet strawberries be planted at the back of the frame, they will ripen in February or the beginning of March; the vines will blossom in April, and the grapes will be ripe in June.

Forcing.

Jacob's
Law Dict.

It should be carefully observed, not to place early and late ripening fruits together, because the heat necessary to force the late ones will be of great injury to the early ones after they have fruited.

The masculine apricot will be ripe in the beginning of April, the early nectarines will be ripe about the same time, and the forward sort of plums by the latter end of that month. Gooseberries will have fruit fit for tarts in January or February, and will ripen in March; and currants will have ripe fruit in April.

The trees need not be planted so distant at these walls as at others, for they do not shoot so freely as in the open air; nine feet asunder is sufficient. They should be pruned about three weeks before the heat is applied.

FORDOUN (John of), the father of Scottish history, flourished in the reign of Alexander III. towards the end of the 13th century. But of his life there is nothing known with certainty, though there was not a monastery that possessed not copies of his work. The first five books of the history which bears his name were written by him: the rest were fabricated from materials left by him, and from new collections by different persons. A manuscript in vellum of this historian is in the library of the university of Edinburgh.

FORDYCE (David), an elegant and learned writer of the present age, was professor of philosophy in the Marischal college, Aberdeen. He was originally designed for the ministry; to prepare himself for which was the whole aim of his ambition, and for a course of years the whole purpose of his studies. How well he was qualified to appear in that character, appears from his "Theodorus, a dialogue concerning the art of preaching." After having finished this work, he went abroad on his travels, in order to obtain fresh stores of knowledge: but after a successful tour through several parts of Europe, he was unfortunately cast away in a storm on the coast of Holland. Besides the above work, he wrote Dialogues on education, 8vo. and a Treatise of Moral Philosophy published in the Preceptor. The third edition of his Theodorus was published in London, after his untimely death, by his brother the Rev. Mr James Fordyce, an eminent dissenting minister, in 1755.

FORECASTLE of a SHIP, that part where the foremast stands. It is divided from the rest by a bulk-head.

FOREIGN, something extraneous, or that comes from abroad.

FOREIGN, in the English law, is used in various significations. Thus,

FOREIGN Attachment, is an attachment of the goods of foreigners found within a city or liberty, for the satisfaction of some citizen to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person.

FOREIGN Kingdom, a kingdom under the dominion of a foreign prince.

At the instance of an ambassador or consul, an offender against the laws here may be sent for hither from a foreign kingdom to which he hath fled. And, where a stranger of Holland, or any foreign country, buys goods at London, for instance, and there gives a note under his hand for payment, and then goes away privately into Holland; in that case, the seller may have

a certificate from the lord mayor, on the proof of the sale and delivery of such goods, whereupon a process will be executed on the party in Holland.

FOREIGN Opposer or *Apposer*, an officer in the exchequer that opposes or makes a charge on all sheriffs, &c. of their green wax; that is to say, fines, issues, amerciements, recognizances, &c.

FOREIGN Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction.

FOREIGN Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural-born subjects.

FOREIGNER, the natural-born subject to some foreign prince.

Foreigners, though made denizens, or naturalized, are disabled to bear any office in government, to be of the privy-council, or members of parliament, &c. This is by the acts of the settlement of the crown. Such persons as are not freemen of a city or corporation, are also called *foreigners*, to distinguish them from the members of the same.

FOREJUDGER, in law, signifies a judgment whereby one is deprived, or put by a thing in question.

To be *forejudged the court*, is where an officer or attorney of any court is expelled the same for malpractice, or for not appearing to an action on a bill filed against him, &c. And where an attorney of the common-pleas is sued, the plaintiff's attorney delivers the bill to one of the criers of the court, who calls the attorney defendant, and solemnly proclaims aloud, that, if he does not appear thereto, he will be forejudged: likewise a rule is given by the secondary for his appearance: and if the attorney appears not in four days, then the clerk of the warrants strikes such an attorney off the roll of attorneys; after which he becomes liable to be arrested like any other person: but where an attorney is forejudged, he may be restored on clearing himself from his contumacy, and making satisfaction to the plaintiff, &c.

FORELOCKS, in the sea-language, little flat wedges made with iron, used at the ends of bolts, to keep them from flying out of their holes.

FORE-MAST of a SHIP, a large round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-mast and fore-top-fall yards. Its length is usually $\frac{2}{3}$ of the main-mast, and the fore-top-gallant-mast is $\frac{1}{2}$ the length of the fore-top.

FOREMAST-MEN, are those on board a ship that take in the top-falls, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

FOREST, in geography, a huge wood; or, a large extent of ground covered with trees. The word is formed of the Latin *foresta*, which first occurs in the capitulars of Charlemagne, and which itself is derived from the German *forst*, signifying the same thing. Spelman derives it from the Latin *foris restat*, by reason forests are out of towns. Others derive *foresta* from *feris*, q. d. *Foresta, quod sit tuta statio ferarum*, as being a safe station or abode for wild beasts.

The Caledonian and Hercynian forests are famous in history. The first was a celebrated retreat of the ancient Picts and Scots: The latter anciently occupied

the greatest part of Europe; particularly Germany, Poland, Hungary, &c. In Cesar's time it extended from the borders of Alsatia and Switzerland to Transylvania; and was computed 60 days journey long, and 9 broad: some parts or cantons thereof are still remaining.

The ancients adored forests, and imagined a great part of their gods to reside therein: temples were frequently built in the thickest forests; the gloom and silence whereof naturally inspire sentiments of devotion, and turns mens thoughts within themselves.

For the like reason, the ancient Druids made forests the place of their residence; performed their sacrifices, instructed their youth, and gave laws therein.

FOREST, in law, is defined, by Manwood, a certain territory of woody grounds and fruitful pastures, privileged for wild-beasts and fowls of forest, chafe, and warren, to rest and abide under the protection of the king, for his princely delight; bounded with unremovable marks and meres, either known by matter of record or prescription; replenished with wild beasts of venery or chafe, with great coverts of vert for the said beasts; for preservation and continuance whereof, the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of such antiquity in England, that, excepting the New-Forest in Hampshire, erected by William the Conqueror, and Hampton Court, erected by Henry VIII. it is said, that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers and in several of our laws and statutes.—Ancient historians tell us, “that New-forest was raised by the destruction of 22 parish-churches, and many villages, chapels, and manors, for the space of 30 miles together, which was attended with divers judgments on the posterity of William I. who erected it: for William Rufus was there shot with an arrow, and before him Richard the brother of Henry I.; and Henry nephew to Robert, the eldest son of the Conqueror, did hang by the hair of the head in the boughs of the forest, like unto Ab-salom.” *Blount.*

Besides the New-forest, there are 68 other forests in England, 13 chafes, and more than 700 parks: the four principal forests are New-Forest on the sea, Shire-wood-forest on the Trent, Dean-forest on the Severn, and Windsor-forest on the Thames.

A forest in the hands of a subject is properly the same thing with a CHASE; being subject to the common law, and not to the forest-laws. But a chase differs from a forest, in that it is not inclosed; and likewise, that a man may have a chase in another man's ground as well as his own; being indeed the liberty of keeping beasts of chase, or royal game therein, protected even from the owner of the land, with a power of hunting them thereon. See PARK.

The manner of erecting a forest is thus: Certain commissioners are appointed under the great seal, who view the ground intended for a forest, and fence it round: this commission being returned into chancery, the king causeth it to be proclaimed throughout the county where the land lieth, that it is a forest; and prohibits all persons from hunting there, without his leave. Though the king may erect a forest on his own ground and waste, he may not do it on the ground of other

persons without their consent; and agreements with them for that purpose ought to be confirmed by parliament.

A forest, strictly taken, cannot be in the hands of any but the king; for no person but the king has power to grant a commission to be justice in eyre of the forest: yet, if he grants a forest to a subject, and that on request made in the chancery, that subject and his heirs shall have justices of the forest, in which case the subject has a forest in law.

A second property of a forest is, the courts thereof. See FOREST-COURTS, *infra*.

A third property is the officers belonging to it, as the justices, warden, verderer, forester, agistor, regarder, keeper, bailiff, beadle, &c. See the articles AGISTOR, BAILIFF, FORESTER, &c.

By the laws of the forest, the receivers of trespassers in hunting, or killing of the deer, if they know them to be the king's property, are principal trespassers. Likewise, if a trespass be committed in a forest, and the trespasser dies, after his death, it may be punished in the life-time of the heir, contrary to common law. Our Norman kings punished such as killed deer in any of their forests with great severity; also in various manners; as by hanging, loss of limbs, gelding, and putting out eyes. By *magna charta de forestis*, it is ordained, that no person shall lose life or member for killing the king's deer in forests, but shall be fined; and if the offender has nothing to pay the fine, he shall be imprisoned a year and a day, and then be delivered, if he can give security not to offend for the future, &c. *9 Hen. III. c. 1.*

Before this statute, it was felony to hunt the king's deer; and by a late act, persons armed and dignified, appearing in any forest, &c. if they hunt, kill, or steal any deer, &c. are guilty of felony. *9 Geo. I. c. 22.*

He who has any licence to hunt in a forest or chase, &c. is to take care that he does not exceed his authority; otherwise he shall be deemed a trespasser from the beginning, and be punished for that fact, as if he had no licence. See further, the articles GAME, and GAME-LAW.

Beasts of the forest are, the hart, hind, buck, doe, boar, wolf, fox, hare, &c. The seasons for hunting whereof are as follow, viz. that of the hart and buck begins at the feast of St John Baptist, and ends at Holy-rod day; of the hind and doe, begins at Holy-rod, and continues till Candlemas; of the boar, from Christmas to Candlemas; of the fox begins at Christmas, and continues till Lady-day; of the hare at Michaelmas, and lasts till Candlemas.

FOREST-COURTS, courts instituted for the government of the king's forests in different parts of the kingdom, and for the punishment of all injuries done to the king's deer or venison, to the vert or greenward, and to the court in which such deer are lodged. These are the courts of attachments, of regard, of swinmote, and of justice-seat. 1. The court of attachments, woodmote, or forty-days court, is to be held before the verderers of the forest once in every forty days; and is instituted to inquire into all offenders against vert and venison: who may be attached by their bodies, if taken with the mainour (or *mainœuvre, à manu*) that is, in the very act of killing venison or stealing wood, or *Blackst. Commens* preparing to do so, or by fresh and immediate pursuit after

Forest ||
Forestalling after the act is done; else they must be attached by their goods. And in this forty-days court the foresters or keepers are to bring in the attachments, or presentments of *viridi et venatione*; and the verderors are to receive the same, and to enroll them, and to certify them under their seals to the court of justice-seat or sweinmote: for this court can only inquire of, but not convict, offenders. 2. The court of regard, or survey of dogs, is to be holden every third year for the lawing or expeditation of malliffs; which is done by cutting off the claws of the forefect, to prevent them from running after deer. No other dogs but malliffs are to be thus lawed or expeditated, for none other were permitted to be kept within the precincts of the forest; it being supposed that the keeping of these, and these only, was necessary for the defence of a man's house. 3. The court of sweinmote is to be holden before the verderors, as judges, by the steward of the sweinmote, thrice in every year; the swains or freeholders within the forest composing the jury. The principal jurisdiction of this court is, firstly, to inquire into the oppressions and grievances committed by the officers of the forest; "*de super-oneratione forestariorum, et aliorum ministrorum forestæ; et de eorum oppressionibus populo regis illatis*;" and, secondly, to receive and try presentments certified from the court of attachments against offences in vert and venison. And this court may not only inquire, but convict also; which conviction shall be certified to the court of justice-seat under the seals of the jury, for this court cannot proceed to judgment. But the principal court is, 4. The court of justice-seat, which is held before the chief justice in eyre, or chief itinerant judge, *capitalis iustitiarum in itinere*, or his deputy; to hear and determine all trespasses within the forest, and all claims of franchises, liberties, and privileges, and all pleas and causes whatsoever therein arising. It may also proceed to try presentments in the inferior courts of the forests, and to give judgment upon conviction of the sweinmote. And the chief justice may therefore, after presentment made or indictment found, but not before, issue his warrant to the officers of the forest to apprehend the offenders. It may be held every third year; and 40 days notice ought to be given of its sitting. This court may fine and imprison for offences within the forest, it being a court of record: and therefore a writ of error lies from hence to the court of king's bench, to rectify and redress any mal-administrations of justice; or the chief justice in eyre may adjourn any matter of law into the court of king's bench.

FOREST-TOWNS, in geography, certain towns of Suabia in Germany, lying along the Rhine, and the confines of Switzerland, and subject to the house of Austria. Their names are *Rhinefeld, Seckingen, Laufenburg, and Waldhut*.

FORE-STAFF, or **CROSS-STAFF**, an instrument used at sea for taking the altitude of the sun, moon, or stars. See **STAFF**.

FORESTALLER, a person who is guilty of forestalling. See the next article.

FORESTALLING, in law, buying or bargaining for any corn, cattle, victuals, or merchandise, in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

The punishment for this offence, upon conviction at the quarter-sessions, by two or more witnesses, is, for the first time, two months imprisonment and the loss of the goods, or the value; for the second offence, the offender shall be imprisoned six months, and lose double the value of the goods; for the third offence, he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattels, and stand on the pillory; but the statute does not extend to maliters buying barley, or to badgers licensed.

FORESTER, a sworn officer of the forest, appointed by the king's letters-patent, to walk the forest at all hours, and watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

If a man comes into a forest in the night, a forester cannot lawfully beat him before he makes some resistance; but in case such a person resists the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. do kill a person that opposes them, it is murder in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

FORETHOUGHT. **FELONY**, in Scots law, signifies premeditated murder. See **MURDER**.

FORFAR, a town of Scotland, and capital of a county of the same name, situated in W. Long. 2. 32. N. Lat. 56. 25. of which Mr Pennant gives the following account. "It contains about 2000 souls; but since the great era of the prosperity of North Britain, has increased above one half. The manufactures of lins in this neighbourhood, from fourpence to sevenpence a-yard, are very considerable, and bring in, as is said, near 20,000l. a-year.—The castle stood on a small hill near the town, but at present not a fragment is left.—The lake lies, or rather did lie, at a small distance from the castle; and, according to tradition, once surrounded the town; there being in several parts, even to this day, marks of the deserted channel. Of late years it has been very considerably reduced by draining; to which the vast quantity of fine marle at the bottom was the temptation. This fine manure is found there in strata from three to ten feet thick, and very often is met with beneath the peat in the moors. The land improved with it yields four crops successively: after which it is laid down with barley and clover." Forfar is a parliament-town, classed with Perth, Dundee, Compar, and St Andrews, which all together send one member to parliament.

FORFAR-SHIRE, a county of Scotland of which Forfar is the capital. Including Angus, Glenila, Glenelch, and Glenprasslin, it extends 29 miles from east to west, and 16 where broadest, though in some places the breadth does not exceed five miles. On the north it is divided from the Brae of Mar, by a ridge of the Binchinnen mountains; it is bounded on the south by the Frith of Tay and the British ocean; on the east by Meams, and on the west by Perthshire. Part of the Grampian mountains runs through this country, which is agreeably diversified with hill and dale. It produces lead and iron in abundance, together with quarries of freestone and slate, with which the inhabitants drive a

tions, ii. 70.

considerable traffic. The county is well watered with lakes, rivers, rivulets, and fountains, shaded with large forests, roughened with brown mountains, and waved with green hills interperfed with fields and meadows, and adorned with fine feats and plantations. Their heaths and woods abound with hart, hind, roebuck, and moor-game; their streams are stocked with trout and falmon. Their hills are covered with flocks of fheep, and their fields afford plentiful harvefts of wheat and all forts of grain. The mountains to the weft and north are inhabited by Highlanders: but the Lowlanders poffefs the towns and champaign country, and are remarkable for their politeness and hofpitality; though this laft virtue often degenerates into downright debauchery, in fomuch, that the gentlemen value themfelves upon their prowefs in drinking. The common people are sober, numerous, and addicted to traffic. Forfarfhire exhibits many monuments of antiquity. At the village of Miggle, in the neighbourhood of Coupar, there are feveral ftones erected in the church-yard, embellifhed with the figures of different animals and other ornaments. In the church-yard of Glamis, we fee an old obelisk or entire ftone 16 feet high, fet up over the grave of king Malcom II. who was murdered by the connivance of his own domeftics. This ftone is engraved with a number of figures alluding to the regicide; and at a little diftance, within the park of Glamis, there is another ftone marked with hieroglyphical fymbols, which feem to exprefs the perpetration of the fame murder. At the village of Coffens, in the fame neighbourhood, a very curious obelisk appears lying in the fields. It is known by the name of *St Orland's ftone*, and exhibits a great variety of figures in bas relief. There is another fmall ftone infcribed with figures at Balutheren, in the neighbourhood of Dundee. At the diftance of a mile to the fouthward of Glamis, ftands Denoon caftle, upon an eminence, environed with fteep rocks almoft inacceffible, having on the north two or three rows of terraces. It is built in a femicircular form, encompassed with a ftupendous wall of ftone and earth, 27 feet high, and 30 feet in thicknefs. It has two entries, one to the fouth-eaft and another to the north. The whole circumference of the wall amounts to 335 yards; and within this area, the ruins of ancient buildings are ftill vifible. About four miles to the fouthward of Brechin, at a place called *Aberlenny*, we find four or five ancient obelisks, one of which is engraved with figures, fuppofed to be monuments of a great victory gained at the village of Loncarty, by the Scots over the Danes; a victory entirely owing to the valour of an hufbandman and his two fons, of the furname of *Hay*, who were ennobled for their prowefs by king Kenneth III. From thefe defended the earls of Errol, hereditary high-constables of Scotland.

FORFEITURE, originally fignifies a tranfgreffion, or offence againft fome penal law. The word is formed of the bafe Latin *forisfactura*; whence *forfaitura* and *forfaitura*, and the French *forfait*. *Forisfactura* comes of *forisfacere*; which, according to Ifidore, fignifies to “hurt or offend,” *facere contra rationem*; and which is not improbably derived of *foris* “out,” and *facere*, “to do,” q. d. an action out of rule, or contrary to the rules. Borel will have *forfait* derived from the uſing of force, or violence: Lo-

bineau in his glosſary will have *forisfacta* properly *Forfeiture*. to fignify a mulct or amend, not a *forfeit*; which latter he derives from the bafe Britiſh *forſed*, “a penalty.”

But, with us, it is now more frequently uſed for the effect of ſuch tranſgreſſion; or the loſing ſome right, privilege, eſtate, honour, office, or effects, in conſequence thereof; than for the tranſgreſſion itſelf.

Forfeiture differs from *confiſcation*, in that the former is more general; while confiſcation is particularly applied to ſuch things as become forfeited to the king's exchequer; and goods confiſcated are ſaid to be ſuch as nobody claims.

Forfeitures may be either in *civil* or *criminal* caſes.

I. With reſpect to the firſt, a man that hath an eſtate for life or years, may forfeit it many ways, as well as by treaſon or felony; ſuch as alienation, claiming a greater eſtate than he hath, or affirming the reverſion to be in a ſtranger, &c. When a tenant in tail makes leaſes, not warranted by the ſtatute; a copyholder commits waſte, refuſes to pay his rent, or do ſuit of court; and where an eſtate is granted upon condition, on non-performance thereof, &c. they will make a forfeiture.

Entry for a forfeiture ought to be by him who is next in reverſion, or remainder, after the eſtate forfeited. As if tenant for life or years commits a forfeiture, he who has the immediate reverſion or remainder ought to enter; though he has the fee, or only an eſtate-tail.

II. Forfeiture in criminal caſes is twofold; of real, and perſonal eſtates.

I. As to real eſtates, by **ATTAINDER** in high-treaſon, a man forfeits to the king all his lands and tenements of inheritance, whether fee-fimple or fee-tail; and all his rights of entry on lands and tenements, which he had at the time of the offence committed, or at any time afterwards, to be for ever veſted in the crown; and alſo the profits of all lands and tenements, which he had in his own right for life or years, ſo long as ſuch intereſt ſhall ſubſiſt. This forfeiture relates backwards to the time of the treaſon committed; ſo as to avoid all intermediate ſales and incumbrances, but not thoſe before the fact: and therefore a wife's jointure is not forfeitable for the treaſon of her huſband; becauſe ſettled upon her previous to the treaſon committed. But her dower is forfeited, by the expreſs provision of ſtatute 5 & 6 Edw. VI. c. 11. And yet the huſband ſhall be tenant by the curteſy of the wife's lands, if the wife be attainted of treaſon: for that is not prohibited by the ſtatute. But, though after attainder the forfeiture relates back to the time of the treaſon committed, yet it does not take effect unleſs an attainder be had, of which it is one of the fruits; and therefore, if a traitor dies before judgment pronounced, or is killed in open rebellion, or is hanged by martial law, it works no forfeiture of his lands: for he never was attainted of treaſon. But if the chief juſtice of the king's bench (the ſupreme coroner of all England) in perſon, upon the view of the body of him killed in open rebellion, records it and returns the record into his own court, both lands and goods ſhall be forfeited.

The natural juſtice of forfeiture or confiſcation of property, for treaſon, is founded on this conſideration: That

Blackſt.
Comment.

That he who hath thus violated the fundamental principles of government, and broken his part of the original contract between king and people, hath abandoned his connexions with society; and hath no longer any right to those advantages, which before belonged to him purely as a member of the community; among which *social* advantages the right of transferring or transmitting property to others is one of the chief. Such forfeitures, moreover, whereby his posterity must suffer as well as himself, will help to restrain a man, not only by the sense of his duty, and dread of personal punishment, but also by his passions and natural affections; and will interest every dependent and relation he has, to keep him from offending: according to that beautiful sentiment of Cicero, "*ne vero me fugit quam sit acerbum, parentum scelera filiorum poenis sui: sed hoc præclare legibus comparatum est, ut caritas liberorum amiciores parentes reipublica redderet.*" And therefore Aulus Cassellius, a Roman lawyer in the time of the triumvirate, used to boast that he had two reasons for despising the power of the tyrants; his old age, and his want of children: for children are pledged to the prince of the father's obedience. Yet many nations have thought, that this posthumous punishment favours of hardship to the innocent; especially for crimes that do not strike at the very root and foundation of society, as treason against the government expressly does. And therefore, although confiscations were very frequent in the times of the earlier emperors, yet Arcadius and Honorius in every other instance but that of treason thought it more just, *ibi esse poenam, ubi et noxa est*; and ordered that "*peccata suos teneant auctores, nec ulterius progrediatur metus, quam reperiarit delictum*:" and Justinian also made a law to restrain the punishment of relations; which directs the forfeiture to go, except in the case of *crimen majestatis*, to the next of kin to the delinquent. On the other hand, the Macedonian laws extended even the capital punishment of treason, not only to the children, but to all the relations of the delinquent: and of course their estates must be also forfeited, as no man was left to inherit them. And in Germany, by the famous golden bull, (copied almost *verbatim* from Justinian's code) the lives of the sons of such as conspire to kill an elector are spared, as it is expressed, by the emperor's *particular bounty*. But they are deprived of all their effects and rights of succession, and are rendered incapable of any honour ecclesiastical and civil: "to the end that, being always poor and necessitous, they may for ever be accompanied by the infamy of their father; may languish in continual indigence; and may find (says this mercilefs edict) their punishment in living, and their relief in dyin."

In England, forfeiture of lands and tenements to the crown for treason is by no means derived from the feudal policy, but was antecedent to the establishment of that system in this island; being transmitted from our Saxon ancestors, and forming a part of the ancient Scandinavian constitution. But in certain treasons relating to the coin, (which seem rather a species of the *crimen falsi* than the *crimen læsæ majestatis*) it is provided by some of the modern statutes which constitute the offence, that it shall work no forfeiture of lands, save only for the life of the offenders; and by all, that it shall not deprive the wife of her dower. And,

in order to abolish such hereditary punishment entirely, it was enacted by statute 7 Ann. c. 21. that, after the decease of the late pretender, no attainer for treason should extend to the disinheriting of any heir, nor to the prejudice of any person, other than the traitor himself. By which, the law of forfeitures for high treason would by this time have been at an end, had not a subsequent statute intervened to give them a longer duration. The history of this matter is somewhat singular, and worthy observation. At the time of the union, the crime of treason in Scotland was, by the Scots law, in many respects different from that of treason in England; and particularly in its consequence of forfeitures of entailed estates, which was more peculiarly English: yet it seemed necessary, that a crime so nearly affecting government should, both in its essence and consequences, be put upon the same footing in both parts of the united kingdoms. In new-modelling these laws, the Scotch nation and the English house of commons struggled hard, partly to maintain, and partly to acquire, a total immunity from forfeiture and corruption of blood; which the house of lords as firmly resisted. At length a compromise was agreed to, which is established by this statute, viz. that the same crimes, and no other, should be treason in Scotland that are so in England; and that the English forfeitures and corruption of blood, should take place in Scotland, till the death of the then pretenders; and then cease throughout the whole of Great Britain: the lords artfully proposing this temporary clause, in hopes (it is said), that the prudence of succeeding parliaments would make it perpetual. This has partly been done by the statute 17 Geo. II. c. 39. (made in the year preceding the late rebellion), the operation of these indemnifying clauses being thereby still farther suspended till the death of the sons of the pretender.

In petit treason and felony, the offender also forfeits all his chattel interests absolutely, and the profits of all freehold estates during life; and, after his death, all his lands and tenements in fee-simple (but not those in tail) to the crown, for a very short period of time: for the king shall have them for a year and a day, and may commit therein what waste he pleases; which is called the king's *year, day, and waste*. Formerly the king had only a liberty of committing waste on the lands of felons, by pulling down their houses, extirpating their gardens, ploughing their meadows, and cutting down their woods. And a punishment of a similar spirit appears to have obtained in the oriental countries, from the decrees of Nebuchadnezzar and Cyrus in the books of Daniel and Ezra; which, besides the pain of death inflicted on the delinquents there specified, ordain, "that their houses shall be made a dunghill." But this tending greatly to the prejudice of the public, it was agreed in the reign of Henry the first, in England, that the king should have the profits of the land for one year and a day, in lieu of the destruction he was otherwise at liberty to commit: and therefore *magna charta* provides, that the king shall only hold such lands for a year and a day, and then restore them to the lord of the fee; without any mention made of waste. But the statute 17 Edw. II. *de prerogativa regis*, seems to suppose, that the king shall have his year, day, and waste; and not the year and day *instead* of waste. Which Sir

Forfeiture.

Edward Coke (and the author of the Mirror, before, him) very justly look upon as an encroachment, tho a very ancient one, of the royal prerogative. This year, day, and walle, are now usually compounded for; but otherwise they regularly belong to the crown: and, after their expiration, the land would naturally have descended to the heir, (as in gavelkind tenure it still does) did not its feudal quality intercept such descent, and give it by way of escheat to the lord. These forfeitures for felony do also arise only upon attainder; and therefore a *felo de se* forfeits no lands of inheritance or freehold, for he never is attainted as a felon. They likewise relate back to the time the offence was committed, as well as forfeitures for treason; so as to avoid all intermediate charges and conveyances. This may be hard upon such as have unwarily engaged with the offender: but the cruelty and reproach must lie on the part, not of the law, but of the criminal; who has thus knowingly and dishonestly involved others in his own calamities.

2. The forfeiture of goods and chattels accrues in every one of the high kinds of offence; in high treason, or misprison thereof, petit treason, felonies of all sorts whether clergyable or not, self-murder or felony *de se*, petty larceny, standing mute, &c. For flight also, on an accusation of treason, felony, or even petit larceny, whether the party be found guilty or acquitted, if the jury find the flight, the party shall forfeit his goods and chattels: for the very flight is an offence, carrying with it a strong presumption of guilt, and is at least an endeavour to elude and flake the course of justice prescribed by the law. But the jury very seldom find the flight: forfeiture being looked upon, since the vast increase of personal property of late years, as too large a penalty for an offence to which a man is prompted by the natural love of liberty.

There is a remarkable difference or two between the forfeiture of lands, and of goods and chattels. (1.) Lands are forfeited upon attainder, and not before: goods and chattels are forfeited by conviction. Because in many of the cases where goods are forfeited, there never is any attainder; which happens only where judgment of death or outlawry is given: therefore, in those cases, the forfeiture must be upon conviction, or not at all; and, being necessarily upon conviction in those, it is so ordered in all other cases, for the law loves uniformity. (2.) The forfeiture of lands has relation to the time the fact was committed, so as to avoid all subsequent sales and incumbrances: but the forfeiture of goods and chattels has no relation backwards; so that those only which a man has at the time of conviction shall be forfeited. Therefore a traitor or felon may *bona fide* sell any of his chattels, real or personal, for the subsistence of himself and family between the fact and conviction: for personal property is of so fluctuating a nature, that it passes through many hands in a short time; and no buyer could be safe, if he were liable to return the goods which he had fairly bought, provided any of the prior vendors had committed a treason or felony. Yet if they be collusively and not *bona fide* dealt with, merely to defraud the crown, the law (and particularly the statute 13 Eliz. c. 5.) will reach them; for they are all the while truly and substantially the goods

of the offender: and as he, if acquitted, might recover them himself, as not parted with for a good consideration; so, in case he happens to be convicted, the law will recover them for the king.

FORFICULA, the EAR-WIG, in zoology, a genus of insects belonging to the order of coleoptera. The antennæ are bristly; the elytra are dimidiated; the wings are covered; and the tail is forked. There are two species, viz. the auriculata, or common earwig, with the tops of the elytra white; and the minor, with testaceous and unpotted elytra.—It is a very troublesome creature, frequently introducing itself into the ears, and causing a great deal of pain by its biting: it likewise burrows in other parts of the body, which it bites in the same manner.

Ear-wigs are very mischievous vermin in gardens, especially where carnations are preferred; for they are so fond of these flowers, that, if care is not taken to prevent them, they will entirely destroy them, by eating off the sweet part at the bottom of the petals or leaves. To prevent which, most people have stands erected, which have a basin of earth or lead round each supporter, which is constantly kept filled with water. Others hang the hollow claws of crabs and lobsters upon sticks in divers parts of the garden, into which those vermin get; and by often searching them, you will destroy them without much trouble, which will be of great service to your wall-fruit, for these are great destroyers also of all soft fruits.

FORGE, properly signifies a little furnace, where-in smiths and other artificers of iron or steel, &c. heat their metals red hot, in order to soften them and render them more malleable and manageable on the anvil.

An ordinary forge is nothing but a pair of bellows, the nozzle of which is directed upon a smooth area, on which coals are placed. The nozzle of a pair of bellows may be also directed to the bottom of any furnace, to excite the combustion of the coals placed there, by which a kind of forge is formed. In laboratories, there is generally a small furnace consisting of one cylindrical piece, open at top, which has at its lower side a hole for receiving the nozzle of a double bellows. This kind of forge-furnace is very convenient for fusions, as the operation is quickly performed, and with few coals. In its lower part, two inches above the hole for receiving the nozzle of the bellows, may be placed an iron-plate of the same diameter, supported upon two horizontal bars, and pierced near its circumference with four holes diametrically opposite to each other. By this disposition, the wind of the bellows, pushed forcibly under this plate, enters at these four holes; and thus the heat of the fire is equally distributed, and the crucible in the furnace is equally surrounded by it. This contrivance is used in the forge-furnaces for melting copper, with this difference only, that these furnaces are square, which is a matter of no consequence.

As the wind of bellows strongly and rapidly excites the action of the fire, a forge is very convenient when a great heat is to be applied quickly: but it is not suitable when the heat is to be gradually increased.

The forge, or blast of bellows, is used in several operations in small; as to fuse salts, metals, ores, &c. It is also much used in works in the great, which require strong heat, without much management; and chiefly in the

Forficula, Forge.

Forge,
Forge.

Forgery,
Forging.

the smelting of ores, and fusion of metallic matters.

FORGE is also used for a large furnace, wherein iron-ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fuled over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGE, in the train of artillery, is generally called a *travelling-Forge*, and may not be improperly called a portable smith's-shop: at this forge all manner of smith's work is made, and it can be used upon a march as well as in camp. Formerly they were very ill contrived, with 2 wheels only, and wooden supporters to prop the forge for working when in the park. Of late years they are made with 4 wheels, which answers their purpose much better.

FORGE for red-hot Balls, is a place where the balls are made red-hot before they are fired off: it is built about five or six feet below the surface of the ground, of strong brick-work, and an iron grate, upon which the balls are laid, with a very large fire under them.

FORGER, in law, one guilty of FORGERY.

FORGERY, (from the French *forger*, i. e. *accudere, fabricare*, "to beat on an anvil," "forge," or "form,") may be defined at common law, to be "the fraudulent making or alteration of a writing to the prejudice of another man's right:" for which the offender may suffer fine, imprisonment, and pillory. And also, by a variety of statutes, a more severe punishment is inflicted on the offender in many particular cases, which are so multiplied of late as almost to become general. We shall mention the principal instances.

By statute 5 *Eliz. c. 14.* to forge or make, or knowingly to publish or give in evidence, any forged deed, court-roll, or will, with intent to affect the right of real property, either freehold or copyhold, is punished by a forfeiture to the party grieved of double costs and damages; by standing in the pillory, and having both his ears cut off, and his nostrils slit, and seared; by forfeiture to the crown of the profits of his lands, and by perpetual imprisonment. For any forgery relating to a term of years, or annuity, bond, obligation, acquittance, release, or discharge of any debt or demand of any personal chattels, the same forfeiture is given to the party grieved; and on the offender is inflicted the pillory, loss of one of his ears, and half a year's imprisonment: the second offence, in both cases, being felony without benefit of clergy.

Besides this general act, a multitude of others, since the revolution, (when paper-credit was first established) have inflicted capital punishment on the forger, altering, or uttering as true when forged, of any bank bills or notes, or other securities; of bills of credit issued from the exchequer; of south-sea bonds, &c.; of lottery tickets or orders; of army or navy debentures; of East-India bonds; of writings under seal of the London or royal-exchange assurance; of the hand of the receiver of the pre-fines, or of the accountant-general and certain other officers of the court of chancery; of a letter of attorney or other power to receive or transfer stock or annuities; and on the personating a proprietor thereof, to receive or transfer such annuities, stock, or dividends: also on the personating, or

procuring to be personated, any seaman or other person, entitled to wages or other naval emoluments, or any of his personal representatives; and the taking, or procuring to be taken, any false oath in order to obtain a probate, or letters of administration, in order to receive such payments; and the forging, or procuring to be forged, and likewise the uttering or publishing, as true, of any counterfeited seaman's will or power: to which may be added, though not strictly reducible to this head, the counterfeiting of mediterranean passes, under the hands of the lords of the admiralty, to protect one from the piratical states of Barbary; the forging or imitating of any stamps to defraud the public revenue; and the forging of any marriage register or licence: all which are, by distinct acts of parliament, made felonies without benefit of clergy. By statutes 13 *Geo. III. c. 52. & 59.* forging or counterfeiting any stamp or mark to denote the standard of gold and silver plate, and certain other offences of the like tendency, are punished with transportation for 14 years. By statute 12 *Geo. III. c. 48.* certain frauds on the stamp-duties, therein described, principally by using the same stamps more than once, are made single felony, and liable to transportation for seven years. And the same punishment is inflicted by statute 13 *Geo. III. c. 38.* on such as counterfeit the common seal of the corporation for manufacturing plate-glass (thereby erected), or knowingly demand money of the company by virtue of any writing under such counterfeit seal.

There are also two other general laws, with regard to forgery; the one 2 *Geo. II. c. 25.* whereby the first offence in forging or procuring to be forged, acting or assisting therein, or uttering or publishing as true, any forged deed, will, bond, writing obligatory, bill of exchange, promissory note, indorsement or assignment thereof, or any acquittance or receipt for money or goods, with intention to defraud any person, (or corporation), is made felony without benefit of clergy. And by statute 7 *Geo. II. c. 22.* it is equally penal to forge, or cause to be forged, or utter as true, a counterfeit acceptance of a bill of exchange, or the number of any accountable receipt for any note, bill, or any other security for money; or any warrant or order for the payment of money, or delivery of goods. So that, through the number of these general and special provisions, there is now hardly a case possible to be conceived, wherein forgery, that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime.

FORGING, in law, the act of FORGERY.

FORGING, in smithery, the beating or hammering iron on the anvil, after having first made it red-hot in the forge, in order to extend it into various forms, and fashion it into works. See FORGE.

There are two ways of forging and hammering iron. One is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron-chains fastened to the ceiling of the forge.

Forgiveness forge. See MILL.

Form.

This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for, requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it when it will not batter under the hammer; and if it be too hot, it will red-scar, that is, break or crack under the hammer.

The several degrees of heats the smiths give their irons, are, first, a blood-red heat; secondly, a white-flame-heat; and, thirdly, a sparkling or welding heat.

FORGIVENESS, the act of pardoning any offender. See MORALS, n° 126.

FORISFAMILIATION, in law. When a child, upon receiving a portion from his father, or otherwise, renounces his legal title to any further share of his father's succession, he is said to be *forisfamiliarized*.

FORLI, an ancient and considerable town of Italy, and capital of a territory of the same name, in Romagna, with a bishop's see. The public structures are very handsome; and it is seated in a fertile, healthy, and pleasant country, 10 miles south-east of Faenza, and 45 north-east of Florence. E. Long. 12. 1. N. Lat. 44. 28.

FORLORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or, at a siege, to storm the counterescarp, mount the breach, or the like.—They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

FORM, in physics, the essential or distinguishing modification of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence; being that which constitutes it such a particular body, and distinguishes it from every other body.

FORM is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

FORM, in law, the rules established and requisite to be observed in legal proceedings.—The formal part of the law, or method of proceeding, cannot be altered but by parliament; for if once these *outworks* were demolished, there would be an inlet to all manner of innovation in the body of the law itself.

FORM, in carpentry, is used to denote the long seats or benches in the cloisters of churches or in schools, for the priests, prebends, religious, or scholars, to sit on. At schools, the word *form* is frequently applied to what is otherwise termed a *class*. See CLASS.

FORM also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness.

FORM is also used, among mechanics, for a sort of mould wherein any thing is fashioned or wrought.

Printer's FORM, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every form is included in an iron-chase, wherein it

is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages, according to the size of the book.

Hatters' FORM, is a large block or piece of wood, of a cylindrical figure; the top thereof rounded, and the bottom quite flat. Its use is, to mould or fashion the crown of the hat, after the matter thereof has been beaten and filled.

Papermakers' FORM, is the frame or mould wherein the sheets are fashioned. See PAPER.

FORMA PAUPERIS, in law, is when a person has just cause of suit, but is so poor, that he cannot defray the usual charges of suing at law or in equity; in which case, on making oath that he is not worth 5*l.* in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in *forma pauperis*; that is, without paying any fee to counsellors, attorneys, or clerk: the statute 1 Hen. VII. c. 12. having enacted, that counsel and attorneys, &c. shall be assigned to such poor persons *gratis*. Where it appears that any pauper has sold or contracted for the benefit of his suit, whilst it is depending in court, such cause shall be thenceforth totally dismissed; and a person suing in *forma pauperis*, shall not have a new trial granted him, but is to acquiesce in the judgment of the court.

FORMAL, something belonging to or constituting the form of a thing. See FORM.

FORMATION, in philosophy, an act whereby something is formed or produced.—For the formation of the fetus in the womb, see GENERATION.

FORMATION of Stones. See STONE.

FORMATION of Metals and Minerals. See METAL and MINERAL.

FORMATION, in grammar, signifies the manner of forming one word from another: thus *accountantship* is formed from *accountant*, and this last from *account*.

FORMEDON, in law, (*breve de forma donationis*) a writ that lies for a person who has a right to lands or tenements, by virtue of any entail, arising from the statute of Westm. 2 Ch. II.

This writ is of three kinds, viz. a descender, remainder, and reverter. Formedon in *descender*, lies where a tenant in tail incloses a stranger, or is disseised and dies, the heir may bring this writ to recover the lands. Formedon in *remainder*, lies where a man gives lands, &c. to a person in tail, and, for default of issue of his body, the remainder to another in tail: here if the tenant in tail dies without issue, and a stranger abates and enters into the land, he in remainder shall have this writ. Formedon in *reverter*, lies where lands are entailed on certain persons and their issue, with remainder over for want of issue; and, on that remainder failing, then to revert to the donor and his heirs: in this case, if the tenant in tail dies without issue, and also he in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, though the same be alienated, &c.

FORMICA, or the ANT, in zoology, a genus of insects belonging to the order of hymenoptera, the characters of which are these: There is a small scale betwix the breast and belly, and the joint is so deep, that the animal appears as if it were almost cut through the body.

Form
||
Formica.

body. The females, and the neuters or working ants which have no sexual characteristics, are furnished with a hidden sting; and both the males and females have wings, but the neuters have none. There are 18 species, most of them distinguished by their colours.

These insects keep together in companies like the bees, and maintain a sort of republic. Their nest is not exactly square, but longer one way than the other; and in it there are a sort of paths, which lead to different magazines. Some of the ants are employed in making the ground firm, by mixing it with a sort of glue, for fear it should crumble and fall down upon their heads. They may be sometimes seen to gather several twigs, which serve them for rafters, which they place over the paths, to support the covering; they lay others across them, and upon them rushes, weeds, and dried grass, which they heap up into a double declivity, which serves to turn off the water from their magazines. Some of these have to lay up their provisions in, and in others they lay their eggs.

As for the provisions, they lay up every thing that is fit for them to eat; and you may often see one loaded with pippin or grain of fruit, another with a dead fly, and several together with the carcase of a may-bug or other insect. If they meet with any they cannot bring away, they eat it upon the spot, or at least so much of it as may reduce it to a bulk small enough for them to carry. They do not run about where they please, at all adventures: for some of them are sent abroad to make discoveries; and if they bring back news that they have met with a pear, or a sugar-loaf, or a pot of sweet-meats, they will run from the bottom of the garden, as high as the third story of a house, to come at it. They all follow each other in the same path, without wandering to the right or the left; but in the fields they are more at their liberty, and are allowed to run about in search of game. There is a sort of green fly, that does a great deal of mischief among the flowers, and which curls up the leaves of peach and pear trees: and these are surrounded with a sort of glue, or honey, which the ants hunt after very greedily; for they touch neither the plant nor the flies themselves.

Next to this, their greatest passion is to lay up hoards of wheat, and other corn; and for fear the corn should sprout by the moisture of the subterraneous cells, they gnaw off the end which would produce the blade. The ants are often seen pushing along grains of wheat, or barley, much larger than themselves.

In Africa, and particularly in Guinea, the ants are exceedingly troublesome, and do a great deal of mischief. They make their nests of earth in the fields, twice as high as a man; besides which they build large nests in high trees, from which places they advance in such prodigious swarms to the houses, that they frequently oblige the inhabitants to quit their beds in the night-time. They will sometimes attack a living sheep; which in a night's time they will reduce to a perfect skeleton, leaving not the least thing except the bones. It is common for them to serve domestic fowls in the same manner, and even the rats themselves cannot escape them. If you place a worm or a beetle where only one or two ants are, they will immediately depart, and bring with them above an hundred; after which they seize their prey, and march off with it in good order. These ants are of various sorts; some great, others

small; some black, and others red: the sting of this last is very painful, and causes an inflammation: the white are as transparent as crystal, and have such strong teeth, that in a night's time they will eat their way through a thick wooden chest, and make it as full of holes as if it had been penetrated by hail-stone.

There are also several sorts of ants in the East Indies, whose numbers are prodigious: some of them are exceeding large, and of a ruddy colour, inclining to black; and some have wings, but others have none. They are very pernicious to the fruits of the earth, and do a great deal of mischief in houses, unless great care is taken to prevent them. It is remarkable, that if one ant meets another that is laden, it always gives way to let it pass freely.

The ant lays eggs in the manner of the common flies, and from these eggs are hatched a sort of small maggots or worms without legs: these are sharp at one end, and blunt at the other; and are white, but so transparent, that the intestines are seen through the skin. These, after a short time, change into large white aureliae, which are what are usually called *ante eggs*. That end which is to be the tail is the largest, and that which is the head is somewhat transparent.

The ants move these about at pleasure with their forceps. It is well known, that when a nest of these creatures is disturbed, and the aureliae scattered about, the ants are at infinite pains to get together all that are unhurt, and make a nest for them again: nay, any ants will do this, and those of one nest will often take care of the aureliae of another.

The affection of the ant for its offspring is amazing. They carry the young worms about in their mouths, that nothing may injure them; and when the earth of the nest is dry, they carry them down to a greater depth, but when wet they bring them to the surface, that they may not be injured by the damps.

The common ant builds only with small pieces of dry earth, and there is always found a vast quantity either of eggs, worms, or aureliae, at the bottom of the nest. The aureliae are covered only with a thin skin; and when carefully opened, they shew the worm perfect, and in its several stages of perfection.

The forecast of ants in providing against the winter is a mistake. They are supposed not to eat in the winter, but to spend that season, like dormice and many other sorts of animals, in a state of sleep. What confirms this is, that they have been observed, as the cold draws on in the autumn, to move very heavily, and in the vintage-time they can hardly stir at all; so that the provision they make seems intended not for themselves, but for their young.

The care these creatures take of their offspring is remarkable. Whenever a hill is disturbed, all the ants are found busied in consulting the safety, not of themselves, but of the eggs or these larger bodies inclosing the maggot or young ant; they carry these down any way so as to get them out of sight, and will do this over and over as often as they are disturbed.

They carry away the eggs and vermicels together in their confusion; but, as soon as the danger is over, they carefully separate them, and place each sort in parcels by themselves under shelter of different kinds, and at various depths, according to the different degrees of warmth and coverture the different states require.

require.

In the warm season of the year, they every morning bring up the eggs, as they are usually called, to the surface, or nearly so; and from ten in the forenoon to five in the afternoon or thereabouts, all these will be found just under the surface; and if the hills be examined toward eight in the evening, they will be found to have carried them all down; and if rainy weather be coming on, it will be necessary to dig a foot deep or more, in order to find them.

These little creatures are very troublesome in gardens, and in pasture-lands; as well by feeding on the fruit, as by making up hills for their habitation. In the hotter countries, as Italy, Spain, and the West Indies, ants are the greatest pest of the fields. Trees may be preserved from them by encompassing the stem, for four fingers breadth, with a roll of wool, newly pulled from the sheep's belly; or by laying saw-dust all round the stump of it. Some anoint the tree with tar, which has the same effect. See *Amr.*

The large, black, winged ants of America, to avoid the great rains which fall there at particular seasons, make to themselves large nests on trees, with a covered way for them to go up and down on the lee-side of the tree. These nests are roundish on the outside, made of light brown earth, plastered smooth. They are larger than a bushel; and in the inside are many sinuous caverns or lodgings communicating with one another. See Plate CVIII. fig. 1. A, The ants nest; B, The tubular passage, made of the same materials.

Formica-Leo, the *Ant-lion*, in zoology, an insect so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resembling the libellæ or dragon-flies; and feeds chiefly upon ants, from which property it derives its name.

It is somewhat of the nature of the spider in its way of taking its prey, its manner of spinning, and the figure and softness of its body. It has, in its general figure, somewhat of the appearance of the millepes or wood-louse, so that some have mistaken it at first sight for that animal. It is of a dirty greyish colour, marked with some black spots; and these are also composed of many points when viewed with a microscope, which make it resemble a hedge-hog or porcupine. Its body is composed of several rings, and has thence a wrinkled look. It has six legs, four are joined to the breast, and the other two to a longer part, which may be taken for its neck. Its head is small and flat, and it has two remarkable horns: these are about a sixth part of an inch long, and as thick as a hair: they are hard, hollow, and hooked at the end like the claws of a cat. At the origin of each of these horns, it has a clear and bright black eye, which sees very distinctly, and gives the creature notice to escape on sight of the smallest object.—This creature is not able to hunt after its prey, nor to destroy large insects; it can only draw into its snares such as come near its habitation, and of these very few are such as he can manage: all the winged kind are able to escape by flight; and the beetle kinds, and others that have hard shells upon their bodies, are of no use to him, as his horns cannot pierce them. The smallness of the ant, and its want of wings, make it the destined prey of this devourer. The manner in which he catches his prey is as follows.

He usually encamps under an old wall, that he may

be sheltered from the injuries of the weather; and he always chooses a place where the soil is composed of a fine dry sand. In this he makes a pit of the shape of a funnel, or an inverted hollow cone. If he intends the pit to be but small, he thrusts down his hinder part into the sand, and by degrees plunges himself backward into it; and when he has got to a certain depth, he tosses out the loose sand which has run down with his head, artfully throwing it off beyond the edges of his pit. Thus he lies at the bottom of a small hollow, which is widest at the top, and comes sloping down to his body.

But if he is to make a larger pit, more pains are required to bring it to perfection. He first traces, in the surface of the sand, a large circle, which is the erected base or mouth of the pit he is to make in form of an inverted cone. He then buries himself in the sand near the edge of this circle, and carefully throws up the sand above him, with his head tossing it out beyond the circumference of the circle. Thus he continues his work, running down backwards in a spiral line all the way, and carefully throwing off the sand from above him, till he is come to the place of his rest, which is the point or reverted apex of the hollow cone he has formed by his passage. The length of his neck, and the flatness of his head, gives him a power of using the whole as a spade, and throwing off the sand with great ease; and his strength in this part is so great, that he is able to throw off a quantity of it to six inches distance. This is a power he exerts oftener, however, in throwing away the remains of the animals he has fed upon, that his den may not become frightful to others of the same species, by seeing their fellow carcases about it.

When he has finished his pit, he buries himself at the bottom of it among the sand, leaving no part above ground but the tips of his two horns, which he expands to the two sides of the pit. In this condition he lies and waits for his prey, and never comes up afterwards. When an ant, or any other such creature, chances to walk over the edges of his pit, its steps throw down a little of the sand, which naturally running down to the bottom of the pit, gives the enemy notice of his prey; he then tosses up the sand which covers his head, to bury the ant, and bring him down with its returning force to the bottom; and as one such attempt cannot be sufficient to prevent the ant's escape, he throws more and more sand upon him, till he by degrees brings him down. All the endeavours of the ant to escape, when once it is within the verge of the pit, are in vain; for, as it attempts to climb, the sand runs away from under its feet, and it sinks the lower for every attempt. This motion of the sand also informs the enemy where it is, and directs him to throw up more sand in the right place; which it does, till the poor ant falls to the bottom between its horns. It then plunges their points deep into the ant's body; and having sucked out all the juice out of the prey, it throws out the empty skin as far from the hole as it can. This done, it mounts up the edges of its pit, and if it has suffered any injury, repairs it with great care, and immediately buries itself again in the centre, to wait for another meal. The horns of this creature are its only organs for receiving nourishment; it never brings any animal which it has seized near to its head, but always holds

it at the tip of the horns. They therefore plainly serve as syringes, to draw into its stomach the juices of the bodies of the insects it feeds upon: neither is there any mouth or trunk, or any other organ to be discovered about its head, which could serve to the purpose of eating; the head seeming only intended for throwing away the sand in forming the pit. The horns of this animal being so necessary to its life, nature has provided for the restoring them in case of accidents; and, if cut off, they are found to grow again.

The food this creature procures by its pit can be but little; and as it has no power of catching its prey any other way, its motion being only backwards, and that slowly, and by small spaces at a time, some people have believed its catching now and then an ant by this means was rather for diversion than hunger. But tho' the formica leo will live a long time without food, and even pass through all its changes when shut up in a box, yet it is always ready to eat when food is offered it; it always appears starved and small when kept thus; and if a fly is given it in this hungry state, it will so suck out all its juices, that the shell remaining may be rubbed to powder between the fingers, while the body of the creature that has sucked it appears remarkably swelled and distended; so that it is plain that the juices of the prey are conveyed into the body of the creature; though it is not easy to see by what means, the horns not appearing to have any perforation.

When the formica leo has lived a proper time in this state, it leaves its pit, and is only seen drawing lines and traces on the surface of the sand. After this it buries itself under the surface; and there incloses itself in a fine web, in which it is to pass its transformation into the winged state. This case is made of a sort of silk which the creature spins in the manner of the spider, and of a quantity of the grains of sand cemented together by a glutinous humour which flows from its pores. This case, however, would be too harsh and coarse for the body of the creature, and therefore it serves only for the outer covering to defend it from injuries; the creature spinning one of pure and incomparably fine silk, of a beautiful pearl colour, within it, which covers its whole body.

When the creature has lain some time in this case, it throws off its outer skin, with the eyes, the horns, and every other part necessary to its life before, and becomes an oblong nymph, in which a careful eye may trace the form of the fly into which it is to be transformed. There may be seen, through its transparent covering, new eyes, new horns, wings, and all the other parts of the animal in its perfect state. This nymph makes its way about half out of the shell, and remains in this condition, but without farther life or motion, till the perfect fly makes its way out at a slit in the back. In this last state it much resembles the libellæ or dragon-flies common about our waters. The male couples with the female in this state only; and M. Ponsart, to whom the world is obliged for this curious description, is of opinion that the females lay only one egg; but this is very different from the course of nature in the other animals of the same class.

When this insect forms its pit in a bed of pure sand, it is made and repaired with great ease; but where it meets with other substances among the sand, the labour becomes greatly the more embarrassing. If, for

instance, when the creature has half-formed its pit, and then comes to a stone of some moderate size, it does not desert the work for this, but goes on, intending to remove that impediment at last. When the pit is finished, the creature crawls backward up the side of the place where the stone is, and getting its backside under it, takes great pains and time to get it on a true poise, and then begins to crawl backward with it up the edge to the top of the pit, to get it out of the way. It is a very common thing to see a formica-leo in this manner labouring at a stone four times as big as its own body; and, as it can only move backward, and the poise is hard to keep, especially up a slope of such crumbly matter as sand, which moulders away from under its feet, and necessarily alters the position of its body, the stone very frequently falls down when near the verge, and then it is sure to roll to the bottom. In this case the animal attacks it again in the same way, and often is not discouraged by five or six miscarriages of this kind, but, after all, attempts again, and at length gets over the verge of the place. When it has done this, it does not leave it there, lest it should roll in again; but is always at the pains of pushing it farther on, till it has removed it to a necessary distance from the edge of the pit.

The common formica-leo moves only backward; but Mr Rouet has observed a species which moves forward in the common way of other animals, and makes no pit of this kind to entrap its prey, but seizes other insects by force.

FORMOSA, an island in the Pacific ocean, between 119° and 122° of E. Long. and between 22° and 25° N. Lat. about 100 miles east of Canton in China. It is subject to the Chinese.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in church-history and theology, signifies a profession of faith.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consilience.

FORMULARY, a writing containing the form of an oath, declaration, attestation, abjuration, &c. to be made on certain occasions.

FORNACALIA, or FORNICALIA, in Roman antiquity, a festival instituted by Numa in honour of Fornax, the goddess of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNICATION, (*Fornicatio*, from the *fornices* in Rome, where the lewd women prostituted themselves for money), is whoredom, or the act of incontinency, between single persons; for if either of the parties is married, it is *adultery*. Formerly court-leets had power to inquire of and punish fornication and adultery; in which courts the king had a fine assessed on the offenders, as appears by the book of Domesday.

In the year 1650, when the ruling powers found fit for their interest to put on the semblance of a very extraordinary strictness and purity of morals, not only incest and wilful adultery were made capital crimes, but also the repeated act of keeping a brothel, or committing fornication, were (upon a second conviction) made felony without benefit of clergy. But, at the restoration,

tion, when men, from an abhorrence of the hypocrisy of the late times, fell into a contrary extreme of licentiousness, it was not thought proper to renew a law of such unfashionable rigour. And these offences have been ever since left to the feeble coercion of the spiritual court, according to the rules of the canon law; a law which has treated the offence of incontinence, nay, even adultery itself, with a great degree of tenderness and lenity; owing perhaps to the constrained celibacy of its first compilers. The temporal courts therefore take no cognizance even of the crime of adultery other-wise than as a private-injury. See ADULTERY.

FORNIX, in anatomy, is part of the corpus callosum in the brain; so called, because of a distant resemblance it hath to the arches of ancient vaults when viewed in a particular manner.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

It is the business of the quarter-master general to appoint the method of forrage, and post proper guards for the security of the foragers.

FORRES, a parliament-town of Scotland in the county of Murray. W. Long. 3. 20. N. Lat. 57. 40. It is classed with Inverness, Fortrose, and Nairn.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town.

FORTALICE, in Scots law, signified anciently a small place of strength, originally built for the defence of the country; and which on that account was formerly reckoned *inter regalia*, and did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage, &c.

FORTESCUE (Sir John), lord chief justice of the king's bench, and lord high chancellor of England, in the reign of king Henry VI. was descended from the ancient family of Fortescue, in the county of Devon. He studied the municipal laws of England in Lincoln's Inn, of which he was made one of the governors in the fourth and seventh years of the reign of king Henry VI. In 1430 he was called to the degree of a serjeant at law, and in 1441 was constituted the king's serjeant. The following year he was made lord chief justice of the king's bench; in which honourable station he continued till near the end of that king's reign, who shewed him many particular marks of his favour, and advanced him to the post of lord high chancellor of England. During the reign of king Edward IV. he followed the fortunes of the house of Lancaster, and was many years in exile with queen Margaret and prince Edward her son. At length, they having a prospect of retrieving their desperate fortunes, the queen and

prince returned to England, and Sir John Fortescue, with many others, accompanied them: but soon after the decisive battle of Tewksbury, he was thrown into prison and attainted, with other Lancastrians; but found means to procure his pardon from Edward IV. He wrote, 1. A learned commentary on the politic laws of England, for the use of prince Edward; to one edition of which Mr Selden wrote notes. 2. The difference between an absolute and limited monarchy, as it more particularly regards the English constitution: (which was published, with some remarks, by John Fortescue, afterwards Lord Fortescue, in 8vo, in 1714; and a second edition was published, with amendments, in 1719.) And several works, which still remain in manuscript. He died near 90 years of age; and was buried in the parish-church of Ebburton, where a monument was erected to his memory, in 1677, by one of his descendants.

FORTH, one of the most noble and commodious rivers in Scotland. It takes its rise near the bottom of Leimon hills; and running from west to east, receives in its passage many considerable streams, deriving their waters from the eminences in the midland counties of North Britain. Between Stirling and Alloa, the Forth winds in a most beautiful and surprising manner; so that, though it is but four miles by land, it is 24 by water between these two places. Below Alloa the river expands itself to a great breadth between the counties of Lothian and Fife, till at Queen's-ferry it is contracted by promontories shooting into it from both coasts; so that, from being four or five, there it is not above two miles broad. In the middle of the channel lies a small island called *Tachgarry*, which has a spring of fresh water: and upon it there was anciently a fort; and if that was thoroughly repaired, or a new one erected, and there were either forts or blockhouses on the opposite promontories, that part of the river which lies between Alloa and Queens-ferry would be as secure and convenient a harbour as could be desired. Below Queen's-ferry the north and south shores receding, the body of the water gradually enlarges till it becomes two or three leagues broad, affording several safe harbours on both sides, and excellent roads throughout, unembarrassed with latent rocks, shoals, or sands; and allowing secure anchorage to the largest ships within a league of the coast, in almost any part of the Frith; and to vessels of a smaller size within a mile or less. The Frith, or (as it is commonly written) the *Frith*, of Forth, is, at the mouth of it, from North Berwick to Fifehead, full five leagues broad; having the little island of May (on which there is a light-house, and there might also be a fort) in the middle of it, and to the west of this the rocky island of Bala; notwithstanding which, the largest fleet may enter and sail up it many miles with the utmost facility and in the greatest safety. From its mouth to Stirling-bridge it is 20 leagues in extent. It was known to the ancients by the name of *Bodotria*, or (as Ptolemy calls it) *Boderia*, and has been ever famous for the number of its havens; some of which are, indeed, in their present condition, scarce worthy of that name; but, however, most of them are capable of being put in a much better state, whenever the commerce of this country shall require it.

F O R T I F I C A T I O N ;

THE art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by, some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end that a small number of men within may be able to defend themselves for a considerable time against the assaults of a numerous army without, so that the enemy in attacking them must of necessity suffer great loss.

The origin and rise of fortification, is undoubtedly owing to the degeneracy of mankind. In the first ages of the world, men were dispersed up and down the countries in separate families, as we are told in the histories of the Jews and Scythians, who wandered from one place to another, for the sake of finding pasture for their cattle. These families became in time so numerous as to form large communities, which settled all together in a place; from whence villages and towns had their origin and rise: but they found it was necessary, for the common security, to surround those towns with walls and ditches, to prevent all violences from their neighbours, and sudden surprisings. This was sufficient for some time, till offensive weapons were invented, and conquering became a fashion. Then walls with loop-holes were made at proper distances, in order to screen the defenders against the arrows of the assailants: but finding that, as soon as the enemy got once close to the walls, they could be from no part be discovered or repulsed; for this reason they added square towers at proper distances from each other, so that every part of the wall might be defended by the adjacent sides of the towers. However, this manner of inclosing of towns was found to be imperfect, because there remained still one of the faces of the towers which fronted the field that could not be seen from any other part, and therefore could not be defended. To remedy this, they made the towers round instead of square, imagining this figure to be the strongest to resist the battering engines, as likewise to be better defended from the other parts of the wall.

Notwithstanding the superiority of this method above the former, there remained yet a part of these towers unseen and incapable of being defended; which made them change the figure of the towers again; that is, they made them square as before; but, instead of presenting a face to the field as formerly, they presented an angle; by this means they effectually found out such a disposition of their works, that no part could be attacked without being seen or defended by some other part.

This last method was in use a long while; and would in all probability have continued to this day, if gun-powder had not been found out: but the violence of the guns and mortars soon convinced the world, that such towers and walls were but a weak defence against these thundering engines; and besides, as the nature of the attack was entirely changed, it was also necessary to change that of fortifying likewise.

From that time, ramparts were added to the walls, the towers enlarged into bastions, and all sorts of out-

works have been added, such as ravelins, counterguards, horn and crown works, and others of the like nature, in order to render the defence in some measure equivalent to the attack.

Notwithstanding all the improvements which have been made in the art of fortifying since the invention of gun-powder, that of attacking is still superior to it: engineers have tried in vain to render the advantages of a fortification equal to those of the attack; the superiority of the besiegers fire, together with the greater number of men, obliges generally, sooner or latter, the besieged to submit.

The greatest improvement made in the art of attacking happened in the year 1697, when M. Vauban made first use of ricochet-firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been none; whereas, before, they had been secure as long as the parapet was not demolished: and the worst is, that there can be no remedy found to prevent this enflaming, without falling into inconveniences almost as bad as those which we endeavour to avoid.

FORTIFICATION is either regular or irregular. Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

SECTION I. Of Regular Fortification.

ALTHOUGH authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be both needless and superfluous to treat of all the different methods hitherto proposed, we shall content ourselves with explaining those only, which are most esteemed by the best judges, and have been mostly put in practice.

Construction of M. VAUBAN'S Method.

THIS method is divided into little, mean, and great; the little is chiefly used in the construction of citadels, the mean in that of all sorts of towns, and the great in particular cases only.

We shall give the construction of the mean, as being most useful; and refer the reader to the table hereafter, for those dimensions which are different in these several fortifications.

Inscribe in a circle a polygon of as many sides as the Plate CXXI. fortification is designed to have fronts; let AB be one fig. 1. of the sides of half an hexagon, which bisect by the perpendicular CD; divide half AC of it into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is, six French feet; and therefore.

fore the whole side AB is supposed to be 180 toises.

As the dividing a line into so many equal parts, is troublesome and tedious; it is more convenient to have a scale of equal parts by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an hexagon inscribed; AB being bisected by the perpendicular CD as before, set off 30 toises from C to D, and draw the indefinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toises; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification.

If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs their parts a, b, c, &c. together with these arcs, will represent the outline of the ditch.

DEFINITIONS.

1. The part FEALN, is called the bastion.
2. AE, AL, the faces of the bastion.
3. EF, LN, the flanks.
4. FG, the curtain.
5. FN, the gorge of the bastion.
6. AG, BF, the lines of defence.
7. AB, the exterior side of the polygon.
8. CD, the perpendicular.
9. Any line which divides a work into two equal parts, is called the capital of that work.

10. a, b, c, the counterescarp of the ditch.

11. A, M, the flanked angles.

12. H, E, L, the angles of the shoulder, or shoulder only.

13. G, F, N, the angles of the flank.

14. Any angle whole point turns from the place is called a *salient angle*, such as A, M: and any angle whole point turns towards the place, *re-entering angle*, such as b, F, N.

15. If there be drawn two lines parallel to the principal or outline, the one at 3 toises distance, and the other at 8 from it; then the space yx included between the principal one and that farthest distant, is called the *rampart*.

And the space x x, contained by the principal line, and that near to it, and which is generally stained black, is called the *parapet*.

16. There is a fine line drawn within four feet of the parapet, which expresses a step called *banquette*.

N. B. All works have a parapet of three toises thick, and a rampart of 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular constructions of engineers.

The parapet is a part of the rampart elevated from 6 to 7½ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

17. The body of the place, is all that which is contained within this first rampart: for which reason, it is often said to construct the body of the place; which means properly, the construction of the bastions and curtains.

18. All the works which are constructed beyond the ditch before the body of the place are called *out-works*.

T A B L E.

Side of Polyg.	Forts.					Little Fortif.					Mean		Great.		
	80	90	100	110	120	130	140	150	160	170	180	190	200	260	
Perpendicular.	10	11	12½	14	15	16	20	21	23	25	30	31	25	22	
Faces bast.	22	25	28	30	33	35	40	42	45	47	50	53	55	60	
Cap. of ravel.	25	28	30	35	38	40	45	50	50	52	55	55	60	50	

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260. In the second, the perpendiculars answering to these sides. In the third, the lengths of the faces of bastions; and in the fourth, the lengths of the capitals of the ravelins.

The forts are mostly, if not always, squares: for which reason, the perpendiculars are made one eighth of the exterior sides; because if they were more, the gorges of the bastions would become too narrow.

The little fortification is chiefly designed for citadels, and are commonly pentagons; the perpendiculars are made one seventh of the exterior side: the mean is used in all kinds of fortifications from an hexagon up-

wards to any number of sides: and the great is seldom used but in an irregular fortification, where there are some sides that cannot be made less without much expence; or in a town which lies near a great river, where the side next the river is made from 200 to 260 toises; and as that side is less exposed to be attacked than any other, the perpendicular is made shorter, which saves much expence.

The faces of the bastions are all ¾ths of the exterior sides, or nearly so, because the fractions are neglected.

It may be observed in general, that in all squares the perpendicular is ¼th of the exterior side, and all pentagons ⅓th, and in all the rest upward ½th.

1. Construction of Orillons and retired Flanks.

DESCRIBE the front MPQRST as before, and divide the flank into three equal parts, of which suppose S r to be one: from the opposite flanked angle M draw a line M r, in which take the part m r of 5 toises; take likewise R n in the line of defence M R, produced, equal to 5 toises, and join n m, upon which as a base describe the equilateral triangle n p m, and from the angle p, opposite to the base as centre, is described the circular flank n m.

And if S r be bisected by the perpendicular r, 2, and another be erected upon the face ST, at S; the intersection 2 of these two perpendiculars, will be the centre of the arc which forms the orillon.

The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be if they were of any other figure.

2. Construction of Ravelins or Half-moons.

FIG. 2. Set off 55 toises, from the re-entering angle O of the counterescarp, on the capital O L or on the perpendicular produced, and from the point L draw lines to the shoulders AB; whose parts LM, LN, terminated by the counterescarp, will be the faces, and MO, ON, the semi-gorges of the ravelin required.

This is Mr Vauban's method of constructing ravelins, according to some authors: and others will have the faces of the ravelin to terminate on those of the bastions within 3 toises of the shoulders; which seems to be the best way, for these ravelins cover the flanks much better than the others.

The ditch before the ravelin is 12 toises, its counterescarp parallel to the faces of the ravelins; and is made in a circular arc, before the salient angle; as likewise all ditches are in general.

When the ravelins are made with flanks, as in fig. 3. the faces should terminate on those of the bastions, at least 5 toises from the shoulders.

The flanks are made by setting off 10 toises from the extremities of the faces, from f to h, and from m to l; and from the points h, l, the flanks h k, l p, are drawn parallel to the capital L O of the ravelin.

There are sometimes redoubts made in the ravelin, such as in fig. 2. which is done by setting off 16 toises from the extremities of the faces on the semi-gorges from N to b, and from M to a; and from the points b, a, the faces are drawn parallel to those of the ravelin: the ditch before the redoubt is 6 toises, and its counterescarp parallel to the faces.

3. Construction of Tenailles.

A tenaille is a work made in the ditch before the curtain, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different sorts: the first are those as in fig. 4. which are made in the direction of the lines of defence, leaving a passage of 3 toises between their extremities and the flanks of the bastions, as likewise another of 2 in the middle for a bridge of communication to the ravelin.

The second fort are those as in fig. 5. Their fa-

ces are in the lines of defence, and 16 toises long, besides the passage of 3 toises between them and the flanks of the bastions; their flanks are found by describing arcs from one shoulder of the tenaille as centre through the other, on which are set off 10 toises for the flanks desired.

And the third fort are those as in fig. 6. Their faces are 16 toises, as in the second fort, and the flanks are parallel to those of the bastions.

The use in general of tenailles, is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which can be defended from no where else so well as from them.

The first fort do not defend the ditch so well as the others, as being too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be seen in the citadel of Lille, at Laudan, New Brisac, and in a great many other places.

The second fort defend the ditch much better than the first, and add a low flank to those of the bastions; but as these flanks are liable to be enfiladed, they have not been much put in practice. This defect might however be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work.

As to the third fort, they have the same advantage as the second, and are likewise liable to the same objections; for which reason, they may be used with the same precautions which have been mentioned in the second.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them: and it is not without reason. For when the ditch is dry, the part behind the tenailles serves as a place of arms, from which the troops may sally, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure: which is a great advantage; for by that means the ravelin may make a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the tenailles to the ravelin, becomes likewise much easier than it would be without them.

4. Construction of Lunettes.

FIG. 7. Lunettes are placed on both sides of the ravelin, such as B, to increase the strength of a place: they are constructed, by bisecting the faces of the ravelin with the perpendicular LN; on which is set off 30 toises from the counterescarp of the ditch, for one of its faces; the other face, PN, is found by making the semi-gorge TP of 25 toises; the ditch before the lunettes is 12 toises, the parapet 3, and the rampart 8, as in the ravelin.

There is sometimes another work made to cover the salient angle of the ravelin, such as A, called *bonnet*, whose faces are parallel to those of the ravelin, and when produced bisect those of the lunettes; the ditch before it is 10 toises.

There are likewise lunettes, such as D in fig. 8. whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their demi-gorges are only 20 toises.

This kind of works may make a good defence, and cost no very great expence; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

5. Construction of Tenaillons.

FIG. 9. Produce the faces of the ravelin beyond the counterescarp of the ditch, at a distance MN of 30 toises, and take on the counterescarp of the great ditch 15 toises from the re-entering angle p to q, and draw Nq; then q N M p will be the tenaillons required; its ditch is 12 toises, that is, the same as that of the ravelin. Sometimes there is made a retired battery in the front of the tenaillons, as in B; this battery is 10 toises from the front to which it is parallel, and 15 toises long.

There are commonly retrenchments made in the tenaillons, such as O; their parapets are parallel to the fronts MN, and bisect the side qN; the ditch before this retrenchment is 3 toises: and there is a banquette before the parapet next to the ditch of about 8 feet, called *berm*; which serves to prevent the earth of the parapet (which seldom has any revetment) from falling into the ditch.

It is to be observed, that the ravelin, before which tenaillons are constructed, must have its salient angle much greater than the former construction makes them; otherwise the salient angles of the tenaillons become too acute; for which reason we made the capital of this ravelin 45 toises, and the faces terminate within 3 toises of the shoulders.

6. Construction of Counterguards.

FIG. 10. 11. When the counterguard is placed before the ravelin, set off 40 toises on the capital of the ravelin from the salient angle A, to the salient angle B, of the counterguard; and 10 from C to D; on the counterescarp of the ditch.

When the counterguard is before the bastion, such as in fig. 2. its salient angle F is 50 toises from the salient angle E of the bastion, and the breadth near the ditch of the ravelin 10 toises as before.

The ditch before the counterguards is 12 toises, and its counterescarp parallel to the faces.

Counterguards are made before the ravelin on some particular occasions only; but are frequently constructed before the bastions, as covering the flanks wonderfully well. Some authors, as Mr Blondel and Mr Coehorn, will have them much narrower than they are here.

7. Construction of Hornworks.

FIG. 12. Produce the capital of the ravelin beyond the salient angle A, at a distance AB of about 80 toises; draw DBE at right angles to AB; in which take BD, BE, each equal to 55 toises; and on the exterior side DE, trace a front of a polygon in the same manner as that of the body of the place, making the perpendicular BF 10 toises, and the faces 30.

The branches D a, E b, of the hornwork, when produced, terminate on the faces of the bastions, within 5 toises of the shoulders. The ditch of the hornwork is 12 toises, and its counterescarp parallel to the branches; and in the front terminates at the shoulders, in the same manner as the great ditch before the bastions.

The capital of the ravelin before the front of the hornwork is 35 toises, and the faces terminate on the shoulders, or rather 2 or 3 toises beyond them: and the ditch before the ravelin is 8 toises.

There are sometimes retrenchments made within the hornwork, such as S, S; which are constructed by erecting perpendiculars to the faces of the ravelins, within 25 toises of their extremities. This retrenchment, like all others, has a parapet turfed only with a berm of 8 feet before it; as likewise, a ditch from 3 to 5 toises broad.

FIG. 13. When a hornwork is made before the bastion, the distance D L of the front from the salient angle of the bastion is 100 toises, and the branches terminate on the faces of the adjacent ravelins within 5 toises from their extremities; all the rest is the same as before.

8. Construction of Crownworks.

FROM the salient angle, A, of the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin produced at C; from the point C, set off the cords CB, CF, each of them equal to 110 toises: and on each of which, as an exterior side, construct a front of a polygon of the same dimensions as in the hornwork; that is, the perpendicular should be 18 toises, the faces 30, and the branches terminate on the faces of the bastions within 25 toises of the shoulders.

The ditch is 12 toises, the capital of the ravelin 35, and its ditch 8; that is, the same as in the hornwork.

Sometimes the crownwork is made before the bastion, as in fig. 2. The arc is described from the salient angle A of the bastion, with a radius of 120 toises, as before; and the branches terminate on the faces of the adjacent ravelins within 25 toises of their extremities: the rest of the dimensions and constructions are the same as before.

Hornworks, as well as crownworks, are never made but when a large spot of ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town.

9. Construction of Covert-ways and Glacis.

ALTHOUGH we have not hitherto mentioned the covert-way, nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking the covert-way, when it is in a good condition and well defended, is generally the most bloody action of the siege.

After having constructed the body of the place, and all the outworks which are thought necessary, lines are drawn parallel to the outmost counterescarp of the ditches, at 6 toises distant from it; and the space m n, m n, included between that line and the counterescarp, will be the covert-way required.

Fig. 3. There is in every re-entering angle of the counterfarp a place of arms, m; which is found by setting off 20 toifes from the re-entering angle a, on both sides from a to b, and from a to c; and from the points b, c, as centres, arcs are described with a radius of 25 toifes, so as to intersect each other in d; then the lines drawn from this intersection to the points b, c, will be the faces of the places of arms.

If lines are drawn, parallel to the lines which terminate the covert way, and the places of arms, at 20 toifes distant from them, the space x, x, x, between these lines and those which terminate the covert-way, will be the glacis.

At the extremities of the place of arms, are traverses made, such as v, v, which serve to inclose them; these traverses are 3 toifes thick, and as long as the covert-way is broad; and a passage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the rest of the covert-way.

There are also traverses of the same dimensions before every salient angle of the balion and outworks, and are in the same direction as the faces of those works produced; and the thickness lies at the same side as the parapets.

The passages round these last traverses are likewise from 6 to 8 feet wide.

In each place of arms are two sally ports z z, which are 10 or 12 feet wide, for the troops to sally out; in time of a siege they are shut up, with barriers or gates.

10. Construction of Arrows and Detached Redoubts.

An arrow is a work made before the salient angles of the glacis, such as A, fig. 3. It is composed of a parapet of 3 toifes thick, and 40 long; and the ditch before it 5 toifes, terminating in a slope at both ends. The communication from the covert way into these arrows is 4 or 5 toifes wide; and there is a traverse, r, at the entrance, of 3 toifes thick, with a passage of 6 or 8 feet round it.

A detached redoubt is a kind of work much like a ravelin, with flanks placed beyond the glacis; such as B: they are made in order to occupy some spot of ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise.

Their distance from the covert-way ought not to exceed 120 toifes, that it may be defended by musket-shot from thence.

The gorge a b is 40 toifes; the flanks a c, b f, which are perpendicular to the gorge, 10; and the faces c d, f d, 30: the ditch before it is 6 toifes, ending in slopes at both ends; the covert-way 4; the branches of the covert-way are 42 toifes long, or thereabouts; the faces of the places of arms y, y, which are perpendicular to the branches, 10; and the other, which is parallel to them, 14.

The communication from the covert-way into the redoubt, is 5 or 6 toifes wide; and there is a traverse made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis.

If these redoubts are above 50 toifes distant from the covert-way, the besiegers carry their trenches

round, and enter through the gorge; by which the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent which, some other outworks should be made to support them.

11. Construction of Second Ditches and Covert-ways.

Fig. 4. When the ground is low, and water to be found, there is often a ditch about 10 or 12 toifes made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch: such as D, whose breadth on the counterfarp of the ditch is 10 toifes, from b to a, and from c to d; and the faces a L, d L, are parallel to those of the places of arms; the ditch before them is from 8 to 10 toifes wide.

The second covert-way is 4 toifes, the semi-gorges of the places of arms, m, about 15; and the faces perpendicular to the counterfarp; the second glacis is from 15 to 18 toifes broad.

This second covert-way has traverses every where, in the same manner as the first.

12. Construction of Profiles.

A PROFILE is the representation of a vertical section of a work; it serves to shew those dimensions which cannot be represented in plans, and is necessary in the building of a fortification. Profiles are generally constructed upon a scale of 30 feet to an inch. It would be endless to describe all their particular dimensions; we shall therefore lay down the principal rules only, given by M. Vauban, on this subject.

1. Every work ought to be at least 6 feet higher than that before it, so that it may command those before it; that is, that the garrison may fire from all the works at the same time, with great and small arms, at the besiegers in their approaches. Notwithstanding this specious pretence, there are several authors who object against it. For, say they, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries; so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it.

But if all the works were of the same height, those within cannot be destroyed, till such time as those before them are taken: guns might be placed in the covert-way and outworks to obstruct the enemy's approach; and when they come near the place, they might be transported into the inner-works: and as the body of the place would be much lower, the expence would be considerably diminished.

But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees: this might however be partly prevented, by making the parapets near the salient angles, for the space of 8 toifes on each side, 5 or 6 feet higher than the rest of the works.

2. The covert-way should be lower than the level-ground, otherwise the body of the place must be raised very high, especially where there are several outworks; this is to be understood only when the works exceed each other in height, otherwise it need not be below the level.

3. The bases of all inward slopes of earth should be at least equal to the height, if not more.

4. The bases of all outward slopes of earth, two thirds of their heights.

5. The slopes of all walls or revetments should be one fifth of their height; or one sixth might perhaps be sufficient: the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation.

6. The slopes of all parapets and traverses are one sixth of their breadth; that is, 3 feet towards the field; or the inside, where the banquettes should be, 3 feet higher than the outside.

7. When the revetment of a rampart goes quite up to the top, 4 feet of the upper-part is a vertical wall of 3 feet thick, with a square stone at the top of it, projecting 6 inches; and a circular one below, or where the slope begins, of 8 or 10 inches diameter: they go quite round the rampart, and the circular projection is called the *cordon*.

Where the straight part of the wall ends and the slope begins, the wall is always made 5 feet thick; and the counterforts or buttresses reach no higher than that place.

7. When the rampart is partly walled, and partly turfed, then one fifth of the height which is turfed must be added to 5 feet, to get the thickness of the wall above.

And having the thickness of any wall above, by adding one fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a sixth part must be added.

For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed; then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 4 added to the thickness 7 above, gives 11 for the thickness near the foundation.

Plate CXIII. fig. 1. Represents, in military perspective, the profiles of the body of a place, the ravelin and covert-way: which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived.

SECT. II. Of Irregular Fortification.

THE most essential principle in fortification, consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides. This can happen no otherwise in a regular fortification situated in a plain or even ground: but as there are but few places which are not irregular, either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular, without too great expence; it is so much the more necessary to shew in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise, if such a place is to be attacked, to know which is the strongest or weakest part.

1. Construction of an irregular place situated in an open country.

If the place to be fortified is an old town inclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature of the ground; and to regulate his plan accordingly, so as to avoid the disadvantages, and gain all the advantages possible: he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place can be reduced into a regular figure, or nearly so; for, if that can be done without increasing the expence considerably, it should by no means be omitted. Old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and mended when it may be done. If there is a rampart without bastions or towers, it must be well considered, whether bastions may not be added, or if it is not better to make only some outworks: if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions; otherwise ravelins and counterguards must be constructed. Special care must be taken, to make all the sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of musket-shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest.

If it should happen, that some of the sides are inaccessible, or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others, which are of easy access, and the flanks need not be so large as the rest; by doing so, there will be some expences saved, which may be used in making the other sides stronger by adding more outworks.

There are few situations, but what are more advantageous in some parts than in others; it is therefore the business of an engineer to distinguish them, and to render those sides strong by art, which are not by nature.

If the situation is low and watery, lunettes or tenailons, and such other small outworks, should be constructed; because they are not of any great expence, and may make a very good defence. But if one side of the place only is low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing, that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled by means of dykes or sluices, so as to overflow the best part of the first glacis, it should be done: for, by so doing, these works will be able to make a very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis; which cannot be done but within a few toises of the first covert-way, where the besieged are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them.

But if the situation is of a dry nature, without any water about it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries

raised.

railed in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis so as to afford no cover for the enemy behind them. Arrows and detached redoubts are likewise very proper to be used in such a case; and sometimes horn or crown-works, if it should be thought convenient: but these works should never be constructed, without an absolute necessity, either to occupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance into the town; for they are of great expence, and their defence seems not to be answerable to it.

Most of the places in Flanders are fortified with horn-works, such as Ipres, Tournay, Lille, and others.

If the place to be fortified is new, and the situation will not admit of a regular construction; particular care must be taken in choosing such a spot of ground as is most advantageous, and least liable to any disadvantages either in the building or in the maintaining of it. All hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters, for the same reason, excepting a lake is or may be made navigable: good water should be had either within the place or near it, for it is absolutely necessary for men and cattle; the air should be wholesome, otherwise the continual sickness that may reign in such a place might prevent people to come and live in it, and the garrison would not be in a condition to defend themselves as they ought to do: in short, all the different circumstances attending such an undertaking should be maturely considered, before a resolution is taken to fortify any place.

When a situation is fixed upon, the next thing to be considered is, the bigness of the town and the number of its outworks; which must absolutely depend upon the consequence such a place is of to a nation. If it is only to guard a pass, or entrance into a country, it need not be so large: but if it is to be a place either to promote or to protect trade, it should be large and commodious; the streets should be wide, and the buildings regular and convenient. As to what regards the fortification, its construction should depend on the nature of the situation; and the number of works, on the funds or expence a prince or a nation will be at; which, however, ought to be according to the benefit arising from such a place: for, as such undertakings are of very great expence, an engineer cannot be too sparing in his works; on the contrary, the greatest economy should be used, both in regard to the number of works, and to their construction. The body of the place may have (A) revetments quite up to the top, or only in part, and the rest turfed: but as to the outworks, they should have half revetments, or they may be made with turf only; as being not so necessary to prevent the place from being surpris'd, which may nevertheless make a good defence.

On Plate CXIII. fig. 2. is the plan of an octagon, one half of which is similar and equal to the other half; it being suppos'd, that the situation would not admit of fortification quite regular; the exterior sides are each 180 toises, and the works are constructed according to our method: but because the sides AB, EF,

are weaker than the rest, as has been proved before, we have added tenailles, redoubts in the ravelins, and lunettes, to render them nearly equal in strength with the others; and if counter-guards were made before the bastions A and B, it would effectually secure that front. Instead of lunettes, any other works may be made, as may be thought convenient and according to the nature of the ground. If it should be judged necessary to add other outworks to the ravelins all round the place, care must be taken to add likewise more to the fronts AB, EF, in order to render the advantages and disadvantages of attacking on either side equal.

2. Construction of an irregular place, situated on a hill or rock.

In the construction of such places, care must be taken that no neighbouring hill commands any part of the works; the town should always be built on the highest part; but if it should be thought more convenient to place it lower, then the upper part must be fortified with a fort; the situation should be made level as near as possible, by removing the earth from some places to fill up others; and if it cannot well be levelled without extraordinary expence, works must be made on the highest part, so as to command and protect the lower. The works ought to occupy all the upper part of the hill; but if it should be too extensive to be all inclosed, or so irregular as not to be fortified without great inconvenience, the parts which fall without should be fortified with some detached works, and a communication with the place must be made either above or under ground. There should be no cavity or hollow roads, within cannon-shot, round about the place, where the enemy might be able to approach under cover. If there should happen to be a spring near the top of the hill, it should be inclosed in the fortification; or if that cannot be done, by some work or other: for there is nothing more necessary, and at the same time scarcer, in such situations, than water; for which reason there cannot be too much care in providing it: several cisterns are to be made to receive the rain-water, and to preserve it; wells should be dug likewise, though ever so deep, the water of which will serve for common use.

Places built on hills or rocks, should never be large: for their use is generally to guard passes or inlets into a country, and are seldom useful in traffic, and it is a difficult matter to provide for a large garrison in such situations, neither should any such place be built without some very material reasons: but when it is absolutely necessary, great care and precaution should be taken to render the works as perfect as the situation will admit of, and at the same time to be as frugal in the expence as possible.

3. Construction of irregular fortifications situated near rivers, lakes, or the sea.

As the intent of building these kind of places is chiefly to facilitate and protect trade, they are of more importance than any other kind, especially in maritime countries, where the principal strength and power depends on them: for which reason, we shall treat of:

(A) Revetments are chiefly made to prevent a place from being surpris'd: outworks do not want to be made so; the taking them by surpris is of no great consequence, except in a siege, when other cautions are used to prevent it.

of this construction more largely than of any other.

The first thing to be considered is their situation, which ought to be such as to afford a good harbour for shipping, or a safe and easy entrance in stormy weather; but as it is hardly possible to find any, where ships may go in and lie secure with all winds, care should be taken to make them safe to enter with those winds which are most dangerous: but it is not sufficient that the harbour is safe against stormy weather, they should likewise be so against an enemy, both by land and water; for it often happens, that ships are destroyed where it was imagined they were secure, which is of too great consequence not to be provided against; for which reason, forts or batteries must be built in the most convenient places, to prevent the enemy's ships from coming too near, so as to be able to cannonade those in the harbour, or sling shells amongst them; and if there is any danger of an enemy's approach by land, high ramparts and edifices must be built, so as to cover them.

When a river is pretty large, and it is not convenient for making a harbour without great expence, the ships may ride along the shore; which, for that reason, must be made accessible for ships of burden: this may be done by advancing the quay into the river, if the water is too shallow, or by digging the river sufficiently deep for that purpose.

And to prevent an enemy from coming up the river, forts must be built on both sides, especially when there are any turnings or windings. Antwerp is such a place: for the Scheld is sufficiently deep to carry ships of great burden, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river.

When the river is but small, so that no ships of burden can come thro' it; it is sufficient to make it run thro' some of the works, where proper landing places are contrived, from whence the goods may be carried in to the place; as at Sarrelouis, where a hornwork is built beyond the Sarre, in the gorge of which the goods are landed.

If the breadth of the river does not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived, as that the river passes through the curtain, in order to have a bastion on each side to defend the coming in and going out.

When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others; such as Hunninghen on the Rhine, and Sarrelouis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author.

But it is plain that the sides which terminate at the river, are the weakest; because the besiegers trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side: besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river

longer, the angles at its extremities become wider, and consequently the adjacent sides stronger.

There are other advantages, besides those mentioned already, which arise from the lengthening that side; for if the river is pretty deep so as not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water-side to any part of the town.

To illustrate this method of M. Vauban's, we shall give the plan of Hunninghen: this place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side AB next to the river is 200 toises, and each of the others but 180.

About the space $a b c$, which lies before the front AB, is a stone wall; and the passages x, x , are shut up with sluices, to retain the water in the ditches in dry seasons: and to prevent an enemy from destroying the sluice near the point c , whereby the water would run out and leave the ditches dry, the redoubt y was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulted from the river side, where the water is shallow in dry season.

The hornwork K beyond the Rhine was built to cover the bridge; but as this work cannot be well defended cros the river, the hornwork H was made to support the other.

Before finishing the description of this plan, we shall shew how to find the long side AB.

After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, so as to be equally distant from the line joining the points E, F, that is parallel to it; on this diameter set off 100 toises on each side of the centre; from these points draw indefinite perpendiculars to the diameter; then if from the points E, F, as centres, two arcs are described with a radius of 180 toises, their intersections A and B, with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever.

When a place near a river is to be fortified, for the safety of commerce, particular care should be taken in leaving a good space between the houses and the water-side, to have a key or landing place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege: and as water-carriage is very advantageous for transporting goods from one place to another, as likewise for bringing the necessary materials, not only for building the fortification, but also the place itself, the expences will be lessened considerably when this convenience can be had; for which reason, places should never be built any where else but near rivers, lakes, or the sea; excepting in extraordinary cases, where it cannot be avoided.

A. B. M. L.

FORTIN, FORTELET, or *Field-Fort*, a scone or little fort, whose flanked angles are generally 120 fathoms distant from one another. See **FORT**.

The extent and figure of fortins are different, according to the situation and nature of the ground; some of them having whole bastions, and others demi-bastions. They are made use of only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

FORTISSIMO, in music, sometimes denoted by FFF, or *fff*, signifies to sing or play very loud or strong.

FORTITUDE, the same with courage or bravery. See **MORALS**, n° 117.

FORTUNATE-ISLANDS, in ancient geography, certain islands, (concerning the situation of which authors are not agreed), famous for the golden apples of the **HESPERIDES**.—The common opinion is, that they are the **CANARY ISLANDS**.

FORTUNE, **FORTUNA**, a goddess worshipped with great devotion by the ancient Greeks and Romans; who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure. The Greeks had a great number of temples dedicated to Fortune, under the name of *τυχη*. The poet Pindar makes her one of the *Parcæ*, or destinies, and the daughter of Jupiter. Ancus Martius, king of the Romans, was the first who built a temple at Rome to this deity, under the name of *Fortuna Virilis*, on account that courage, no less than good-fortune, is requisite to obtain a victory. Servius Tullius built a temple to Fortune, under the name of *Primigenia*. The Romans gave several other appellations to Fortune, such as *Fortuna Libera*, *Redux*, *Publica*, &c.

There was a statue of Fortune at Athens, holding betwixt her arms Plutus the god of riches. Pausanias says, that her most ancient form was that which Bupalus made in Greece, in shape of a woman with a round ball on her head, and a cornucopia under her arm. Macrobius says, that she was first set forth with wings on her shoulders, having by her side the rudder of a ship; and that she was placed upon a wheel, and had in her right hand a golden ball, and in her left a whip. In Egypt she was painted like a woman, turning a great glass wheel, on the top of which were represented a great number of men playing, others climbing up, and others having attained the summit of the wheel, precipitating themselves and falling down again. Modern painters represent Fortune by a naked woman standing on a globe, with a bandage on her eyes.—Horace's description of this goddess, and her great power, may be seen in Ode xxv. lib. 1. Juvenal, in Satire x. 365, calls Fortune the deity of fools.

FORTUNE-TELLERS. Persons pretending to tell fortunes are to be punished with a year's imprisonment, and standing four times on the pillory. *Stat. 9 Geo. II. c. 5.*

FORTY-DAYS Court, the court of attachment or *woodmote*, held before the verderors of the forest once every forty days, to inquire concerning all offenders against vert and venison. See **FOREST**.

FORUM, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

FORUM, was also used for a place of traffic, answer-

ing to our market-place: of these there were vast numbers, as the *forum piscarium*, *olitorium*, &c. These were generally called *fora venalia*; in contradistinction to the former, which were called *fora civilia*.

FORUM, is also used, among casuists, &c. for jurisdiction; thus they say, *In foro legis*, &c.

FOSS, or **Fossa**, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

Foss, in fortification, a hollow place, commonly full of water, lying between the scarp and counterescarp, below the rampart; and turning round a fortified place or a post, that is to be defended. See **MOAT**.

Foss-Way, one of the four principal highways of England, that anciently led through the kingdom, supposed to be made by the Romans, having a ditch upon one side thereof.

FOSSARII, in antiquity, a sort of officers in the eastern church, whose business it was to inter the dead. St Jerom assures us, that the rank of the *fossarii* held the first place among the clerks: but he is to be understood of those clerks only who had the direction and intendance of the interment of the devout. Some authors insinuate, that the *fossarii* were instituted in the time of the apostles.

FOSSIL, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, salts, earthen, and other minerals; or extraneous, reposit in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See **METAL**, **STONE**, &c.

Native fossils, according to Dr Hill, are substances found either buried in the earth, or lying on its surface, of a plain simple structure, and shewing no signs of containing vessels or circulating juices. These are subdivided, by the same author, 1. Into fossils naturally and essentially simple. Of these, some are neither inflammable, nor soluble in water; as simple earthen, talcs, fibrarizæ, gypsum, selenitæ, crystal, and spars: others, though uninflamable, are soluble in water; as all the simple salts: and others, on the contrary, are inflamable, but not soluble in water; as sulphur, auripigmentum, zarnick, amber, ambergrease, gagate, asphaltum, amplexites, lithanthrax, naphtha, and pifalphaltæ. 2. The second general subdivision of fossils comprehends all such as are naturally compound, but unmetallic. Of these, some are neither inflammable, nor soluble in water; as compound earthen, stones, septariæ, siderochitæ, scrupi, semipellucid gems, lithidia, conissalæ, and pellucid gems: others are soluble in water, but not inflammable; as all the metallic salts: and, lastly, some are inflamable, but not soluble in water; as the marcasites, pyrites, and phlogonia. 3. The third, and last, general division of fossils comprehends all the metallic ones; which are bodies naturally hard, remarkable heavy, and fusible in fire. Of these, some are perfectly metallic, as being malleable when pure; such are gold, lead, silver, copper, iron, and tin: others are imperfectly metallic, as not being malleable even in their purest state; such are antimony, bismuth, cobalt, zinc, and quicksilver or mercury. Of all which substances, the reader will find a particular description under their respective heads, **EARTH**, **TALC**, **MERCURY**, **GYPNUM**, &c.

Extraneous fossils are bodies of the vegetable or animal

Foster || Fothergill, Fothering, || Foundation

mal kingdoms accidentally buried in the earth. Of the vegetable kingdom, there are principally three kinds, trees or parts of them, herbaceous plants, and corals; and of the animal kingdom there are four kinds, sea-shells, the teeth or bony palates and bones of fishes, complete fishes, and the bones of land-animals. See TREE, WOOD, PLANT, SHELL, &c.

As to the reason why these extraneous fossils come to be lodged in the bowels of the earth, the common opinion is, that this great change was effected by the universal deluge. See DELUGE.

FOSTER (Dr James), a most distinguished and popular dissenting minister, born at Exeter in 1697. He began to preach in 1718; and strong disputes arising soon after, among the dissenters, concerning the Trinity and subscription to tests, his judgment determining him to the obnoxious opinions, the clamour grew loud against him, and occasioned more than one removal. His talents were hid among obscure country congregations, until 1724; when he was chosen to succeed Dr Gale in Barbican, where he laboured as pastor above 20 years. The Sunday evening-lecture, begun in the Old Jury meeting-house in 1728, and which he conducted with such uncommon applause for more than 20 years, indisputably shewed his abilities as a preacher. Persons of all persuasions and ranks in life flocked to hear him: and Mr Pope has honoured him with a commendatory couplet in his satires; which, however, his commentator laboured to destroy the intention of by a frivolous note. In 1746, he attended the unhappy lord Kilmarnock, at his execution on Tower-hill; an office which those who lived with him imagined made too deep an impression on his sympathizing spirit, as his vivacity abated from that time. He died in 1753; after having published several valuable compositions and sermons; particularly, 1. A defence of Christianity, against "Tindal's Christianity as old as the Creation." 2. An essay on fundamentals. 3. Four volumes of sermons. 4. Discourses on natural religion and social virtue, in 4to.

FOSTER (Samuel), an ingenious English mathematician of the last century, and astronomical professor in Gresham college, was one of that learned association which met for cultivating the new philosophy during the political confusions, and which Charles II. established into the Royal Society. Mr Foster, however, died in 1652, before this incorporation took place; but wrote a number of mathematical and astronomical treatises, too many to particularize.—There were two other mathematical students of this name; William Foster, a disciple of Mr Oughtred, who taught in London; and Mark Foster, author of a treatise on trigonometry, who lived later than the former two.

FOTHERGILL (Dr George), was born in Westmoreland in 1705, where his family had been long seated on a competent estate that had descended regularly for several generations. After an academical education in Queen's college, Oxford, of which he became a fellow, he was, in 1751, elected principal of St Edmund's-hall, and presented to the vicarage of Brumley in Hampshire. Having been long afflicted with an asthma, he died in 1760. He was the author of a collection of much esteemed sermons, in 2 vols 8vo. The first volume consists of occasional discourses, published by himself; the second printed from his MSS.

FOTHERING, a peculiar method of endeavouring to stop a leak in the bottom of a ship while she is afloat, either under sail, or at anchor. It is usually performed in the following manner: A basket is filled with ashes, cinders, and chopped rope-yarns, and loosely covered with a piece of canvas; to this is fastened a long pole, by which it is plunged repeatedly in the water, as close as possible to the place where the leak is conjectured to lie. The oakum or chopped rope-yarns being thus gradually shaken through the twigs, or over the top of the basket, are frequently sucked into the hole along with the water, so that the leak becomes immediately choked; and the future entrance of the water is thereby prevented.

FOUGADE, or FOUGASSE, in the art of war, a little mine, about 8 or 10 feet wide, and 10 or 12 deep, dug under some work or post, which is in danger of falling into the enemy's hands; and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a faucille. See MINE.

FOUL, or FOULE, in the sea-language, is used when a ship has been long untrimmed, so that the grass-weeds, or barnacles, grow to her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run or be over-hauled.

Foul imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a share. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury: but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

Foul-Water. A ship is said to make foul-water, when, being under sail, the comes into such shoal-water, that though her keel do not touch the ground, yet it comes so near it, that the motion of the water under her raises the mud from the bottom.

Foul is also a disease in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell.

Foul or Pimpled Face. See GUTTA Rosacea.

FOULA, or Foul Island, one of the Shetland isles, lying between six and seven leagues west from the mainland. It is about three miles long, narrow, and full of rough, steep, and bare rocks; one of which is so large, and runs up to such an height, that it may be clearly seen from Orkney. This, therefore, may be reckoned with the greatest probability to be the *Thule* of Tacitus, whatever might be the *Thule* of the Phenicians and Greeks. It has scarce any pasturage, and but very little arable land; but that, however small in extent, is very fertile, out of the produce of which, with fowl and fish, the poor inhabitants subsist. They have nothing that can be called a port; and the only commodities they have are stock-fish, train-oil, and feathers.

FOUMART, in zoology, a species of MUSTELA. FOUNDATION, in architecture, is that part of a building which is under-ground. See ARCHITECTURE, n° 101, — 112. 129, &c.

Foundation Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging; unless there be cellars underground, in which case he would have it somewhat lower.

FOUNDATION, denotes also a donation or legacy, either in money or lands, for the maintenance and support of some community, hospital, school, &c.

Jacob's Law Dist. The king only can *found* a college, but there may be a college in reputation founded by others. If it cannot appear by inquiry who it was that founded a church or college, it shall be intended that it was the king, who has power to found a new church, &c. The king may found and erect an hospital, and give a name to the house upon the inheritance of another, or license another person to do it upon his own lands; and the words *fundo, erect*, &c. are not necessary in every foundation, either of a college or hospital, made by the king; but it is sufficient if there be words equivalent: the incorporation of a college or hospital is the very foundation; but he who endows it with lands is the founder; and to the erection of an hospital, nothing more is requisite but the incorporation and foundation. Persons seized of estates in fee-simple, may erect and found hospitals for the poor by deed enrolled in chancery, &c. which shall be incorporated, and subject to such visitors as the founder shall appoint, &c. stat. 39 Eliz. c. 5.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. See **FOUNDATION**.

FOUNDER, also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing-characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure founders, letter-founders, founders of small works, &c. See **FOUNDRY**.

FOUNDER, in the sea-language: A ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lie like a log; and not being able to swim long, will at last sink.

FOUNDERED, in farriery. See there, § xli.

FOUNDERY, or **FOUNDRY**, the art of casting all sorts of metals into different forms. It likewise signifies the work-house or smelting-hut wherein these operations are performed.

FOUNDRY of Small-works, or Casting in Sand. The sand used for casting small-works is at first of a pretty soft, yellowish, and clammy nature: but it being necessary to strew charcoal-dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them so to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through,

Vol. IV.

when melted, into the models or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame; only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame, thus moulded, is carried to the melter, who, after extending the chief canal of the counter-part, and adding the cross canals to the several models in both, and stirring mill-dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing thro' the chief cylindrical canal, they are screwed or wedged up like a kind of press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is worked over again for other castings.

FOUNDRY of Statues. The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone, or brick; or, when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair and horse-dung; or of plaster of Paris mixed with brick-dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core: Though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick-dust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of

Foundry. the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water to the consistence of a colour fit for painting; accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whiles. For the second impression, they add horse-dung and natural earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron girts, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate.

If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone or brick. At the bottom is made a hole of the same materials with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting-furnace. For the rest the method is the same in both. The mould being finished, and inclosed as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented, till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they take out the bricks and fill up their place with earth moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From

this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen basin, over the mould, into the bottom of which all the big branches of the jets, or casts, which are to convey the metal into all the parts of the mould, are inserted.

These casts or jets are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brassy, which gushes out with violence, may not enter any of them, till the basin be full enough of matter to run into them all at once. Upon which occasion they pull out the plugs, which are long iron rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest being the sculptor's or carver's business, who, taking the figure out of the mould and earth wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chisels, gravers, puncheons, &c.

Foundry of Bells. The metal, it is to be observed, is different for bells, from what it is for statues; there being no tin in the statue-metal: but there is a fifth, and sometimes more, in the bell-metal.

The dimensions of the core and the wax for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapasen, which gives the height, aperture, and thickness, necessary for the several tones required.

It is on the wax that the several mouldings and other ornaments are formed to be represented in relievo, on the outside of the bell.

The business of bell-foundry is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould; and, 3. The melting of the metal.

The proportions of our bells differ much from those of the Chinese: in ours, the modern proportions are, to make the diameter fifteen times the thickness of the brim, and twelve times the height.

There are two kinds of preparations, viz. the simple and the relative: the former are those proportions only that are between the several parts of a bell, to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The particulars necessary for making the mould of a bell are, 1. The earth: the most cohesive is the best; it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon trestles. Upon this they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spataula.

The compasses of construction is the chief instrument for making the mould, which consist of two different

ferent legs joined by a third piece. And last of all, the founders shelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case, or cannon, under ground; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole, or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a *mill-stone*. The parts of the mould are, the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying of each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse-dung; on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth that has been separately baked. The first fire consumes the stake, and the fire is left in the core half or sometimes a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chaffing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they

cover it with a second of the same matter, but somewhat thicker: when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings; the seventh is called the *bridge*, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated 12 times for 12 half-moulds, that two and two united may make the hollows of the six rings: the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and soldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist to fix on the place, which is strewed at several times upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal, they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the millstone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould, they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between

the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and folder it with thin cement, which is dried gradually by covering it with burning coals. Then, they fill up the pit with earth, beating it strongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal, is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame re- vibrates; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross, or scorie, of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

Foundry of Great Guns and Mortar-Pieces. The method of casting these pieces is little different from that of bells: they are run maffy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trepan, that is worked either by horses or a water-mill.

For the metal, parts, proportions, &c. of these pieces, see GUNNERY.

Letter-Foundry, or Casting of Printing-Letters. The first thing requisite is to prepare good steel-punches, on the face of which is drawn the exact shape of the letter with pen and ink, if the letter be large, or with a smooth blunted point of a needle, if small; and then, with proper gravers, the cutter digs deep between the strokes, letting the marks stand on the punch; the work of hollowing being generally regulated by the depth of the counter-punch: then he fills the outside, till it is fit for the matrice.

They have a mould to justify the matrices by, which consists of an upper and under part, both which are alike, except the stool and spring behind, and a small roundish wire in the upper part, for making the nick in the flank of the letter. These two parts are exactly fitted into each other, being a male and female gage, to slide backwards and forwards.

Then they justify the mould, by casting about 20 samples of letters, which are set in a composing-stick, with the nicks towards the right hand; and comparing these every way with the pattern-letters set up in the same manner, they find the exact measure of the body to be cast.

Next they prepare the matrix, which is of brass or copper, an inch and a half long, and of a proportionable thickness to the size of the letter it is to contain. In this metal is sunk the face of the letter, by striking the letter-punch the depth of an *n*. After this, the sides and face of the matrice are justified, and cleared, with files, of all bunnings that have been made by sinking the punch.

Then it is brought to the furnace, which is built up-

right of brick with four square sides, and a stone at top, in which is a hole for the pan to stand in.

Printing-letters are made of lead, hardened with iron or stub-nails. To make the iron run, they mingle an equal weight of antimony, beaten small in an iron mortar, and stub-nails together. They charge a proper number of earthen-pots, that bear the fire, with the two ingredients, as full as they can hold; and melt it in an open furnace, built for that purpose.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compost is ladled into an iron-pot, wherein is melted lead, that is fixed on a furnace close to the former, 3 lb of melted iron to 25 lb of lead; this they incorporate according to art.

The caster taking the pan off the stone, and having kindled a good fire, he sets the pan in again, and metal in it to melt. If it be a small-bodied letter, or a thin letter with great bodies, that he intends to cast, his metal must be very hot, and sometimes red-hot, to make the letter come. Then taking a ladle, of which he has several sorts, that will hold as much as will make the letter and break, he lays it at the hole where the flame bursts out: then he ties a thin leather, cut with its narrow end against the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice-check; and places the foot of the matrice on the stool of the mould, and the broad end of the leather on the wood of the upper half of the mould, but not tight up, lest it hinder the foot of the matrice from sinking close down upon the stool, in a train of work. Afterwards laying a little rosin on the upper part of the mould, and having his casting-ladle hot, he, with the boiling side, melts the rosin, and presses the broad end of the leather hard down on the wood, and so fastens it thereto. Now he comes to casting; when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the lower part of the ball of his thumb and his three hinder fingers: then he lays the upper half of the mould upon the under half, so as the male gages may fall into the female, and at the same time the foot of the matrice places itself upon the stool; and clapping his left-hand thumb strongly over the upper half, he nimbly catches hold of the bow or spring, with his right-hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the back-side of the matrice, pressing it forwards as well towards the mould, as downwards, by the shoulder of the notch, close upon the stool, while, at the same time, with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of his thumb, and thrusts, by the ball of his thumb, the upper part towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both sides of the mould close together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three strokes outwards upon the surface of the melted metal, to clear it of the scum; then he takes up the ladle full, and having the mould in his left hand, turns his left side a

little from the furnace, and brings the heat of his ladle to the mouth of his mould; and turns the upper part of his right hand towards him, to pour the metal into it, while, at the same instant, he puts the mould in his left hand forwards, to receive the metal with a strong shake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the flask. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he tosses the letter, break and all, out upon a sheet of waste paper, laid on a bench, a little beyond his left hand; and then is ready to cast another letter, as before, and likewise the whole number in that matrix.

Then boys, commonly employed for this purpose, separate the breaks from the flanks, and rub them on a stone, and afterwards a man cuts them all of an even height, which finishes the font for the use of the printer. See the next article.

A workman will ordinarily cast 3000 of these letters in a day. The perfection of letters thus cast, consists in their being all severally square and straight on every side; and all generally of the same height, and evenly lined, without stooping one way or other; neither too big in the foot, nor the head; well grooved, so as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and scrapped, with a sensible notch, &c. See PRINTING.

FONT, or FONT, among printers, a set or quantity of letters, and all the appendages belonging thereto; as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted.

FOUNTAIN, in philosophy, a spring or source of water rising out of the earth. Among the ancients, fountains were held sacred, and even worshipped as a kind of divinities. For the phenomena, theory, and origin of fountains or springs, see SPRING.

Artificial FOUNTAIN, called also a *jet d'eau*, is a contrivance by which water is violently spouted upwards. See HYDRAULICS.

FOUNTAIN-Tree, a very extraordinary vegetable growing in one of the Canary islands, and likewise said to exist in some other places, which distils water from its leaves in such plenty as to answer all the purposes of the inhabitants who live near it. Of this tree we have the following account in Glasse's history of the Canary Islands.—"There are only three fountains of water in the whole island of Hierro, wherein the fountain-tree grows. One of these fountains is called *Acof*, which, in the language of the ancient inhabitants, signifies river; a name, however, which does not seem to have been given it on account of its yielding much water, for in that respect it hardly deserves the name of a fountain. More to the northward is another called *Hapio*; and in the middle of the island is a spring, yielding a stream about the thickness of a man's finger. This last was discovered in the year 1565, and is called the fountain of *Antou Hernandez*. On account of the scarcity of water, the sheep, goats, and swine, here do not drink in the summer, but are taught to dig up the roots of fern, and chew them to quench their thirst. The great cattle are watered at those fountains, and at a place where water distils from the leaves

of a tree. Many writers have made mention of this famous tree, some in such a manner as to make it appear miraculous: others again deny the existence of any such tree; among whom is Father Feyjoo, a modern Spanish author, in his *Theatro Critico*. But he, and those who agree with him in this matter, are as much mistaken as those who would make it appear to be miraculous. This is the only island of all the Canaries which I have not been in; but I have failed with natives of Hierro, who, when questioned about the existence of this tree, answered in the affirmative.

"The author of the *History of the discovery and conquest* has given us a particular account of it, which I shall here relate at large.

"The district in which this tree stands is called *Tigulahe*; near to which, and in the cliff, or steep rocky ascent that surrounds the whole island, is a narrow gutter or gully, which commences at the sea, and continues to the summit of the cliff, where it joins or coincides with a valley, which is terminated by the steep front of a rock. On the top of this rock grows a tree, called in the language of the ancient inhabitants, *Garfe*, "Sacred or Holy Tree," which for many years has been preserved found, entire, and fresh. Its leaves constantly distil such a quantity of water as is sufficient to furnish drink to every living creature in Hierro; nature having provided this remedy for the drought of the island. It is situated about a league and a half from the sea. Nobody knows of what species it is, only that it is called *Til*. It is distinct from other trees, and stands by itself; the circumference of the trunk is about 12 spans, the diameter four, and in height from the ground to the top of the highest branch, 40 spans: the circumference of all the branches together is 120 feet. The branches are thick and extended; the lowest commence about the height of an ell from the ground. Its fruit resembles the acorn, and tastes something like the kernel of a pine-apple, but is softer and more aromatic. The leaves of this tree resemble those of the laurel, but are larger, wider, and more curved; they come forth in a perpetual succession, so that the tree always remains green. Near to it grows a thorn which fastens on many of its branches, and interweaves with them; and at a small distance from the *garfe* are some beech-trees, bresos, and thorns. On the north side of the trunk are two large tanks or cisterns, of rough stone, or rather one cistern divided, each half being 20 feet square, and 16 spans in depth. One of these contains water for the drinking of the inhabitants; and the other that which they use for their cattle, washing, and such-like purposes. Every morning, near this part of the island, a cloud or mist arises from the sea, which the south and easterly winds force against the fore-mentioned steep cliff; so that the cloud having no vent but by the gutter, gradually ascends it, and from thence advances slowly to the extremity of the valley, where it is stopped and checked by the front of the rock which terminates the valley, and then rests upon the thick leaves and wide-spreading branches of the tree, from whence it distils in drops during the remainder of the day, until it is at length exhausted, in the same manner that we see water drip from the leaves of trees after a heavy shower of rain. This distillation is not peculiar to the *garfe*, or *til*; for the bresos, which.

Fountain.

Fouquiere

Fowling.

which grow near it, likewise drop water; but their leaves being but few and narrow, the quantity is so trifling, that though the natives have some of it, yet they make little or no account of any but what distills from the til, which, together with the water of some fountains, and what is saved in the winter season, is sufficient to serve them and their flocks. This tree yields most water in those years when the Levant or easterly winds have prevailed for a continuance; for, by these winds only the clouds or mists are drawn hither from the sea. A person lives on the spot near which this tree grows, who is appointed by the council to take care of it and its water; and is allowed a house to live in, with a certain salary. He every day distributes to each family of the district seven pots or vessels full of water, besides what he gives to the principal people of the island.

“Whether the tree which yields water at this present time be the same as that mentioned in the above description, I cannot pretend to determine: but it is probable there has been a succession of them; for Pliny, describing the Fortunate island, says, ‘In the mountains of Ombrion are trees resembling the plant ferula, from which water may be procured by pressure. What comes from the black kind is bitter, but that which the white yields is sweet and potable.’”

Trees yielding water are not peculiar to the island of Hierro; for travellers informs us of one of the same kind on the island of St Thomas, in the bight or gulph of Guiney. In Cockburn's voyages we find the following account of a dropping tree, near the mountains of Fera Paz, in America.

“On the morning of the fourth day, we came out on a large plain, where were great numbers of fine deer, and in the middle stood a tree of unusual size, spreading its branches over a vast compass of ground. Curiosity led us up to it. We had perceived, at some distance off, the ground about it to be wet; at which we began to be somewhat surpris'd, as well knowing there had no rain fallen for near six months past, according to the certain course of the season in that latitude: that it was impossible to be occasioned by the fall of dew on the tree, we were convinced, by the sun's having power to exhale away all moisture of that nature a few minutes after its rising. At last, to our great amazement as well as joy, we saw water dropping, or as it were distilling, fast from the end of every leaf of this wonderful (nor had it been amiss if I had said *miraculous*) tree; at least it was so with respect to us, who had been labouring four days through extreme heat, without receiving the least moisture, and were now almost expiring for the want of it.

“We could not help looking on this as liquor sent from heaven to comfort us under great extremity. We catch'd what we could of it in our hands, and drank very plentifully of it; and liked it so well, that we could hardly prevail with ourselves to give over. A matter of this nature could not but incite us to make the strictest observations concerning it; and accordingly we staid under the tree near three hours, and found we could not fathom its body in five times. We observed the soil where it grew to be very strong; and upon the next inquiry we could afterwards make, both of the natives of the country and the Spanish inhabitants, we could not learn there was any such tree

known throughout New Spain, nor perhaps all America over; but I do not relate this as a prodigy in nature, because I am not philosopher enough to ascribe any natural cause for it: the learned may perhaps give substantial reasons in nature for what appeared to us a great and marvellous secret.”

FOUQUIERE (James), an excellent Flemish painter of landscapes, born at Anvers. De Piles says, the difference between his pictures and those of Titian consist rather in the countries represented, than in the goodness of the pieces; the principles of both are the same, and the colouring alike good and regular. He painted for Rubens, of whom he learned the most essential part of his art. The elector Palatine employed him at Heidelberg; and thence going to Paris, he painted the Louvre, under the reign of Lewis XIII. and acquired great reputation by his pictures. He died at Paris, in 1659.

FOURCHEE, or FOURCHY, in heraldry, an appellation given to a cross forked at the ends. See HERALDRY.

FOURMONT (Stephen), professor of the Arabic and Chinese languages, and one of the most learned men of his time, was born Herblai, a village four leagues from Paris, in 1683. He studied in Mazarine college, and afterwards in the Seminary of Thirty-three. He was at length professor of Arabic in the Royal college, and was made a member of the Academy of Inscriptions. In 1738, he was chosen a member of the Royal Society in London, and of that of Berlin in 1741. He was often consulted by the duke of Orleans, first prince of the blood; who had a particular esteem for him, and made him one of his secretaries. He wrote a great number of books; the most considerable of those which have been printed are, 1. The roots of the Latin tongue, in verse. 2. Critical reflections on the histories of ancient nations, two volumes, quarto. 4. A Chinese grammar, in Latin, folio. 5. Several dissertations printed in the Memoirs of the Academy of Inscriptions, &c. He died at Paris, in 1745.

He ought not to be confounded with Michael Fourmont, his youngest brother; who took orders, was professor of the Syriac language in the Royal college, and a member of the Academy of Inscriptions. He died in 1746.

FOURTH REDUNDANT, in music. See INTERVAL. FOWEY, or FOY, a town of Cornwall in England. It is seated on an ascent, is fortified, and its haven well secured with blockhouses. It is a good trading place, and its market well supplied with corn. It sends two members to parliament. W. Long. 5°. N. Lat. 50. 27.

FWOL, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such as geese, pheasants, partridges, turkey, ducks, &c.

Tame fowl make a necessary part of the stock of a country farm. See the article POULTRY.

Fowls are again distinguished into two kinds, viz. *land* and *water* fowl, the last being so called from their living much in and about water: also into those which are accounted *game*, and those which are not. See the article GAME.

FWOLING, the art of catching birds by means of bird-lime, decoys, and other devices, or the killing of them by the gun. See BIRD-Catching, BIRD-Lime,

Dr.

FOWLING, SHOOTING, and the names of the different birds in the order of the alphabet.

FOWLING, is also used for the pursuing and taking birds with hawks, more properly called **FALCONRY** or **HAWKING**. See these articles.

FOWLING-Piece, a light gun for shooting birds. That piece is always reckoned best which has the longest barrel, from 5½ to 6 feet, with a moderate bore; though every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal bigness from one end to the other; which may be proved, by putting in a piece of palst-board, cut of the exact roundness of the top: for if this goes down without stops or flipping, you may conclude the bore good. The bridge-pan must be somewhat above the touch-hole, and ought to have a notch to let down a little powder: this will prevent the piece from recoiling, which it would otherwise be apt to do. As to the locks, choose such as are well filed with true work, whose springs must be neither too strong nor too weak. The hammer ought to be well hardened, and pliable to go down to the pan with a quick motion.

FOX, in zoology. See **CANIS**.

The fox is a great nuisance to the husbandman, by taking away and destroying his lambs, geese, poultry, &c. The common way to catch him is by gins; which being baited, and a train made by drawing raw flesh across in his usual paths or haunts to the gin, it proves an inducement to bring him to the place of destruction.

The fox is also a beast of chase, and is taken with grey-hounds, harriers, &c. See the article **HUNTING**.

FOX (John), the martyrologist, was born at Bolton in Lincolnshire, in the year 1517. At the age of 16 he was entered a student of Brazen-nose college in Oxford: and in 1543, he proceeded master of arts, and was chosen fellow of Magdalen college. He discovered an early genius for poetry, and wrote several Latin comedies, the subjects taken from scripture, which his son assures us were written in an elegant style. Forsaking the muses, he now applied himself with uncommon assiduity to the study of divinity, particularly church-history; and, discovering a premature propensity to the doctrine of reformation, he was expelled the college as an heretic. His distress on this occasion was very great; but it was not long before he found an asylum in the house of Sir Thomas Lucy, of Warwickshire, who employed him as a tutor to his children. Here he married the daughter of a citizen of Coventry. Sir Thomas's children being now grown up, after residing a short time with his wife's father, he came to London; where finding no immediate means of subsistence, he was reduced to the utmost degree of want; but was at length, (as his son relates) miraculously relieved, in the following manner: As he was one day sitting in St Paul's church, emaciated with hunger, a stranger accosted him familiarly, and, bidding him be of good cheer, put a sum of money into his hand; telling him at the same time, that in a few days new hopes were at hand. He was soon after taken into the family of the duchess of Richmond, as tutor to the earl of Surrey's children, who, when their father was sent to the tower, were committed to her care. In this family he lived, at Ryegate in Surrey, during the latter part of

the reign of Henry VIII. the entire reign of Edward VI. and part of that of queen Mary: but at length, persecuted by his implacable enemy bishop Gardiner, he was obliged to seek refuge abroad. Basil in Switzerland was the place of his retreat, where he subsisted by correcting the press. On the death of queen Mary, he returned to England; where he was graciously received by his former pupil the duke of Norfolk, who retained him in his family as long as he lived, and bequeathed him a pension at his death. Mr secretary Cecil also obtained for him the rectory of Shipton, near Salisbury; and we are assured that he might have had considerable church-preference, had it not been for his unwillingness to subscribe to the canons. He died in the year 1587, in the 70th year of his age; and was buried in the chancel of St Giles's, Cripplegate. He was a man of great industry, and considerable learning; a zealous, but not a violent reformer; a nonconformist, but not an enemy to the church of England. He left two sons; one of which was bred a divine, the other a physician. He wrote many pieces: but his principal work is the *Acts and monuments of the church*, &c. commonly called *Fox's Book of Martyrs*. His facts are not always to be depended on, and he often loses his temper; which, considering the subject, is not much to be wondered at.

FOX (George), the founder of the sect of English Quakers, was a shoemaker in Nottingham. The accounts of those times tell us, that as he wrought at his trade, he used to meditate much on the scriptures: which, with his solitary course of life, improving his natural melancholy, he began at length to fancy himself inspired; and in consequence thereof set up for a preacher.

He proposed but few articles of faith; insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the spirit: he required a plain simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence the directions of the Holy Spirit. Fox met with much rough treatment for his zeal, was often imprisoned, and several times in danger of being knocked on the head. But all discouragements notwithstanding, his sect prevailed much, and many considerable men were drawn over to them; among whom were **BARCLAY** and **PENN**. He died in 1681. His followers were called *Quakers*, in derision of some unusual shakings and convulsions with which they were seized at their first meetings. See the article **QUAKERS**.

Fox-Glove, in botany. See **DIGITALIS**.

FRACASTOR (Jerome), a most eminent Italian poet and physician, was born at Verona in the year 1482. Two singularities are related of him in his infancy: one is, that his lips adhered so closely to each other, when he came into the world, that a chirurgeon was obliged to divide them with his incision-knife; the other, that his mother was killed with lightning, while he, though in her arms at the very moment, escaped unhurt. Fracastor was of parts so exquisite, and made so wonderful a progress in every thing he undertook, that he became eminently skilled, not only in the belles lettres, but in all arts and sciences. He was a poet, a philosopher, a physician, an astronomer, a mathematician, and what not? He was a man of vast consequence

Fracastor
||
Fragaria.

quence in his time; as appears from pope Paul III.'s making use of his authority to remove the council of Trent to Bologna, under the pretext of a contagious distemper, which, as Fracastor deplored, made it no longer safe to continue at Trent. He was intimately acquainted with cardinal Bembo, Julius Scaliger, and all the great men of his time. He died of an apoplexy at Cast near Verona, in 1553: and in 1559, the town of Verona erected a statue in honour of him.

He was the author of many performances, both as a poet and as a physician; yet never man was more disinterested in both these capacities than he. Evidently so as a physician, for he practised without fees; and as a poet, whose usual reward is glory, nothing could be more indifferent. It is owing to this indifference, that we have so little of his poetry, in comparison of what he wrote; and that, among other compositions, his Odes and Epigrams, which were read in manuscript with infinite admiration, yet, never passing the press, were lost. What we have now of his, are the three books of "Siphilis, or of the French disease;" a book of Miscellaneous Poems; and two books of his poem intitled *Joseph*, which he began at the latter end of his life, but did not live to finish. And these works, it is said, would have perished with the rest, if his friends had not taken care to preserve and communicate copies of them: for Fracastor, writing merely for amusement, never troubled himself in the least about what became of his works after they once got out of his hands. Fracastor composed also a poem, called *Alcon, sive de cura canum venatorum*. His poems, as well as his other works, are written all in Latin. His medical pieces are, *De Sympthia & Antipathia*,—*De contagione & contagiosis morbis*,—*De causis criticorum dierum*,—*De vini temperatura*, &c. His works have been printed separately and collectively. The best edition of them is that of Padua 1735, in 2 vols 4to.

FRACHES, in glass-making, flat iron-pans, wherein the new-made vessels are put, to be removed gradually from the fire. See the article GLASS.

FRACTION, in arithmetic. See ARITHMETIC, n° 21. 26.

FRACTURE, in surgery, a rupture of a bone, or a solution of continuity in a bone when it is crushed or broken by some external cause. See SURGERY.

FRÆNUM, in anatomy, a term applied to some membranous ligaments of the body; as,

FRÆNUM *Lingue*. See ANATOMY, n° 403, d.

FRÆNUM *Penis*. See ANATOMY, n° 381, r.

FRAGA, a strong town with a handsome castle in the kingdom of Arragon in Spain. It is strong by situation among the mountains; having the river Cinca before it, whose high banks are difficult of access; and at its back a hill, which cannot easily be approached with large cannon. Alfonso VII. king of Arragon, and the first of that name of Castile, was killed by the Moors in 1134, when he besieged this town. E. Long. o. 23. N. Lat. 41. 28.

FRAGARIA, the STRAWBERRY; a genus of the polygynia order, belonging to the icofandria class of plants. There is but one species, viz. the vesca, or cultivated strawberry. The principal varieties are, 1. The sylvestris, or wood-strawberry, with oval sawed leaves, and small round fruit. 2. The Virginian scarlet, or Virginian strawberry, with oblong oval sawed

leaves, and a roundish scarlet-coloured fruit. 3. The molchata, or hauboy, or mulky strawberry, having oval, lanceolate, rough leaves, and large pale-red fruit. 4. The Chilensis, or Chili strawberry, with large, oval, thick, hairy leaves, large flowers, and very large, firm fruit. 5. The Alpina, Alpine, or monthly strawberry, having small oval leaves, small flowers, and moderate sized, oblong, pointed fruit.

All these varieties are hardy, low, perennials, durable in root, but the leaves and fruit-stalks are renewed annually in spring. They flower in May and June, and their fruit comes to perfection in June, July, and August; the Alpine kind continuing till the beginning of winter. They all prosper in any common garden soil, producing abundant crops annually without much trouble. They increase exceedingly every summer, both by off-sets or suckers from the sides of the plants, and by the runners or strings, all of which rooting and forming plants at every joint, each of which separately planted bears a few fruit the following year, and bear in great perfection the second summer. Those of the Alpine kind will even bear fruit the same year that they are formed. All the sorts are commonly cultivated in kitchen-gardens, in beds or borders of common earth, in rows lengthwise 15 or 18 inches distance; the plants the same distance from one another in each row. Patches of the different sorts disposed here and there in the fronts of the different compartments of the pleasure ground, will appear ornamental both in their flowers and fruit, and make an agreeable variety.

Strawberries, eaten either alone, or with sugar and milk, are universally esteemed a most delicious fruit. They are grateful, cooling, subacid, and juicy. They taken in large quantities, they seldom disagree. They promote perspiration, impart a violet smell to the urine, and dissolve the tartareous incrustations on the teeth. People afflicted with the gout or stone have found relief by using them very largely; and Hoffman says, he has known consumptive people cured by them. The bark of the root is astringent.—Sheep and goats eat the plant; cows are not fond of it; horses and swine refuse it.

FRAGUIER (Claude Francis), a polite and learned French writer, born at Paris, of a noble family, in 1666. He was educated under the Jesuits, and was even admitted into the order, though he afterwards quitted it; and being thus at liberty to follow his inclinations, he soon after assisted the Abbé Bignon in conducting the *Journal de Scavans*, having all the qualifications for such a work. His works consist of Latin poems, and a great number of very excellent dissertations. He died in 1728.

FRAIL, a basket made of rushes, or the like, in which are packed up figs, raisins, &c. It signifies also a certain quantity of raisins, about 75 pounds.

FRAISE, in fortification, a kind of defence, consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, or the like, to prevent any approach or scalade.

Fraises differ from palisades chiefly in this, that the latter stand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly so, being usually made a little sloping, or with the points hanging

France.

France.

hanging down. Fraises are chiefly used in retrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone-works.

To *FRAISE a Battalion*, is to line the musketeers round with pikes, that, in case they should be charged with a body of a horse, the pikes being presented, may cover the musketeers from the shock, and serve as a barricade.

FRAME, in joinery, a kind of case, wherein a thing is set or inclosed, or even supported; as a window-frame, a picture-frame, &c.

FRAME is also a machine used in divers arts; as,

FRAME, among printers, is the stand which supports the cases. See CASE.

FRAME, among founders, a kind of ledge inclosing a board; which, being filled with wetted sand, serves as a mould to cast their works in. See FOUNDRY.

FRAME more particularly used for a sort of loom, whereon artificers stretch their lincins, silks, fluffs, &c. to be embroidered, quilted, or the like.

FRAME, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called *reticula*. It serves to reduce figures from great to small; or, on the contrary, to augment their size from small to great.

FRANCE, a large kingdom of Europe, situated between 5° W. and 7° E. Long. and between 43° and 51° N. Lat. being bounded by the English channel and the Austrian Netherlands, on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and, by the bay of Biscay, on the west.

The kingdom of France was originally possessed by the *Celts* or *Gauls*. They were a very warlike people, and often checked the progress of the Roman arms; nor did they yield till the time of Julius Cæsar, who totally subdued their country, and reduced it to the form of a Roman province*. The Romans continued in quiet possession of Gaul, as long as their empire retained its strength, and they were in a condition to repress the incursions of the German nations, whom even in the zenith of their power they had not been able to subdue. But, in the reign of the emperor Valerian, the ancient Roman valour and discipline had begun to decline, and the same care was not taken to defend the provinces that had formerly been done. The barbarous

nations, therefore, began to make much more frequent incursions; and among the rest the *Franks*, a German nation, inhabiting the banks of the Rhine, proved particularly troublesome. Their first irruption, we are told by Valefius, happened in the year 254, the second of Valerian's reign. At this time they were but few in number; and were repulsed by Aurelian, afterwards emperor. Not discouraged by this check, they returned two years afterwards in far greater numbers; but were again defeated by Gallienus, whom Valerian had chosen for his partner in the empire. Others, however, continued to pour in from their native country in such multitudes, that Gallienus, no longer able to drive them out by force of arms, made advantageous proposals to one of their chiefs,

whom he engaged to defend the frontiers against his countrymen as well as other invaders.

This expedient did not long answer the purpose. In 260 the Franks, taking advantage of the defeat and captivity of Valerian in Persia, broke into Gaul, and afterwards into Italy, committing every where dreadful ravages. Five years afterwards they invaded Spain; which they possessed, or rather plundered, for the space of 12 years: nor could they be driven out of Gaul till the year 275, when the emperor Probus not only gave them a total overthrow in that country, but pursued them into their own, where he built several forts to keep them in awe. This intimidated them so much, that nine of their kings submitted to the emperor, and promised an annual tribute.—They continued quiet till the year 287; when, in conjunction with the Saxon pirates, they plundered the coasts of Gaul, carrying off an immense booty. To revenge this insult, the emperor Maximian entered the country of the Franks the following year, where he committed such ravages that two of their kings submitted to him; and to many of the common people who chuse to remain in Gaul, he allowed lands in the neighbourhood of Treves and Cambray.

The restless disposition of the Franks, however, did not allow them to remain long in quiet. About the year 293, they made themselves masters of Batavia, and part of Flanders; but were entirely defeated and forced to surrender at discretion, by Constantius the father of Constantine the Great, who transplanted them into Gaul. Their countrymen in Germany continued quiet till the year 306, when they renewed their depredations; but being overcome by Constantine the Great, two of their kings were taken prisoners, and thrown to the wild beasts in the shows exhibited on that occasion.

All these victories, however, as well as many others said to have been gained by the Romans, were not sufficient to prevent the incursions of this restless and turbulent nation; inasmuch that, in the year 355, they had made themselves masters of 40 cities in the province of Gaul. Soon after, they were totally defeated by the emperor Julian, and again by count Theodosius father to the emperor of that name; but, in the year 388, they ravaged the province with more fury than ever, and cut off a whole Roman army that was sent against them. As the western empire was at this time in a very low state, they for some time found more interruption from other barbarians than from the Romans, till their progress was checked by Aetius.

When the war with Aetius broke out, the Franks³ were governed by one *Pharamond*, the first of their first kings of whom we have any distinct account. He is king, supposed to have reigned from the year 417 or 418, to the year 428; and is thought by archbishop Usher, to have been killed in the war with Aetius. By some he is supposed to have compiled the Salique Laws, with the assistance of four sages named *Wisegeaf*, *Loesegaf*, *Widegaf*, and *Solegaf*. But Valefius is of opinion that the Franks had no written laws till the time of Clovis.

Pharamond was succeeded by his son Clodius, who likewise carried on a war against the Romans. He is said to have received a terrible overthrow from Aetius near the city of Lens; notwithstanding which, he advanced

² Invaded by the Franks.

³ Pharamond
the first king.

France. vanced to Canbray, and made himself master of that city, where for some time he took up his residence. After this he extended his conquests as far as the river Somme, and destroyed the cities of Treves and Cologne, Tournay and Amiens. He died in the year 448, and was succeeded by Merovæus.

5 Merovæus. Authors are not agreed whether the new king was brother, or son, or any relation at all, to Clodio. It seems probable, indeed, that he was of a different family; as from him the first race of French kings were titled *Merovingian*. He was honoured and respected by his people, but did not greatly enlarge the boundaries of his kingdom. He died in 458.

6 Childeric. Merovæus was succeeded by his son Childeric; who being no longer kept in awe by Aëtius, made war on the Romans, and extended his conquests as far as the river Loire. He is said to have taken the city of Paris after a siege of five years, according to some, and of ten, according to others. The Roman power was now totally destroyed in Italy; and therefore *Clodovæus*, *Clovis*, or *Louis*, for his name is differently written, who succeeded Childeric, set himself about making an entire conquest of Gaul. Part of the province was still retained by a Roman named *Syagrius*, who probably had become sovereign of the country on the downfall of the Western empire in 476. He was defeated and taken prisoner by Clovis, who afterwards caused him to be beheaded, and soon after totally reduced his dominions.

7 French monarchy established by Clovis. Thus was the French monarchy established by Clovis in the year 487. He now possessed all the country lying between the Rhine and the Loire; which, though a very extensive dominion, was yet considerably inferior to what it is at present. In 493, he married Clotildis, niece to Gondebaut duke of Burgundy, and embraced the Christian religion. He reduced Armorica, or Brittany; and afterwards made war on the Burgundians, in which he had Theodoric king of the Ostrogoths for his ally. About this time; however, Alaric king of the Visigoths inhabiting Auvergne, made war upon Clovis; and a decisive battle ensuing, the former were entirely defeated, their king killed, and his dominions became a province of France.

Clovis after this destroyed all the petty kings or Christians among the Franks, which he did not accomplish without the vilest treachery; but by that means his power became absolute throughout all his dominions. Having removed the seat of his government first from Tournay to Soissons, and then to Paris, he died in 511; and was buried in the church of Sts. Peter and Paul, now Geneviève, where his tomb is still to be seen.

8 His dominions divided among his children. After the death of Clovis, his dominions were divided among his four sons. Thieri, or Theodoric, the eldest, had the eastern part of the empire; and, from his making the city of Metz his capital, is commonly called the *king of Metz*. Clodomir, the eldest son by Clotildis, had the kingdom of Orleans; Childerbart, and Clotaire, who were both infants, had the kingdoms of Paris and Soissons, under the tutelage of their mother. The prudence of Clotildis kept matters quiet in all the parts of the empire for eight years: but, about the year 520, a numerous fleet of Danes arrived at the mouth of the Meuse; and their king Cochiliac, having landed his forces, began to destroy

the country with fire and sword. Against him Thieri sent his son Theodobert, who defeated the Danish army and navy, and killed their king, forcing the rest to retire with precipitation.

In 522, Hermanfroi king of Thuringia, having destroyed one of his brethren named *Berthaire*, and seized on his dominions, applied to Thieri for assistance against his other brother Baldric, whom he intended to treat in the same manner. In this infamous enterprise Thieri embarked, on condition that he should have one half of Baldric's dominions; but after the unhappy prince was overcome and killed in battle, Hermanfroi seized all his dominions. Thieri had no opportunity of revenging himself till the year 531; when perceiving the power of the Ostrogoths, whom he much dreaded, to be considerably lessened by the death of king Theodoric, he engaged his brother Clotaire to assist him, and they accordingly entered Thuringia with two powerful armies. They joined their forces as soon as they had passed the Rhine, and were quickly after reinforced by a considerable body of troops under the command of Theodobert. The allies attacked the army of Hermanfroi, which was advantageously posted; and having totally defeated it, he was forced to fly from place to place in disguise. Soon after this the capital was taken, and Hermanfroi himself being invited to a conference by Thieri was treacherously murdered; after which his extensive dominions became feudatory to Thieri.

In the mean time, Clotildis had excited her children to make war on the Burgundians, in order to revenge the death of her father Childeric, whom Gondebaut king of Burgundy had caused to be murdered. Gondebaut was now dead, and had left his dominions to his sons Sigismund and Godemar. Sigismund's forces were quickly defeated; and he himself was soon after delivered up by his own subjects to Clodomir, who caused him to be thrown into a pit, where he perished miserably. By his death Godemar became sole master of Burgundy. Clodomir marched against him, and defeated him; but pursuing his victory too eagerly, was surrounded by his enemies and slain. After the reduction of Thuringia, however, Childerbart and Clotaire entered the kingdom of Burgundy at the head of a powerful army, and in 534 completed the conquest of it; in which, according to some, Godemar was killed; according to others, he retired into Spain, and from thence into Africa.

In 560 Clotaire became sole monarch of France. He had murdered the sons of Clodomir, who was killed in Burgundy as above related. Thieri and his children were dead, as was also Childerbart; so that Clotaire was sole heir to all the dominions of Clovis. He had five sons; and the eldest of them, named *Chramnes*, had some time before rebelled against his father in Auvergne. As long as Childerbart lived, he supported the young prince; but on his death, Chramnes was obliged to implore his father's clemency. He was at this time pardoned; but he soon began to cabal afresh, and engaged the count of Bretagne to assist him in another rebellion. The Bretons, however, were defeated, and Chramnes determined to make his escape; but perceiving that his wife and children were surrounded by his father's troops, he attempted to rescue them. In this attempt he was taken prisoner, and with his family

was

9 Clotaire becomes sole monarch.

France.

was thrust into a thatched cottage near the field of battle; of which the king was no sooner informed, than he commanded the cottage to be set on fire, and all that were in it perished in the flames.

Clotaire did not long survive this cruel execution of his son, but died in 562; and after his death the French empire was divided among his four remaining sons, Caribert, Gontran, Sigebert, and Chilperic.—The old king made no division of his dominions before he died, which perhaps caused the young princes to fall out sooner than they would otherwise have done. After his death, however, they divided the kingdom by lot; when Caribert, the eldest, had the kingdom of Paris; Gontran, the second, had Orleans; Sigebert, had Metz, (or the kingdom of Austrasia); and Chilperic had Soissons. Provence and Aquitaine were possessed by all of them in common. The peace of the empire was first disturbed in 563, by an invasion of the Abares; a barbarous nation, said to be the remains of the Huns. They entered Thuringia, which belonged to the dominions of Sigebert; but by him they were totally defeated, and obliged to repair the Elbe with precipitation. Sigebert pursued them close, but readily concluded a peace with them on their first proposals. To this he was induced, by hearing that his brother Chilperic had invaded his dominions, and taken Rheims and some other places in the neighbourhood. Against him, therefore, Sigebert marched with his victorious army, made himself master of Soissons his capital, and of the person of his eldest son Theodobert. He then defeated Chilperic in battle; and not only recovered the place which he had seized, but conquered the greater part of his dominions; nevertheless, on the mediation of the other two brothers, Sigebert abandoned all his conquests, set Theodobert at liberty, and thus restored peace to the empire.

Soon after this, Sigebert married Brunehaut daughter to Athanagild, king of the Visigoths in Spain; and in a little time after the marriage died Caribert king of Paris, whose dominions were divided among his three brethren. In 567 Chilperic married Galswintha, Brunehaut's eldest sister, whom he did not obtain without some difficulty. Before her arrival, he dismissed his mistress called *Fredegonde*; a woman of great abilities and firmness of mind, but ambitious to the highest degree, and capable of committing the blackest crimes in order to gratify her ambition. The queen, who brought with her immense treasures from Spain, and made it her whole study to please the king, was for some time entirely acceptable. By degrees, however, Chilperic suffered *Fredegonde* to appear again at court, and was suspected of having renewed his intercourse with her; which gave such umbrage to the queen, that she desired leave to return to her own country, promising to leave behind her all the wealth she had brought. The king, knowing that this would render him extremely odious, found means to dissipate his wife's suspicions, and soon after caused her to be privately strangled, upon which he publicly married *Fredegonde*.

Such an atrocious action would not fail of exciting the greatest indignation against Chilperic. His dominions were immediately invaded by Sigebert and Gontran, who conquered the greatest part of them; after which they suddenly made peace, Chilperic consenting that Brunehaut should enjoy those places which on

France.

his marriage he had bestowed upon Galswintha, viz. Bourdeaux, Limoges, Cahors, Bigorre, and the town of Bearn, now called *Lascar*.

The French princes, however, did not long continue at peace among themselves. A war quickly ensued, in which Gontran and Chilperic allied themselves against Sigebert. The latter prevailed, and having forced Gontran to a separate peace, seemed determined to make Chilperic pay dear for his repeated perfidy and infamous conduct; when he was assassinated by a contrivance of *Fredegonde*, who thus saved herself and Chilperic from the most imminent danger. Immediately on his death, Brunehaut fell into the hands of Chilperic; but Gondebaud, one of Sigebert's best generals, made his escape into Austrasia with Childbert, the only son of Sigebert, an infant of about five years of age, who was immediately proclaimed king in room of his father. In a short time, however, Meroveus, eldest son to Chilperic, fell in love with Brunehaut, and married her without acquainting his father. Chilperic, on this news, immediately went to Rouen, where Meroveus and his consort were; and having seized them, sent Brunehaut and her two daughters to Metz, and carried Meroveus to Soissons. Soon after, one of his generals being defeated by Gontran, who espoused Brunehaut's cause, Chilperic in a fit of rage caused Meroveus to be shaved and confined in a monastery. From hence he found means to make his escape, and with great difficulty arrived in Austrasia, where Brunehaut would gladly have protected him; but the jealousy of the nobles was so strong, that he was forced to leave that country; and being betrayed into the hands of his father's forces, was murdered, at the instigation of *Fredegonde*, as was generally believed.

The French empire was at this time divided between Gontran king of Orleans, called also king of Burgundy, Chilperic king of Soissons, and Childbert king of Austrasia. Chilperic found his affairs in a very disagreeable situation. In 579, he had a dispute with Varoc count of Bretagne, who refused to do him homage. Chilperic dispatched a body of troops against him; who were defeated, and he was then forced to clap up a dishonourable peace. His brother and nephew lived in strict union, and had no reason to be very well pleased with him. His own subjects, being oppressed with heavy taxes, were miserably poor and discontented. His son Clovis, by a former queen named *Andovera*, hated *Fredegonde*, and made no secret of his aversion. To add to his embarrassment, the seasons were for a long time so unfavourable, that the country was threatened with famine and pestilence at the same time. The king and queen were both attacked by an epidemic disease which then raged. They recovered; but their three sons, Clodobert, Samson, and Dagobert, died; after which, the sight of Clovis became so disagreeable to *Fredegonde*, that she caused him to be murdered, and likewise his mother *Andovera*, lest Chilperic's affection for her should return after the tragical death of her son.

In 583 Chilperic himself was murdered by some unknown assassins, when his dominions were on the point of being conquered by Gontran and Childbert, who had entered into a league for that purpose. After his death *Fredegonde* implored the protection of Gontran for herself and her infant son Clotaire; which he very

readily granted, and obliged Childebert to put an end to the war. He found himself, however, greatly diffcult to keep Fredegonde and Brunehaut in awe; for these two princesses having been long rivals and implacable enemies, were continually plotting the destruction of each other. This, however, he accomplished by favouring sometimes Brunehaut and sometimes Fredegonde; so that, during his life, neither of them durst undertake any thing against the other.

14
Death of
Contran.

On the 28th of March 593, died Contran, having lived upwards of 60, and reigned 32 years. Childebert succeeded to his dominions without opposition, but did not long enjoy them; he himself dying in the year 596, and his queen shortly after. His dominions were divided between his two sons Theodobert and Thierry; the first of whom was declared king of Austrasia, and the latter king of Burgundy. As Theodobert was only in the 11th year of his age, and Thierry in his 10th, Brunehaut governed both kingdoms with an absolute sway. Fredegonde, however, took care not to let slip such a favourable opportunity as was offered her by the death of Childebert, and therefore made herself mistress of Paris and some other places on the Seine. Upon this Brunehaut sent against her the best part of the forces in Austrasia, who were totally defeated; but Fredegonde died before she had time to improve her victory, leaving her son Clotaire heir to all her dominions.

15
And Fre-
degonde.

For some time Brunehaut preserved her kingdom in peace; but in the end her own ambition proved her ruin. Instead of instructing Theodobert in what was necessary for a prince to know, she took care rather to keep him in ignorance, and even suffered him to marry a young and handsome slave of his father's. The new queen was possessed of a great deal of affability and good-nature; by which means she in a short time gained the affection of her husband so much, that he readily consented to the banishment of Brunehaut. Upon this disgrace she fled to Thierry king of Burgundy, in the year 599. By him she was very kindly received; and instead of exciting jealousies or misunderstandings between the two brothers, the engaged Thierry to attempt the recovery of Paris and the other places which had been wrested from their family by Fredegonde, procuring at the same time a considerable body of auxiliaries from the Visigoths. This measure was so acceptable to Theodobert, that he likewise raised a numerous army, and invaded Clotaire's dominions in conjunction with his brother. A battle ensued, in which the forces of Clotaire were totally defeated, and himself obliged soon after to sue for peace; which was not granted, but on condition of his yielding up the best part of his dominions.

16
Brunehaut
banished.

This treaty was concluded in the year 600; but three years afterwards, it was broken by Clotaire. He was again attacked by the two brothers, and the war carried on with great vigour till the next spring. At this time Thierry having forced Landri, Clotaire's general, to a battle, gave him a total overthrow, in which the king's infant son Meroveus, whom he had sent along with Landri, was massacred; to gratify, as Clotaire pretended, the malice of Brunehaut. After this victory, Thierry marched directly to Paris; fully bent on the destruction of his cousin, which now seemed inevitable. This, however, was prevented by Theodo-

bert; who no sooner heard of the victory gained by Thierry, than he became jealous of his success, and offered Clotaire such terms of peace as he gladly accepted. The latter having then nothing to fear on the side of Austrasia, quickly compelled Thierry to listen to terms of accommodation also.

This behaviour of Theodobert greatly provoked his brother; and his resentment was highly inflamed by Brunehaut, who never forgot her disgrace in being banished from his court. A war was therefore commenced between the two brothers in 605; but it was so highly disapproved of by the nobility, that Thierry found himself obliged to put an end to it. The tranquillity which now took place, was again disturbed in 607, by Theodobert's sending an embassy to demand some part of Childebert's dominions which had been added, by the will of that monarch, to those of Burgundy. The nobility of both kingdoms were so much averse to war, that they constrained their kings to consent to a conference, attended by an equal number of troops; but Theodobert, by a scandalous breach of his faith, brought double the number, and compelled his brother to submit to what terms he pleased. This piece of treachery instantly brought on a war; for Thierry was bent on revenge, and his nobility no longer opposed him. It was necessary, however, to secure Clotaire by a negotiation; and accordingly a promise was made of restoring those parts of his dominions which had formerly been taken from him, provided he would remain quiet. This treaty being finished, Thierry entered Theodobert's dominions, defeated him in two battles, took him prisoner, used him with the utmost indignity; and having caused an infant son of his to be put to death, sent him to his grandmother Brunehaut. By her orders he was first shaved and confined in a monastery; but afterwards, fearing lest he should make his escape, the caused him to be put to death.—Clotaire, in the mean time, thought that the best method of making Thierry keep his word was to seize on those places which he had promised to restore to him, before his return from the war with Theodobert. This he accordingly did; and Thierry no sooner heard of his having done so, than he sent him a message requiring him to withdraw his forces, and, in case of his refusal, declared war. Clotaire was prepared for this; and accordingly assembled all the forces in his dominions, in order to give him a proper reception. But before Thierry could reach his enemies, he was seized with a dysentery; of which he died in the year 612, having lived 26 years, and reigned 17.

17
Death of
Thierry.

On the death of Thierry, Brunehaut immediately caused his eldest son, named *Sigibert*, then in the 10th year of his age, to be proclaimed king. It is probable that she intended to have governed in his name with an absolute sway; but Clotaire did not give her time to discover her intentions. Having great intelligence in Austrasia and Burgundy, and knowing that the nobility in both kingdoms were disaffected to Brunehaut, he declared war against her; and the being betrayed by her generals, fell into the hands of her enemies. Clotaire gave her up to the nobles; who generally hated her, and who used her in the most cruel manner. After having led her about the camp, exposed to the insults of all who had the means to insult her, she was tied by the leg and arm to the tail of an

18
Brunehaut
put to a
cruel death.

un-

untamed horse, which, setting off at full speed, quickly dashed out her brains. After this her mangled body was reduced to ashes, which were afterwards interred in the abbey of St Martin at Autun.

Thus Clotaire became sole monarch of France; and quietly enjoyed his kingdom till his death, which happened in the year 628. He was succeeded by Dagobert; who proved a great and powerful prince, and raised the kingdom of France to a high degree of splendor. Dagobert was succeeded by his sons Sigebert and Clovis; the former of whom had the kingdom of Austrasia, and the latter that of Burgundy. Both the kings were minors at the time of their accession to the throne, which gave an opportunity to the mayors of the palace (the highest officers under the crown) to usurp the whole authority. Sigebert died in 640, after a short reign of one year; leaving behind him an infant son named *Dagobert*, whom he strongly recommended to the care of Grimoalde his mayor of the palace. The minister caused Dagobert to be immediately proclaimed king, but did not long suffer him to enjoy that honour. He had not the cruelty, however, to put him to death; but sent him to a monastery in one of the Western islands of Scotland; and then, giving out that he was dead, advanced his own son Childebert to the throne. Childebert was expelled by Clovis king of Burgundy; who placed on the throne Childeric, the second son of Sigebert. Clovis died soon after the revolution, and was succeeded in his dominions by his son Clotaire; who died in a short time, without issue. He was succeeded by his brother Childeric; who, after a short reign, was murdered with his queen, at that time big with child, and an infant son named *Dagobert*; tho' another, named *Daniel*, had the good luck to escape.

The affairs of the French were now in the most deplorable situation, without king, magistrates, or law of any kind; nor did this confusion end but with the total extinction of the family of Clovis. The princes of the Merovingian race were, in fact, deprived of their power by Pepin d'Heristal, who obliged Thierry king of Austrasia to receive him as mayor of the palace. He governed every thing in the most absolute manner; but, however, conducted matters with so much prudence, that the nation was very much respected during the time of his administration, which continued 28 years. He died in 711, and was succeeded in his post by his youngest son Theudobalde, at that time but six years old. In 717, Theudobalde was expelled by Charles Martel, Pepin's son by a former wife, who compelled the nominal king at that time to own him as mayor of the palace. He was attended with surprising success in all his undertakings; defeated the Arabs who invaded the kingdom*; overthrew the Frisians, and killed their duke with his own hands. At last he was chosen by pope Gregory III. for his protector. He offered to shake off his dependence on the Greek emperor, and to make Charles consul at Rome, sending him at the same time the keys of the tomb of St Peter. But while this affair was in agitation, Charles Martel died, and was succeeded in his power by his sons Carloman and Pepin.

Though Charles had never assumed the title of *sovereign*, he divided the empire between his sons as if he had been actually king. In 746, Carloman being weary of his greatness, retired into a convent, and

thus left Pepin absolute master of the empire; who, five years afterwards, resolved to assume the title of *king*, as he had long possessed the authority of one. This prince, surnamed *le Bref*, or the *Short*, was the first of the second race of French kings named *Carlovingian*; and was one of the greatest and most prudent monarchs that ever sat on the throne of France. He protected pope Stephen III. against Astolphus king of the Lombards, who had seized the exarchate of Ravenna, and insisted upon his being acknowledged king of Rome. Pepin conducted the pope, who had come to France, with an army back into Italy; besieged Astolphus in Pavia; and obliged him to renounce, not only all claim to the sovereignty of Rome, but also the exarchate of Ravenna, and all his other conquests in Italy. The exarchate he bestowed upon the pope; who, however, did not consider it as a gift from him, but only as the restoring to him a territory which was justly his right. Pepin was no sooner gone, than Astolphus broke the treaty he had concluded, and laid siege to Rome itself. However, the king of France very soon returned, and forced him to accept of a peace on vastly worse terms than before; after which he made a tour to Rome; but finding that his stay gave great uneasiness to the Greeks, as well as to the pope himself, he quickly left the city.

After his return to his own dominions, Pepin employed himself in regulating the national affairs; but was soon obliged to take the field against the duke of Aquitaine, which country he entirely reduced in the space of nine years. Soon after this, he died of a dropy at St Denis, in the year 768, the 17th of his reign, and 54th of his life.

Pepin was succeeded by his two sons Charles and Carloman. The latter, who was the younger, died in 769, the year after their accession to the throne; and thus Charles became sole master of the French empire, which he enlarged farther than ever it was either before or since. His first expedition was against the Saxons, who had long been tributaries to France, but frequently revolted, and now thought they had a good opportunity, by the death of Pepin, of freeing themselves from that tribute, which they regarded as an intolerable grievance. Charles, however, entered their country with a great army; and having defeated them in a number of small engagements, advanced to their capital post of Erfelbourg near Paderborn; where was the temple of their god Irminful, represented as a man completely armed, with a standard in one hand, placed on a column. The Saxons made an obstinate defence; but were at last obliged to yield, and Charles employed his army three days in demolishing the monuments of pagan superstition in this place. This disheartened them to such a degree, that they submitted to whatever terms he chose to prescribe; and which were rendered easier to them than, perhaps, they would have been, by the news which Charles now received from Italy.

Didier, king of the Lombards, having seized and frightened to death pope Stephen IV. endeavoured to the utmost of his power to reduce his successor Adrian I. to a state of dependence. The pope implored the assistance of Charles against his adversaries, and this Charles was very ready of himself to grant; but the nobility were so much averse to an Italian war, that he was obliged to act with the greatest circumspection.

He

France.

France

He sent, therefore, several embassies to Didier; in which, after expressing a great desire to preserve a strict harmony between the two nations, he at length offered him a large sum of money if he would restore the places he had taken from the pope. These offers being rejected, Charles at length obtained the consent of his nobility, and set out for Lombardy with a powerful army. Didier, however, had made such excellent dispositions, that all Charles's officers reckoned it would be impossible for him to force a passage. But Didier's troops being seized with a sudden panic, abandoned all their posts, and retired with precipitation. Charles pursued them with such impetuosity, that numbers were killed. Didier with one part of the troops took shelter in Pavia; the rest, under the command of his only son Adalgisie, threw themselves into Verona. Charles formed the siege of both places at once. Both of them were taken, after making a vigorous resistance. Didier fell into the hands of Charles, who carried him prisoner into France; but Adalgisie escaped to Constantinople: after which all the other places of strength in the country submitted to the conqueror, and thus Charles became master of the whole kingdom of the Lombards in a single campaign.

22
He conquers the Lombards.

After this success the king set out for Rome, whence he was very soon recalled by the news of a fresh revolt of the Saxons. Them he quickly reduced; but was next year obliged to return into Italy, in order to subdue some of the Lombard lords who had set up for independent princes. While he was employed in subduing them, the Saxons revolted, so that Charles found himself again under a necessity of returning into Germany. They submitted in a short time, and promised to become Christians; and the king took care now to force them to keep their promises, by building forts in several parts of the country.

23
His conquests in Spain and Germany.

In 778, being invited by some Moorish lords, he made an expedition into Spain. Here he took Pompeluna and Saragossa; after which, the emirs of Huesca and Jacca voluntarily submitted to him, as did also the governor of Barcelona and Gironne. Having taken all methods in his power to secure his new conquests, he set out on his return; but the Gascons, having attacked the rear of his army, cut off great numbers of his men. In 779 and 780, he was employed in quelling new insurrections in Saxony and Italy. The Saxons he treated with the utmost cruelty, causing 4500 prisoners to be beheaded at once, because they could not deliver up Witikind, one of their chiefs who had fled into Denmark. This piece of barbarity soon excited a general revolt; and it was not till the year 785, that Charles was able totally to reduce them. This, however, he at last accomplished, after having made terrible devastation.

All the endeavours of this great monarch, however, to keep his new subjects quiet, were ineffectual. He had no sooner finished this last conquest of the Saxons, than he was called into Italy to quiet some new insurrections which had taken place there. This was no sooner accomplished, than he was obliged to take the field against the Slavonians, who harassed some of his Germans subjects. In the mean time the duchy of Bavaria was harassed by the Huns to such a degree, that after subduing the Slavonians, Charles found it necessary to turn his arms against them. But while he meditated

this expedition the Saxons again revolted, and new troubles broke out in Italy. Charles behaved with the greatest prudence and resolution. In 794, he marched against the Saxons; and so great was their fear of him, that their army began to disband as soon as he entered the country. Upon this the Saxon chiefs sued for peace; which they could obtain upon no other terms than that they should receive the Christian clergy, and deliver up a third part of the army to be sent wherever he pleased. Hard as this last article was, they complied with it; and Charles distributed these Saxon troops on the coasts of Holland and Flanders, where they proved of great use in repelling the invasions of the Normans, who about this time began to be formidable. The war with the Abares, or Huns, was conducted by Pepin son to Charles, whom he had appointed king of Italy, and who is said to have almost extirpated the nation. After this Charles himself returned into Italy; and having there quieted all disturbances, he proceeded to Rome, where he was solemnly crowned emperor of the West by pope Leo III. in the year 800. He continued to reign with uninterrupted prosperity till the year 813; when he died of a pleurisy on the 28th of January, leaving the empire to his only surviving son, Lewis king of Aquitaine, whom he had before taken for his partner in the imperial dignity.

24
Is crowned emperor of the West.

The good fortune of Charles did not descend to his children. Lewis, though a very mild and religious prince, was by no means fit for governing those turbulent nations with whom he had to do. His reign, therefore, was a continued scene of troubles. His own children conspired against him; and more than once made him prisoner, and treated him with the utmost indignity. Lothaire, the eldest, even pronounced a formal sentence of deposition against him. At last, however, this ungrateful prince was obliged to submit to his father, and ask his pardon in the most humble manner; who forgave him, and did not punish his associates with such severity as they deserved. This lenity produced a fresh cabal among his children; and before they could be reduced the emperor died, being worn out with sickness and grief for the unnatural conduct of his sons.

Lewis left behind him three sons: Lothaire, whom he had associated with himself in the empire; Lewis, king of Bavaria; and Charles, only 17 years of age, king of France, under the tuition of his mother. On the death of their father, however, Lothaire attempted to seize the whole empire for himself; but after a long and ruinous war with his two brothers, was forced to consent to a new division: by which Charles had Aquitaine and all the country between the Loire and the Meuse; Lewis had the whole of Germany; and Lothaire, besides Italy, had the whole tract of country lying within the rivers Rhone, Rhine, Saone, Meuse, and Scheld. The whole of what he held on this side of the mountains, was from him called *Lotharingia*, and by corruption *Lorraine*; though this name is now given to a duchy which contains only a small part of that kingdom.

25
Empire divided into three parts.

This division happened in the year 845; and the empire was now so much weakened by the civil wars which had preceded, that it became a prey to the barbarous nations, who invaded it in on all sides. The Spanish dominions were almost entirely lost; the Bretons revolted, and could not be subdued; and in 855, Lothaire

Decline of its strength.

France.

thaire died, leaving his dominions among his three sons: so that, by the setting up of so many independent sovereigns, it was next to impossible that the empire could preserve its tranquillity, which had been so dearly bought. In fact, for a long time the history of France affords nothing but an account of civil discords. Charles (furnamed the *Bald*), king of France, by deceit got himself crowned emperor in preference to Lewis, who was his elder brother; and having made himself master of Italy, he thought it would be an easy matter to seize on all the dominions of his brother Lewis, who died about the year 876. In this, however, he was deceived; being defeated with great loss, and obliged totally to abandon the enterprise. Next year he himself was poisoned by a Jewish physician named *Zedechar*; and died in the 34th year of his reign, and 54th of his age.

Charles the Bald was succeeded by his only son, named *Lewis*; and, from an impediment in his speech, furnished the *Stammerer*. He was a prince of no great abilities; and as he found the affairs of the kingdom in considerable disorder at the time of his accession, so it was not in his power to extricate them from it. He died on the 10th of April 879, while on a march to suppress some insurrections in Burgundy. He left his queen *Adelaide* pregnant; who some time after his decease was delivered of a son, named *Charles*. After his death followed an interregnum; during which a faction was formed for setting aside the children of *Lewis* the *Stammerer*, in favour of the German princes, sons to *Lewis* the brother of *Charles* the *Bald*. This scheme, however, proved abortive; and the two sons of the late king, *Lewis* and *Carloman*, were crowned kings of France. Another kingdom, however, was at that time erected by an assembly of the states, namely, the kingdom of *Provence*, which consisted of the countries now called *Lyonnois*, *Savoys*, *Dauphiny*, *Franche Comte*, and part of the duchy of *Burgundy*; and this kingdom was given to duke *Boson*, brother-in-law to *Charles* the *Bald*. In 881, both kings of France died; *Lewis*, as was suspected, by poison; and *Carloman* of a wound he received accidentally while hunting. This produced a second interregnum; which ended with the calling in of *Charles* the *Gros*, emperor of Germany. His reign was more unfortunate than that of any of his predecessors. The Normans, to whom he had given leave to settle in *Friesland*, sailed up the *Seine* with a fleet of 700 ships, and laid siege to *Paris*. *Charles*, unable to force them to abandon their undertaking, prevailed on them to depart by a large sum of money. But as the king could not advance the money at once, he allowed them to remain in the neighbourhood of *Paris* during the winter; and they in return plundered the country, thus amassing vast wealth besides the sum which *Charles* had promised. After this ignominious transaction *Charles* returned to Germany, in a very declining state of health both as to body and mind. Here he quarrelled with his empress; and being abandoned by all his friends, he was despoiled, and reduced to such distress, that he would not even have had bread to eat, had not he been supplied by the archbishop of *Mentz*, out of a principle of charity.

On the deposition of *Charles* the *Gros*, *Eudes* count of *Paris* was chosen king by the nobility during the minority of *Charles* the son of *Adelaide*, afterwards

named *Charles* the *Simple*. He defeated the Normans, and repressed the power of the nobility; on which account a faction was formed in favour of *Charles*, who was sent for, with his mother, from England. *Eudes* did not enter into a civil war; but peaceably resigned the greatest part of the kingdom to him, and contented to do homage for the rest. He died soon after this agreement, in the year 898.

During the reign of *Charles* the *Simple*, the French government declined. By the introduction of siefs, those noblemen who had got into the possession of governments, having these confirmed to them and their heirs for ever, became in a manner independent sovereigns; and as these great lords had others under them, and they in like manner had others under them, and even these again had their vassals; instead of the easy and equal government which prevailed before, a vast number of insupportable little tyrannies were erected. The Normans, too, ravaged the country in the most terrible manner, and desolated some of the finest provinces in France. At last *Charles* ceded to *Rollo*, the king or captain of these barbarians, the duchy of *Neustria*; who thereupon became Christian, changed his own name to *Robert*, and that of his principality to *Normandy*.

During the remainder of the reign of *Charles* the *Simple*, and the entire reigns of *Lewis* IV. furnished the *Stranger*, *Lothaire*, and *Lewis* V. the power of the *Carlovingian* race continually declined; till at last they were supplanted by *Hugh* *Capet*, who had been created duke of France by *Lothaire*. This revolution happened in the year 987, and was brought about much in the same manner as the former one had been by *Pepin*. He proved an active and prudent monarch, and possessed other qualities as were requisite for keeping his tumultuous subjects in awe. He died on the 24th of October 997, leaving his dominions in perfect quiet to his son *Robert*.

The new king inherited the good qualities of his father. In his reign the kingdom was enlarged by the death of *Henry* duke of *Burgundy*, the king's uncle, to whom he fell heir. This new accession of territory, however, was not obtained without a war of several years continuance, on account of some pretenders to the sovereignty of that duchy; and had it not been for the assistance of the duke of *Normandy*, it is doubtful whether the king would have succeeded.—As *Robert* was of opinion, that peace and tranquillity were preferable to wide extended dominions with a precarious tenure, he resigned the kingdom of *Italy* and the imperial crown of Germany, both which were offered him. He died on the 20th of July 1030; having reigned 33 years, and lived 60.

Robert was succeeded by his eldest son *Henry* I. who in the beginning of his reign met with great opposition from his mother. She had always hated him; and preferred his younger brother *Robert*, in whose favour she now raised an insurrection. By the assistance of *Robert* duke of *Normandy*, however, *Henry* overcame all his enemies, and established himself firmly upon the throne. In return for this, he supported *William*, *Robert's* natural son, and afterwards king of *England*, in the possession of the duchy of *Normandy*. Afterwards, however, growing jealous of his power, he not only supported the pretenders to the duchy of

France.

Normandy secretly, but invaded that country himself in their favour. This enterprize proved unsuccessful, and Henry was obliged to make peace: but no sincere reconciliation ever followed; for the king retained a deep sense of the disgrace he had met with, and the duke never forgave him for invading his dominions. The treaty between them, therefore, was quickly broken; and Henry once more invaded Normandy with two armies, once commanded by himself, and the other by his brother. The first was harassed by continual skirmishes, and the last totally defeated; after which Henry was obliged to agree to such terms as the duke thought proper: but the rancour between them never ceased, and was in reality the cause of that implacable aversion which for a long series of years produced perpetual quarrels between the kings of France and those of the Norman race in England.

Philip.³⁰

Henry died in 1059, not without a suspicion of being poisoned; and was succeeded by his eldest son Philip, at that time in the eighth year of his age. Baldwin earl of Flanders was appointed his guardian; and died in the year 1066, about the time that William of Normandy became king of England. After the death of his tutor, Philip began to shew a very insincere, haughty, and oppressive disposition. He engaged in a war with William the Conqueror, and supported his son Robert in his rebellion against him*. But after the death of William, he assisted Robert's brothers against him, by which means he was forced to consent to a partition of his dominions.

* See
England,
no 88.

In 1092, king Philip being wearied of his queen Bertha, procured a divorce from her under pretence of consanguinity, and afterwards demanded in marriage Emma daughter to Roger count of Calabria. The treaty of marriage was concluded; and the princess was sent over, richly adorned with jewels, and with a large portion in ready money: but the king, instead of espousing her, carried off from her husband the countess of Anjou, who was esteemed the handsomest woman in France. With her he was so deeply enamoured, that not satisfied with the illegal possession of her person, he procured a divorce between her and her husband, and prevailed upon some Norman bishops to solemnize his own marriage with her. The whole of these transactions, however, were so scandalous, that the pope having caused them to be revised in a council at Autun, in the year 1094, pronounced sentence of excommunication against Philip in case he did not part with the countess. On his repentance, the censure was taken off; but as the king paid no regard to his promises, he was, in 1095, excommunicated a second time. He again professed repentance, and was absolved; but soon after, living with the countess of Anjou as formerly, he was excommunicated a third time. This conduct, so unworthy of a prince, exposed him to the contempt of the people. Too many of the nobility followed his example, and at the same time despised his authority; not only making war upon each other, but spoiling and robbing his subjects with impunity.

In the year 1110, Philip prevailed on the court of Rome to have his affair reviewed in an assembly at Poitiers; where, notwithstanding his utmost efforts, sentence of excommunication was a fourth time pronounced against him. Yet, in spite of all these sen-

France.

tences, as queen Bertha was dead, and the count of Anjou offered, for a large sum of money, to give whatever assistance was requisite for procuring a dispensation, Philip at last prevailed, and the countess was proclaimed queen of France. But tho' the king's domestic affairs were now in some measure quieted, his negligence in government had thrown the affairs of the nation into the greatest disorder. He therefore associated with him in the government his eldest son Lewis. This prince was the very reverse of his father; and by his activity and resolution, keeping constantly in the field with a considerable body of forces, he reduced the rebellious nobility to subjection, and, according to the best historians, at this time saved the state from being utterly subverted.

For these services the queen looked upon the young prince with so jealous an eye, and gave him so much disturbance, that he found it necessary to retire for some time into England; where he was received by king Henry I. with the greatest kindness. He had not been long at court, before Henry received, by an express, a letter from Philip; telling him, that, for certain important reasons, he should be glad if he closely confined his son, or even dispatched him altogether. The king of England, however, instead of complying with this infamous request, shewed the letter to Lewis, and sent him home with all imaginable marks of respect. Immediately on his return, he demanded justice; but the queen procured poison to be given him, which operated so violently that his life was despaired of. A stranger, however, undertook the cure, and succeeded; only a paleness remained in the prince's face ever afterwards, though he grew so fat that he was surmised the Grosi.

On his recovery, the prince was on the point of revenging his quarrel by force of arms; but his father having caused the queen to make the most humble submissions to him, his resentment was at length appeased, and a perfect reconciliation took place.

Nothing memorable happened in the reign of king Philip after this reconciliation. He died in the year 1108, and was succeeded by his son Lewis the Grosi.³¹ The first years of his reign were disturbed by insurrections of his lords in different places of the kingdom; and these insurrections were the more troublesome, as they were secretly fomented by Henry I. of England, that by weakening the power of France his duchy of Normandy might be the more secure. This quickly brought on a war; in which Henry was defeated, and his son William obliged to do homage to Lewis for the duchy of Normandy. As the kings of England and France, however, were rivals, and exceedingly jealous of each other, the latter espoused the cause of William the son of Robert duke of Normandy, whom Henry had unjustly deprived of that duchy. This brought on a new war; in which Lewis, receiving a great defeat from Henry, was obliged to make peace upon such terms as his antagonist thought proper. This tranquillity, however, was but of short duration. Lewis renewed his intrigues in favour of William, and endeavoured to form a confederacy against Henry. In this, however, he was disappointed. Henry found means not only to dissipate this confederacy, but to prevail upon Henry V. emperor of Germany to invade France with the whole

France.

whole strength of the empire on one side, while he prepared to attack it on the other. But, Lewis having collected an army of 200,000 men, both of them thought proper to desist. Upon this the king of France would have marched into Normandy, in order to put William in possession of that duchy. His great vassals, however, told him they would do no such thing; that they had assembled in order to defend the territories of France from the invasion of a foreign prince, and not to enlarge his power by destroying that balance which arose from the king of England's possession of Normandy, and which they reckoned necessary for their own safety. This was followed by a peace with Henry; which, as both monarchs had now seen the extent of each other's power, was made on pretty equal terms, and kept during the life of Lewis, who died in 1137, leaving the kingdom to his son Lewis VII.

34
Lewis VII.
a weak
prince.

The young king was not endowed with any of those qualities which constitute a great monarch. From the superstition common to the age in which he lived, he undertook an expedition into the Holy Land, from whence he returned without glory. In this expedition he took his queen Eleanor along with him; but was so much offended with her gallantries during her stay there, as well as her behaviour afterwards, that he divorced her, and returned the duchy of Guienne which he received with her as a portion. Six weeks after this the married Henry duke of Normandy, count of Anjou and Maine, and heir apparent to the crown of England. This marriage was a very great mortification to Lewis; and procured him the surname of *the Young*, on account of the folly of his conduct. When Henry ascended the throne of England, some wars were carried on between him and Lewis, with little advantage on either side: at last, however, a perfect reconciliation took place; and Lewis took a voyage to England, in order to visit the shrine of St Thomas of Canterbury. On his return he was struck with an apoplexy; and though he recovered for that time, yet he continued ever after paralytic on the right side. After having languished for about a year under this malady, he died on the 18th of September 1180, leaving the kingdom to his son Philip.

33
Philip the
Great.

This prince, furnished *The Gift of God*, *The Magnanimous*, and *The Conqueror*, during his lifetime; and, as if all these titles had fallen short of his merit, styled *Augustus* after his death,—is reckoned one of the greatest princes that ever sat on the throne of France, or any other.—It doth not, however, appear that these titles were altogether well founded. In the beginning of his reign he was opposed by a strong faction excited by his mother. Them indeed he repressed with vigour and spirit which did him honour; but his taking part with the children of Henry II. of England in their unnatural contests with their father, and his treacherous combination with John to seize his brother's kingdom when he was detained in prison by the emperor of Germany, must be indelible stains in his character, and for ever exclude him from the title of *Magnanimous*. As to military skill and personal valour, he was evidently inferior to Richard I. of England; nor can his recovering of the provinces held by the English in France, from such a mean and dastardly prince as king John, entitle him with any justice to

VOL. IV.

the surname of *Conqueror*. In politics he was evidently the dupe of the Pope, who made use of him to intimidate John into a submission, by promising him the kingdom of England, which he never meant that he should enjoy. An account of these transactions, which are the principal ones of this reign, is given under the article ENGLAND, n° 119—139.

34
Reign of
Lewis IX.

Philip died in 1223, and was succeeded by his son Lewis VIII.; and he, in 1226, by Lewis IX. afterwards styled *St Lewis*. This prince was certainly possessed of many good qualities, but deeply tainted with the superstition of the times. This induced him to engage in two crusades. The first was against the Saracens in Egypt: in which he was taken prisoner by the Infidels, and treated with great cruelty; but at last obtained his ransom, on condition of paying a million of pieces of gold, and surrendering the city of Damietta. He no sooner regained his liberty, than he entered Syria with a view of doing something worthy of his rank and character. From this expedition he was obliged to return sooner than he intended, by the news of the decease of his mother queen Blanch, whom he had appointed regent in his absence, and who had managed the national affairs with the greatest prudence. The king, however, found many disorders in the kingdom upon his return; and these he set himself to reform with the utmost diligence. Having succeeded in this, he yielded to Henry III. of England, the Limousin, Quercy, Perigord, and some other places; in consideration of Henry and his son prince Edward their renouncing, in the fullest manner, all pretensions to Normandy and the other provinces of France which the English had formerly possessed.

The reputation of this monarch for candour and justice was so great, that the barons of England, as well as king Henry III. consented to make him umpire of the differences which subsisted between them. But though he decided this matter very justly, his decision was not productive of any good effect. At last the king, having settled every thing relating to his kingdom in a proper manner, set out on another crusade for Africa; where he died of the plague, on the 25th of August 1270.

During the reigns of Philip the Hardy, Philip the Fair, Lewis Hutin or the *Quarrelsome*, Philip the Tall, and Charles the Fair, the French history affords no transactions which much affected the general state of the kingdom. The government, however, seems to have declined; the nation to have been in low circumstances; and the seeds of those disorders sown, which now brought it to the brink of ruin.

35
Cause of the
war with
Edward III.
of England.

Charles the Fair died in 1328 without male issue, but leaving his queen pregnant. As it was necessary in this case to appoint a regent, Philip count of Valois offered himself. His title was founded on his being the late king's cousin-german, and his nearest heir-male descended from a male. This title was disputed by Edward III. of England; who insisted, that he, as nephew to the deceased king, was a nearer relation than Philip. He acknowledged indeed, that his own title came by a female; but though he owned that females were incapable of holding the crown of France for themselves, yet he maintained that this incapacity did not extend to their male descendants. The parliament of France, however, thought otherwise; and

17 Y

there-

therefore sustained Philip's claim to the regency, in preference to that of Edward. Soon after, the queen dowager was delivered of a princefs, and thus Philip became poffeffed of the crown; and his attaining it in this manner procured him the furname of *the Fortunate*.

Philip was crowned at Rheims on the 29th of April 1328; and next year Edward III. of England came over to France, in order to do homage for the territories he had in that country, and to lay claim to fome lands in Guienne. Great difputes arofe about the nature of the homage he was to pay: Philip, however, contented himfelf with receiving homage in general terms; and was afterwards to examine his own archives at leifure, in order to determine what the nature of it was. On thefe terms Edward did homage in the cathedral at Amiens, on the 6th of June; and very foon after returned to England.

After a reasonable delay, the king fent ambaffadors into England, in order to explain the nature of the homage which Edward had done; and Edward being at that time embarraffed with his domeftic affairs, found it requifite to own the homage to be of that nature which he knew to be agreeable to Philip. Soon after this, Edward again came over to France in order to settle fome new difputes; and in a little time returned to England in perfect friendfhip with the French monarch. This difpofition, however, was of no long duration. Philip having found it neceffary to banifh Robert de Artois his own brother-in-law, on account of fome criminal practices, the latter fled to England; where being well received by Edward, he never ceafed to incenfe him againft Philip.

As both monarchs were poffeffed of great prudence and fagacity, they foon penetrated each other's designs. Philip, under pretence of taking the crofs, began to make prodigious armaments, ftrengthening himfelf at the fame time by alliances on every fide; while Edward, determining to renew his claim to the crown of France, projected the conqueft of Scotland. This, however, he could not accomplifh; and in the mean time Philip, in order to favour the Scots, with whom he was in alliance, fuffered his fubjects to make irruptions into Guienne.

In 1337, the war broke out openly. Philip having detached a fquadron of his fleet againft the Infidels, employed the reft, confifting chiefly of Genoefe veffels, againft the Englifh. As in this war it was of great importance which fide was taken by the Flemings, thefe people were courted by both parties. Lewis count of Flanders declared for Philip, but his fubjects were more inclined to king Edward. James Arteville a brewer, the moft able and artful man in the country, governed them at that time as much as if he had been their prince; and, the advantages arifing from the Englifh commerce determining him in favour of Edward, that prince, at his request, embarked for Sluis with a numerous army. Here he landed in 1338; and on his firft landing, it was refolved that the German princes in alliance with him fhould act againft France. But for this a pretence was wanting. The vaffals of the empire could not act by Edward's orders, or even as his allies, without directions from the emperor, and he was in league with France. This difficulty, however, was foon overcome: the French had made them-

felves mafters of Cambray, and the emperor refolved that it fhould be retaken. With this view he created Edward *Vicar General of the Empire*; an empty title, but which feemed to give him a right of commanding the fervices of the princes of Germany. The Flemings, who were vaffals of France, likewise pretended scruples at invading the territories of their liege lord. To quiet thefe, Edward, by the advice of Arteville, affumed the title of *king of France*; and by virtue of this right, challenged their affiftance for dethroning Philip de Valois, the ufurper of his kingdom. This ftep, which, he feared, would beget endless animofities and jealousies, he did not take without hesitation; and, according to Mr Hume, from this time we may date the commencement of that great animofity which the Englifh have always borne to the French.

Edward's firft attempt was upon the city of Cambray, to which he laid fiege; but in a fhort time he was prevailed upon by Robert de Artois, to raife the fiege and march into Picardy. This country he entered with an army of near 50,000 men, compofed moftly of foreigners. Philip came within fight of him with an army of near 100,000, compofed chiefly of native fubjects; and it was daily expected that a battle would enfue. But the Englifh monarch was averfe to engage againft fo great a fuperiority; and Philip thought it fufficient if he eluded the attacks of his enemy, without running any unneceffary hazard. The two armies faced each other for feveral days; mutual defiance was fent; and Edward at laft retired into Flanders, and difperfed his army.

Such was the fruitlefs, and almoft ridiculous conclufion of Edward's firft expedition, which had plunged him into the greateft difficulties. He had contracted near 300,000 pounds of debt; he had anticipated all his revenue; he had pawned every thing of value which belonged either to himfelf or his queen; nay, he was obliged in fome meafure even to pawn himfelf to his creditors, by defiring their permiffion to go over to England in order to procure fupply, and by promifing on his word of honour to return in perfon if he did not remit their money. On his arrival in England, however, he procured a large fupply, fufficient to enable him to make all the neceffary preparations for a new invasion; and fo certain were the Englifh that France would now be conquered, that the parliament, before Edward's departure, protefted that they owed him no obedience as king of France, but that the two kingdoms muft remain for ever diftinct and independent.

The king of England fet out on his fecond expedition with a fleet of 240 veffels. Philip had prepared a fleet of 400 veffels, manned with 40,000 men; which he ftationed off Sluis, in order to intercept him in his paffage. The two fleets met on the 13th of June 1340; but the Englifh, either by the fuperior abilities of Edward, or the greater dexterity of his feamen, gained the wind of the enemy, and had the fun in their backs; and with thefe advantages began the action. The battle was fierce and bloody: the Englifh archers, whose force and addrefs were now much celebrated, galled the French on their approach; and when the fhips grappled together, the example of the king and the nobility who were with him fo animated the feamen and foldiers, that they maintained every where a fuperiority over the enemy. mings, observing the battle, hurried out of their ports, and brought a reinforcement to the English; which, coming unexpectedly, had a greater effect than in proportion to its power and numbers. Two hundred and thirty French ships were taken; and 30,000 Frenchmen were killed, with two of their admirals: the loss of the English was inconsiderable, compared to the greatness and importance of the victory. None of Philip's courtiers, it is said, dared to inform him of the event; till his fool or jester gave him a hint, by which he discovered the loss he had sustained.

After this great victory, Edward landed his forces, and laid siege to Tournay. Philip marched to its relief with a very numerous army; but acted with so much caution, that Edward found himself in a manner blocked up in his camp: and the countess dowager of Hainault, sister to Philip, mother-in-law to Edward, and sister-in-law to Robert de Artois, coming out of a convent, to which she had retired, interposed with so much spirit and address, that she engaged all parties to agree to a truce for a year; and might perhaps have brought about a peace, if she had survived.

In 1341, however, Edward's ambition was once more excited by the invitation of the count de Mountfort, who had possessed himself of the province of Brittany, and applied to Edward to second his claims. An offer of this kind entirely coincided with Edward's most sanguine desires. He was happy in the promised assistance of Mountfort, an active and valiant prince, closely united to him by interest, and thus opening to him an entrance into the heart of France. These flattering prospects, however, were for a while damped by the imprisonment of Mountfort; whose aims being discovered, he was besieged in the city of Nantz, and taken. But Jane of Flanders, his wife, soon made up for the loss of her husband. This lady courageously undertook to support the falling fortunes of her family. She assembled the inhabitants of Rennes, where she then resided; and carrying her infant son in her arms, deplored her misfortunes, and attempted to inspire the citizens with an affection for her cause. The inhabitants of Nantz instantly espoused her interests, and all the other fortress of Brittany embraced the same resolution. The king of England was apprised of her efforts; and was intreated to send her succours with all possible expedition to the town of Hennebone, in which place she resolved to sustain the attacks of the enemy. Charles de Blois, Philip's general, anxious to make himself master of so important a fortress as Hennebone, and still more to take the countess a prisoner, fat down before the place with a large army, and conducted the siege with indefatigable industry. The defence was no less vigorous; several sallies were made by the garrison, in which the countess herself was still the most active, and led on to the assault. Observing one day that their whole army had quitted the camp to join in a general storm, she sallied out by a postern at the head of 300 horse, set fire to the enemies tents and baggage, put their sutlers and servants to the sword, and occasioned such an alarm, that the French desisted from the assault, in order to cut off her communication with the town. Thus intercepted, she retired to Auray, where she continued five or six days; then returning at the head of 500 horse, she fought her way through one quarter of the French camp, and returned to her faith-

ful citizens in triumph. But the besiegers had at length made several breaches in the walls; and it was apprehended that a general assault, which was hourly expected, would be fatal. A capitulation was therefore proposed, and a conference was already begun, when the countess, who had mounted on a high tower, and was looking towards the sea with great impatience, descried some ships at a distance. She immediately exclaimed that succours were arrived, and forbid any further capitulation. She was not disappointed in her wishes; the fleet she discerned carried a body of English gentlemen, with 6000 archers, whom Edward had prepared for the relief of Hennebone, but who had been long detained by contrary winds. They entered the harbour, under the conduct of Sir Walter Manny, one of the most valiant commanders of his time. This relief served to keep up the declining spirits of the Bretons, until the time appointed by the late truce with Edward was expired, on which he was at liberty to renew the war in greater form.

He accordingly soon after landed at Morbion, near Vannes, with an army of 12,000 men; and being master of the field, where no enemy dared to appear against him, he endeavoured to give lustre to his arms by besieging some of the most capital of the enemy's fortifications. The vigour of his operations led on to another truce, and this was soon after followed by a fresh infraction. The truth is, neither side observed a truce longer than it coincided with their interests; and both had always sufficient art to throw the blame of perfidy from themselves. The earl of Derby was sent by Edward to defend the province of Guienne, with instructions also to take every possible advantage that circumstances might offer. At first, therefore, his successes were rapid and brilliant; but as soon as the French king had time to prepare, he met with a very unexpected resistance; so that the English general was compelled to stand upon the defensive. One fortress after another was surrendered to the French; till at length nothing appeared but a total extinction of the power of England upon the continent. In this situation, Edward resolved to bring relief in person to his distressed subjects and allies; and accordingly embarked in 1346 at Southampton, on board a fleet of near 1000 sail, of all dimensions. He carried with him, besides all the chief nobility of England, his eldest son, the prince of Wales (afterwards surnamed the *Black Prince*); a youth of about 15 years old, and already remarkable both for understanding and valour above his age. His army consisted of 4000 men at arms, 10,000 archers, 10,000 Welsh infantry, and 6000 Irish; all which he landed safely at La Hogue, a port in Normandy, which country he determined to make the seat of the war.

The intelligence of Edward's landing, and the devastation caused by his troops, who dispersed themselves over the whole face of the country, soon spread universal consternation through the French court. The rich city of Caen was taken and plundered by the English, without mercy; the villages and towns, even up to Paris, shared the same fate; and the French had no other resource but by breaking down their bridges, to attempt putting a stop to the invader's career. In the mean time, Philip was not idle in making preparations to repress the enemy. He had stationed one of his generals,

my in Nor-
mandy.

als, Godemar de Faye, with an army on the opposite side of the river Somme, over which Edward was to pass; while he himself, at the head of 100,000 fighting men, advanced to give the English battle. Edward, thus unexpectedly exposed to the danger of being inclosed and starved in an enemy's country, published a reward to any that should bring him intelligence of a passage over the river Somme. This was discovered by a peasant of the country; and Edward had just time to get his whole army over the river, when Philip appeared in his rear.

41
The battle
of Crecy.

As both armies had been for some time in sight of each other, nothing was so eagerly expected on each side as a battle: and although the forces were extremely disproportioned, the English amounting only to 30,000, the French to 120,000; yet Edward resolved to indulge the impetuosity of his troops, and put all to the hazard of a battle. He accordingly chose his ground, with advantage, near the village of Crecy; and there determined to wait with tranquillity the shock of the enemy. He drew up his men on a gentle ascent, and divided them into three lines. The first was commanded by the young prince of Wales; the second was conducted by the earls of Northampton and Arundel; and the third, which was kept as a body of reserve, was headed by the king in person. As his small army was in danger of being surrounded, he threw up trenches on his flank; and placed all his baggage in a wood behind him, which he also secured by an entrenchment. Having thus made the proper dispositions, he and the prince of Wales received the sacrament with great devotion; and all his behaviour denoted the calm intrepidity of a man resolved on conquest or death. It is said also by some, that he first made use of artillery upon this occasion; and placed in his front some pieces, which contributed not a little to throw the enemy into disorder.

On the other side, Philip, impelled by resentment, and confident of his numbers, was more solicitous in bringing the enemy to an engagement, than prudent in taking measures for the success of it. He was advised by some of his generals to defer the combat till the ensuing day, when his army would have recovered from their fatigue, and might be disposed into better order than their present hurry permitted them to observe. But it was now too late; the impatience of his troops was too great to be restrained; they pressed one upon the other, and no orders could curb their blind impetuosity. They were led on, however, in three bodies to oppose those of the English. The first line, consisting 15,000 Genoese cross-bow men, were commanded by Anthony Doria. The second body was led by the count Alençon, brother to the king; and the king himself was at the head of the third.

About three in the afternoon, the famous battle of Crecy began, by the French king's ordering the Genoese archers to charge; but they were so fatigued with their march, that they cried out for a little rest before they should engage. The count Alençon, being informed of their petition, rode up and reviled them as cowards, commanding them to begin the onset without delay. Their reluctance to begin was still more increased by an heavy shower which fell that instant and relaxed their bow-strings, so that the discharge they made produced but very little effect. On the o-

ther hand, the English archers, who had kept their bows in cases, and were favoured by a sudden gleam of sun-shine, that rather dazzled the enemy, let fly their arrows so thick, and with such good aim, that nothing was to be seen among the Genoese but hurry, terror, and dismay. The young prince of Wales had presence of mind to take an advantage of their confusion, and to lead on his line to the charge. The French cavalry, however, commanded by count Alençon, wheeling round, sustained the combat, and began to hem the English round. The earls of Arundel and Northampton now came in to assist the prince, who appeared foremost in the very shock; and, wherever he appeared, turning the fortune of the day. The thickest of the battle was now gathered round him, and the valour of a boy filled even veterans with astonishment; but, being apprehensive that some mischance might happen to him in the end, an officer was dispatched to the king, desiring that succours might be sent to the prince's relief. Edward, who had all this time, with great tranquillity, viewed the engagement from a wind-mill, demanded with seeming deliberation if his son were dead: but being answered that he still lived, and was giving astonishing instances of valour; "Then tell my generals," (cried the king), "that he shall have no assistance from me; the honour of this day shall be his; let him shew himself worthy the profession of arms, and let him be indebted to his own merit alone for victory." This speech being reported to the prince and his attendants, it inspired them with new courage: they made a fresh attack upon the French cavalry; and count Alençon, their bravest commander, was slain. This was the beginning of their total overthrow: the French, being now without a competent leader, were thrown into confusion; the Welsh infantry rushed into the midst of the conflict, and dispatched those with their long knives who had survived the fury of the former onset. It was in vain that the king of France himself seemed almost singly to maintain the combat; he endeavoured to animate his few followers, both by his voice and example, but the victory was too decisive to be resisted; while he was yet endeavouring to face the enemy, John de Hainault seized the reins of his horse, and, turning him round, carried him off the field of battle. In this engagement, 30,000 of the French were killed upon the field: and, among this number, were John king of Bohemia; James, king of Majorca; Ralph, duke of Lorraine; 9 counts, 24 bannerets, 1200 knights, 1500 gentlemen, and 4000 men at arms. There was something remarkable in the fate of the Bohemian king; who, though blind, was yet willing to share in the engagement. This unfortunate monarch, inquiring the fate of the day, was told that all was lost, and his son Charles obliged to retire desperately wounded; and that the prince of Wales bore down every thing before him. Having received this information, blind as he was, he commanded his knights to lead him into the hottest part of the battle against the young warrior; accordingly, four of them rushed with him into the thickest part of the enemy, where they were all quickly slain.

The whole French army took to flight; and were put to the sword by the pursuers without mercy, till night stopped the carnage. The next morning was foggy; and a party of the militia of Rouen coming to join

42
French to-
tally defeat-
ed.

France.

join the French army, were routed by the English at the first onset; many more also were decoyed by some French standards, which the victors placed upon the mountains, and to which the fugitives resorted, where they were cut in pieces without mercy. Notwithstanding the great slaughter of the enemy, the conquerors lost but one esquire, three knights, and a few of inferior rank. The crest of the king of Bohemia was three ostrich feathers, with this motto, *Ich Dien*; which signifies, in the German language, "I serve." This was thought to be a proper prize to perpetuate the victory; it was accordingly added to the arms of the prince of Wales, and it has been adopted by all his successors.

43
Calais taken.

Edward next laid siege to Calais, which was then defended by John de Vienne, an experienced commander, and supplied with every thing necessary for defence. It was at length taken, after a twelvemonth's siege, the defendants having been reduced to the last extremity by famine and fatigue. The obstinate resistance, made by the townsmen, was not a little displeasing to Edward; and he had often declared, that when put in possession of the place, he would take signal revenge for the numbers of men he had lost during the siege. It was with great difficulty, therefore, that he was persuaded to accept of their submission; and to spare their lives, upon condition, that six of the most considerable citizens should be sent to him, to be disposed of as he should think proper: but on these he was resolved to wreck his resentment; and he gave orders that they should be led into his camp, bare-headed and barefooted, with ropes about their necks, in the manner of criminals just preparing for instant execution. When the news of this fierce resolution was brought into the city, it spread new consternation among the inhabitants. Who should be the men, that were thus to be offered up as victims to procure the safety of all the rest, and by their deaths appease the victor's resentment? In this terrible suspense, one of the principal inhabitants, whose name was *Eustace de St Pierre*, walked forward, and offered himself as willing to undergo any tortures that could procure his fellow-citizens safety. Five more soon followed his noble example; and these, marching out like criminals, laid the keys of their city at Edward's feet: but no submissions seemed to appease his resentment; and they would in all probability have suffered death, had not the generosity of their conduct affected the queen, who interceded in their behalf, and with some difficulty obtained their pardon.

In 1350, a short truce, which had been concluded between Edward and Philip, was dissolved by the death of the latter, who was succeeded by his son John; and Edward, well pleased with the factions that then prevailed in France, was resolved to seize the opportunity of increasing its distresses. Accordingly, the Black Prince was sent into France with an army, on board a fleet of 100 sail; and landing in Gascony, carried his devastations into the heart of the country. At the same time, Edward himself made an irruption on the side of Calais, at the head of a numerous army, and ravaged all the open country. On the other hand, John, who was as yet unprepared to oppose the progress of the enemy, continued a spectator of their insults; nor was it till the summer's campaign, in 1355, that he resolved to attack

France.

the Black Prince, whose army was by this time reduced to a body of about 12,000 men. With such a trifling complement of forces had this young warrior ventured to penetrate into the heart of France, with a design of joining the duke of Lancaster in Guienne. But he soon found that his scheme was impracticable: the country before him was too well guarded to permit his advancing further; and all the bridges behind were broken down, which effectually barred a retreat. In this embarrassing situation, his perplexity was increased, by being informed, that the king of France was actually marching at the head of 60,000 men to intercept him. He at first thought of retreating; but soon finding it impossible, he determined calmly to await the approach of the enemy; and, notwithstanding the disparity of forces, to commit all to the hazard of a battle.

It was at a place called *Mauportuis*, near Poitiers, ⁴⁴ Battle of Poitiers. that both armies came in sight of each other. The French king might very easily have harried the English into any terms he thought proper to impose; but such was the impatient valour of the French nobility, and such their certainty of success, that it might have been equally fatal to attempt repressing their ardour to engage. In the mean time, while both armies were drawn out, and expecting the signal to begin, they were stopped by the appearance of the cardinal of Perigord, who attempted to be a mediator between them. However, John, who made himself sure of victory, would listen to no other terms than the restitution of Calais; with which the Black Prince refusing to comply, the onset was deferred till the next morning, for which both sides waited in anxious suspense.

During this interval, the young prince strengthened his post by new entrenchments; and placed 300 men in ambush, with as many archers, who were commanded to attack the enemy in flank during the heat of the engagement. Having taken these precautions, he ranged his army in three divisions; the van was commanded by the earl of Warwick, the rear by the earls of Salisbury and Suffolk, and the main body by himself. In like manner, the king of France arranged his forces in three divisions; the first commanded by the duke of Orleans; the second by the Dauphin, attended by his younger brothers; while he himself led up the main body, seconded by his youngest and favourite son, then about 14 years of age. As the English were to be attacked only by marching up a long narrow lane, the French suffered greatly from their archers, who were posted on each side, behind the hedges. Nor were they in a better situation upon emerging from this danger, being met by the Black Prince himself, at the head of a chosen body of troops, who made a furious onset upon their forces, already in great disorder. A dreadful overthrow ensued: those who were as yet in the lane recoiled upon their own forces; while the English troops who had been placed in ambush, took that opportunity to increase the confusion, and confirm the victory. The dauphin and the duke of Orleans were among the first that fled. The king of France himself made the utmost efforts to retrieve, by his valour, what his rashness had forfeited: but his single courage was unable to stop that conflagration, which had now become general through his army; and his cavalry soon flying, he found himself exposed to the enemy's fury.

45
French defeated.

At

France.

46
King John
taken pri-
soner.

At length, spent with fatigue, and despairing of success, he thought of yielding himself a prisoner; and frequently cried out, that he was ready to deliver himself to his cousin the prince of Wales. The honour of taking him, however, was reserved for a much more ignoble hand; he was seized by Dennis de Morbec, a knight of Arras, who had been obliged to fly his country for murder.

In April following, the prince conducted his royal prisoner through London, attended by an infinite concourse of people of all ranks and stations. His modesty upon this occasion was very remarkable: the king of France was clad in royal apparel, and mounted on a white steed distinguished by its size and beauty; while the prince himself rode by his side upon a mean little horse, and in very plain attire.

47
Decline of
the English
affairs.

Notwithstanding all this success of the English, however, the conquest of France appeared very distant; nor could all the valour of the Black Prince afterwards accomplish any thing of moment. The dauphin, being created regent of France, collected all his forces; and, by acting on the defensive, prevented Edward from gaining any considerable advantage. All the considerable towns were put into a posture of defence, and every thing valuable in the kingdom was secured in fortified places. It was therefore at last concluded, that king John should be restored to liberty upon paying a ransom of about a million and a half of our money. It was stipulated, that Edward should for ever renounce all claim to the kingdom of France: and should only remain possessed of the territories of Poitou, Saintonge, l'Agenois, Perigord, the Limousin, Quercy, Rouvergne, l'Angoumois, and other districts in that quarter, together with Calais, Guines, Montreuil, and the county of Ponthieu on the other side of France. Some other stipulations were made in favour of the allies of England, as a security for the execution of these conditions.

48
John, un-
able to pay
his ransom,
returns to
England.

Upon John's return to his dominions, he found himself very ill able to ratify those terms of peace that had been just concluded. He was without finances, at the head of an exhausted state; his soldiers without discipline, and his peasants without subordination. There had risen in great numbers; and one of the chiefs of their banditti assumed the title of *The Friend of God, and the Terror of Man*. A citizen of Sens, named *John Gouge*, also got himself, by means of his robberies, to be acknowledged king; and he soon caused as many calamities by his devastations, as the real king had brought on by his misfortunes. Such was the state of that wretched kingdom, upon the return of its captive monarch: and yet, such was his absurdity, that he immediately prepared for a crusade into the Holy Land, before he was well replaced on the throne. Had his exhausted subjects been able to equip him for this chimerical project, it is probable he would have gone through with it; but their miseries were such, that they were even too poor to pay his ransom. This was a breach of treaty that John would not submit to; and he was heard to express himself in a very noble manner upon the occasion: "Tho' (says he) good faith should be banished from the rest of the earth, yet she ought still to retain her habitation in the breast of kings." In consequence of this declaration, he actually returned to England once more; and yielded

himself a prisoner, since he could not be honourably free. It is said by some, that his passion for the countess of Salisbury was the real cause of his journey: but we want at this time the foundations for such an injurious report. He was lodged in the Savoy, the palace where he had resided during his captivity; and soon after he closed a long and unfortunate reign, by his death, which happened in the year 1384, about the 56th year of his age.

Charles, surnamed *the Wise*, succeeded his father on the throne of France; and this monarch, merely by the force of a finely conducted policy, and even tho' suffering some defeats, restored his country once more to tranquillity and power. He quelled and dissipated a set of banditti, who had associated themselves under the name of *Companions*, and who had long been a terror to the peaceable inhabitants. He had them enrolled into a body, and led them into the kingdom of Castile against Peter, surnamed *the Cruel*, whom his subjects had dethroned, and who, by means of an alliance with the English, endeavoured to get himself reinstated upon the throne. In consequence of these alliances, the English and French again came to an engagement; their armies on the one side commanded by the Black Prince; on the other, by Henry of Transtamare, and Bertrand du Guesclin, one of the most consummate generals and accomplished characters of the age in which he lived. However, the usual good fortune of the English prince prevailed; the French lost above 20,000 men, while only four knights and 40 private men on the side of the English were slain.

Nevertheless, these victories were attended with very few good effects. The English, by their frequent levies, had been quite exhausted, and were unable to continue an army in the field. Charles, on the other hand, cautiously forbore coming to any decisive engagement; but was contented to let his enemies waste their strength in attempts to plunder a fortified country. When they were retired, he then was sure to fall forth, and possess himself of such places as they were not strong enough to defend. He first fell upon Ponthieu; the citizens of Abbeville opened their gates to him; those of St Valois, Rue, and Crotoy, imitated the example; and the whole country was, in a little time, reduced to total submission. The southern provinces were, in the same manner, invaded by his generals with equal success: while the Black Prince, destitute of supplies from England, and wasted by a cruel and consumptive disorder, was obliged to return to his native country, leaving his affairs in the south of France in a desperate condition.

In this exigence, the resentment of the king of England was excited to the utmost pitch; and he seemed resolved to take signal vengeance on his enemies of the continent. But the fortunate occasion was now elapsed; and all his succeeding designs were marked with ill success. The earl of Pembroke, and his whole army, were intercepted at sea, and taken prisoners by Henry king of Castile. Sir Robert Knolles, one of his generals on the continent, at the head of 30,000 men, was defeated by Bertrand du Guesclin; while the duke of Lancaster, at the head of 25,000 men, had the mortification of seeing his troops diminished one half by flying parties, without ever coming to a battle.

Bad success
of the Eng-
lish.

At last, the English affairs were totally ruined by the death of the Black Prince and king Edward. On receiving this news, the armies of Charles attacked the English on all sides. One, under the command of the duke of Burgundy, entered Artois; another entered Auvergne, under the command of the duke of Berry; that which acted in Guienne was commanded by the duke of Anjou; and the forces in Bretagne were under the constable Guesclin: the king himself had a powerful body of troops, that he might be able to repair any accident which should happen through the chance of war. The constable joined the duke of Burgundy, who found it difficult to oppose Sir Thomas Felton and the Seneschal of Bourdeaux. Soon after his arrival, the constable attacked and defeated them, making both the commanders prisoners of war. This victory was followed, that, at the close of the campaign 1377, Bayonne and Bourdeaux, with the districts about them, and the fortresses of Calais with its dependencies, were all the places left to England on the continent.

51
Charles VI.

In 1379 the king died; and was succeeded by his son Charles VI. at that time 12 years old. During his minority, the public affairs fell into confusion, and the people were plundered by the nobility with impunity. In 1385, a prodigious armament was fitted out against England. A vast fleet was assembled in the harbour of Sluys, and a very numerous army in the neighbourhood. According to some writers, the armament consisted of 1200 ships, 20,000 foot differently armed, 20,000 cavalry, and 20,000 cross-bow men. There was besides a vast wooden edifice or floating-town, which was contrived for the protection of the soldiers when landed; but all these preparations were at last brought to nothing through the obstinacy of the duke of Berry; who, having been originally against this measure, carried on his part of the armament so slowly, that he did not arrive at Sluys till the middle of September, when the season was so far advanced, that no invasion was practicable. A storm that happened soon after, drove the greatest part of the fleet on shore, and beat the wooden edifice all to pieces; the remains of which the king bestowed on the duke of Burgundy, to whom he gave also the port of Sluys, which was then very commodious, and of the utmost importance.

In 1391, one P. Craon attempted to assassinate the new constable de Clisson; and, (after having, with a band of ruffians, given him 50 wounds, of all which, however, he recovered), fled to Bretagne, where he was protected by the duke of that country. The king demanded the assassin to be given up to him in chains; but the duke answered, that he knew nothing of him: to which the king giving no credit, marched with all his forces into his territories. When the army arrived at Mans, the king was seized with a flow fever; but could not be prevailed upon to rest or take physic. On the 5th of August, having marched all day in the heat of the sun, a miserable, ragged, wild-looking fellow darted from behind a tree, and laying hold of the bridle of his horse, cried out, "Stop! where are you going, king? You are betrayed;" and immediately withdrew again into the wood. The king passed on, not a little disturbed; and soon after one of the pages, who rode behind and carried his lance, overcame with heat, fell asleep, and let it fall upon the helmet which was carried by the other. The king, hearing the noise, look-

ed about; and perceiving the page lifting the lance, killed him immediately: then riding furiously with his sword drawn, he struck on every side of him, and at every person, till he broke his sword; upon which one of his gentlemen leaped up behind him and held his arm. He fell soon after, and lay as if he had been dead; so that being taken up and bound in a wagon, he was carried back to Mans, where he lay two days in a lethargy, after which he came a little to himself. From this time the king continued frantic at intervals, which gave occasion to the greatest disorders throughout the kingdom. The administration of affairs was disputed between his brother Lewis duke of Orleans, and his cousin-german John duke of Burgundy. Isabella, his queen, also had her party; and the king vainly attempted to secure one likewise in his favour. Each of these, as they happened to prevail, branded their captives with the name of traitors; and the gibbets were at once hung with the bodies of the accused and the accusers. This, therefore, was thought by Henry V. of England a favourable opportunity to recover from France those grants that had been formerly given up by treaty. But previously, to give his intended expedition the appearance of justice, he sent over ambassadors to Paris, offering a perpetual peace and alliance, on condition of being put in possession of all those provinces which had been ravished from the English during some former reigns, and of espousing Catharine, the French king's daughter, in marriage, with a suitable dowry. Though the French court was at that time extremely averse to war, yet the exorbitance of these demands could not be complied with; and Henry very probably made them in hopes of a denial. He therefore assembled a great fleet and army at Southampton; and having allured all the military men of the kingdom to attend him, from the hopes of conquest, he put to sea, and landed at Harfleur, at the head of an army of 6000 men at arms, and 24,000 foot, mostly archers.

His first operations were upon Harfleur; which being pressed hard, promised at a certain day to surrender, unless relieved before that time. The day arriving, and the garrison, unmindful of their engagement, still resolving to defend the place, Henry ordered an assault to be made, took the town by storm, and put all the garrison to the sword. From thence, the victor advanced farther into the country, which had been already rendered desolate by factions, and which he now totally laid waste. But although the enemy made a feeble resistance, yet the climate seemed to fight against the English; a contagious dysentery carrying off three parts of Henry's army. In this situation, he had recourse to an expedient common enough in that barbarous age, to inspire his troops with confidence in their general. He challenged the dauphin, who commanded in the French army, to single combat, offering to stake his pretensions on the event. This challenge, as might naturally be expected, was rejected; and the French, though disagreeing internally, at last seemed to unite, at the appearance of the common danger. A numerous army of 14,000 men at arms, and 40,000 foot, was by this time assembled under the command of count Albert, and was now placed to intercept Henry's weakened forces on their return. The English monarch, when it was too late, began to re-

repeat

England.

France.

France.

pent of his rash inroad into a country, where disease and a powerful army every where threatened destruction; he therefore thought of retiring into Calais. In this retreat, which was at once both painful and dangerous, Henry took every precaution to inspire his troops with patience and perseverance; and shewed them in his own person the brightest example of fortitude and resignation. He was continually harraressed on his march by flying parties of the enemy; and whenever he attempted to pass the river Somme, across which his march lay, he saw troops on the other side ready to oppose his passage. However, he was so fortunate as to seize by surprise a passage near St Quintin, which had not been sufficiently guarded; and there he safely carried over his army.

54
Battle of
Azincourt.

But the enemy was still resolved to intercept his retreat: and after he had passed the small river of Ternois at Blangh, he was surprised to observe from the heights the whole French army drawn up in the plains of Azincourt; and so posted, that it was impossible for him to proceed on his march, without coming to an engagement. No situation could be more unfavourable than that in which he then found himself. His army was wasted by disease; the soldiers spirits worn down with fatigue; destitute of provisions, and discouraged by their retreat. Their whole body amounted but to 9000 men; and these were to sustain the shock of an enemy near ten times their number, headed by expert generals, and plentifully supplied with provisions. This disparity, as it depressed the English, so it raised the courage of the French in proportion; and so confident were these of success, that they began to treat for the ransom of their prisoners. Henry, on the other hand, though sensible of his extreme danger, did not omit any circumstance that could assist his situation. As the enemy were so much inferior, he drew up his army on a narrow ground between two woods, which guarded each flank; and patiently expected, in that position, the attack of the enemy. The constable of France was at the head of one army; and Henry himself, with Edward duke of York, commanded the other. For a time both armies, as if afraid to begin, kept silently gazing at each other, neither being willing to break their ranks by making the onset: which Henry perceiving, with a cheerful countenance he cried out, "My friends, since they will not begin, it is ours to let them the example; come on, and the blessed Trinity be our protection." Upon this, the whole army set forward with a shout, while the French still continued to wait their approach with interdict. The English archers, who had long been famous for their great skill, first let fly a shower of arrows three feet long, which did great execution. The French cavalry advancing to repel these, 200 bow-men, who lay till then concealed, rising on a sudden, let fly among them, and produced such a confusion, that the archers threw by their arrows, and, rushing in, fell upon them sword in hand. The French at first repulsed the assailants, who were enfeebled by disease: but these soon made up the defect by their valour; and, resolving to conquer or die, burst in upon the enemy with such impetuosity, that the French were obliged to give way.

In the mean time a body of English horse, which had been concealed in a neighbouring wood, rushing out, flanked the French infantry, and a general disor-

der began to ensue. The first line of the enemy being routed, the second line began to march up to interrupt the progress of the victory. Henry, therefore, alighting from his horse, presented himself to the enemy with an undaunted countenance; and at the head of his men fought on foot, encouraging some and assisting others. Eighteen French cavaliers, who were resolved to kill him, or die in the attempt, rushing from the ranks together, advanced; and one of them stunned the king with a blow of his battle-ax. They then fell upon him in a body; and he was upon the point of sinking under their blows, when David Gam, a valiant Welshman, aided by two of his countrymen, came up to the king's assistance, and soon turned the attention of the assailants from the king to themselves, till at length, being overpowered, they fell dead at his feet. Henry had by this time recovered his senses; and fresh troops advancing to his relief, the 18 French cavaliers were slain; upon which he knighted the Welshman who had so valiantly fallen in his defence. The heat of the engagement still increasing, Henry's courage seemed also to increase; and the most dangerous situation was where he fought in person: his brother, who was stunned by a blow, fell at his feet; and while the king was endeavouring to succour him, he received another blow himself, which threw him upon his knees. But he soon recovered: and leading on his troops with fresh ardour, they ran headlong upon the enemy; and put them into such disorder, that their leaders could never after bring them to the charge. The duke of Alençon, who commanded the second line, seeing it fly, resolved by one desperate stroke to retrieve the fortune of the day, or fall in the attempt. Wherefore, running up to Henry, and at the same time crying aloud, "that he was the duke of Alençon," he discharged such a blow on his head, that it carried off a part of the king's helmet; while, in the mean time, Henry, not having been able to ward off the blow, returned it, by striking the duke to the ground, and he was soon killed by the surrounding crowd, all the king's efforts to save him proving ineffectual. In this manner, the French were overthrown in every part of the field; their number, being crowded into a very narrow space, were incapable of either flying, or making any resistance; so that they covered the ground with heaps of slain. After all appearance of opposition was over, the English had leisure to make prisoners; and having advanced with uninterrupted success to the open plain, they there saw the remains of the French rear-guard, which still maintained a show of opposition. At the same time was heard an alarm from behind, which proceeded from a number of peasants, who had fallen upon the English baggage, and were putting those who guarded it to the sword. Henry, now seeing the enemy on all sides of him, began to entertain apprehensions from his prisoners, the number of whom exceeded even that of his army. He thought it necessary, therefore, to issue general orders for putting them to death; but on the discovery of the certainty of his victory, he stopped the slaughter, and was still able to save a great number.

This battle was very fatal to France, the number of princes and nobility slain or taken prisoners. The killed are computed on the whole to have amounted to 10,000 men; and as the loss fell chiefly upon the

55
French de-
fated.

France.

cavalry, it is pretended, that of these 8000 were gentlemen. The number of prisoners are computed at 14,000. All the English who were slain did not exceed 40; a number amazingly inconsiderable, if we compare the loss with the victory.

This victory, gained on the 25th of October 1415, how great soever it might have been, was attended with no immediate effects. Henry still continued to retreat after the battle of Azincourt, out of the kingdom; and carried his prisoners to Calais, and from thence to England. In 1517, he once more landed an army of 25,000 men in Normandy; and prepared to strike a decisive blow for the crown of France, to which the English monarchs had long made pretensions. That wretched country was now in a most deplorable situation. The whole kingdom appeared as one vast theatre of crimes, murders, injustice, and devastation. The duke of Orleans was assassinated by the duke of Burgundy; and the duke of Burgundy, in his turn, fell by the treachery of the dauphin. At the same time, the duke's son, desirous of revenging his father's death, entered into a secret treaty with the English; and a league was immediately concluded at Arras, between Henry and the young duke of Burgundy, in which the king promised to revenge the murder of the late duke; and the son seemed to insist upon no further stipulations. Henry, therefore, proceeded in his conquests, without much opposition from any quarter. Several towns and provinces submitted on his approach; the city of Rouen was besieged and taken; Pontoise and Gisors he soon became master of. He even threatened Paris by the terror of his power, and obliged the court to remove to Troye. It was at this city that the duke of Burgundy, who had taken upon him the protection of the French king, met Henry in order to ratify that treaty which was formerly begun, and by which the crown of France was to be transferred to a stranger. The imbecility into which Charles had fallen, made him passive in this remarkable treaty; and Henry dictated the terms throughout the whole negotiation. The principal articles of this treaty were, That Henry should espouse the princess Catharine; that king Charles should enjoy the title and dignity of king for life; but that Henry should be declared heir to the crown, and should be intrusted with the present administration of the government; that France and England should for ever be united under one king, but should still retain their respective laws and privileges; that Henry should unite his arms with those of king Charles and the duke of Burgundy, to depress and subdue the dauphin and his partizans.

It was not long after this treaty, that Henry married the princess Catharine; after which he carried his father-in-law to Paris, and took a formal possession of that capital. There he obtained, from the estates of the kingdom, a ratification of the late compact; and then turned his arms, with success, against the adherents of the dauphin, who, in the mean time, wandered about a stranger in his own patrimony, and to his enemies successful only opposed fruitless expostulations.

Henry's supplies were not provided in such plenty as to enable him to carry on the war, without returning in person to prevail upon his parliament for fresh succours; and upon his arrival in England, though

he found his subjects highly pleased with the splendor of his conquests, yet they seemed somewhat doubtful as to the advantage of them. A treaty, which in its consequences was likely to transfer the seat of empire from England, was not much relished by the parliament. They therefore, upon various pretences, refused him a supply equal to his exigencies or his demands; but he was resolved on pursuing his schemes; and, joining to the supplies granted at home, the contributions levied on the conquered provinces, he was able once more to assemble an army of 28,000 men, and with these he landed safely at Calais.

In the mean time, the dauphin, a prince of great prudence and activity, omitted no opportunity of repairing his ruined situation, and to take the advantage of Henry's absence from France. He prevailed upon the regent of Scotland to send him a body of 8000 men from that kingdom; and with these, and some few forces of his own, he attacked the duke of Clarence, who commanded the troops in Henry's absence, and gained a complete victory.

This was the first action which turned the tide of success against the English. But it was of short duration: for Henry soon after appearing with a considerable army, the dauphin fled at his approach; while many of the places, which held out for the dauphin in the neighbourhood of Paris, surrendered to the conqueror. In this manner, while Henry was every where victorious, he fixed his residence at Paris; and while Charles had a small court, he was attended with a very magnificent one. On Whit Sunday 1421, the two kings and their two queens with crowns on their heads dined together in public; Charles receiving apparent homage, but Henry commanding with absolute authority.

In the mean time, the dauphin was chafed beyond the Loire, and almost totally dispossessed of all the northern provinces. He was even pursued into the south, by the united arms of the English and Burgundians, and threatened with total destruction. In this exigence, he found it necessary to spin out the war, and to evade all hazardous actions with a rival who had been long accustomed to victory. His prudence was every where remarkable; and, after a train of long persecutions from fortune, he found her at length willing to declare in his favour, by the death of the king of England.

Charles VI. died a short time after; and Charles VII. succeeded his father to a nominal throne. Nothing could be more deplorable than the situation of that monarch on assuming his title to the crown. The English were masters of almost all France; and Henry VI. though yet but an infant, was solemnly invested with regal power by legates from Paris. The duke of Bedford was at the head of a numerous army, in the heart of the kingdom, ready to oppose every insurrection; while the duke of Burgundy, who had entered into a firm confederacy with him, still remained steadfast, and seconded his claims. Yet, notwithstanding these favourable appearances, Charles found means to break the leagues formed against him, and to bring back his subjects to their natural interests and their duty.

However, his first attempts were totally destitute of success. Wherever he endeavoured to face the enemy he was overthrown, and he could scarcely rely on the

friends next his servant. His authority was insulted even by his own persons; advantage after advantage was gained against him; and a battle fought near Verneuil, in which he was totally defeated by the duke of Bedford, seemed to render his affairs altogether desperate. But from the impossibility of the English keeping the field without new supplies, Bedford was obliged to retire into England; and, in the mean time, his vigilant enemy began to recover from his late consternation. Dunois, one of his generals, at the head of 1000 men, compelled the earl of Warwick to raise the siege of Montargis; and this advantage, slight as it was, began to make the French suppose that the English were not invincible.

60
The French
affairs re-
trieved by
the Maid
of Orleans.

But they soon had still greater reason to triumph in their change of fortune, and a new revolution was produced by means apparently the most unlikely to be attended with success. In the village of Domremi, near Vaucouleurs, on the borders of Lorraine, there lived a country-girl, about 27 years of age, called *Joan of Arc*. This girl had been a servant at a small inn; and in that humble station had submitted to those hardy employments which fit the body for the fatigues of war. She was of an irreproachable life, and had hitherto testified none of those enterprising qualities which displayed themselves soon after. She contentedly fulfilled the duties of her situation, and was remarkable only for her modesty and love of religion. But the miseries of her country seemed to have been one of the greatest objects of her compassion and regard. Her mind inflamed by these objects, and brooding with melancholy steadfastness upon them, began to feel several impulses, which she was willing to mistake for the inspirations of heaven. Convinced of the reality of her own admonitions, she had recourse to one Baudricourt, governor of Vaucouleurs, and informed him of her destination by heaven to free her native country of its fierce invaders. Baudricourt treated her at first with neglect: but her importunities at length prevailed; and willing to make a trial of her pretensions, he gave her some attendants, who conducted her to the court, which at that time resided at Chinon.

The French court were probably sensible of the weakness of her pretensions; but they were willing to make use of every artifice to support their declining fortunes. It was therefore given out, that Joan was actually inspired; that she had been able to discover the king among the number of his courtiers, although he had laid aside all the distinctions of his authority; that she had told him some secrets, which were only known to himself; and that she had demanded, and minutely described, a sword in the church of St Catharine de Fierbois, which she had never seen. In this manner, the minds of the vulgar being prepared for her appearance, she was armed cap-à-pie, and shown in that martial dress to the people. She was then brought before the doctors of the university; and they, tinctured with the credulity of the times, or willing to second the imposture, declared that she had actually received her commission from above.

When the preparations for her mission were completely blazoned, the next aim was to send her against the enemy. The English were at that time besieging the city of Orleans, the last resource of Charles, and every thing promised them a speedy surrender. Joan

undertook to raise the siege; and to render herself still more remarkable, girded herself with the miraculous sword, of which she before had such extraordinary notices. Thus equipped, she ordered all the soldiers to confess themselves before they set out; the displayed in her hand a consecrated banner, and assured the troops of certain success. Such confidence on her side soon raised the spirits of the French army; and even the English, who pretended to despise her efforts, felt themselves secretly influenced with the terrors of her mission. A supply of provisions was to be conveyed into the town; Joan, at the head of some French troops, covered the embarkation, and entered Orleans at the head of the convoy which she had safely protected. While she was leading her troops along, a dead silence and astonishment reigned among the English; and they regarded with religious awe that temerity, which they thought nothing but supernatural assistance could inspire. But they were soon roused from their state of amazement by a sally from the town; Joan led on the besieged, bearing the sacred standard in her hand, encouraging them with her words and actions, bringing them to the trenches, and overpowering the besiegers in their own redoubts. In the attack of one of the forts, she was wounded in the neck with an arrow; but instantly pulling out the weapon with her own hands, and getting the wound quickly dressed, she hastened back to head the troops, and to plant her victorious banner on the ramparts of the enemy. These successes continuing, the English found that it was impossible to resist troops animated by such superior energy; and Suffolk, who conducted the attack, thinking that it might prove extremely dangerous to remain any longer in the presence of such a courageous and victorious enemy, raised the siege, and retreated with all imaginable precaution.

From being attacked, the French now in turn became the aggressors. Charles formed a body of 6000 men, and sent them to besiege Jargeau, whither the English, commanded by the earl of Suffolk, had retired, with a detachment of his army. The city was taken; Suffolk yielded himself a prisoner; and Joan marched into the place in triumph, at the head of the army. A battle was soon after fought near Patay, where the English were worsted, as before; and the generals, Scyles and Talbot, were taken prisoners.

The raising of the siege of Orleans was one part of the maid's promise to the king of France; the crowning him at Rheims was the other. She now declared, that it was time to complete that ceremony; and Charles, in pursuance of her advice, set out for Rheims at the head of 12,000 men. The towns thro' which he passed opened their gates to receive him; and Rheims sent him a deputation, with its keys, upon his approach. The ceremony of his coronation was there performed with the utmost solemnity; and the Maid of Orleans (for so she was now called) seeing the completion of her mission, desired leave to retire, alleging, that she had now accomplished the end of her calling. But her services had been so great, that the king could not think of parting with her; he pressed her to stay so earnestly, that she at length complied with his request.

A tide of successes followed the performance of this solemnity; Laon, Soissons, Chateau-Thierry, Provins,

France

France

vins, and many other fortresses in that neighbourhood, submitted to him on the first summons. On the other hand, the English, discomfited and dispirited, fled on every quarter; not knowing whether to ascribe their misfortunes to the power of sorcery, or to a celestial influence; but equally terrified at either. They now found themselves deprived of the conquests they had gained, in the same manner as the French had formerly submitted to their power. Their own divisions, both abroad and at home, unfitted them entirely for carrying on the war; and the duke of Bedford, notwithstanding all his prudence, saw himself divested of his strong-holds in the country, without being able to stop the enemy's progress. In order, therefore, to revive the declining state of his affairs, he resolved to have Henry crowned king at Paris, knowing that the natives would be allured to obedience by the splendour of the ceremony. In 1430, Henry was accordingly crowned, all the vassals that still continued under the English power swearing fealty and homage. But it was now too late for the ceremonies of a coronation to give a turn to the affairs of the English; the generality of the kingdom had declared against them, and the remainder only waited a convenient opportunity to follow the example.

An accident ensued soon after, which, though it promised to promote the English cause in France, in the end served to render it odious, and conducted to the total evacuation of that country. The duke of Burgundy, at the head of a powerful army, had laid siege to Compeign; and the Maid of Orleans had thrown herself into the place, contrary to the wishes of the governor, who did not desire the company of one whose authority would be greater than his own. The garrison, however, were rejoiced at her appearance, and believed themselves invincible under her protection. But their joy was of short duration; for Joan having the day after her arrival headed a sally, and twice driven the enemy from their intrenchments, she was at last obliged to retire, placing herself in the rear, to protect the retreat of her forces. But in the end, attempting to follow her troops into the city, she found the gates shut, and the bridge drawn up by order of the governor, who is said to have long wished for an opportunity of delivering her up to the enemy.

Nothing could exceed the joy of the besiegers, in having taken a person who had been so long a terror to their arms. The service of Te Deum was publicly celebrated on this occasion; and it was hoped, that the capture of this extraordinary person would restore the English to their former victories and successes. The duke of Bedford was no sooner informed of her being taken, than he purchased her of the count Vendome, who had made her his prisoner, and ordered her to be committed to close confinement. The credulity of both nations was at that time so great, that nothing was too absurd to gain belief, that coincided with their passions. As Joan but a little before, from her successes, was regarded as a saint, she was now, upon her captivity, considered as a sorceress, forsaken by the demon who had granted her a fallacious and temporary assistance. Accordingly it was resolved in council to send her to Rouen to be tried for witchcraft: and the bishop of Beauvais, a man wholly devoted to the English interest, presented a petition against her for

that purpose. The university of Paris was so mean as to join in the same request. Several prelates, among whom the cardinal of Winchester was the only Englishman, were appointed as her judges. They held their court in Rouen, where Henry then resided; and the Maid, clothed in her former military apparel, but loaded with irons, was produced before this tribunal. Her behaviour there noway disgraced her former gallantry; she betrayed neither weakness nor womanish submission; but appealed to God and the pope for the truth of her former revelations. In the issue, she was found guilty of heresy and witchcraft; and sentenced to be burnt alive, the common punishment for such offences.

But previous to the infliction of this dreadful sentence upon her, they were resolved to make her abjure her former errors; and at length so far prevailed upon her, by terror and rigorous treatment, that her spirits were entirely broken, by the hardships she was obliged to suffer. Her former visionary dreams began to vanish, and a gloomy distrust to take place of her late inspirations. She publicly declared herself willing to recant, and promised never more to give way to the vain delusions which had hitherto misled her, and imposed on the people. This was what her oppressors desired; and willing to shew some appearance of mercy, they changed her sentence into perpetual imprisonment, and to be fed during life on bread and water. But the rage of her enemies was not yet fatiated. Suspecting that the female dress, which she had consented to wear, was disagreeable to her, they purposely placed in her apartment a suit of men's apparel, and watched for the effect of their temptation upon her. Their cruel artifices prevailed. Joan, struck with the sight of a dress in which she had gained so much glory, immediately threw off her penitent's robes, and put on the forbidden garment. Her enemies caught her equipped in this manner; and her imprudence was considered as a relapse into her former transgressions. No recantation would suffice, and no pardon would be granted. She was condemned to be burnt alive in the market-place of Rouen; and this infamous sentence was accordingly executed with most brutal severity.

One of the first misfortunes which the English felt after this punishment, was the defection of the duke of Burgundy; who had for some time seen the error of his conduct, and wished to break an unnatural connection, that only served to involve his country in ruin. A treaty was therefore begun, and concluded, between him and Charles, in which the former agreed to assist him in driving the English out of France. This was a mortal blow to their cause; and such was its effects upon the populace of London, when they were informed of it, that they killed several of the duke of Burgundy's subjects, who happened to be among them at the time. It might perhaps also have hastened the duke of Bedford's death, who died at Rouen a few days after the treaty was concluded; and the earl of Cambridge was appointed his successor to the regency of France.

From this period, the English affairs became totally irretrievable. The city of Paris returned once more to a sense of its duty. Lord Willoughby, who commanded it for the English, was contented to stipulate

for the safe retreat of his troops to Normandy. Thus ground was continually, though slowly, gained by the French; and notwithstanding their fields were laid waste, and their towns depopulated, yet they found protection from the weakness and divisions of the English. At length, both parties began to grow weary of a war, which, though carried on but feebly, was yet a burden greater than either could support. But the terms of peace insisted upon by both were so wide of each other, that no hopes of an accommodation could quickly be expected. A truce, therefore, for twenty-two months, was concluded in 1443, which left every thing on the present footing between the parties. No sooner was this agreed upon, than Charles employed himself with great industry and judgment in repairing those numberless ills to which his kingdom, from the continuance of wars, both foreign and domestic, had so long been exposed. He established discipline among his troops, and justice among his governors. He revived agriculture, and repressed faction. Thus being prepared once more for taking the field, he took the first favourable occasion of breaking the truce; and Normandy was at the same time invaded by four powerful armies; one commanded by Charles himself, a second by the duke of Brittany, a third by the count of Alençon, and a fourth by the count Dunois. Every place opened their gates almost as soon as the French appeared before them. Rouen was the only one that promised to hold out a siege; but the inhabitants clamoured so loud for a surrender, that the duke of Somerset, who commanded the garrison, was obliged to capitulate. The battle, or rather the skirmish, of Fourmings, was the last stand which the English made in defence of their French dominions. However, they were put to the rout, and above a thousand were slain. All Normandy and Guienne, that had so long acknowledged subjection to England, were lost in the space of a year; and the English saw themselves entirely dispossessed of a country, which for above three centuries they had considered as annexed to their native dominions. Calais alone remained of all their conquests; and this was but a small compensation for the blood and treasure which had been lavished in that country, and only served to gratify ambition with a transient applause.

65
Death of
Charles VII.

Charles having thus expelled the English, found himself involved in domestic troubles. His son Lewis rebelled against him, and neither the king's valour nor wisdom were sufficient to bring him back to a sense of his duty. The king died in 1461, of a very strange disorder. One of his old servants intimated to him that he would do well to be cautious, since there was reason to suspect a design to poison him: which affected the king to such a degree, that he obstinately refused all sustenance for several days; and being at length persuaded to eat, it proved too late, for his bowels were collapsed, and nothing would pass. He died on the 22d of July 1461, in the 60th year of his age, and 39th of his reign.

66
Lewis XI.

Lewis XI. who succeeded his father Charles, was reckoned one of the greatest politicians that ever existed. He managed all his affairs with his neighbours, indeed, in such a manner as always to have the advantage over them, though this was often very much to the detriment of his moral character. He united to the

France.

crown of France, Burgundy, Anjou, Maine, Bar, and Provence, the best part of the county of Artois, and some great towns in Picardy; together with the counties of Rouillon, Cerdagne, and Boulogne. He first used the title of *Most Christian King* constantly, which has since passed to his successors; and he seems likewise to have been the first French monarch treated with the title of *Majesty*, in addresses to him from foreigners, as well as from his own subjects. He died in 1483, in the 61st year of his age, and 23d of his reign.

67
Charles VIII.

His successor Charles VIII. conquered Bretagne in the year 1489. The duke of this country was in alliance with Henry VII. of England. It was the interest of this monarch to have exerted himself to prevent such a conquest; but as his predominant passion was the love of money, he could not bear the thoughts of embarking in such an expensive project, till it was too late. In 1491, the king of France annexed that duchy unalienably to his crown, by marrying the young duchess, though she had been already contracted to the emperor Maximilian. By this piece of negligence, Henry suffered a great check on the power of the French monarchs to be removed; and ever since that time, England, even though united to Scotland, hath found it much harder to cope with France than before. After Bretagne was irreparably lost, however, the English monarch, urged by the clamours of his people, invaded France in 1492. He gave out that he had nothing less in view than an entire conquest of the country: nevertheless, on the third of November the same year, he made peace with Charles, on condition of his paying him 745,000 crowns, at that time, and a yearly pension of 25,000 crowns ever after.

68
His expedition
into
Italy, and
surprising
successes.

The king of France agreed to these terms the more readily, that he was impatient to undertake an expedition into Italy, in order to conquer the kingdom of Naples, to which he claimed a right. Most of his counsellors were against the expedition; but the king was inflexible, even though Ferdinand king of Naples offered to do homage for his kingdom, and pay him a tribute of 50,000 crowns a-year. He appointed Peter duke of Bourbon regent, in his absence, after which he set out on his expedition with very few troops and very little money. By the way he fell ill of the small-pox, but in a short time recovered, and entering Italy with only 6000 horse and 12,000 foot, he was attended with the most surprising success, traversing the whole country in six weeks, and becoming master of the kingdom of Naples in less than a fortnight. Such extraordinary good fortune seemed miraculous, and he was reckoned an instrument raised up by God to destroy the execrable tyrants with which Italy was at that time infested. Had Charles made use of this prepossession in his favour, and acted up to the character generally given him, he might have raised his name as high as any hero of antiquity. His behaviour, however, was of a very different nature. He amused himself with feasts and shews; and leaving his power in the hands of favourites, they abandoned it to whoever would purchase titles, places, or authority, at the rates they imposed; and the whole force he proposed to leave in his new conquered dominions amounted to no more than 4000 men.

But while Charles was thus losing his time, a league was concluded against him at Venice; into which entered

France.

tered the pope, the emperor Maximilian, the archduke Philip, Ludowick Sforza, and the Venetians. The confederates assembled an army of 40,000 men, commanded by Francis marquis of Mantua; and they waited for the king in the valley of Farnova, in the duchy of Parma, into which he defended with 9000 men. On the 6th of July 1495, he attacked the allies; and, notwithstanding their great superiority, defeated them, with the loss of only 80 of his own men. Thus he got safe to France; but his Italian dominions were lost almost as soon as he departed. Some schemes were proposed for recovering these conquests; but they were never put in execution, and the king died of an apoplexy in 1498.

69

His death.

Lewis XII. duke of Orleans, succeeded to the throne of France; and on his accession found the face of affairs in Italy very much changed to his advantage. The pope, Alexander VI. was very much in his interests, from the hopes of getting his son Cesar Borgia provided for: he had conciliated the friendship of the Venetians by promising them a part of the Milanese; he concluded a truce with the archduke Philip; and renewed his alliances with the crowns of England, Scotland, and Denmark. He then entered Italy with an army of 20,000 men; and being assisted by the Venetians, quickly conquered one part of the duchy, while they conquered the other, the duke himself being obliged to fly with his family to Inpruck. He then attacked Ferdinand of Spain with three armies at once, two to act by land, and one by sea; but none of these performing any thing remarkable, he was obliged to evacuate the kingdom of Naples in 1504.

70
Expedition
of Lewis
XII. into
Italy.

In 1506, the people of Genoa revolted; drove out the nobility; chose eight tribunes; and declared Paul Nuova, a silk-dyer, their duke: after which they expelled the French governor, and reduced a great part of the Riviera. This occasioned Lewis's return into Italy; where, in 1507, he obliged the Genoese to surrender at discretion; and, in 1508, entered into the league of Cambray, with the other princes who at that time wanted to reduce the overgrown power of the Venetians. Pope Julius II. who had been the first contriver of this league, very soon repented of it; and declared, that if the Venetians would restore the cities of Faenza and Rimini, which had been unjustly taken from him, he would be contented. This was refused; and in 1509, the forces of the republic received such an entire defeat from Lewis, that they agreed to restore not only the two cities demanded by pope Julius, but whatever else the allies required.

The pope now, instead of executing his treaties with his allies, made war on the king of France without the least provocation. Lewis called an assembly of his clergy; where it was determined, that in some cases it was lawful to make war upon the pope; upon which the king declared war against him, and committed the care of his army to the Marshal de Trivulce. He soon obliged the pope to retire into Ravenna; and in 1511, Gaston de Foix, duke of Nemours, gained a great victory at Ravenna, but was himself killed in the engagement. After his death the army disbanded for want of pay; and the French affairs in Italy, and every where else, fell into great confusion. They recovered the duchy of Milan, and lost it again in a few weeks. Henry VIII. of England invaded France, and took

France.

Terrunne and Tournay; and the Swifs invaded Burgundy with an army of 25,000 men. In this desperate situation of affairs the queen died, and Lewis put an end to the opposition of his most dangerous enemies by negotiating marriages. To Ferdinand of Spain, he offered his second daughter for either of his grandsons, Charles or Ferdinand; and to renounce, in favour of that marriage, his claims on Milan and Genoa. This proposal was accepted; and Lewis himself married the princess Mary, sister to Henry VIII. of England. This marriage he did not long survive, but died on the 2d of January 1514; and was succeeded by Francis I. count of Angoulême, and duke of Bretagne and Valois.

71

His marriage with the princess Mary of England, and death.

72

The new king was no sooner seated on the throne, Francis I. than he resolved on an expedition into Italy. In this he was at first successful, defeating the Swifs at Marignano, and reducing the duchy of Milan. In 1518, the emperor Maximilian dying, Francis was very ambitious of being his successor, and thereby restoring to France such a splendid title, which had been so long lost. But Maximilian, before his death, had exerted himself so much in favour of Charles V. of Spain, that Francis found it impossible to succeed; and from that time an irreconcilable hatred took place between the two monarchs. In 1521, this ill-will produced a war; which, however, might perhaps have been terminated if Francis could have been prevailed upon to restore the town of Fontarabia, which had been taken by his admiral Bonivet: but this being refused, hostilities were renewed with greater vigour than ever; nor were they concluded till France was brought to the very brink of destruction. The war was continued with various success, till the year 1524; when Francis, having invaded Italy, and laid siege to Pavia, he was utterly defeated before that city, and taken prisoner on the 24th of February, and taken prisoner.

Italy.

73

Defeated that city, and taken prisoner on the 24th of February, and taken prisoner.

This disaster threw the whole kingdom into the utmost confusion. The Flemish troops made continual incursions; many thousand boors assembled in Alsace, in order to make an invasion from that quarter; Henry VIII. had assembled a great army, and threatened the kingdom on that side also; and a party was formed in the kingdom, in order to dispossess the dukes of the regency, and confer it upon the duke de Vendosme. This prince, however, who, after the constable, was the head of the House of Bourbon, went on purpose to Lyons, where he assured the regent that he had no view but for her service, and that of his country; upon which she formed a council of the ablest men of the kingdom, and of this he made him president. The famous Andrew Doria sailed with the French galleys to take on board the remains of the French troops under the duke of Alva, whom he landed safely in France. Those who escaped out of the Milanese also made their way back again as well as they could. Henry VIII. under the influence of cardinal Wolsey, resolved not to oppress the oppressed: he therefore assured the regent that he had nothing to fear from him; and at the same time advised her not to consent to any treaty by which France was to be dismembered. To the emperor, however, he used another language. He told him, that the time was now come when this pious monarchy lay at their mercy; and therefore, that so favourable an opportunity should not be let slip: that, for his part, he should be content with Norman-

dy.

dy, Guienne, and Gascony, and hoped the empire would make no scruple of owning him king of France; adding, that he expected the emperor would make a right use of his victory, by entering Guienne in person, in which case he was ready to bear half the expenses of the war. He foresaw what fell out: the emperor was alarmed at these conditions, and did not care to have him for a neighbour; for which reason he agreed to a truce with the regent for six months. In Picardy the Flemings were repulsed; and the count de Guise, with the duke of Lorrain, had the good fortune, with a handful of troops, to defeat and cut to pieces the German peasants.

74
Francis I.
carried to
Madrid,
where he
signs a dis-
advanta-
geous treat-
ty;

In the mean time, Francis was detained in captivity in Italy: but being wearied of his confinement in that country, and the princes of Italy beginning to cabal for his deliverance, he was carried to Madrid; where, on the 14th of January 1525, he signed a treaty, the principal articles of which were, That he should resign to the emperor the duchy of Burgundy in full sovereignty; that he should desist from the homage which the emperor owed him for Artois and Flanders; that he should renounce all claim to Naples, Milan, Asti, Tournay, Lisle, and Hesdin, &c.; that he should persuade Henry d'Albret to resign the kingdom of Navarre to the emperor, or at least should give him no assistance; that within 40 days he should restore the duke of Bourbon and all his party to their estates; that he should pay the king of England 500,000 crowns which the emperor owed him; that when the emperor went to Italy to receive the Imperial crown, he should lend him 12 galleys, four large ships, and a land-army, or instead of it 200,000 crowns.

All these articles the king of France promised on the word and honour of a prince to execute; or, in case of non-performance, to return prisoner into Spain. But, notwithstanding these professions, Francis had already protested before certain notaries and witnesses in whom he could trust, that the treaty he was about to sign was against his will, and therefore null and void. On the 21st of February, the emperor thought fit to release him from his prison, in which he had been closely confined ever since his arrival in Spain; and after receiving the strongest assurances from his own mouth, that he would literally fulfil the terms of the treaty, sent him under a strong guard to the frontiers, where he was exchanged for his two eldest sons, who were to remain as hostages for his fidelity.

75
And breaks
it.

When the king returned to his dominions, his first care was to get himself absolved by the Pope from the oaths he had taken; after which he entered into a league with the pontiff, the Venetians, the duke of Milan, and the king of England, for preserving the peace of Italy. In the month of June, he publicly received remonstrances from the states of Burgundy; in which they told him, without ceremony, that by the treaty of Madrid he had done what he had no right to do, in breach of the laws and his coronation-oath; adding, that if he persisted in his resolution of throwing them under a foreign yoke, they must appeal to the General States of the kingdom. At these remonstrances the viceroy of Naples and the Spanish ministers were present. They perceived the end which the king aimed at, and therefore expostulated with him in pretty warm terms. At last the viceroy told

him, that he had now nothing left but to keep his royal word in returning to the castle of Madrid, as his predecessor John had done in a like case. To this the king replied, that king John acted rightly; that he returned to a king who had treated him like a king, but that at Madrid he had received such usage as would have been unbecoming to a gentleman: that he had often declared to the emperor's ministers, that the terms they extorted from him were unjust and impracticable; but, that he was still willing to do all that was fit and reasonable; and to ransom his sons, at the rate of two millions of gold, in lieu of the duchy of Burgundy.

Hitherto the treaty for the tranquillity of Italy had been kept secret, in hopes that some mitigation of the treaty of Madrid would have been obtained: but now it was judged expedient to publish it, though the viceroy of Naples and the Spanish lords were still at the French court; and the emperor was to be admitted into it, provided he accepted the king's offer of two millions for the release of his children, and left the duke of Milan and other Italian princes in quiet possession of their dominions. It is the common misfortune of all leagues, that the powers who enter into them keep only their own particular interests in view, and thus defeat the general intention of the confederacy. This was the case here. The king's great point was to obtain his children upon the terms he had proposed; and he was desirous of knowing what hopes there were of that, before he acted against the monarch who had them in his power. Thus the duke of Milan and the Pope were both sacrificed. The former was obliged to surrender to the duke of Bourbon, and the latter was surprised by the Colonnas; both of which disasters would have been prevented if the French success had entered Italy in time. See ITALY.

According to an agreement which had been made between Francis and Henry, their ambassadors went into Spain, attended each of them by a herald, in order to summon the emperor to accept the terms which had been offered him; or, in case of refusal, to declare war. It seems the emperor's answer was foreseen in the court of France: and therefore, the king had previously called together an assembly of the notables; that is, persons of the several ranks of his people in whom he could confide. To them he proposed the great question: Whether he was bound to perform the treaty of Madrid; or, Whether, if he did not perform it, he was obliged in honour to return to Spain? To both these questions, the assembly answered in the negative: they said, that Burgundy was united to the crown of France, and that he could not separate it by his own authority; that his person also was the property of the public, of which therefore he could not dispose; but for the two millions, which they looked upon as a just equivalent, they undertook that it should be raised for his service. When the ambassadors delivered their propositions, Charles treated the English herald with respect, and the French one with contempt; which produced a challenge from Francis to the emperor*. All differences, however, were at last adjusted; and a treaty was concluded at Cambray, on the 5th of August 1528. By this treaty, instead of the possession, the emperor contented himself with reserving his rights to the duchy of Burgundy, and the

Cambray.

France.

two millions of crowns already mentioned. Of these he was to receive 1,200,000 in ready money; the prince's lands in Flanders belonging to the House of Bourbon, were to be delivered up; these were valued at 400,000 more: and the remaining 400,000 were to be paid by France in discharge of the emperor's debt to England. Francis was likewise to discharge the penalty of 500,000 crowns which the emperor had incurred, by not marrying his niece the princess Mary of England; and to release a rich *seigneur* which had been many years before pawned by the house of Burgundy for 50,000 crowns. The town and castle of Hesdin were also yielded; together with the sovereignty of Flanders and Artois, and all the king's pretensions in Italy. As for the allies of France, they were abandoned to the emperor's mercy, without the least stipulation in their favour; and Francis himself protested against the validity of the treaty before he ratified it, as did also his attorney general before he registered it in parliament; but both of them with the greatest secrecy imaginable.

Nothing farther of much consequence happened during the remainder of the reign of Francis I. The war was soon renewed with Charles, who made an invasion into France, but with very bad success; nor was peace fully established but by the death of Francis, which happened on the 3d of March, 1547. He was succeeded by his son Henry II. who ascended the throne that very day on which he was 29 years of age. In the beginning of his reign, an insurrection happened in Guienne, owing to the oppressive conduct of the officers who levied the salt tax. The king dispatched against the insurgents two bodies of troops; one commanded by the duke of Aumale son to the duke of Guise, the other by the constable. The first behaved with the greatest moderation, and brought back the people to their duty without making many examples: the other behaved with the utmost haughtiness and cruelty; and though the king afterwards remitted many of his punishments, yet from that time the constable became odious to the people, while the family of Guise were highly respected.

In 1548, the king began to execute the edicts which had been made against the Protestants, with the utmost severity; and, thinking even the clergy too mild in the prosecution of heresy, erected for that purpose a chamber composed of members of the parliament of Paris. At the queen's coronation, which happened this year, he caused a number of Protestants to be burned, and was himself present at the spectacle. He was, however, so much shocked, that he could never forget it; but complained, as long as he lived, that, at certain times, it appeared before his eyes, and troubled his understanding.

In 1549, a peace being concluded with England, the king purchased Boulogne from the latter, for the sum of 400,000 crowns; one half to be paid on the day of restitution, and the other a few months after. Scotland was included in the treaty, and the English restored some places they had taken there. This was the most advantageous peace that France had hitherto made with England; the vast arrears which were due to that crown being in effect remitted; and the pension, which looked so like tribute, not being mentioned, was in fact extinguished. The earl of Warwick him-

self, who had concluded the peace, was so sensible of the disgrace suffered by his nation on this occasion, that he pretended to be sick, in order to avoid setting his hand to such a scandalous bargain.

This year, an edict was made to restrain the extravagant remittances which the clergy had been in use of making to the court of Rome, and for correcting some other abuses committed by the papal notaries. With this edict pope Julius III. was highly displeased; and the following year (1550), war was declared by the king of France against the pope and the emperor. The pretence was, that Henry protected Octavio Farnese duke of Parma, whom the pope was desirous of depriving of his dominions. In this war the king was threatened with the censures of the church, more especially when it was known that he had entered into an alliance with the Turks, and a Turkish fleet entered the Mediterranean, where they threatened the Isle of Gozo, and made descents upon Sicily. Henry, however, strongly denied any such connection, and insisted that the emperor had given them sufficient provocation: but, be this as it will, the emperor soon found himself in such danger from these new enemies, that he could not support the pope as he intended, who on that account was obliged to sue for peace. After this, the king continued the war against the emperor with success; reducing the cities of Toul, Verdun, and Metz. He then entered the country of Alsace, and reduced all the fortresses between Haguenau and Wissemburg. He failed, however, in his attempt on Strasburgh; and was soon after obliged by the German princes and the Swiss to desist from further conquests on that side. This war continued with very little interruption, and as little success on the part of the French, till the year 1557, when a peace was concluded; and soon after, the king was killed at a tournament by one count de Montgomery, who was reckoned one of the strongest knights in France, and who had done all he could to avoid this encounter with the king.

The reign of his successor Francis II. was remarkable only for the persecution of the Protestants; which became so grievous, that they were obliged to take up arms in their own defence. This occasioned several civil wars, the first of which commenced in the reign of Charles IX. who succeeded to the throne in 1560. This first war continued till the year 1562, when a peace was concluded, by which the Protestants were to have a free pardon, and liberty of conscience. In 1565, the war broke out anew, and was continued with very little interruption till 1569, when peace was again concluded upon very advantageous terms for the Protestants. After this, king Charles, who had now taken the government into his hands, cared for the Protestants in an extraordinary manner. He invited to court the admiral Coligni, who was the head of the Protestant party; and caressed him so, that he was lulled into a perfect security, notwithstanding the many warnings given him by his friends, that the king's fair speeches were by no means to be trusted: but he had soon reason to repent his confidence. On the 22d of August 1571, as he was walking from the court to his lodgings, he received a shot from a window; which carried away the second finger of his right hand, and wounded him grievously in the left arm. This he himself ascribed

ascribed to the malice of the duke of Guise, the head of the Catholic party. After dinner, however, the king went to pay him a visit, and amongst others made him this compliment, " You have received the wound, but it is I who suffer;" desiring at the same time, that he would order his friends to quarter about his house, and promising to hinder the Catholics from entering that quarter after it was dark. This satisfied the admiral of the king's sincerity; and hindered him from complying with the desires of his friends, who would have carried him away, and who were strong enough to have forced a passage out of Paris if they had attempted it.

82
Dreadful
massacre of
the Prote-
stants.

In the evening, the queen-mother, Katherine de Medicis, held a cabinet-council to fix the execution of the massacre of the Protestants, which had been long meditated. The persons of which this council was composed, were, Henry duke of Anjou, the king's brother; Gonzague duke of Nevers; Henry of Angoulême, grand prior of France, and bastard brother of the king; the marshal de Tavannes; and Albert de Gondi, count de Rhetz. The direction of the whole was given to the duke of Guise, to whom the administration had been entirely confided during the former reign. The guards were appointed to be in arms, and the city-officers were to dispose the militia to execute the king's orders, of which the signal was the ringing of a bell near the Louvre. Some say, that when the hour approached, which was that of midnight, the king grew indetermined: that he expressed his horror at shedding so much blood, especially considering that the people whom he was going to destroy were his subjects, who had come to the capital at his command, and in confidence of his word; and particularly the admiral, whom he had detained so lately by his caresses. The queen-mother, however, reproached him with his cowardice, and represented to him the great danger he was in from the Protestants; which at last induced him to consent. According to others, however, the king himself urged on the massacre; and when it was proposed to him to take off only a few of the heads, he cried out, " If any are to die, let there not be one left to reproach me with breach of faith."

As soon as the signal was given, a body of Swiss troops, of the Catholic religion, headed by the duke of Guise, the chevalier d'Angoulême, accompanied by many persons of quality, attacked the admiral's house. Having forced open the doors, the foremost of the assassins rushed into his apartment; and one of them asked if he was Coligni? To this he answered that he was; adding, " Young man, respect these grey hairs:" to which the assassin replied by running him through the body with his sword. The duke of Guise and the chevalier, growing impatient below stairs, cried out to know if the business was done; and being told that it was, commanded that the body should be thrown out at the window. As soon as it fell on the ground, the chevalier, or (as some say) the duke of Guise, wiping the blood off the face kicked it with his foot. The body was then abandoned to the fury of the populace; who, after a series of indignities, dragged it to the common gallows, to which they chained it by the feet, the head being cut off and carried to the queen-mother; who, it is said, caused it to be embalmed and sent to

Rome. The king himself went to see the body hang upon the gibbet; where, a fire being kindled under it, part was burnt, and the rest scorched. In the Louvre the gentlemen belonging to the king of Navarre and the prince of Conde were murdered under the king's eye. Two of them wounded, and pursued by the assassins, fled into the bed-chamber of the queen of Navarre, and jumped upon her bed, beseeching her to save their lives; and as she went to ask this favour of the queen-mother, two more, under the like circumstances, rushed into the room, and threw themselves at her feet. The queen-mother came to the window to enjoy these dreadful scenes; and the king, seeing the Protestants who lodged on the other side of the river, flying for their lives, called for his long gun, and fired upon them. In the space of three or four days, many thousands were destroyed in the city of Paris, by the most cruel deaths which malice itself could invent. Peter Ramus, professor of philosophy and mathematics, after being robbed of all he had, his belly being first ripped open, was thrown out of a window. This so much affected Denis Lambin the king's professor, that, though a zealous Catholic, he died of terror. The first two days, the king denied it was done by his orders, and threw the whole blame on the house of Guise: but, on the 28th of August, he went to the parliament, avowed it, was complimented upon it, and directed a process against the admiral, by which he was stigmatized as a traitor. Two innocent gentlemen suffered as his accomplices in a pretended plot against the life of the king, in order to set the crown on the head of the prince of Conde. They were executed by torch-light; and the king and the queen-mother (with the king of Navarre and the prince of Conde by force), were spectators of this horrid fact; and they also assisted at the jubilee to thank God for the execution of such an infamous design.

This massacre was not confined to the city of Paris alone. On the eve of St Bartholomew, orders had been sent to the governors of provinces to fall upon the Protestants themselves, and to let loose the people upon them: and though an edict was published before the end of the week, assuring them of the king's protection, and that he by no means designed to exterminate them because of their religion, yet private orders were sent, of a nature directly contrary; in consequence of which, the massacre, or (as, in allusion to the Sicilian vespers*, it was now styled) the *Matins of Paris*,* See Sicily. were repeated in Meaux, Orleans, Troyes, Angers, Tholouse, Rouen, and Lyons; so that in the space of two months 30,000 Protestants were butchered. The next year Rochelle, the only strong fortress which the Protestants held in France, was besieged, but was not taken without the loss of 24,000 of the Catholics who besieged it. After this a pacification ensued on terms favourable to the Protestants, but to which they never trusted.

This year the duke of Anjou was elected king of Poland, and soon after set out to take possession of his new kingdom. The king accompanied him to the frontiers of the kingdom; but during the journey was seized with a slow fever, which from the beginning had a very dangerous appearance. He lingered for some time under the most terrible agonies both of body and mind; and at last died on the 30th of May 1572, ha-
after

France.

France.

ving lived 24 years, and reigned 13. It is said, that after the dreadful massacre abovementioned, this prince had a fierceness in his looks and a colour in his cheeks which he never had before. He slept little, and never found. He waked frequently in agonies, and had soft music to compose him again to rest.

84
Henry III.

During the first years of the reign of Henry III. who succeeded his brother Charles, the war with the Protestants was carried on with indifferent success on the part of the Catholics. In 1575, a peace was concluded, called by way of eminence the *Edict of Pacification*. It consisted of no fewer than 63 articles; the substance of which was, that liberty of conscience, and the public exercise of religion, were granted to the reformed, without any other restriction than that they should not preach within two leagues of Paris or any other part where the court was: Party-chambers were erected in every parliament, to consist of equal numbers of Catholics and Protestants, before whom all judgments were to be tried: The judgments against the admiral, and, in general, all who had fallen in the war or been executed, were reversed; and eight cautionary towns were given to the Protestants.

88
Catholic
league
formed.

This edict gave occasion to the Guises to form an association in defence, as was pretended, of the Catholic religion, afterwards known by the name of the *Catholic League*. In this league, though the king was mentioned with respect, he could not help seeing that it struck at the very root of his authority: for, as the Protestants had already their chiefs, so the Catholics were, for the future, to depend entirely upon the chief of the league; and were, by the very words of it, to execute whatever he commanded, for the good of the cause, against any, without exception of persons. The king, to avoid the bad effects of this, by the advice of his council declared himself head of the league; and of consequence recommenced the war against the Protestants, which was not extinguished as long as he lived.

86
Duke of
Guise murdered, and
likewise the
king.

The faction of the duke of Guise, in the mean time, took a resolution of supporting Charles cardinal of Bourbon, a weak old man, as presumptive heir of the crown. In 1584, they entered into a league with Spain, and took up arms against the king: and tho' peace was concluded the same year, yet, in 1587, they again proceeded to such extremities, that the king was forced to fly from Paris. Another reconciliation was soon after effected, but it is generally believed that the king from this time resolved on the destruction of Guise. Accordingly, finding that this nobleman still behaved towards him with his usual insolence, the king caused him to be stabbed, as he was coming into his presence, by his guards, on the 23d of December 1587. The king himself did not long survive him; being stabbed by one James Clement, a Jacobine monk, on the 1st of August 1588. His wound at first was not thought mortal: but his frequent swooning quickly discovered his danger; and he died next morning, in the 39th year of his age, and 16th of his reign.

Before the king's death, he nominated Henry Bourbon king of Navarre for his successor on the throne of France; but as he was a Protestant, or at least one who greatly favoured their cause, he was at first owned by very few except those of the Protestant party.

Vol. IV.

Met with the most violent opposition from the members of the Catholic league; and was often reduced to such straits, that he went to people's houses under colour of visits, when in reality he had not a dinner in his own. By his activity and perseverance, however, he was at last acknowledged throughout the whole kingdom, to which his abjuration of the Protestant religion contributed not a little. As the king of Spain had laid claim to the crown of France, Henry no sooner found himself in a fair way of being firmly seated on the throne, than he formally declared war against that kingdom; in which he at last proved successful, and in 1597 entered upon the quiet possession of his kingdom.

87
Henry IV.

The king's first care was to put an end to the religious disputes which had so long distracted the kingdom. For this purpose, he granted the famous edict, dated at Nantes, April 13th 1598. It re-established, in a most solid and effectual manner, all the favours that had ever been granted to the reformed by other princes; adding some which had not been thought of before, particularly the allowing them a free admission to all employments of trust, profit, and honour; the establishing chambers in which the members of the two religions were equal; and the permitting their children to be educated without constraint in any of the universities. Soon after, he concluded peace with Spain upon very advantageous terms. This gave him an opportunity of restoring order and justice throughout his dominions; of repairing all the ravages occasioned by the civil war; and abolishing all those innovations which had been made, either to the prejudice of the prerogatives of the crown, or the welfare of the people. His schemes of reformation, indeed, he intended to have carried beyond the boundaries of France. If we may believe the duke of Sully, he had in view no less a design than the new-modelling of all Europe. He imagined that the European powers might be formed into a kind of Christian republic, by rendering them as nearly as possible of equal strength; and that this republic might be maintained in perpetual peace, by bringing all their differences to be decided before a senate of wise, disinterested, and able judges: and then, he thought, it would be no difficult matter to overturn the Ottoman empire. The number of these powers was to be 15, viz. the Papacy; the empire of Germany; France, Spain; Hungary; Great Britain; Bohemia; Lombardy; Poland; Sweden; Denmark; the Republic of Venice; the States-General; the Swiss Cantons; and the Italian commonwealth, which was to comprehend the States of Florence, Genoa, Lucca, Modena, Parma, Mantua, and Monaco. In order to render the States equal, the empire was to be given to the duke of Bavaria; the kingdom of Naples to the pope; that of Sicily to the Venetians; Milan to the duke of Savoy, who, by this acquisition, was to become king of Lombardy; the Austrian Low Countries were to be added to the Dutch republic; Franche Compe, Alsace, and the country of Trent, were to be given to the Swiss. With a view, it is now thought, of executing this grand project, but under pretence of reducing the exorbitant power of the House of Austria, Henry made immense preparations both by sea and land; but if he really had such a design, he was prevented by death from

at-

France. attempting to execute it. He was stabbed in the
 90
 He is mur- coach by one Ravilliac, on the 12th of May 1608.

On the death of Henry IV. the queen-mother assumed the regency. Ravilliac was executed, after suffering horrid tortures. It is said that he made, a confession, which was so written by the person who took it down, that not one word of it could ever be read, and thus his infligators and accomplices could never be discovered. The regency, during the minority of

91
 Lewis XIII. Lewis XIII. was only remarkable for cabals and intrigues of the courtiers. In 1617, the king assumed the government himself, banished the queen-mother to Blois, and caused her favourite marshal d'Ancre to be killed. In 1620, a new war broke out between the Catholics and Protestants, which was carried on with the greatest fury on both sides; and we may judge of the spirit which actuated both parties, by what happened at Negrepisse a town in Quercy. This place was besieged by the king's troops, and it was resolved to make an example of the inhabitants. The latter, however, absolutely refused to surrender upon any terms. They defended themselves, therefore, most desperately; and the city being at last taken by storm, they were all massacred, without respect of rank, sex, or age, except ten men. When these were brought into the king's presence, he told them they did not deserve mercy: they answered, that they would not receive it; that the only favour they asked, was to be hanged on trees in their own gardens; which was granted, and the place reduced to ashes. Both parties soon became weary of such a destructive war; and a peace was concluded in 1621, by which the edict of Nantes was confirmed. This treaty, however, was of no long duration. A new war broke out which lasted till the year 1628, when the edict of Nantes was again confirmed, only the Protestants were deprived of all their cautionary towns, and consequently of the power of defending themselves in time to come. The next year, the king was attacked with a slow fever which nothing could allay, an extreme depression of spirits, and a surprising swelling in his stomach and belly. The year after, however, he recovered, to the great disappointment of his mother, who had been in hopes of regaining her power. She was arrested; but found means to escape into Flanders, where she remained during the rest of this reign. The king died in 1643, having carried on a long war with Spain with indifferent success.

92
 Lewis XIV. Lewis XIV. furnished *Le Grand*, succeeded to the throne when he was only five years of age. During his minority, the cardinal Mazarine, to whom the administration was wholly intrusted, procured a revocation of the edict of Nantes, and rendered the government absolute. This monarch brought the glory of France to the highest pitch, for which he was indebted to the famous generals who commanded his armies, the viscount Turenne, the prince of Conde, &c.; an account of whose exploits is given under the articles SPAIN, GERMANY, ITALY, UNITED-PROVINCES, &c. At last the immeasurable ambition of Lewis occasioned a general confederacy of the states of Europe against him. At the head of this confederacy was William III. king of England; but as long as he had the command of the allied army, the arms of Lewis proved successful. On his death, the war was renewed; and the allies, under the command of the duke of Marl-

borough and prince Eugene, reduced France to the lowest ebb*. When the British forces were withdrawn, it became necessary for the other contending powers to conclude a peace; which was done at Utrecht, in 1713.

Lewis XIV. died on the 1st of September 1715; and was succeeded by his son Lewis XV. at that time only six and XVI. years of age. He maintained two bloody wars with Great Britain, an account of which is given under the article BRITAIN. After a reign of 59 years, he died in 1774; and was succeeded by his son Lewis XVI. the present king of France.

The kingdom of France, according to Mr Temple-
 94
 Division of the king-
 dom.
 man, is divided into the following provinces.

Countries Names.	Square miles.	Length.	Breadth.	Chief Cities.
Orleannois	22,050	230	180	Orleans
Guienne	12,800	216	120	Bordeaux
Gascoigne	8,800	125	90	Aux or Auh
Languedoc	13,175	200	115	Thoulouse
Lyonnois	12,500	175	130	Lyons
Champagne	10,000	140	110	Rheims
Bretagne	9,100	170	105	Rennes
Normandy	8,200	155	85	Rouen
Provence	6,800	95	92	Aix
Burgundy	6,700	150	86	Dijon
Dauphine	5,820	107	90	Grenoble
Isle of France	5,200	100	85	PARIS } N. Lat. 48. 50. E. Lon. 2. 25.
French Compté	4,000	100	60	Befaugon
Picardy	3,650	120	87	Amiens
Rouffillon	1,400	56	44	Perpignan
Total—131,095				

To these may be added several fine provinces, which, since the Reformation, have been annexed to this overgrown kingdom by marriage, purchase, or conquest, viz. part of the Netherlands, which will be found under the article NETHERLANDS; the duchy of Lorrain; the countries of Alsace, Lower Navarre, and the island of Corsica: but the city of Avignon, and the Venaissin, was, in 1774, ceded to the pope.

The air is pure, healthy, and temperate. The king-
 95
 Climate, soil, inha-
 bitants, &c.
 dom is so happily seated in the middle of the temperate zone, that some make it equal to Italy, with regard to the delightfulness of the landscapes, and the fertility of the soil: however, it is certainly much more healthful. The soil produces corn, wine, oil, and flax, in great abundance; and they have very large manufactures of linen, woollen, silk, and lace. They have a foreign trade to Spain, Italy, Turkey, and to the East and West Indies. They themselves reckon that the number of the inhabitants is 20,000,000. This kingdom contains 21 universities; 18 archbishopsricks; 12 parliaments; 12 boards of accounts; 12 courts of aids; 2 courts, and 30 mints, for coining money; 2 supreme councils, besides the grand council; and 31 governors. The king has the title of *Mess Christiam*; and is an absolute prince, to whom his subjects are extremely devoted, though he rule them ever so severely. The politeness of the inhabitants is well known; but most people think them too ceremonious. In general, they are men of bright parts; and have so high an opinion of themselves, that they look upon other nations

France
||
Francfort.

nations with contempt: however, they are of a very reflexive disposition, and engaged in war more than any other country in Europe; for which reason they are generally poor, though they might certainly be very rich, if they could let their neighbours live in quiet, without attempting continually to enlarge their dominions. They are such ill observers of treaties, that *French faith* is now become a proverb; for they are bound by no ties, and never fail beginning a war when they think it is for their advantage. The king's revenue is large, his army very numerous, and he has 10,000 men always about his person. The kingdom is watered by a great number of rivers; of which the four principal are, the Loire, the Seine, the Rhone, and the Garonne, or Gironde. The parliaments have little or no share in the government; and their business now is, to pass the arrests or laws which the king is pleased to send them: however, they do not always pay a blind obedience to the king, for we have recent instances of their making a noble stand. In civil causes these parliaments are still the last resort, provided the court does not interpose. That of Paris is the most considerable, where the king often comes in person to see his royal acts recorded. It consists of the dukes and peers of France, besides the ordinary members, who purchase their places; and they only take cognizance of causes belonging to the crown. The revenues of the crown arise from the *taille* or land-tax, and the aids which proceed from the customs and duties on all merchandise except salt, for the tax upon that commodity is called the *gabelles*: besides these, there are other taxes; as, the capitation or poll-tax; the tenths of all estates, offices, and employments; besides the 15th penny, from which neither the nobility nor clergy are exempted. Add to these, the tenths and free-gifts of the clergy, who are allowed to tax themselves; and lastly, crown-rents, fines, and forfeitures, which bring in a considerable sum. All these are said to amount to 15,000,000 Sterling a-year. But the king has other resources and ways of raising money, whenever necessity obliges him. The army, in time of peace, is said to consist of 200,000 men, and in time of war of 400,000; among which are many Swiss, Germans, Scots, Irish, Swedes, and Danes. There is no religion allowed in France but the Roman Catholic, ever since the revocation of the edict of Nantz, in 1685; though they are not so devoted to the Pope as other nations of that communion, nor have they any inquisition among them.

FRANCE, *the Ile of*, a province of France, so called, because it was formerly bounded by the river Seine, Marne, Oise, Aisne, and Ourque. It comprehends, besides Paris, the Beauvoisis, the Valcis, the county of Senlis, the Vexin, the Hurepois, the Gatinois, the Multien, the Goele, and the Mantois. Paris is the capital.

FRANCESCA (Peter), an eminent Florentine painter of night-pieces and battles, was employed to paint the Vatican. He drew several portraits, and wrote on arithmetic and geometry: he died in 1458.

FRANCFORT *on the Main*, an Imperial and Hanseatic town of Franconia in Germany. It is a handsome, strong, and rich place, and has a great deal of commerce, but is built after the ancient taste. Here the golden bull is preserved, which is the original of

the fundamental laws of the empire. The emperor is generally elected here, unless the plague or war will not admit of the solemnities proper to the occasion. It is seated in a fine fertile plain, in E. Long. 8. 40. N. Lat. 49. 55.

FRANCFORT, *on the ODER*, a rich and handsome town of Germany, in the middle Marche of Brandenburg, formerly imperial, but now subject to the king of Prussia. E. Long. 15. 0. N. Lat. 52. 20.

FRANCHE-COMTE, a province of France, bounded on the south and west by Champagne and Burgundy; on the north by Lorraine; and to the east by the earldom of Mumplegard, and Switzerland. It is in length from north to south about 30 leagues, in breadth about 20. It is partly flat and partly hilly. The flat country is fruitful in grain, wine, hemp, and pasture; and the hilly country abounds in cattle, producing also some wine and corn, copper, lead, iron, and silver ores, mineral waters, and quarries of stone, marble, and alabaster.

FRANCHISE, in law. *Franchise and liberty* are used as synonymous terms; and their definition is, "a *Blackf. Comment.* royal privilege, or branch of the king's prerogative, subsisting in the hands of a subject." Being therefore derived from the crown, they must arise from the king's grant; or, in some cases, may be held by prescription, which, as has been frequently said, presupposes a grant. The kinds of them are various, and almost infinite. We shall here briefly touch upon some of the principal; premising only, that they may be vested in either natural persons or bodies-politic; in one man, or in many: but the same identical franchise, that has before been granted to one, cannot be bestowed on another, for that would prejudice the former grant.

To be a county-palatine, is a franchise vested in a number of persons. It is likewise a franchise for a number of persons to be incorporated and subsist as a body-politic; with a power to maintain perpetual succession, and do other corporate acts: and each individual member of such corporation is also said to have a franchise or freedom. Other franchises are, to hold a court-leet: to have a manor or lordship; or, at least, to have a lordship paramount: to have waifs, wrecks, estrays, treasure-trove, royal fish, forfeitures, and deodands: to have a court of one's own, or liberty of holding pleas and trying causes: to have the cognizance of pleas; which is a still greater liberty, being an exclusive right, so that no other court shall try causes arising within that jurisdiction: to have a bailiwick, or liberty exempt from the sheriff of the county; wherein the grantee only, and his officers, are to execute all process: to have a fair or market; with the right of taking toll, either there or at any other public places, as at bridges, wharfs, or the like; which tolls must have a reasonable cause of commencement, (as in consideration of repairs, or the like), else the franchise is illegal and void: or lastly, to have a forest, chase, park, warren, or fishery, endowed with privileges of royalty. See CHASE, FOREST, &c.

FRANCIA (Francesia), a celebrated Bolognese painter, born in 1450. He was first a goldsmith or jeweller, afterwards a graver of coins and medals; but applying at last to painting, obtained great reputation by his works, particularly by a piece of St Sebastian, whom he had drawn bound to a tree with his hands

Francfort
||
Francia.

Francis tied over his head. He pined himself into a consumption, by despairing to equal Raphael; and died in 1518.

FRANCIS I. king of France, the rival of the emperor Charles V. and the restorer of learning and politeness in France. See (*History of*) FRANCE.

FRANCIS of *Affisi* (St.), founder of the Franciscan friars, was born at Affisi in Italy in 1181. One of the most extraordinary things told of St Francis of Affisi is, that Jesus Christ imprinted on him the marks of his five wounds; and there is a festival in memory of those holy prints, and an office for it. His preaching to the fishes to make them Christians, and his conversion of millions of them, is famous; as is his mercy to worms and lice. The order he founded, and which bears his name, was approved by Innocent III. in 1215, and confirmed by Honorius III. in 1223. It has since branched into several others, as Minims, Ricollets, Capuchins, &c. called in Roman-Catholic countries, *Frates Minores*.

FRANCISCAN MONKS, FRIARS *Minor*, or *Grey-Friars*; religious of the order of St Francis, founded by him in the year 1209. See FRANCIS of *Affisi*.

The rule of the Franciscans, as established by St Francis himself, is briefly this: they are to live in common, to observe chastity, and to pay obedience to the pope and their superiors.

Before they can be admitted into the order, they are obliged to sell all they have, and give it to the poor: they are to perform a year's novitiate; and, when admitted, never to quit the order upon any account. They are to fast from the feast of All-saints, to the Nativity. This order has produced four popes, 42 cardinals, and an infinite number of patriarchs.

FRANCONIA, a circle of the German empire, lying between Bohemia on the east, and the electorate of Mentz on the west. Its capital is Nuremberg; and from this country the Franks, who conquered and gave name to the kingdom of France, are said to have come.

FRANGULA, in botany. See RHAMNUS.

FRANK LANGUAGE, *Lingua Franca*, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

FRANK, or *Franc*, an ancient coin, either of gold or silver, struck and current in France. The value of the gold franc was something more than that of the gold crown; the silver franc was a third of the gold one: this coin is long out of use, tho' the term is still retained as the name of a money of account; in which sense it is equivalent to the *livre*, or 20 *sols*.

FRANK, or *Franc*, meaning literally *free* from charges and impositions, or exempt from public taxes, has various significations in the ancient English customs.

FRANK *Almoigne*, (*libera elemosyna*), or "free alms;" a tenure of a spiritual nature, whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and their successors for ever. The service which they were bound to render for these lands was not certainly defined: but only in general to pray for the souls of the donor and his heirs, dead or alive; and therefore they did no fealty, (which is incident to all other services but this), because this divine service was of a higher and more exalted nature. This

is the tenure by which almost all the ancient monasteries and religious houses held their lands; and by which the parochial clergy, and very many ecclesiastical and eleemosynary foundations hold them at this day; the nature of the service being upon the reformation altered, and made conformable to the purer doctrines of the church of England. It was an old Saxon tenure; and continued under the Norman revolution, through the great respect that was shewn to religion and religious men in ancient times. This is also the reason that tenants in frankalmoign were discharged of all other services except the *trinoda necessitas*, of repairing the highways, building castles, and repelling invasions; just as the druids, among the ancient Britons, had *omnium rerum immunitatem*. And even at present, this is a tenure of a very different nature from all others; being not in the least feudal, but merely spiritual. For, if the service be neglected, the law gives no remedy by distress, or otherwise, to the lord of whom the lands are holden; but merely a complaint to the ordinary or visitor to correct it.

FRANK-Chace is defined to be a liberty of free chase, whereby persons that have lands within the compass of the same, are prohibited to cut down any wood, &c. out of the view of the forester.

FRANK-Fee, signifies the same thing as holding lands and tenements in fee-simple; that is, to any person and his heirs, and not by such service as is required by ancient demesne, but is pleaded at common law. See FEE.

FRANK-Law, a word applied to the free and common law of the land, or the benefit a person has by it.

He that for any offence loseth this frank-law, incurs these inconveniences, viz. He may not be permitted to serve on juries, nor used as an evidence to the truth; and if he has any thing to do in the king's court, he must not approach it in person, but appoint his attorney; his lands, goods, and chattels, shall be seized into the king's lands; and his lands be estranged, his trees rooted up, and his body committed to custody.

FRANK-Marriage, in law, is where tenements are given by one man to another, together with a wife, who is the daughter or cousin to the donor, to hold in frank-marriage. By such gift, though nothing but the word *frank-marriage* is expressed, the donees shall have the tenements to them, and the heirs of their two bodies begotten; that is, they are tenants in special tail. For this one word, *frank-marriage*, denotes, *ex vi termini*, not only an inheritance, like the word *frankalmoigne*, but likewise limits that inheritance; supplying, not only words of descent, but of procreation also. Such donees in frank-marriage are liable to no service but fealty; for a rent reserved therein is void until the fourth degree of consanguinity be past between the issues of the donor and donee.

FRANK-Pledge, law, signifies a pledge or surety for the behaviour of freemen.

According to the ancient custom of England, for the preservation of the public peace, every free-born man, at the age of fourteen, except religious persons, clerks, knights, and their eldest sons, was obliged to give security for his truth and behaviour towards the king and his subjects, or else be imprisoned. Accordingly, a certain

Franked
Franks.

Frascati
Fraud.

certain number of neighbours became interchangeably bound for each other, to see each person of their pledge forthcoming at all times, or to answer for the offence of any one gone away: so that whenever any person offended, it was presently inquired in what pledge he was, and there the persons bound either produced the offender in 31 days, or made satisfaction for his offence.

FRANK Tenement. See **TENURE.**

FRANKED LETTERS. The privilege of letters coming free of postage, to and from members of parliament was claimed by the house of commons in 1660, when the first legal settlement of the present post-office was made; but afterwards dropped, upon a private assurance from the crown, that this privilege should be allowed the members. And accordingly a warrant was constantly issued to the postmaster-general, directing the allowance thereof to the extent of two ounces in weight: till at length it was expressly confirmed by 4 Geo. III. c. 24. which adds many new regulations, rendered necessary by the great abuses crept into the practice of franking; whereby the annual amount of franked letters had increased from L. 23,600 in the year 1715, to L. 170,700 in the year 1763.

FRANKEN (Franciscus), commonly called *Old Frank*, a famous Flemish painter, supposed to have been born about the year 1544: but tho' his works are well known, very few of the circumstances of his life have been transmitted to posterity. This master painted historical subjects from the Old and New Testaments; and was remarkable for introducing a great number of figures into his compositions, which he had the address to groupe very distinctly. Vandyck often commended his works, and thought them worthy of a place in any collection.

FRANKEN (Franciscus), distinguished by the name of *Young Frank*, was the son of the former, born in the year 1580. He was instructed by his father; whose style he adopted so closely, that their works are frequently mistaken. When he found himself sufficiently skilled at home, he travelled into Italy for improvement in colouring; and, on his return, his works were much coveted. The most capital performance of this painter are, a scriptural performance in the church of Notre-dame at Antwerp; and an excellent picture, in a small size, of Solomon's idolatry. *Young Frank* died in 1642.

FRANKENDAL, a strong town of Germany, in the dominions of the Elector Palatine. It was taken by the Spaniards in 1623, by the Swedes in 1632, and burnt by the French in 1688. E. Long. 8. 29. N. Lat. 49. 28.

FRANKINCENSE. See **INCENSE.**

FRANKS, FRANKIS, or Franquis, an appellation given by the Turks, and other nations of Asia, to all the people of the western parts of Europe, to which they give the name of *Frankishan*.

Frank, or *Frenc*, primarily denotes a Frenchman; and, by extension, an European, because, according to some, the French distinguished themselves above the other nations engaged in the holy war*. But Fa. Goar, in his notes on Codinus, cap. v. n. 43. furnishes another origin of the appellation *Frank*, of greater antiquity than the former.—He observes, that the Greeks at first confined the name to the *Franci*, i. e. the

German nations, who had settled themselves in France or Gaul: but afterwards they gave the same name to the Apulians and Calabrians, after they had been conquered by the Normans; and at length the name was further extended to all the Latins. In this sense, is the word used by divers Greek writers; as Comnenus, &c. who, to distinguish the French, call them the *western Franks*.

Du Cange adds, that about the time of Charlemagne, they distinguished—eastern France; western France; Latin, or Roman, France; and German France, which was the ancient France, afterwards called *Franconia*.

FRASCATI, a handsome town of Italy, seated near the same spot with the Tusculum of Cicero. Here are a great number of magnificent palaces and delightful gardens. E. Long. 11. 43. N. Lat. 41. 48.

FRATERNITY, in the Roman Catholic countries, signifies a society for the improvement of devotion.

Of these there are several sorts; as, 1. The fraternity of the rosary, founded by St Dominic. It is divided into two branches, called the *common rosary*, and the *perpetual rosary*; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. See **ROSARY**.

2. The fraternity of the scapulary, whom the blessed Virgin, according to the fabbatin bull of pope John XXII. has promised to deliver out of hell the first Sunday after their death. See **SCAPULARY**.

3. The fraternity of St Francis's girdle, are clothed with a sack of a grey colour, which they tie with a cord; and, in processions, walk bare-footed, carrying in their hands a wooden cross.

4. That of St Austin's leathern girdle, comprehends a great many devotees.

Italy, Spain, and Portugal, are the countries where one sees the greatest number of these fraternities, some of which assume the name of *arch-fraternities*. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to 40 poor girls on the feast of St Jerom their patron. The fraternity of death, buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

FRATRICELLI, LITTLE BROTHERS, in church-history, a sect of heretics who appeared in Italy about the year 1293, and afterwards spread all over Europe. They wore the habit of the Franciscan order, and pretended that ecclesiastics ought to have no possessions of their own.

FRATRIAGE, the partition among brothers or coheirs, coming to the same inheritance or succession.

FRATRES ARVALES. See **ARVALES**.

FRATRICIDE, the crime of murdering one's brother. See **PARRICIDE**.

FRAUD, in law, signifies deceit in grants, or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

A fraudulent conveyance of lands or goods to deceive creditors, as to creditors is void in law. And a fraudulent conveyance in order to defraud purchasers, is also to such purchasers void; and the persons justifying

* See *Croftade*.

Fraustadt
||
Freckles.

fyng or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewise shall be imprisoned. See CHEATING.

FRAUSTADT, a town of Silesia, on the frontiers of Poland, remarkable for a battle gained by the Swedes over the Saxons in 1706. E. Long. 15. 50. N. Lat. 51. 45.

FRAXINUS, the Ash; a genus of the diœcia order, belonging to the polygamia class of plants. There are six species; of which the most useful is the common ash, which is so well known, that it needs no description. If a wood of these trees is rightly managed, it will turn greatly to the advantage of the owner; for, by the underwood, which will be fit to cut every eight or ten years, there will be a continual income, more than sufficient to pay the rent of the ground and all other charges; and still there will be a stock preserved for timber, which in a few years will be worth 40s. or 50s. per tree. This tree flourishes best in groves, but grows very well in rich soil in open fields. It bears transplanting and lopping. In the north of Lancashire they lop the tops of these trees to feed the cattle in autumn when the grass is on the decline; the cattle peeling off the bark as food. The wood hath the singular property of being nearly as good when young as when old. It is hard and tough, and is much used to make the tools employed in husbandry. The ashes of the wood afford very good potash. The bark is used in tanning calf-skin. A slight infusion of it appears of a pale yellowish colour when viewed betwixt the eye and the light; but when looked down upon, or placed betwixt the eye and an opaque object, appears blue. This blueness is destroyed by the addition of an acid, but recovered by alkalies. The seeds are acrid and bitter. In the church-yard of Lochaber in Scotland, Dr Walker measured the trunk of a dead ash-tree, which at five feet from the surface of the ground was 58 feet in circumference.—Horses, cows, sheep, and goats eat it; but it spoils the milk of cows, so that it should not be planted in dairy farms.

FRAY, among sportsmen. A deer is said to fray its head, when it rubs it against a tree, to cause the pills of the new horns to come off.

FREAM, a name given by farmers to ploughed lands worn out of heart, and laid fallow till it recover.

FRECKLES, LENTIGINES, spots of a yellowish colour, of the bigness of a lentile-seed, scattered over the face, neck, and hands. Freckles are either natural, or proceeding accidentally from the jaundice, or the action of the sun upon the part. Heat, or a sudden change of the weather, will often cause the skin to appear of a darker colour than natural; and thereby produce what is called *tan*, *sunburn*, and *morpheus*, which seem to differ only in degree; and usually disappear in winter.

Persons of a fine complexion, and such whose hair is red, are the most subject to freckles, especially in those parts which they expose to the air.

To remove freckles, put juice of lemons in a glass-vial, and, mixing it with sugar and borax finely powdered, let it digest eight days, and then use it. Homberg proposes bullock's gall mixed with alum, and, after the alum has precipitated, exposed three or four months to the sun in a close vial, as one of the best re-

medies known for the removing of freckles.

FREDBERG, a rich, strong, and fine town of Germany, in Misnia, remarkable for its mines, and for being the burying place of the princes of the house of Saxony. It is a delightful place, seated on the river Multa. E. Long. 13. 40. N. Lat. 51. 2.

FREDERICA, a town of North America, in Georgia, seated at the mouth of the river Altamaha, lately built and fortified by general Oglethorpe. The island it stands upon is called *St Simon's*; and is about 13 miles in length, and 4 in breadth. W. Long. 81. 35. N. Lat. 31. 0.

FREDERICKSBURG, a fort and colony of Brandenburg, on the gold-coast of Guinea, in Africa, near Cape Three-points, and about 75 miles from Cape Coast. It mounts 46 pieces of cannon on four batteries; and formerly belonged to the Prussians, but is now subject to Denmark. W. Lon. 1. 15. N. Lat. 4. 30.

FREDERICKSHALL, or FREDERICKTADT, a strong town of Norway, in the prefecture of Agerhuys, where Charles XII. king of Sweden was killed by a musket-ball in 1718, when he was besieging this town. It is seated on the coast of the Catagate, in E. Long. 10. 45. N. Lat. 59. 2.

FREDERICKSODE, a town of Denmark, in Jutland, taken by the Swedes in 1657, but now subject to Denmark. It is seated near the sea, in E. Long. 10. 0. N. Lat. 55. 42.

FREDERICKSTADT, a town of Denmark, in South Jutland, built in 1621. It is seated on the river Eyder, in E. Long. 9. 23. N. Lat. 54. 32.

FREDERICKSTADT, a town of Norway, in the province of Agerhuys, seated on a bay of the sea, near the frontiers of Sweden, in E. Long. 11. 6. N. Lat. 59. 12.

FREE, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

FREE-BENCH, signifies that estate in copy-hold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor.

In regard to this free-bench, different manors have different customs: and in the manor of east and west Enbourne in the county of Berks, and in other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, *dam sola & casa fuerit*, "whilst she lives single and chaste;" but if she is found to be guilty of incontinency, she shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, the steward is bound by custom to restore her to her free-bench. The words are,

Here I am,
Riding on a black Ram,
Like a whore as I am;
And for my criminal cranium
Have lost my bincum banicum,
And for my tail's game
Have done this worldly shame:
Therefore, pray, Mr Steward, let me have my land again.

FREE Fishery. See FREE-FISHERY.

FREE Warren. See WARREN.

FREE-

Fredberg
||
Free.

FREE-Hold, signifies lands or tenements which a person holds in fee-simple, fee-tail, or for term of life. See **Fee** and **Tail**.

Free-Stone, a whitish stone, dug up in many parts of Britain, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a kind of the grit stone, but finer sand, and smoother; and is called *free*, from its being of such a constitution as to cut freely in any direction.

The qualities of the several kinds of free-stones used in the different parts of Europe are very different. They all agree in this general property indeed, that they are softer while in the quarry, than when they have been some time exposed to the air: but even this general property differs greatly in degree. They have a sort of grey free-stone in use at Paris, (of which we do not yet seem to have met with any in this country,) which has the abovementioned quality in so great a degree, that the expence of working it is in a great measure saved.

This stone lies every-where on the south-side of the river Seine, and is of a coarse and large grit. It is so soft when newly taken out of the strata, that they fashion it very conveniently with a sort of broad ax, and form as many stones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this stone is as soft as dry clay when first taken up, it is found to harden so considerably in the air, that it becomes more than equal to our ordinary free-stone.

Our Portland stone of the finest kind, which is white, and of a close grit, is very fit for hewing and carving; but it will neither resist water nor fire, which is a very singular instance in so dense a stone; while the free-stone of Kent, which is less beautiful to the eye, and is of a greyish colour, and considerably close, though of a larger grain, resists the air and water very well.

The free-stone of Derbyshire, on the other hand, is so brittle as to be unfit for any fine working; and so coarse and open in its texture, that it lets water thro': yet it bears the fire extremely well, and is fit for ovens, hearths, &c.

FREEBOOTER, or **FLIBUSTER**, a name given to the pirates who scour the American seas, particularly such as make war against the Spaniards. See **BUCANEER**.

The French call them *sybustiers*, deducing the word from the English *sybote*, or *sybote*; by reason the first adventurers of this kind were the people of St Domingo, who made their excursions with sybotes, which they had taken from the English.

FREEDOM, in general, the state or quality of being free. See **LIBERTY**.

FREEDOM of a Corporation, the right of enjoying all the privileges and immunities belonging to it. See **CORPORATION**.

The freedom of cities, and other corporations, is regularly obtained by serving an apprenticeship; but it is also purchased with money, and sometimes conferred by way of compliment.

FREEDOM of Conscience. See **TOLERATION**.

FREEDOM of the Will, that power or faculty of the mind, whereby it is capable of acting or not acting, choosing or rejecting whatever it judges proper. Of this every man must be sensible, who finds in himself a

power to begin or forbear, continue or end several actions, barely by a thought or preference of the mind.

FREEZE, or **FRIEZE**, *Frize*, in commerce, a coarse kind of woollen stuff, or cloth, for winter wear; so called, as being frozen or naped on each side.

FREEZING, in philosophy, the same with congelation. See **CONGELATION** and **FROST**.

FREEZING Rain, or *Raining Ice*, a very uncommon kind of shower, which fell in the west of England, in December 1672; whereof we have divers accounts in the Philosophical Transactions.

This rain, as soon as it touched any thing above ground, as a bough or the like, immediately settled into ice; and by multiplying and enlarging the icicles, broke all down with its weight. The rain that fell on the snow, immediately froze into ice, without sinking in the snow at all.

It made an incredible destruction of trees, beyond any thing in all history. "Had it concluded with some gust of wind, (says a gentleman on the spot), it might have been of terrible consequence.

"I weighed the sprig of an ash tree, of just three quarters of a pound; the ice on which weighed 16 pounds. Some were frighted with the noise in the air; till they discerned it was the clatter of icy boughs, dashed against each other." Dr Beale observes, that there was no considerable frost observed on the ground during the whole; whence he concludes, that a frost may be very intense and dangerous on the tops of some hills, and plains; while in other places it keeps at two, three, or four foot distance above the ground, rivers, lakes, &c. and may wander about very furious in some places, and remits in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits. See **FROST**.

FREIGHT, in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel. See **Maritime LAWS**.

FREIND (John), a most learned English physician and writer in the 18th century, was born at Croton, Northamptonshire, in 1675. In 1696, he published, in conjunction with Mr P. Foulkes, an edition of two Greek orations, one of Alcibiades against Ctesiphon, and the other of Demosthenes de *Coronâ*, with a new Latin version. In 1699, he wrote a letter to Dr Sloane concerning an *Hydrocephalus*, published in the Philosophical Transactions; and another letter in Latin to the same gentleman, *De spasmi ravior. historia*, printed in the same Transactions. In 1703, his *Emmenologia* appeared; which gained him great reputation. In 1704, he was chosen professor of chemistry in the university of Oxford. In 1705, he attended the earl of Peterborough to Spain, as physician to the army there; and upon his return in 1707, published an account of the earl's expedition and conduct. In 1709, he published his *Chemical Lectures*. In 1712, he attended the duke of Ormond in Flanders, as his physician. In 1716, he was admitted a fellow of the college of physicians in London. This year he published the first and third books of Hippocrates *De morbis popularibus*, with a Commentary on Fevers, written by himself. He sat a member for the borough of

Laun-

Freinthe-
n ius
||
Fresco.

Launceston in Cornwall, in 1722, where he distinguished himself by his opposition to the administration. March 1722, he was committed to the tower on a charge of high-treason: and while he was under confinement, he wrote a Latin epistle to Dr Mead, *De quibusdam variorum generibus*; and began his History of Physic, the first part of which was published in 1725, and the second in 1726. Upon the accession of George II. to the throne, he was appointed physician in ordinary to the queen, who shewed the utmost regard and esteem for him. He died at London in 1728. His works were published together in Latin at London, 1733, in folio, and dedicated to the queen.

FREINSHEMIUS, a learned and elegant author, born at Ulm in 1608. He made supplements to Livy, Tacitus, and Q. Curtius, in 60 books, printed at Strasbourg in 1654. He wrote likewise Notes upon Q. Curtius, Florus, Tacitus, and some other Latin authors; and died in 1660.

FRENCH, in general, something belonging to France: thus we say, the French language, French customs, polity, &c.

The French language is made up of Latin, Greek, Teutonic, and the language spoken by the old Gauls. It is natural, and easily pronounced; and therefore used by most nations in Europe in conversing with foreigners. There are very few compound words in French; which is acknowledged to be its disadvantage. It has also few diminutives: but as to purity, easiness, and flexibility, it yields to none.

FRESCO, a method of painting in relievo on walls, so as to endure the weather.

It is performed with water-colours on fresh plaster, or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

The compost should be made of rubbish stones mixed with well-burnt flint, or lime and water: but the saltiness of the lime must be washed out, by pouring water frequently on it. But this should not be done in moist weather.

To prevent the plaster from peeling, strike into the joints of the wall stumps of horse-nails six inches distant from each other. First plaster the walls pretty thick; then let it dry for some time, the design and colours being first ready prepared. This painting is chiefly performed on walls and vaults newly plastered with lime and sand; and the plaster is only to be put on in proportion as the painting proceeds.

Plaster the wall a second time, about the thickness of half a crown, only so much as you intend to work upon; and while it is wet, work the colours therein, which will incorporate with the plaster so as never to wash out.

The painting must be worked with a free hand, and your colours made high enough at first, as there can be no alteration made after the first painting.

In this work scarce any thing else is used but earths, which still retain their colour, defending it from the burning and salt of the lime. The colours are white, made of lime slacked some time, and white marble dust, red and yellow ocher, violet red, verditer, lapis lazuli, smalt, black Spanish brown, Spanish white, &c. all which are ground and worked up with water.

The brushes and pencils for this work must be long and soft, or else they will rake and raze the painting: the colours must be full and flowing from the brush, and the design or cartoon must be perfect in the paper-copy.

FRESNOY (Charles Alphonse du), an excellent poet and painter, was born at Paris in 1611. He was instructed there by Perrier and Simon Vouet, but did not long adhere to Vouet's manner of colouring; for as soon as he fixed himself at Rome, he made the works of Titian the models for his imitation. He was, however, more celebrated as a poet than as a painter; and bestowed more attention to the theory than to the practice of the pencil. Accordingly, he is better known by his incomparable poem *De arte graphica*, than by his performances on the canvas: and on this poem he bellowed so much pains, that he died in 1665, before it was published. It was printed afterward, with a French prose translation and notes, by M. de Piles; and was translated into English by Mr Dryden, who prefixed to it an original preface containing a parallel between painting and poetry.

FRET, or FRETTE, in architecture, a kind of knot or ornament, consisting of two lints or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

FRET, in heraldry, a bearing composed of six bars, crossed, and variously interlaced. Some call it the *truelover's knot*. See HERALDRY.

FRET, in music, signifies a kind of stop on some instruments, particularly bass-viol and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

FRET-Work, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but it is mostly practised in roofs, which are fretted over with plaster work.

FRIABLE, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are pumice and all calcined stones.

FRIAR, a term common to all monks of all orders; founded on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, *viz.* 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars, or carmelites. From these four the rest of the orders descend. See FRANCISCANS, AUGUSTINES, &c.

FRIBURG, a large town of Germany, and capital of Brisgaw; remarkable for the steeple of the great church, which, next to that of Strasbourg, is the finest in Germany; and for its university. The inhabitants are famous for polishing crystal and precious stones. It has been several times taken and retaken, particularly by the French in 1744, who demolished the fortifications. It is seated on the river Triser, ten miles east of Brisach, and 30 south of Strasbourg. E. Long. 7. 57. N. Lat. 48. 4.

FRIBURG, a town of Switzerland, and capital of the canton of the same name. The public buildings, especially the cathedral, are very handsome; and the inhabitants are Papists. It is governed in spirituals by the bishop

Fresnoy
||
Friburg.

Friburg
Friedland.

bishop of Laufanne, who resides there; and in temporal by a council, over which an avoyer presides. Its situation is very extraordinary; for only the western side is near plain ground, and all the rest is built among rocks and hills. The streets are clean and large; and it is divided into four parts, the town, the city, the off-land or meadow, and the hospital. In 1737, the powder-magazine, which contained 750 tons of gunpowder, was set on fire by lightning, which did considerable damage. It is seated on the river Save, in E. Long. 7. 5. N. Lat. 46. 50.

FRIEBURG (the canton of), and one of the 13 republics of Switzerland. It is surrounded on all sides by the canton of Bern. The land is fertile in corn, fruits, and pastures; and it is said the canton can fend 18,000 men into the field.

FRIEBURG (the hermitage of); a celebrated hermitage in Switzerland, three miles from the city of Friburg. It is cut in a rock; and contains a church and steeple, a vestry, a kitchen, a large hall, two rooms on each side, two pair of stairs, and a cellar. The church is 63 feet long, 36 broad, and 22 high. But the most wonderful thing of all is the steeple, which is 70 feet high above the rock. The chimney of the kitchen is also very surprising, for the passage up it is 90 feet in height. This hermitage is said to have been the work of one man with his servant, who were employed in it 25 years.

FRICENTI, an episcopal town of Italy, in the kingdom of Naples, and in the farther principato, near the river Tripalto, in E. Long. 14. 13. N. Lat. 40. 59.

FRICTION, in mechanics, the rubbing of the parts of the engines and machines against each other, by which means a great part of their effect is destroyed. See MECHANICS.

FRICTION, in medicine. See (the *Index* subjoined to) that article.

FRIDAY, the sixth day of the week; so named of Freya, a Saxon deity. By the Romans it was called *dies Veneris*. See DAY.

Good-Friday. See GOOD-FRIDAY.

FRIEDBURG, an imperial town of Germany, in Wetteravia. It is seated on a mountain, in E. Long. 8. 50. N. Lat. 50. 14. It was formerly much more considerable than at present.

FRIESTOL, mentioned, in our ancient writers, among the immunities granted to churches, signifies a seat, chair, or place of peace and security, where criminals might find safety and protection: of these there were many in England; but the most famous were that at Beverly, and that in St Peter's church at York, granted by charter of king Henry I.

FRIENDSHIP, a state of mutual good-will, or desire of doing good to each other, betwixt two or more individuals. See MORALS, n° 142, 143.

FRIESLAND, one of the united provinces of the Low Countries. It is bounded on the east by the river Lauvers, which parts it from the lordship of Groningen, on the south by Overijssel, on the west by the Zuider-Zee, and on the north by the German ocean. It is 30 miles from north to south, and 28 from east to west. The land is very fertile in corn and pasture, the horses are large, and the cows and sheep prolific. It is divided into three parts; We-

stergo to the west, Oftergo to the east, and Sevenwalden to the south. The islands of Sheling, Ameland, and other small ones, are dependent on this province. The principal towns are Leuwarden the capital, Franeker, Dockum, Harlingen, and Staveren.

FRIESLAND (East), a province of Germany, in the circle of Westphalia, lying near the German ocean. It is bounded on the south by the bishopric of Munster, on the east by the county of Oldenburg, on the west by the province of Groningen, and on the north by the sea. It is about 50 miles in length, and 30 in breadth, and was formerly called the *county of Embden*. It is a very fertile country, and feeds a great number of cattle; but it was greatly damaged by an inundation in 1717, and the repair of the dykes cost an immense sum. The principal towns are Norden, Leer, Essens, Whitmunde, and Aurick. Embden was an imperial city, and the principal place in the country; but now belongs to the king of Prussia, who bought it of the Dutch.

FRIGATE, in the navy, a light nimble ship built for the purposes of sailing swiftly. These vessels mount from 20 to 38 guns, and are esteemed excellent cruisers.

Formerly the name of *frigate* was only known in the Mediterranean, and applied to a kind of long vessel navigated in that sea with sails and oars. The English were the first who appeared on the ocean with those ships, and equipped them for war as well as commerce.

FRIGID, is applied to a jejune style, that is unanimated by any ornaments, and consequently without any force or vigour.

FRIGIDITY, in medicine, the same with IMPOTENCE.

FRIGORIFIC, in physiology, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which we call cold. See COLD.

FRILL, in falconry. When a hawk trembles, or shivers, they say she frills.

FRINGILLA, in ornithology, a genus belonging to the order of passerines. The bill is conical, straight, and sharp-pointed. There are no less than 30 species comprehended under this genus, distinguished principally by varieties in their colour. The following are natives of Britain.

1. The *carduelis*, or GOLDFINCH, with the quill. Gold-finch. feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. The young bird, before it moults, is grey on the head; and hence it is termed by the bird-catchers a *grey-pate*. There is a variety of goldfinches called by the London bird-catchers a *cheverel*, from the manner in which it concludes its jerk. It is distinguished from the common sort by a white streak, or by two, sometimes three, white spots under the throat. Their note is very sweet; and they are much esteemed on that account, as well as for their great docility. Towards winter, they assemble in flocks; and feed on seeds of different kinds, particularly those of the thistle. It is fond of orchards, and frequently builds in an apple or pear tree: its nest is very elegantly formed of fine moss, liverworts, and bents,

Frigate
Fringilla.

Fringilla.

Fringilla.

bents, on the outside; lined first with wool and hair, and then with the goblin or cotton of the fallow. It lays five white eggs, marked with deep purple spots on the upper end.

This bird seems to have been the *χρυσωπις* of Aristotle; being the only one that we know of that could be distinguished by a golden fillet round its head, feeding on the seeds of prickly plants.

2. The *coelebs*, or CHAFFINCH, hath black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It has its name from its delighting in chaff.

Chaffinch.

This species entertains us agreeably with its song very early in the year, but towards the latter end of summer assumes a chirping note: both sexes continue with us the whole year. What is very singular in Sweden, the females quit that country in September, migrating in flocks into Holland, leaving their mates behind; in the spring they return. In Hampshire Mr White has observed something of this kind; vast flocks of females with scarcely any males among them. Their nest is almost as elegantly constructed as that of the goldfinch, and of much the same materials, only the inside has the addition of some large feathers. They lay four or five eggs of a dull white colour, tinged and spotted with deep purple.

They are caught in plenty in flight-time; but their nests are rarely found, though they build in hedges and trees of all sorts. They make their nests of moss and wool, or any thing they can gather up; and have young ones thrice a-year. They are seldom bred from the nest, as being a bird not apt to learn another's song, nor to whistle; so that it is best to leave the old ones to bring them up.

The Essex finches are generally allowed to be the best sort, both for length of song and variety, ending with several notes that are very pretty. It is an hardy bird, and will live almost upon any feeds, none coming amiss to him. He is seldom subject to disease, but will be very lousy if not sprinkled with wine two or three times a-month.

3. The *domestica*, or SPARROW, hath the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings.

Sparrow.

These birds are proverbially falacious: they breed early in the spring; make their nests under the eaves of houses, in holes of walls, and very often in the nests of the martin, after expelling the owner. Linnæus tells us (a tale from Albertus Magnus), that this insult does not pass unrevenge: the injured martin assembles its companions, who assist in plastering up the entrance with dirt; then fly away, twittering in triumph, and leave the invader to perish miserably. See the article BRUTE.

They will often breed in plum-trees and apple-trees, in old rooks nests, and in the forks of boughs beneath them.

Siskin.

4. The *spinus*, or SISKIN, hath the prime feathers of the wings yellow in the middle, and the four first chief tail-feathers without spots; but they are yellow at the base, and black at the points.

Mr Willoughby tells us, that this is a song-bird: that in Sussex it is called the *barley-bird*, because it comes

to them in barley-feed time. We are informed that it visits these islands at very uncertain times, like the grosbeak, &c. It is to be met with in the bird-shops in London; and being rather a scarce bird, sells at a higher price than the merit of its song deserves: it is known there by the name of the *aberdavine*. The bird-catchers have a notion of its coming out of Russia. Dr Kramer informs us, that this bird conceals its nest with great art; though there are infinite numbers of young birds in the woods on the banks of the Danube, that seem just to have taken flight, yet no one could discover it.

5. The *linaria*, or LINNET, hath the bottom of the breast of a fine blood-red, which heightens as the spring advances.

Linnet.

These birds are much esteemed for their song: they feed on seeds of different kinds, which they peel before they eat: the seed of the linum or flax is their favourite food; from whence the name of the linnet tribe. They breed among furze and white thorn: the outside of their nest is made with moss and bents, and lined with wool and hair. They lay five whitish eggs, spotted like those of the goldfinch.

6. The *cannabina*, or RED-HEADED LINNET, is less than the former, and hath a blood-coloured spot on the forehead.

It is a common fraud in the bird-shops in London, when a male-bird is distinguished from the female by a red breast, as in the case of this bird, to stain or paint the feathers, so that the deceit is not easily discovered, without at least close inspection. These birds are frequent on our sea-coasts; and are often taken in flight-time near London: it is a familiar bird; and is cheerful in five minutes after it is caught.

7. The *canaria*, or CANARY-BIRD, hath a whitish body and bill, with the prime feathers of the wings and tail greenish. It was originally peculiar to those isles to which it owes its name; the same that were known to the ancients by the addition of the *fortunate*. Though the ancients celebrate the isle of Canaria for the multitude of birds, they have not mentioned any in particular. It is probable, then, that our species was not introduced into Europe till after the second discovery of these isles, which was between the 13th and 14th centuries. We are uncertain when it first made its appearance in this quarter of the globe. Belon, who wrote in 1555, is silent in respect to these birds: Gesner is the first who mentions them; and Aldrovand speaks of them as rarities; that they were very dear on account of the difficulty attending the bringing them from so distant a country, and that they were purchased by people of rank alone. Olinia says, that in his time there was a degenerate sort found on the isle of Elba, off the coast of Italy, which came there originally by means of a ship bound from the Canaries to Leghorn, and was wrecked on that island. These birds will produce with the goldfinch and linnet; and the offspring is called a *mule-bird*, because, like that animal, it proves barren. They are still found on the same spot to which we were first indebted for the production of such charming songsters; but they are now become so numerous in our own country, that we are under no necessity of crossing the ocean for them.

Canary-bird.

FRIPPERY, a French term sometimes used in our language.

language to signify the trade or traffic of old second-hand clothes and goods. The word is also used for the place where such sort of commerce is carried on, and even for the commodities themselves. The company of frippiers, or fripperers, at Paris, are a regular corporation, of an ancient standing, and make a considerable figure in that city.

FRITT, a mixture of several substances intended to be fused together for the purpose of making glass. After these substances have been mixed together, they are generally exposed during a certain time to a more or less strong heat, which is, however, incapable of completely fusing them. The intention of this operation is either to effect a slight union betwixt these matters, or to free them more perfectly from any inflammable or extraneous matter, by this calcination.

FRITH, in its most usual acceptation, signifies an arm of the sea; such are the Frith of Forth or of Edinburgh, the Frith of Clyde, Murray Frith, &c.

FRITILLARIA, FRITILLARY; a genus of the monogynia order, belonging to the hexandria class of plants. There are five species, all of them bulbous-rooted flowery perennials, producing annual stalks from about one foot to a yard or more high, terminated by large, bell-shaped, lilaceous flowers, of a great variety of colours. They are all propagated by offsets, which they furnish abundantly from the sides of their roots, and which may be separated every second or third year; they are hardy plants, and will thrive in any of the common borders.

FRIULI, a province of Italy, subject to Venice, and bounded by Carinthia in Germany on the north, by Carniola on the east, by the Gulph of Venice on the south, and by the Bellunese and Feltrin on the west.

FRIZING OF CLOTH, a term in the woollen manufactory, applied to the forming of the nap of cloth, or stuff, into a number of little hard burrs or prominences, covering almost the whole ground thereof.

Some cloths are only frized on the back side, as black cloths; others on the right side, as coloured and mixed cloths, rateens, bays, friezes, &c.

Frizing may be performed two ways; one with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument.

The other way is by a mill, worked either by water or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The structure of this useful machine is as follows.

The three principal parts are the frizer or crisper, the frizing table, and the drawer or beam. The two first are two equal planks or boards, each about 10 feet long and 15 inches broad; differing only in this, that the frizing-table is lined or covered with a kind of coarse woollen stuff, of a rough sturdy nap; and the frizer is incrustated with a kind of cement composed of glue, gum-arabic, and a yellow sand, with a little aqua-vitæ, or urine. The beam, or drawer, thus called, because it draws the stuff from between the frizer and the frizing-table, is a wooden roller, beset all over with little, fine, short points or ends of wire, like those of cards used in carding of wool.

The disposition and use of the machine is thus. The table stands immovable, and bears or sustains the cloth to be frized, which is laid with that side uppermost on which the nap is to be raised: over the table is placed the frizer, at such a distance from it as to give room for the stuff to be passed between them: so that the frizer, having a very slow semicircular motion, meeting the long hairs or naps of the cloth, twists, and rolls them into little knobs or burrs; while, at the same time, the drawer, which is continually turning, draws away the stuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is a-going, is to stretch the stuff on the table as fast as the drawer takes it off, and from time to time to take off the stuff from the points of the drawer.

The design of having the frizing-table lined with stuff of a short, stiff, stubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which must otherwise be the case, as it is not held by any thing at the other end. It were unnecessary to say any thing particular of the manner of frizing stuffs with the hand, it being the aim of the workmen to imitate, as near as they can with their wooden instrument, the slow, equable, and circular motion of the machine: it needs only be added, that their frizer is but about two feet long and one broad; and that to form the nap more easily, they moisten the surface of the stuff lightly, with water mingled with whites of eggs or honey.

FROBENIUS (John), a famous and learned printer in the 16th century, was born at Hamelburgh in Franconia, and settled at Basil. He had before studied in that university, where he acquired the reputation of being uncommonly learned; and now settling up a printing-house in that city, was the first of the German printers who brought that admirable art to any degree of perfection. Being a man of great probity and piety, as well as skill, he was particularly choice in the authors he printed; and would never, for the sake of profit, suffer libels, or any thing that might hurt the reputation of another, to go through his press. The great character of this printer was the principal motive which induced Erasmus to reside at Basil, in order to have his own works printed by him. A great number of valuable authors were printed by Frobenius, with great care and accuracy; among which were the works of St Jerome, Augustine, and Erasmus. He designed to have printed the Greek Fathers; but died in 1527, before he could execute his design. Erasmus wrote his epitaph in Greek and Latin.

John Frobenius left a son, named *Jerome Frobenius*, and a daughter married to Nicholas Episcopius; who, joining in partnership, continued Frobenius's printing-house with reputation, and printed correct editions of the Greek Fathers.

FROBISHER, or FORBISHER, (Sir Martin), an excellent navigator and sea-officer in the 16th century, was born near Doncaster in Yorkshire, and was from his youth brought up to navigation. He was the first Englishman who attempted to find a north-west passage to China; and, in 1576, he failed with two barks and a pinnacle, in order to attempt that passage.

Profisher,
Frog.

this voyage he discovered a cape, to which he gave the name of *Queen Elizabeth's Foreland*, and the next day discovered a strait to which he gave his own name. This voyage proving unsuccessful, he attempted the same passage in 1577; but discovering some ore in an island, and his commission directing him in this voyage only to search for ore, and to leave the farther discovery of the north-west to another time, he returned to England. He sailed again, with 15 ships, and a great number of adventurers, to form a settlement: but being obstructed by the ice, and driven out to sea by a violent storm, they, after encountering many difficulties, returned home, without making any settlement, but brought a large quantity of ore.—He afterwards commanded the *Aid* in Sir Francis's Drake's expedition to the West Indies, in which St Domingo in Hispaniola, Cartagena, and Santa Justina, in Florida, were taken and sacked. In 1588, he bravely exerted himself in defence of his country, against the Spanish armada, when he commanded the *Triumph*, one of the largest ships in that service; and, as a reward for his distinguished bravery, received the honour of knighthood from the lord high-admiral at sea. He afterwards commanded a squadron which was ordered to cruise on the Spanish coast; and, in 1592, took two valuable ships and a rich carrack. In 1594, he was sent to the assistance of Henry IV. king of France against a body of the Leaguers and Spaniards, who had strongly entrenched themselves at Croyzon near Brest; but in an assault upon that fort, on the 7th of November, Sir Martin was unfortunately wounded with a ball, of which he died soon after he had brought back the fleet to Plymouth, and was buried in that town.

PROFISHER'S *Strait*, lie a little to the northward of cape Farewell in West Greenland, and were discovered by Sir Martin Profisher. W. Long. 48. 16. N. Lat. 63. 12.

FROG, in zoology. See RANA.

Bull-FROG. See RANA.

FROG-Fish of Surinam, a very singular animal, of which a figure is given by Mr Edwards, *Hist. of Birds*, Vol. I. There is no specimen in the British museum, nor in any private collection, except that of Dr Fothergill. It was brought from Surinam in South America.—Frogs, both in Asia and Africa, according to Merian, change gradually from fishes to frogs, as those in Europe; but after many years revert again into fishes, though the manner of their change has never been investigated. In Surinam these fishes are called *jakjés*. They are cartilaginous, of a substance like our mustela, and exquisite food: they are formed with regular vertebrae, and small bones all over the body divided into equal parts; are first darkish, and then grey: their scales make a beautiful appearance. Whether this animal is, in its perfect state, a species of frog with a tail, or a kind of water-lizard, Mr Edward's does not pretend to determine; but observes, that when its size is considered, if it should be deemed a tadpole at first produced from spawn, and in its progress towards a frog, such an animal, when full grown, if it bears the same proportion to its tadpole as those in Europe do, must be of enormous size; for our full-grown frogs exceed the tadpoles at least 50 times. See a reduced figure on Plate CV.

FRONDESCENTIA, from *frons*, a "leaf;" the

precise time of the year and month in which each species of plants unfolds its first leaves.

All plants produce new leaves every year; but all do not renew them at the same time. Among woody plants, the elder, and most of the honey-suckles; among perennial herbs, crocus and tulip, are the first that push or expand their leaves. The time of sowing the seeds decides with respect to annuals. The oak and ash are constantly the latest in pushing their leaves: the greatest number unfold them in spring; the mosses and firs in winter. These striking differences with respect to so capital a circumstance in plants as that of unfolding their leaves, seem to indicate that each species of plants has a temperature proper or peculiar to itself, and requires a certain degree of heat to extricate the leaves from their buds, and produce the appearance in question.

This temperature, however, is not so fixed or constant as it may appear to a superficial observer. Among plants of the same species, there are some more early than others; whether that circumstance depends, as it most commonly does, on the nature of the plants, or is owing to differences in heat, exposure, and soil. In general, it may be affirmed, that small and young trees are always earlier than larger or old ones.

The pushing of the leaves is likewise accelerated or retarded according to the temperature of the season; that is, according as the sun is sooner or later in dispensing that certain degree of heat which is suitable to each species.

FRONTINUS (Sextus Julius), an ancient Roman writer, was of consular dignity, and flourished under the emperors Vespasian, Titus, Domitian, Nerva, and Trajan. He commanded the Roman armies in Britain; was made city-prefect when Vespasian and Titus were consuls; and Nerva made him curator of the aqueducts, which occasioned his writing *De aqueductibus urbis Romæ*. He wrote four books upon the Greek and Roman art of war; a piece *De re agraria*, and another *De limitibus*. These have been often separately reprinted; but were all collected together in a neat edition at Amsterdam in 1661, with notes by Robertus Kenchenius. He died under Trajan.

FRONTISPIECE, in architecture, the portrait or principal face of a building. See ARCHITECTURE.

FRONTISPIECE, is also used to signify an ornament fronting the title-page of a book, which, in some measure, should express the subject treated of.

FRONTO (Marcus Cornelius), was chosen for his eloquence to instruct the emperors Marcus Aurelius and Lucius Verus in rhetoric; in recompence of which he was promoted to the consulate, and a statue was erected to his honour. He taught Marcus Aurelius not only eloquence, but the duty of kings, and excellent morals. Some say he wrote against the Christians. A sect was formed of those who looked upon him as a model of perfect eloquence, and these were called *Frontoniani*. The Civilians, whose names were *Fronto*, mentioned in the pandects, were probably descended from him.

FROST, in physiology, such a state of the atmosphere as occasions the congelation or freezing of water and other fluids. See CONGELATION.

Under the articles COLD, CONGELATION, EVAPORATION.

Fronde-
centia.
Frost.

Frost.

PORATION, FLUIDITY, &c. it is shewn, that water and other fluids are capable of containing the element of fire, or heat, in two very different states. In the one, they seem to imbibe the fire in such a manner, that it eludes all the methods by which we are accustomed to observe it, either by our sensation of feeling, or the thermometer; in the other, it manifests itself obviously to our senses, either by the touch, the thermometer, or the emission of light.

In the first of these states, we call the body *cold*; and are apt to say that this coldness is occasioned by the *absence* of heat. But this manner of expressing ourselves is certainly improper; for, even those fluids which are coldest to the touch, contain a vast deal of heat. Thus, vapour, which is colder to the touch than the water from which it was raised, contains an immense quantity of fire, even more than sufficient to heat it red hot. The like may be said of common salt, and snow, or ice. If a quantity of each of these substances is separately reduced to the degree of 28 or 30 of Fahrenheit's thermometer, upon mixing them together, the heat which would have raised the thermometer to the degree abovementioned, now enters into the substance of them in such a manner that the mercury falls down to 0.—Here an excessive degree of cold is produced, and yet we are sure that the substances contain the very same quantity of heat that they formerly did: nay, they will even seem exceedingly cold, when they most certainly contain a great deal more heat than they originally did; for they absorb it from all bodies around them; and if a small vessel full of water is put in the middle of such a mixture, it will in a short time be full of ice.

It appears, therefore, that our senses, even when assisted by thermometers, can only judge of the state in which the element of fire is with relation to the bodies around us, without regard to the quantity contained in them. Thus, if heat flows from any part of our body into any substance actually in contact with it, the sensation of cold is excited, and we call that substance *cold*; but if it flows from any substance into our body, the sensation of heat is excited, and we call that substance *hot*, without regard to the absolute quantity contained in either case. See HEAT.

Of all known substances, the atmosphere either absorbs or throws out heat with the most remarkable facility; and in one or other of these states it always is with respect to the surface of the earth, and such bodies as are placed on or near it; for these, properly speaking, have no temperature of their own, but are entirely regulated by that of the atmosphere.—When the air has been for some time absorbing the heat from terrestrial bodies, a frost must be the undoubted consequence, for the same reason that water freezes in a vessel put into a freezing mixture; and were this absorption to continue for a length of time, the whole earth would be converted into a frozen mass. There are, however, certain powers in nature, by which this effect is always prevented; and the most violent frost we can imagine, must always as it were defeat its own purposes, and end in a thaw. To understand this subject, we must observe,

1. In that state of the atmosphere which we denominate frost, there is a most intimate union between the air and the water it contains; and therefore frosty

weather, except in very high latitudes, is generally Frost.

2. When such an union takes place, either in winter or summer, we observe the atmosphere also inclined to absorb heat, and consequently to frost. Thus in clear settled weather, even in summer, though the day may be excessively hot, by reason of the continued sunshine, yet the mornings and evenings are remarkably cold, and sometimes even disagreeably so.

3. The air being, therefore, always ready in the time of frost, or in clear weather, to absorb heat from every substance which comes into contact with it, it follows that it must also absorb part of that which belongs to the vapours contained in it.

4. Though vapour is capable of becoming much colder than water without being frozen, yet by a continued absorption it must at last part with its latent heat, *i. e.* that which essentially constitutes it vapour; and without which it is no longer vapour, but water or ice. No sooner, therefore, does the frost arrive at a certain pitch, than the vapours, every where dispersed through the air, give out their latent heat: the atmosphere then becomes clouded; the frost either totally goes off, or becomes milder by reason of the great quantity of heat discharged into the air; and the vapours descend in rain, hail, or snow, according to the particular disposition of the atmosphere at the time.

5. Even in the polar regions, where it may be thought that the frost must increase beyond measure, there are also natural means for preventing its running to extremes. The principal cause here is, the mixture of a great quantity of vapours from the more temperate regions of the globe with the air in those dreary climates. It is well known, that aqueous vapour always flies from a warm to a colder place. For this reason, the vapours raised by the sun in the more temperate regions of the earth, must continually travel northward and southward in great quantities. Thus they furnish materials for those immense quantities of snow and ice which are to be found in the neighbourhood of the poles, and which we cannot imagine the weak influence of the sun in these parts capable of raising. It is impossible that a quantity of vapour can be mixed with frosty air, without communicating a great deal of heat to it; and thus there are often thaws of considerable duration even in those climates where, from the little influence of the sun, we should suppose the frost would be perpetual.

6. We may now account with some probability for the uncertain duration of frosts. In this country they are seldom of a long continuance; because the vapours raised from the sea with which our island is surrounded, perpetually mix with the air over the island, and prevent a long duration of the frost. For the same reason, frosts are never of such long duration in maritime places on the continent, as in the inland ones. There is nothing, however, more uncertain than the motion of the vapours with which the air is constantly filled, and therefore it is impossible to prognosticate the duration of a frost with any degree of certainty. In general, we may always be certain, that if a quantity of vapour is accumulated in any place, no intense frost can subsist in that place for any length of time; and by whatever causes the vapours are driven from place to place, by the same causes the frosts are regulated throughout

Frost. throughout the whole world. See THAW, VAPOUR, &c.

Frost
||
Fructescen-
tia.

The effects of frost in several different countries, are enumerated under the article CONGELATION. In the northern parts of the world, even solid bodies are liable to be affected by frost. Timber is often apparently frozen, and rendered exceedingly difficult to saw. Marble, chalk, and other less solid terrestrial concretions, will be shattered by strong and durable frosts. Metals are contracted by frost: thus, an iron tube, 12 feet long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, frost swells or dilates water near one tenth of its bulk. Mr Boyle made several experiments with metalline vessels, exceedingly thick and strong; which being filled with water, close stopped, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently destroyed by frost, as if burnt up by the most excessive heat; and in very strong frosts, walnut-trees, ashes, and even oaks, are sometimes split and cleft, so as to be seen through, and this with a terrible noise, like the explosion of fire-arms.

Frost naturally proceeds from the upper parts of bodies downwards: but how deep it will reach in earth or water, is not easily known; because this depth may vary with the degree of coldness in the air, by a longer or shorter duration of the frost, the texture of the earth, the nature of the juices wherewith it is impregnated, the constitution of its more internal parts as to heat and cold, the nature of its effluvia, &c. Mr Boyle, in order to ascertain this depth, after four nights of hard frost, dug in an orchard, where the ground was level and bare, and found the frost had scarce reached three inches and a half, and in a garden nearer the house only two inches, below the surface. Nine or ten successive frosty nights froze the bare ground in the garden six inches and a half deep; and in the orchard, where a wall sheltered it from the south sun, to the depth of eight inches and a half. He also dug in an orchard, near a wall, about a week afterwards, and found the frost to have penetrated to the depth of 14 inches. In a garden at Moscow, the frost in a hard season only penetrates to two feet: and the utmost effect that Captain JAMES mentions the cold to have had upon the ground of Charlton island, was to freeze it to 10 feet deep: whence may appear the different degrees of cold of that island and Russia. And as to the freezing of water at the abovementioned island, the Captain tells us, it does not naturally congeal above the depth of six feet, the rest being by accident. Water also, exposed to the cold air in large vessels, always freezes first at the upper surface, the ice gradually increasing and thickening downwards: for which reason, frogs retire in frosty weather to the bottom of ditches; and it is said, that shoals of fish retire in winter to those depths of the sea and rivers, where they are not to be found in summer. Water, like the earth, seems not disposed to receive any very intense degree of cold at a considerable depth or distance from the air. The vast masses of ice found in the northern seas being only many flakes and fragments, which, sliding under each other, are, by the congelation of the intercepted water, cemented together.

In cold countries, the frost often proves fatal to mankind; not only producing gangrenes, but even death

itself. Those who die of it have their hands and feet first seized, till they grow past feeling it; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, viz. by freezing the abdomen and viscera, which on dissection are found to be mortified and black.

Hoar-Frost, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy crystals of various figures. Hoar-frost, therefore, is nothing but dew turned into ice by the coldness of the air.

Melioration of Aromatic Spirits by Frost. Mr Baume observes, that aromatic spirituous waters have less scent when newly distilled than after they have been kept about six months: and he found that the good effects of age was produced in a short time by means of cold; and that, by plunging quart-bottles of the liquor into a mixture of pounded ice and sea-salt, the spirit, after having suffered for six or eight hours the cold hence resulting, proves as grateful as that which hath been kept many years. Simple waters also, after having been frozen, prove far more agreeable than they were before. Geoffroy takes notice of this melioration by frost; *Hist. Acad.* 1713.

Melioration of Land by Frost. See AGRICULTURE, n° 30.

Frost-Bitten. See (the *Index* subjoined to) MEDICINE.

FROTH, a white, light substance, formed on the surface of fluids, by vehement agitation, consisting of little spherules or globules.

FROTH-Spit, or Cuckoo-Spit, a name given to a white froth, or spume, very common in the spring and first months of summer, on the leaves of certain plants, particularly on those of the common white field-lychnis or catch-fly, thence called by some *spatling poppy*.

All writers on vegetables have taken notice of this froth, though few have understood the cause or origin of it till of late. It is formed by a little leaping animal, called by some the *sea grass-hopper*, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which, containing some air in it, is soon elevated into a small bubble: before this is well formed, it deposits such another drop; and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see. Within this spume it is seen to acquire four tubercles on its back, wherein the wings are inclosed: these bursting, from a reptile it becomes a winged animal; and thus, rendered perfect, it flies to meet its mate, and propagate its kind. It has an oblong, obtuse body, and a large head with small eyes. The external wings, for it has four, are of a dusky brown colour, marked with two white spots: the head is black. It is a species of CICADA.

FRUCTESCENCIA, (from *fructus*, "fruit,") comprehends the precise time in which, after the fall of the flowers, the fruits arrive at maturity, and disperse their seeds.

In general, plants which flower in spring, ripen their fruits in summer, as rye; those which flower in summer, have their fruits ripe in autumn, as the vine; the fruit of autumnal flowers ripens in winter, or the following

Fruitful-
Fruit.

lowing spring, if kept in a stove or otherwise defended from excessive frosts. These frosts, says M. Adanson, are frequently so pernicious and violent as to destroy the greatest part of the perennial plants of Virginia and Mississippi, that are cultivated in France, even before they have exhibited their fruit. The plants which flower during our winter, such as those of the Cape of Good Hope, ripen their fruit in spring in our stoves.

FRUCTIFEROUS, signifies properly any thing that produces fruit.

FRUCTIFICATION, among botanists, in a more lax sense, includes the flower and fruit, with their several coverings. See FRUCTUS.

FRUCTUS, in botany, the FRUIT, is defined by Jungius and former botanists to be an annual part of the plant, which adheres to the flower and succeeds it; and, after attaining maturity, separates or detaches itself from the parent plant; and, being commodiously lodged in the bosom of the earth, gives birth to a new vegetable. This definition is sufficiently accurate, and so perspicuous, that it requires no illustration whatever. We shall only observe, that, in its vulgar acceptation, the word *fruit* is expressive, not of the seeds, which are doubtless the essence of every fruit; but of the case or vessel in which they are contained. Thus, when we speak of the fruit of an apple-tree, we always mean the luscious pulp which enfolds the seeds; although that, in strict propriety, is only the cover of the fruit.

Colours Extracted from FRUITS. See the article COLOUR-Making, n° 35.

FRUIT-FLIES, a name given by gardeners and others to a sort of small black flies found in vast numbers among fruit trees, in the spring season, and supposed to do great injury to them. Mr Lewenhoeck preserved some of these flies for his microscopical observations. He found that they did not live longer than a day or two, but that the females during this time laid a great number of longish eggs. The gardeners who suppose that these flies wound the leaves of the trees, are mistaken: it is true that they feed on their juices; but they have no instruments wherewith they can extract these for themselves: they feed on such as are naturally extravasated; and when there is not a sufficient quantity of these for their purpose, they haunt the places to which the pucerons resort, and feed on the juices which these little creatures extravasate by means of the holes they bore in the leaves with their trunks.

FRUIT-STONES. The mischiefs arising from the cumber which many people have of swallowing the stones of plums and other fruit are very great. The Philosophical Transactions give an account of a woman who suffered violent pains in her bowels for 30 years, returning once in a month or less. At length, a strong purge being given her, the occasion of all these complaints was driven down from the bowels to the anus; where it gave a sensation of distension and stoppage, producing a continual desire of going to stool, but without voiding any thing. On the assistance of a careful hand in this case, there was taken out with a forceps, a ball of an oval figure, of about ten drachms in weight, and measuring five inches in circumference. This had caused all the violent fits of pain which she had suffered for so many years; and, after voiding it, she became perfectly well. The ball extracted looked like a stone, and felt very hard, but it swam in water.

Fruit
Frumentaceous.

On cutting it through with a knife, there was found in the centre of it a plum-stone; round which, several coats of this hard and tough matter had gathered. Another instance given in the same papers is of a man, who, dying of an incurable colic which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found a ball similar to that above-mentioned; but somewhat larger, being six inches in circumference, and weighing an ounce and an half. In the centre of this, as of the other, there was found the stone of a common plum, and the coats were of the same nature with those of the former.

These and several other instances mentioned in the same place, sufficiently shew the folly of that common opinion that the stones of fruits are wholesome. For though by nature the guts are so defended by their proper mucus, that people very seldom suffer by things of this kind; yet if we consider the various circumvolutions of the guts, their valves and cells, and at the same time consider the hair of the skins of animals we feed on, the wool or down on herbs and fruit, and the fibres, vessels, and nerves of plants, which are not altered by the stomach; it will appear a wonder that instances of this sort of mischief are not much more common. Cherry-stones, swallowed in great quantities, have occasioned the death of many people; and there have been instances even of the seeds of strawberries collecting into a lump in the guts, and causing violent disorders, which could not be cured without great difficulty.

FRUIT-TREES. With regard to these it may be observed, 1. That the cutting and pruning them when young, scrimp their bearing, though it contributes to the richness and flavour of the fruit, as well as to the beauty of the tree. 2. That kernel-fruit trees come later to bear than stone-fruit trees: the time required by the first before they come to any fit age for bearing, being one with another five years; but when they do begin, they bear in greater plenty than stone-fruit. 3. That stone-fruit, figs, and grapes, commonly bear considerably in three or four years, and bear full crops the fifth and sixth years; and hold it for many years, if well ordered. 4. That fruit-trees in the same neighbourhood will ripen a fortnight sooner in some grounds, than in others of a different temperature. 5. That, in the same country, hot or cold summers set considerably forwards, or put backwards, the same fruit. 6. That the fruit on wall-trees generally ripen before those on standards, and those on standards before those on dwarfs. 7. That the fruit of all wall-trees planted in the south and east quarters, commonly ripen about the same time, only those in the south rather earlier than those in the east; those in the west are later by eight or ten days; and those in the north, by 15 or 20. For the planting, pruning, grafting, &c. of fruit-trees, see the articles PLANTING, TRANSPLANTING, PRUNING, GRAFTING, ORCHARD, NURSERY, &c.

FRUITERY, a place for the keeping of fruit, a fruit-house, or fruit-loft.

A fruitery should be inaccessible to any thing of moisture; and should be as much as possible free from frost.

FRUMENTACEOUS, a term applied by botanists.

nists to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

FRUMENTARIII, a kind of soldiers, or archers, under the western empire.

The first time we read of these officers is in the reign of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed, that they were at first a number of young persons, disposed by Augustus throughout the provinces, particularly on all the grand roads, to acquaint the emperor, with all expedition, of every thing that happened.

Afterwards they were incorporated into the troops themselves, where they still retained their ancient name. As their principal office was the giving intelligence, they were often joined with the curiosi, with whom they agreed in this part of their office.

Their name of *frumentarii* is derived from their being also a sort of purveyors to the armies, cities, &c. collecting all the corn from the several provinces to furnish the commonwealth.

FRUMENTATION, in Roman antiquity, a largess of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans, and frequently used to soothe the turbulent humour of the populace. At first the number of those to whom this largess was given was indeterminate, till Augustus fixed it at 200,000.

FRUSH, or **RUNNING-THRUSH**. See **FARRIERY**, §. xlv.

FRUSTUM, in mathematics, a part of some solid body separated from the rest.

The frustum of a cone is the part that remains, when the top is cut off by a plane parallel to the base; and is otherwise called a *truncated cone*. See **CONIC SECTIONS**.

The frustum of a pyramid is also what remains after the top is cut off by a plane parallel to its base.

The frustum of a globe or sphere is any part thereof cut off by a plane, the solid contents of which may be found by this rule: To three times the square of the semidiameter of the base, add the square of its height; then multiply that sum by the height; and this product multiplied by .5236 gives the solidity of the frustum.

FRUTEX, a **SHRUB**. Shrubs, according to Linnæus, make a branch of the seventh family in the vegetable kingdom; and are distinguished from trees, in that they come up without buds. But this distinction is not universal, though it be generally just with regard to those of Europe. Nature hath made no absolute distinction between trees and shrubs. *Frutex*, in its general acceptation, is a plant whose trunk is perennial, gemmiparous, woody, dividing and subdividing into a great number of branches. In short, it is the epitome of a tree, exemplified in the rose-bush.

FRYTH (John), a martyr to the Protestant religion in the reign of Henry VIII. He was the son of an inn-keeper at Seven-oaks in Kent; and educated in the king's college, Cambridge, where he took the degree of bachelor of arts. Thence he removed to Oxford, and was made a junior canon of Wolfey's college. He

had not been long in this university, before he became acquainted with William Tyndale, a zealous Lutheran, with whom he conversed frequently on the abuses in religion. Fryth became a convert to Lutheranism, and publicly avowed his opinions. He was apprehended, examined by the commissary, and confined to his college. At length, having obtained his liberty, in 1528 he went over to Germany, where he continued about two years; and then returned to England, more than ever determined in his religious sentiments. Finding at that time but few associates, he wandered about from place to place, till at last he was taken up at Reading as a vagrant, and set in the stocks, where he remained till he was near expiring for want of sustenance. He was at length relieved by the humanity of Leonard Cox, a schoolmaster; who finding him a man of letters, procured his enlargement, and administered to his necessities. Fryth now set out for London, where, with more zeal than prudence, he began to make proselytes; but was soon apprehended by order of the chancellor Sir Thomas More, and sent prisoner to the Tower. Refusing to recant his opinions, he was condemned to the flames, and accordingly burnt in Smithfield, on the fourth of July 1533. He left several works behind him, which were printed in folio in 1573.

FUAGE, in old English writers, a tax of 12d. for every fire, levied in the time of Edward III.

FRY, in zoology, signifies the spawn, or rather young, of fish.

FUCUS, in botany, a genus of submarine plants, belonging to the cryptogamia class.

The fucus consists of a tough matter, formed into a kind of leaves, which are flat and variously divaricated; and which have some appearance of fructification, in punctated tubercles, covering oblong vesicles, supposed by Linnæus to be male flowers; and smooth roundish vesicles, hollow and interwoven with filaments, which appear to him to be female flowers. There are 34 species of fucus, or sea-wrack, many of them to be found on our coasts.

The ancients used a purple sea-plant to dry woollen and linen things of that colour, and called it *fucus*. The dye was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. This is the account Theophrastus gives of it.

The women of those times also used something called *fucus*, to stain their cheeks red; and many have supposed, from the same word expressing both, that the same substance was used on both occasions. But this, on a strict inquiry, proves not to be the case. The Greeks called every thing *fucus*, that would stain or paint the flesh. But this peculiar substance used by the women to paint their cheeks was distinguished from the others by the name of *rizon* among the more correct writers, and was indeed a root brought from Syria into Greece. The Latins, in imitation of the Greek name, called this root *radicula*, and Pliny very erroneously confounds the plant with the *radix lunaria*, or *struthion* of the Greeks.

The word *fucus* was in those times become such an universal name for paint, that the Greeks and Romans had a *fucus metallicus*, which was the cerufs used for painting the neck and arms white; after which they used the *purpurissum*, or red fucus of the *rizzium*, to give

give the colour to the cheeks. In after-times they also used a peculiar *fucus* or paint for this purpose; prepared of the *Creta argentaria*, or silver-chalk, and some of the rich purple dyes that were in use at that time: and this seems to have been very little different from our rose-pink; a colour commonly fold at the colour-shops, and used on like occasions.

FUEGO, or **Fogo**, one of the Cape de Verd islands, in the Atlantic ocean. It is much higher than any of the rest; and seems, at sea, to be one single mountain, though on the sides there are deep valleys. There is a volcano at the top, which burns continually, and may be seen a great way off at sea. It vomits a great deal of fire and smoke, and throws out huge pieces of rock to a vast height; and sometimes torrents of melted matter run down the sides. The Portuguese, who first inhabited it, brought negro slaves with them, and a flock of cows, horses, and hogs; but the chief inhabitants now are blacks, of the Romish religion. W. Long. 24. 47. N. Lat. 15. 20.

FUEL, whatever is proper to burn or make a fire; as wood, turf, peat, bituminous earths, coal, &c.

FUGALIA, in Roman antiquity, a feast supposed by some to be the fame with the *refugium*, held on the 24th of February, in memory of the expulsion of the kings, and the abolishing of monarchical government. Others again distinguish the *fugalia* from the *refigie*. And others think, that the *fugalia* was the fame with the *poplifugia*, or the feast of Fugia, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery.

FUGITIVE, a person obliged to fly his country, or remove from a place where he had home abode or establishment, on account of his crimes, debts, or other occasions.

FUGUE, in music, (from the Latin *fuga*, a "chase.") A piece of music, sometimes longer and sometimes shorter, in which, agreeable to the rules of harmony and modulation, the composer treats a subject; or, in other words, what expresses the capital thought or sentiment of the piece, in causing it to pass successively and alternately from one part to another.

These are the principal rules of the fugue; of which some are peculiar to itself, and others common to it with what the French call *imitation*.

1. The subject proceeds from the tonic to the dominant, or from the dominant to the tonic, in rising or descending.

2. Every fugue finds its response in the part immediately following that which commenced.

3. That response ought to resume the subject in the interval of a fourth or fifth above or below the key, and to pursue it as exactly as the laws of harmony will admit; proceeding from the dominant to the tonic when the subject is introduced from the tonic to the dominant, and moving in a contrary direction when the subject is introduced from the dominant to the tonic. One part may likewise resume the same subject in the octave or unison of the preceding; but in that case, it is a repetition rather than a real response.

4. As the octave is divided into two unequal parts, of which the one contains four gradations ascending from the tonic to the dominant, and the other only three in continuing the ascent from the dominant to

the tonic; this renders it necessary to have some regard to this change in the expression of the subject, and to make some alterations in the response, that we may not quit the chords that are essential to the mode. It is a different case when the composer intends to alter the modulation; for there the exactness of the response itself, when taken in a different tone, produces the alteration proper for this change.

5. It is necessary that the fugue should be planned in such a manner, that the response may commence before the close of the first air, so that both the one and the other may be in part heard at the same time; that, by this anticipation, the subject may be as it were connected with itself, and that the art of the composer may discover itself in this concourse. It is absolute mockery, instead of a fugue, to impose upon the hearers the same air, merely transposed from one key to another, without any other restraint than an accompaniment afterwards formed at pleasure. This deserves at best no better name than what the French call *imitation*. See **IMITATION**.

Besides these rules, which are fundamental, there are others which, though prescribed by taste alone, are not less essential. Fugues, in general, render music more noisy than agreeable; it is for this reason that they are more agreeable in the chorus than any where else. Now, as their chief merit consists in fixing the ear on the principal air or subject, which for this reason is made to pass incessantly from part to part, and from mode to mode, the composer ought to exert his care in preserving that air always distinct; or to prevent it from being absorbed in, or confounded with, the other parts. To produce this effect, there are two different ways: one in the movement, which must be incessantly contrasted with itself; so that, if the procedure of the fugue be accelerated, the other parts move gravely and with protracted notes; or, on the contrary, if the motion of the fugue be slow and solemn, the accompaniments must have more and quicker business. The other method is to extend the harmony, by removing the parts at a greater distance one from the other; lest the others, too nearly approximated to that which contains the subject, should be confounded with it, and prevent it from being distinguished with sufficient clearness; so that what would be an imperfection any where else, becomes here a beauty.

The unity of melody should be preserved: this is the great and general rule, which must frequently be practised by different means. The chords must be chosen, and the intervals, so that one particular sound may produce the chief effect; this can only result from the unity of the melody. It will sometimes be necessary to employ voices and instruments of different kinds, that the part which ought to prevail may be most easily distinguished: this again shews the necessity of preserving the unity of the melody. Another object of attention no less necessary, is, in the different connections of modulation which are introduced by the procedure and progress of the fugue, to cause all these modulations to correspond at the same time in all the parts, to connect the whole in its progress by an exact conformity of modes; lest, if one part be in one mode, and another in another, the general harmony should be in none at all, and for that reason should no longer be able to produce simple effects upon the ear, nor simple

Fulcrum
Fulica.

Fuliginosus
Fuller.

ideas in the mind: which is another reason for preferring unity of melody. In a word, in every fugue the confusion of melodies and modulations is at once what a composer has most to fear, and will find the greatest difficulty in avoiding; and as this kind of music never produces a pleasure above mediocrity, one may say that a fine fugue is, though the masterpiece of an excellent harmonist, ungrateful to his toil.

* See Canon. There are still several other kinds of fugues; such as the perpetual fugue *, the double fugue, the inverted fugue.

The inverted fugue is a manner of composition, in which the flying part proceeds in a contrary direction to the other fugue, which had been formerly fixed in the same piece of music. Thus, when the first fugitive part is heard in ascending from the tonic to the dominant, or from the dominant to the tonic, the counter fugue ought to be heard in descending from the dominant to the tonic, or from the tonic to the dominant, and *vice versa*. Its other rules are exactly like those of the common fugue.

FULCRUM, in mechanics, the prop or support by which a lever is sustained.

FULDE, a considerable town of Germany, in the circle of the upper Rhine, and in the Buchow, with a celebrated abbey; whose abbot is primate of the abbeys of the empire, perpetual chancellor of the emperor, and sovereign of a small territory lying between Hesse, Franconia, and Thuringia. It is seated on the river Fulde, 55 miles south of Cassel, and 58 north-east of Francfort. E. Long. 9. 53. N. Lat. 50. 40.

FULICA, the coot, in ornithology, a genus of birds, of the order of gallæ. It has a convex bill, with the upper mandible forked over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald; and the feet have four toes, a little lobated. There are four species.

1. The *atra*, or COMMON COOT, hath a bald forehead, a black body, and lobated toes. They frequent lakes and still rivers; making their nest among the rushes, with grass, reeds, &c. floating on the water, so as to rise and fall with it. They lay five or six large eggs, of a dirty whitish hue, sprinkled over with minute deep rust-coloured spots; and it is said, that sometimes they will lay 14 or more eggs. The young when just hatched are very deformed, and the head mixed with a red coarse down. In winter they often repair to the sea, and the channel near Southampton is sometimes observed almost covered with them. They are often brought to that market, where they are exposed to sale without their feathers, and scalded like pigs.

2. The *chloropus*, or COMMON GALLINULE, hath a bald forehead, and toes without webs. It gets its food on grassy banks, and borders near fresh waters, and in the very waters if they be weedy. It builds upon low trees and shrubs by the water-side; breeding twice or thrice in a summer; and, when the young are grown up, drives them away to shift for themselves. They lay seven eggs of a dirty white, thinly spotted with rust-colour. This bird strikes with its bill like a hen, and in the spring has a shrill call. In flying, it hangs down its legs; in running, it often flirts up its tail, and shews the white feathers. We may observe, that the bottoms of its toes are so very flat and broad (to enable

it to swim), that it seems to be the bird which connects the cloven-footed aquatics with the next tribe, *viz.* the fin-toed.

3. The FULICA with a bald forehead, a violet-coloured body, and toes without webs, is the purple water-hen of Edwards; and it inhabits Asia and America.

4. The FULICA with a carunculated head, a variegated body, spinous shoulders, and toes without webs; but the nail on the hinder toe is exceeding long. It is the spur-winged water-hen of Edwards, and is an inhabitant of South America. The nail on the hind toe is straight, and longer than a man's finger. The pollex rests upon one joint, and the wings are green.

FULIGINOSUS, whatever proceeds from a thick, sooty smoke; such as litharge and lamp-black.

FULIGNO, a city of Italy, in the pope's territories, 10 miles north of Spoleto.

FULIGO, in natural history, a species of pumice-stone. See PUMICE.

FULK (William), a learned and eminent divine of the church of England, in the 16th century. He was patronized by the earl of Leicester, who, in 1571, presented him to the living of Warley in Essex, and soon after to that of Diddington in Suffolk. He attended Leicester, when he went ambassador to France; and on his return was made master of Pembroke-hall, and Margaret professor of divinity at Cambridge. His works are very numerous, levelled chiefly at the Papists; the most considerable of them is his Comment on the Rhemish Testament. He died in 1589.

FULLER (Nicholas), prebendary of Salisbury, and a learned English critic; who published, in 1617, *Miscellanea Theologica*, in four books; and afterward two more of *Miscellanea Sacra*. He died in 1623; and there are some MSS of his remaining in the Bodleian library, that shew his great skill in Hebrew and philosophy.

FULLER (Dr Thomas), a learned English divine; was born at Allwinckle, near Oundle, in Northamptonshire, about the year 1608, and studied at Cambridge. He was chosen minister of St Bennet's there; and at about 23 years of age, his merit procured him a fellowship in Sidney college, and a prebend in Salisbury cathedral. He was soon after presented to the rectory of Broad Windsor, in Dorsetshire; and afterwards was made lecturer of the Savoy in London; but upon the pressing of the covenant, he retired to Oxford; and soon after accompanied Sir Ralph Hopton as his chaplain in the army, which he attended in their marches from place to place. After the death of king Charles I. he obtained the living of Waltham-abbey, and was appointed lecturer of St Clement's; and shortly after removed to the lecture of St Bride's, Fleet-street. Upon the restoration, he recovered his prebend in the cathedral of Salisbury, was appointed chaplain extraordinary to his majesty, and created doctor of divinity. It is said his memory was so amazingly tenacious and comprehensive, that he could make use of a sermon *verbatim*, if he once heard it. He once undertook, in passing to and from Temple-bar to the Poultry, to tell at his return every sign as it stood in order on both sides of the way, repeating them either backwards or forwards; and this task he actually performed. He wrote, 1. A history of the holy war. 2. The church-history of Britain, in folio. 3. Andronicus,

or the unfortunate politician, in 8vo. 4. A Pisgah sight of Palestine. 5. A history of English worthies; and other works. He died in August 1664; and was interred in the chancel of Cranford church, in Middlesex, whither his body was attended by at least 200 of his brethren of the ministry.

FULLER, a workman employed in the woollen manufactories, to mill or scour cloths, ferges, and other stuffs, in order to render them more thick, compact, and durable. See CLOTH.

FULLER'S Earth, in natural history, a soft, greyish, brown, dense, and heavy marle: when dry, it is of a greyish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast: it is very hard and firm, of a compact texture, of a rough and somewhat dusty surface that adheres slightly to the tongue: it is very soft to the touch, not staining the hands, nor breaking easily between the fingers: it has a little harshness between the teeth, and melts freely in the mouth: thrown into water, it makes no ebullition or hissing; but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with aqua fortis.

The greatest quantity, and the finest earth of this kind in the world, is dug in the pits at Wavedon, near Woburn in Bedfordshire. The strata in these pits lie thus: From the surface to the depth of six feet, there are several layers or beds of sand, all reddish, but some lighter-coloured than others. Under these there is a thin stratum of a sand-stone, which they break through, and then there is the fuller's earth. The upper stratum of this is about a foot thick: the workmen call it *cledge*, and throw it aside as useless; being commonly fouled with the sand which originally covered it, and which insinuates itself a good way into it. After this, they come to the fine fuller's earth for sale, which lies to the depth of eight feet more. The matter of this is divided into several layers, there being commonly about a foot and an half between one horizontal fissure and another. Of these several layers, the upper half, where the earth breaks itself, is tinged red; which seems to be owing to the running of the water upon it from among the sands above; some of which are probably of a ferruginous nature, or have ferruginous matter among them. This reddish fuller's earth the workmen call *crop*; and between the *cledge* and this there is a thin stratum of matter, of less than an inch, which in taste, colour, and external appearance, resembles the terra Japonica of the shops. The lower half of the strata of fuller's earth they call *wall-earth*. This is untinted with the red colour of the other, and seems the most proper for fulling. Under the fuller's earth there is a stratum of white and coarse stone about two feet thick. They seldom dig thro' this; but if they do, they find more strata of sand.

This earth is of great use in scouring cloths, stuffs, &c. imbibing all the grease and oil used in preparing, dressing, &c. of the wool; for which reason it is exported a contraband commodity, and is not to be made under the penalty of 1s. for every pound weight. See FULLING.

FULLER'S Weed, in botany. See DIPSACUS.

FULLERY, a place where cloths, &c. are fulled. See the next article.

FULLING, the art or act of cleansing, scouring,

and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer: called also *milling*. Pliny, (*lib. vii. cap. 56.*) assures, that one Nicias, the son of Hermias, was the first inventor of the art of fulling: and it appears by an inscription, quoted by Sir G. Wheeler, in his travels thro' Greece, that this same Nicias was a governor in Gece in the time of the Romans.

The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called a *fulling* or *scouring* mill.

These mills, excepting in what relates to the mill-stones and hopper, are much the same with corn-mills. And there are even some which serve indifferently for either use; corn being ground, and cloths fulled, by the motion of the same wheel. Whence, in some places, particularly in France, the fullers are called *millers*; as grinding corn, and milling stuffs, at the same time.

The principal parts of the fulling-mill are, The wheel, with its trundle; which gives motion to the tree, or spindle, whose teeth communicate it to the pestles, or stampers, which are hereby raised and made to fall alternately according as its teeth catch on or quit a kind of latch in the middle of each pestle. The pestles and troughs are of wood; each trough having at least two, sometimes three pestles, at the discretion of the master, or according to the force of the stream of water. In these troughs are laid the cloths, stuffs, &c. intended to be fulled: then, letting the current of water fall on the wheel, the pestles are successively let fall thereon, and by their weight and velocity stamp and press the stuffs very strongly, which by this means become thickened and condensed. In the course of the operation, they sometimes make use of urine, sometimes of fuller's earth, and sometimes of soap. To prepare the stuffs to receive the first impressions of the pestle, they are usually laid in urine; then in fuller's earth, and water; and lastly in soap, dissolved in hot water. Soap alone would do very well; but this is expensive: though fuller's earth, in the way of our dressing, is scarce inferior thereto; but then it must be well cleared of all stones and grittinesses, which are apt to make holes in the stuff. As to urine, it is certainly prejudicial, and ought to be entirely discarded; not so much on account of its ill smell, as of its sharpness and saltness, which qualities are apt to render the stuffs dry and harsh.

The true method of fulling with soap is delivered by Monsr. Colinet, in an authentic memoir on that subject, supported by experiments made by order of the marquis de Lonois, then superintendent of the arts and manufactories of France; the substance of which we shall here subjoin.

Method of FULLING cloths and woollen stuffs with Soap.—A coloured cloth, of about 45 ells, is to be laid in the usual manner, in the trough of a fulling-mill; without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required; one half of which is to be melted in two pails of river or spring water, made as hot as the hand can well bear it. This solution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough: and thus it is to be fulled for at least two hours; after which, it is to be taken out and stretched. This done, the cloth is imme-

Fulmar
Fulmaria.

diately returned into the same trough, without any new soap; and there fullled two hours more. Then taking it out, they wring it well, to expels all the grease and filth. After the second fulling, the remainder of the soap is dissolved as in the former, and cast four different times on the cloth; remembering to take out the cloth every two hours, to stretch it, and undo the plaits and wrinkles it has acquired in the trough. When they perceive it sufficiently fullled, and brought to the quality and thickness required, they scour it for good in hot water, keeping it in the trough till it be quite clean. As to white cloths; in regard these full more easily and in less time than coloured ones, a third part of the soap may be spared.

FULLING OF *Stockings, Caps, &c.* should be performed somewhat differently; viz. either with the feet or the hands; or a kind of rack, or wooden machine, either armed with teeth of the same matter, or else horses or bullocks teeth. The ingredients made use of herein are urine, green soap, white soap, and fuller's earth. But the urine also is reckoned prejudicial here. Woven stockings, &c. should be fullled with soap alone: for those that are knit, earth may be used with the soap. Indeed, it is frequent to full these kinds of works with the mill, after the usual manner of cloth, &c. But that is too coarse and violent a manner; and apt to damage the work, unless it be very strong.

FULMAR, in ornithology. See PROCELLARIA.

FULMINATING, something that thunders, or resembles thunder.

FULMINATING Gold. See CHEMISTRY, n° 256.

FULMINATING Powder. See CHEMISTRY, n° 475.

FULMINATION, in chemistry, the same with detonation. See NITRE.

FULMINATION, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed that some bull sent from the pope shall be executed.

FUMARIA, FUMITORY; a genus of the hexandria order, belonging to the diadelphia class of plants. There are a number of different species; all of them low, shrubby, and deciduous and evergreen plants, growing from two to six or seven feet high, adorned with small simple leaves, and papilionaceous flowers of different colours. The most remarkable is the officinalis, or common fumitory; which grows naturally in shady cultivated grounds, and produces spikes of purplish flowers in May and June. It is very juicy, of a bitter taste, without any remarkable smell.—The medical effects of this herb are, to strengthen the tone of the bowels, gently loosen the belly, and promote the urinary and other natural secretions. It is principally recommended in melancholic, scorbutic, and cutaneous disorders, for opening obstructions of the viscera, attenuating and promoting the evacuation of viscid juices. Frederic Hoffman had a very great opinion of it as a purifier of the blood; and assures us, that in this intention scarce any plant exceeds it.—Cows and sheep eat the plant; goats are not fond of it; horses and swine refuse it.

FUMIGATION, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded, or softened, by receiving certain fumes for that purpose.

FUMIGATION, in medicine. By the subtle fumes that are inspired as well as inhaled into our bodies, much benefit or prejudice is produced, according to the nature of the matter, and the constitution into which it is received; as is evident from the palsies produced among workers in lead-mines, &c. and the benefits received in many cases when the air is impregnated with salutary materials. Catarrhs and catarrhus coughs are relieved by fumes received with the breath; and, by the same method, expectoration is assisted in humoral asthma; and even ulcers in the lungs are said to have been healed by this method. The advantage of mercurial fumigations in the cure of venereal ulcers is known to every practitioner.

FUMITORY, in botany. See FUMARIA.

FUNAMBULUS, among the Romans, was what we call a *rape-dancer*, and the Greeks *schenobates*. See *Rope-DANCER*.

There was a funambulus, it seems, who performed at the time when the Hecyra of Terence was acted; and the poet complains, that the spectacle prevented the people from attending to his comedy. *Ille populus studio stupidus in funambulo, animum occupat.*

At Rome, the funambuli first appeared under the consulate of Sulpicius Peticus and Licinius Stolo, who were the first introducers of the scenic representations. It is added, that they were first exhibited in the island of the Tyber, and that the censors Messala and Cassius afterwards promoted them to the theatre.

FUNCHAL, an episcopal town of Madeira, in an island of the Atlantic Ocean, over-against the coast of Morocco. It is large, strong, handsome, and populous, with fine churches. The principal trade consists in sweetmeats and wines. It belongs to the Portuguese; and is seated in a fertile valley, at the foot of a mountain from whence several streams proceed. W. Long. 14. 30. N. Lat. 31. 30.

FUNCTION, the act of fulfilling the duties of any employment.

FUNCTION, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The *vital* functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The *natural* functions are such as it cannot subsist any considerable time without; as the digestion of the aliment, and its conversion into blood. Under *animal* functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion; without any or all of which an animal may live, but not very comfortably.

The animal-functions perform the motion of the body by the action of the muscles; and this action consists chiefly in the shortening the fleshy fibres, which is called *contraction*, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

All parts of the body have their own functions, or actions, peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exercise of them.

FUND, in general, signifies any sum of money appropriated for a particular purpose. Thus, that part of the national revenue which is set aside for the pay-

Funigation
Funds.

Fig. 2.
Machine for Blowing Air into
FURNACE &c.

A Bellows!

Funds.

ment of the national debt, is called the *sinking fund*. But, when we speak of the *funds*, we generally mean the large sums which have been lent to government, and constitute the national debt; and for which the lenders, or their assignees, receive interest from revenues allotted for that purpose. The term *stock* is used in the same sense, and is also applied to the sums which form the capital of the bank of England, the East India and South-Sea companies; the proprietors of which are entitled to a share of the profits of the respective companies.

The practice of funding was introduced by the Venetians and Genoese in the 16th century, and has been adopted since by most of the nations in Europe. Princes had often borrowed money, in former times, to supply their exigencies, and sometimes mortgaged their territories in security: but these loans were generally extorted, and their payment was always precarious; for it depended on the good faith and success of the borrower, and never became a regular burden on posterity. The origin of funds is derived from the peculiar manners and circumstances of modern Europe. Since the invention of gun-powder, and the progress of commerce, the military occupation has become a distinct employment in the hands of mercenaries; the apparatus of war is attended with more expence; and the decision of national quarrels has often been determined by command of money, rather than by national bravery. Ambitious princes have therefore borrowed money, in order to carry on their projects with more vigour. Weaker states have been compelled, in self-defence, to apply to the same resource; the wealth introduced by commerce has afforded the means; and the regularity of administration, established in consequence of the progress of civility, has increased the confidence of individuals in the public security; the complicated system of modern policy has extended the scenes of war, and prolonged their duration; and the colonies established by the mercantile nations have rendered them vulnerable in more points, and increased the expence of defending them.

When a greater sum has been required for the annual expence, than could easily be supplied by annual taxes, the government have proposed terms, to their own subjects, or foreigners, for obtaining an advance of money, by mortgaging the revenue of future years for their indemnification. This mortgage may either be for a limited period, or perpetual. If the sum allotted annually for the benefit of those who advance the money, be considerably greater than the interests of the sums advanced, they may agree to accept of such allowance, for a limited time, as a full equivalent. Thus, they may either agree for the casual produce of the revenue assigned; or a fixed annuity for a greater or less number of years; or a life-annuity to themselves or nominees; or an annuity for two or more lives; or an annuity, with the benefit of survivorship, called a *tontine*, in which scheme, the whole sum to which the original annuitants were entitled continues to be distributed among the survivors.

When the sum allotted to the creditors of the public is only equivalent to the interest of the money advanced, the grant must be perpetual, unless the debt be redeemed by payment of the principal.

The establishment of the funds was introduced in

Britain at the revolution; and has since been gradually enlarged, and carried to an amazing extent. The various methods above mentioned have been used in their various forms; but perpetual annuities have been granted for the greatest part; and, even when the money was originally advanced on other conditions, the lenders have been sometimes induced, by subsequent offers, to accept of perpetual annuities, instead of the former terms. The debt for which perpetual annuities are granted, is called the *redeemable debt*, and the other is called the *irredeemable debt*. Although the debts thus contracted by government are seldom paid for a long term of years; yet, any creditor of the public may obtain money for what is due him when he pleases, by transferring his property in the funds to another; and regular methods are appointed for transacting these transfers, in an easy manner. By means of this, the stocks become a kind of circulating capital; and have the same effect, in some respects, as the circulating money in the nation. When a stockholder transfers his share, he may sometimes be able to obtain a greater price than the original value, and at other times be obliged to accept of a less one. The value of the funds depends on the proportion between the interest they bear, and the benefit which may be obtained by applying the money to other purposes. It is influenced by the plenty or scarcity of money, and by the quantity of the public debt; and it is impaired by any event which threatens the safety, or weakens the credit, of the government.

The business of stock-jobbing is founded on the variation of the prices of stock. Persons possessed of real property may buy or sell stock, according to their notion that the value is likely to rise or fall, in expectation of making profit by the difference of price. And a practice has taken place among persons who often possess no property in the funds, to contract for the sale of stock against a future day, at a price now agreed on. For instance: A agrees to sell B 1000 *l.* of bank-stock, to be transferred, in 20 days, for 1200 *l.* A has, in fact, no such stock; but, if the price of bank-stock, on the day appointed for the transfer, should be only 118 *per cent.* A may purchase as much as will enable him to fulfil his bargain for 1180 *l.*, and thus gains 20 *l.* by the transaction; on the contrary, if the price of bank-stock be 125 *per cent.* he will lose L. 50. The business is generally settled without any actual purchase or transfer of stock, by A paying to B, or receiving from him, the difference between the current price of the stock on the day appointed, and the price bargained for.

This practice, which is really nothing else than a wager concerning the price of stock, is contrary to law; yet it is carried on to a great extent. In the language of Exchange-alley, where matters of this kind are transacted, the buyer is called a *bull*, and the seller a *bear*. As neither party can be compelled by law to implement these bargains, their sense of honour, and the disgrace and loss of future credit, which attend a breach of contract, are the principles by which the business is supported. When a person declines to pay his loss, he is called a *lame duck*, and dare never afterwards appear in the Alley. This odious treatment, however, is not bestowed on those whose failure is owing to want of ability, providing they make

Funds.

make the same surrender of their property voluntarily, which the law would have exacted if the debt had been entitled to its sanction.

The interest or dividend on the stock is paid half-yearly; and the purchaser has the benefit of the interest due on the stock he buys, from the last term to the time of purchase. Therefore the prices of the stocks rise gradually, *ceteris paribus*, from term to term, and fall at the term when the interest is paid. In comparing the prices of the different stocks, it is necessary to advert to the term when the last interest was paid; and, allowance being made for this circumstance, the prices of all the government stocks, which bear interest at the same rate, must be nearly the same, as they all depend on the same security.

When a loan is proposed, such terms must be offered to the lenders, as may render the transaction beneficial; and this is now regulated by the prices of the old stocks. If the stocks, which bear interest at 4 per cent. fell at par, or rather above, the government may expect to borrow money at that rate; but, if these stocks are under par, the government must either grant a higher interest, or some other advantage to the lenders, in compensation for the difference. For this purpose, besides the perpetual annuity, another annuity has sometimes been granted for life, or for a term of years. Lotteries have frequently been employed to facilitate the loan, by entitling the subscribers to a certain number of tickets, for which no higher price is charged than the exact value distributed in prizes, though their market-price is generally L. 2 or L. 3 higher. Sometimes an abatement of a certain proportion of the capital has been granted, and a lender entitled to hold L. 100 stock, though in reality he advanced no more, perhaps, than L. 95.

It belongs to the Chancellor of the Exchequer to propose the terms of the loan in parliament; and he generally makes a previous agreement with some wealthy merchants, who are willing to advance the money on the terms proposed. The subscribers to the loan deposit a certain part of the sum subscribed; and are bound to pay the rest by instalments, or stated proportions, on appointed days, under pain of forfeiting what they have deposited. For this they are entitled, perhaps, not only to hold their share in the capital, but to an annuity for 10 years, and to the right of receiving a certain number of lottery-tickets on advantageous terms. They may sell their capital to one person, their annuity to a second, and their right to the tickets to a third. The value of all these interests together is called *omnium*; and, in order to obtain a ready subscription, it ought to amount to L. 102, or upwards, on L. 100 of capital. This difference is called the *bonus* to the subscribers.

When a loan is made, a new tax is imposed to defray the annuities. For some time, each tax was particularly appropriated for the payment of annuities then created: but the method was found inconvenient, as some of the taxes fell short of the sum expected, while others exceeded it; and the multiplicity of funds produced confusion. This gave occasion to unite the various branches of the revenue into a few funds. The *South-Sea Fund* was established in the year 1711, for payment of the annuities due to that company. The *Aggregate Fund* was established in

1715, and the *General Fund* in 1717, for the payment of other annuities. All the other branches of the revenue then subsisting, except the annual land and malt tax, and the branches applied for the support of the civil government, were appropriated to one or other of these funds. And, as these revenues were considerably greater than the charges for which the funds were answerable, the overplus was appointed to be collected together, and remain at the disposal of parliament; and is known by the name of the *Sinking Fund*, because intended for the discharge of the national debt. At the beginning of the present reign, the revenues appropriated to the civil list were added to the aggregate fund, and that fund charged with the nett sum of L. 800,000, since increased to L. 900,000, in place of the same. When money has been borrowed since the establishment of these funds, the sinking fund is made a collateral security, in case the tax imposed for the payment of the annuity should prove deficient; and sometimes the new taxes have been directly paid into that fund, and the annuities charged on the same; and the faith of parliament is pledged to corroborate the security. The sinking fund has yielded an annual overplus, for many years, of more than two millions Sterling; which, in time of war, is applied to the current services; and, even in time of peace, a considerable part is diverted to the same purpose; as the annual land and malt tax, the only other unappropriated funds, are insufficient for defraying the charge of a peace-establishment.

The terms of the government loans have been very different, according to the circumstances under which they took place. The interest has generally been lower than the current interest of the nation, because it is punctually paid; and the government security is esteemed preferable to any of a private kind. Sometimes, however, when the exigencies were pressing, and the national resources, in some measure, exhausted by the continuance of war, a higher interest has been granted than was current in private debts. But, as the prices of such stocks rose above par in peaceable times, advantage was taken of that circumstance to prevail on the holders to consent to a reduction of the interest, by offering payment of the principal, in case they refused. Thus, the interest on the greater part of the national debt, contracted before the late war with France, was reduced to 3 per cent. and the stocks were united under the names of *reduced* and *consolidated* annuities. Part of the consolidated annuities bear interest at 4 per cent. till the year 1781, when it falls, like the rest, to 3 per cent. In subsequent loans, the faith of parliament has sometimes been engaged, that the debt shall not be redeemed, and, of consequence, the interest not reduced, for a number of years condensed on.

The rise of the terms of the public loans, during the continuance of war, will appear from the following abstract of those which was made during the late war with France and Spain, and the present contest with America.

Loans for French War.

1755. At 3 per cent, by lottery	L. 900,000
1756. At 3½ per cent.	1,500,000
At 3 per cent. by lottery	500,000
	1757. At

Funds.	1757. At 3 per cent. and an additional life-annuity of 1 per cent.	3,100,000
	1758. At $3\frac{1}{2}$ per cent.	4,500,000
	At 3 per cent. by lottery	500,000
	1759. At 3 per cent. and a premium of 15 per cent. additional capital.	7,590,000
	1760. At 4 per cent. irredeemable for 20 years, and 3 per cent. thereafter, with a premium of 3 per cent. additional capital	8,240,000
	1761. At 3 per cent. irredeemable for 20 years, besides ann. of L. 1 : 2 : 6 per L. 100 for 99 years	11,400,000
	At 3 per cent. by lottery	600,000
	1762. At 4 per cent. irredeemable for 20 years, and an annuity of 1 per cent. for 98 years	12,000,000
	The remaining debt, not provided for at the peace, was partly paid off in the subsequent years, and the rest funded at 3 per cent.	
	<i>Loans for American war.</i>	
	1776. At 3 per cent. with premium of 8 per cent. additional capital, and benefit of lottery	L. 2,160,000
	1777. At 4 per cent. irredeemable for 10 years, with an annuity of 1 per cent. for 10 years, and benefit of lottery	5,500,000
	1778. At 3 per cent. perpetual annuity, with an additional annuity of 2 per cent. for 30 years, and benefit of lottery	6,000,000
	1777. At 3 per cent. perpetual annuity, and L. 3 : 15 s. per cent. annuity for 29 years, and benefit of lottery	7,000,000

The capital advanced to the public, in the form of transferable stocks, and bearing interest from taxes appropriated for that purpose, is called the *funded debt*. Besides, there is generally a considerable sum due by government, which is not disposed of in that manner, and therefore is distinguished by the appellation of the *unfunded debt*. This may arise from any sort of national expence, for which no provision has been made, or for which the provision has proved insufficient. The forms of the unfunded debts are various, according to the circumstances by which it is occasioned. But there are two regular branches of this debt, which always subsist, to a greater or lesser extent.

1st, *Exchequer Bills*. These are issued from the exchequer, generally by appointment of parliament, and sometimes without such appointment, when exigencies require. They bear interest from the time when issued, and are taken in by the bank of England, which promotes their circulation.

2d, *Navy-Bills*. The sums annually granted for the navy have always fallen short of what that service required. To supply that deficiency, the admiralty issues bills in payment of victuals, stores, and the like, which bear interest six months after the time issued. The debt of the navy thus contracted is discharged, from time to time, by parliament.

In time of war, the public expences, since the revolution, have always been much greater than the annual revenue; and large sums have consequently been borrowed. In time of peace, the revenue exceeds the expence, and part of the public debts have frequently been paid off. But, though there have been more years of peace than of war since the funds were established, the debts contracted during each war have much exceeded the payments during the subsequent peace. This will appear by the following abstract of the progress of the national debt.

Debt at peace of Ryfwick, 1697	L.	21,515,472
Debt at the beginning of war 1701		16,394,701
Discharged during peace 1697 to 1701		5,121,071
Debt at peace of Utrecht 1714, including value of annuities afterwards subscribed to South-Sea stock		55,282,978
Contracted in war 1701 to 1714		38,888,277
Debt at beginning of war 1740, including L. 1,000,000, charged on civil list		47,954,623
Discharged during peace 1714 to 1739		7,328,355
Debt at Peace of Aix-la-Chapelle, 1748		79,193,313
Contracted during war 1740 to 1748		31,238,690
Debt at beginning of war 1756		73,289,673
Paid off during peace 1748 to 1756		5,903,640
Debt funded at the peace 1763, including L. 9,839,597 then owing, which was funded in the subsequent years		133,957,270
Besides this, there was about L. 6,000,000 of debt paid off, without ever being funded.		
Funded debt, 1775		125,00,000
Paid off during peace 1763 to 1775, besides unfunded debt above mentioned		8,959,270
Funded debt contracted during the American war 1776 to 1779, inclusive		20,600,000

FUNDAMENT, in anatomy, the lowest part of the intestinum rectum, called by anatomists the *anus*. See ANATOMY, n° 354.

FUNDAMENTAL, in general, something that serves as a base or foundation for another.

FUNDAMENTAL, in music. A *fundamental sound* is that which forms the lowest note of the CHORD, and from whence are deduced the harmonical relations of the rest; or, which serves for a key to the tone*. The *fundamental bass* is that which serves for a foundation to the harmony. A *fundamental chord* is that whose bass is fundamental, and in which the sounds are ranged in the same order as when they are generated, according to the experiment so often repeated by M. d'Alembert, in his Preliminary Discourse and Elements of Music†. But as this order removes the parts to an extreme distance one from the other, they must be approximated by combinations or inversions; but if the bass remains the same, the chord does not for this reason cease to bear the name of *fundamental*. Such an example is this chord, *ut mi sol*, included in the interval of a fifth: whereas, in the order of its generation, *ut sol mi*, it includes a tenth, and even a seventeenth; since the fundamental *ut* is not the fifth of *sol*, but the octave of that fifth.

FUNDAMENTAL Bass. This part in music is, according to Rousseau, and indeed according to all authors

* See Tonic.

† See Music.

thors who have proceeded upon M. Rameau's experiment, in its primary idea, that bass which is formed by the fundamental notes of every perfect chord that constitutes the harmony of the piece; so that under each chord it causes to be heard, or understood, the fundamental found of that particular chord; that is to say, the found from whence it is derived by the rules of harmony. From whence we may see, that the fundamental bass can have no other contexture than that of a regular and fundamental succession, without which the procedure of the upper parts would be illegitimate.

To understand this well, it is necessary to be known, that, according to the system of Rameau, which Rousseau has followed in his Dictionary, every chord, tho' composed of several sounds, can only have one which is its fundamental, *viz.* that which produces this chord, and which is its bass according to the direct and natural order. Now, the bass which prevails under all the other parts, does not always express the fundamental sounds of the chords: for amongst all the sounds which form a chord, the composer is at liberty to transfer to the bass that which he thinks preferable; regard being had to the procedure of that bass, to the beauty of the melody, and above all to the expression, as may afterwards be explained. In this case the real fundamental found, instead of retaining its natural station, which is in the bass, will either be transferred to some of the other parts, or perhaps even entirely suppressed, and such a chord is called an *inverted* chord.

In reality, says Rameau, a chord inverted does not differ from the chord in its direct and natural order from which it was produced: but as these sounds form different combinations, these combinations have long been taken for fundamental chords; different names have been given them, (which may be seen at the word *Accord*, in Rousseau's Dictionary). These names, by the persons who bestowed them, were thought to create and sanctify their distinctions; as if a difference in names could really produce a difference in the species.

Mr Rameau in his Treatise of Harmony has shown, and M. D'Alembert in his Elements of Music has still more clearly evinced, that many of these pretendedly different chords were no more than inversions of one single chord. Thus the chord of the sixth is no more than the perfect chord of the third transferred to the bass; by adding a fifth, we shall have the chord of the sixth and fourth. Here there are three combinations of a chord, which only consists of three sounds; those which contain four sounds are susceptible of four combinations, since each of these sounds may be transferred to the bass. But in adding beneath this another bass which, under all the combinations of one and the same chord, always presents the fundamental found; it is evident, that consonant chords are reduced to the number three, and the number of dissonant chords to four. Add to this all the chords by supposition, which may likewise be reduced to the same fundamentals, and you will find harmony brought to a degree of simplicity in which no person could ever hope to see it whilst its rules remained in that state of confusion where M. Rameau found them. It is certainly, as that author observes, an astonishing occurrence, that the practice of this art could be carried so far as it really was, without knowing its foundation; and that all the rules

were so exactly found, without having discovered the principle on which they depended.

After having shown what is the fundamental bass beneath the chords, let us now speak of its procedure, and of the manner in which it connects these chords among themselves. Upon this point the precepts of the art may be reduced to the six following rules.

1. The fundamental bass ought never to sound any other notes than those of the series or tone in which the composer finds himself, or at least those of the series or tone to which he chooses to make a transition. This of all the rules for the fundamental bass is the first and most indispensable.

2. By the second, its procedure ought to be so implicitly subjected to the laws of modulation, as never to suffer the idea of a former mode to be lost till that of a subsequent one can be legitimately assumed; that is to say, that the fundamental bass ought never to be devious, or suffer us to be one moment at a loss in what mode we are.

3. By the third, it is subjected to the connection of chords and the preparation of dissonances: a manoeuvre which, as we shall afterwards see, is nothing else but a method of producing this connection, and which of consequence is only necessary when the connection cannot subsist without it. See CONNECTION, PREPARATION.

4. By the fourth, it is necessitated, after every dissonance, to pursue that career which the resolution of the dissonance indispensably prescribes. See RESOLUTION.

5. By the fifth, which is nothing else but a consequence of the former, the fundamental bass ought only to move by consonant intervals; except alone in the operation of a broken cadence, or after a chord of the seventh diminished, where it rises diatonically. Every other motion of the fundamental bass is illegitimate.

6. By the sixth, in short, the fundamental bass or harmony ought not to be syncopeated; but to distinguish the bars and the times which they contain, by changes of chords properly marked with cadences; in such a manner, for instance, that the dissonances which ought to be prepared may find their preparation in the imperfect time, but chiefly that all the repose may happen in the perfect time. This sixth rule admits of an infinite number of exceptions; but the composer ought however to be attentive to it, if he would form a music in which the movements are properly marked, and in which the bars may end gracefully.

Wherever these rules are observed, the harmony shall be regular and without fault: this, however, will not hinder the music from being detectable. See COMPOSITION.

A word of illustration on the fifth rule may not be useless. Whatever turn may be given to a fundamental bass, if it is properly formed, one of these alternatives must always be found: either, perfect chords moving by consonant intervals, without which these chords would have no connexion; or, dissonant chords in operations of cadence: in every other case, the dissonance can neither be properly placed nor properly resolved.

From thence it follows, that the fundamental bass cannot move regularly but in one of these three manners. $\frac{1}{2}$, To rise or descend by a third or by a sixth. $\frac{2}{3}$, By a fourth or a fifth. $\frac{3}{4}$, To rise diatonically

by means of the dissonance which forms the connection, or by a licence upon a perfect chord. With respect to a diatonic descent, it is a motion absolutely prohibited to the fundamental bass; or, at most, merely tolerated in cases where two perfect chords are in succession, divided by a close expressed or understood. This rule has no other exception: and it is from not discerning the foundation of certain transitions, that M. Rameau has caused the fundamental bass to descend diatonically under chords of the seventh; an operation which is impracticable in legitimate harmony. See CADENCE, DISSONANCE.

The fundamental bass, which they add for no other reason than to serve as a proof of the harmony, must be retrenched in execution, and often in practice it would have a very bad effect; for it is, as M. Rameau very properly observes, intended for the judgment and not for the ear. It would at least produce a monotony extremely nauseous by frequent returns of the same chord, which they disguise and vary more agreeably by combining it in different manners upon the continued bass, without reckoning upon the different inversions of harmony which furnish a thousand means of adding new beauties to the music, and new energy to the expression. See CHORD, INVERSION.

But it will be objected, If the fundamental bass is not useful in composing good music, if it must even be retrenched in practice, what good purpose, then, can it serve? We answer, that, in the first place, it serves for a rule to scholars, upon which they may learn to form a regular harmony, and to give to all the parts such a diatonic and elementary procedure as is prescribed them by that fundamental bass. It does more, as we have already said: it proves whether a harmony already formed be just and regular; for all harmony which cannot be subjected to the test of a fundamental bass, must according to all rules be bad. Finally, it serves for the investigation of a continued bass under a given air: tho' in reality, he who cannot directly form a continued bass, will scarcely be able to form a fundamental bass, which is better; and much less still will he be able to transform that fundamental bass into a legitimate continued bass. These which follow are, however, the principal rules which M. Rameau prescribes for finding the fundamental bass of a given air.

1. To ascertain with precision the mode in which the composer begins, and thence through which he passes. There are also rules for investigating the modes; but so long, so vague, so incomplete, that, with respect to this, the ear may be formed long before the rules are acquired; and the dunce who should try to use them, would gain no improvement but the habit of proceeding always note by note, without even knowing where he is.

2. To try in succession under each note the principal chords of the mode, beginning by those which are most analogous, and passing even to the most remote, when the composer feels himself under a necessity of doing so.

3. To consider whether the chord chosen can suit the upper part in what precedes and in what follows, by a just fundamental succession; and when this is impracticable, to return the way he came.

3. Not to change the note of the fundamental bass till after having exhausted all the notes which are al-

lowed in succession in the upper part, and which can enter into its chord; or till some syncopated note in the air may be susceptible of two or a greater number of notes in the bass, to prepare the dissonance which may be afterwards resolved according to rule.

5. To study the intertexture of the phrases; the possible succession of cadences, whether full or avoided; and above all, the pauses which for ordinary return at the end of every four, or of every two bars, so that they may always fall upon perfect and regular cadences.

6. In short, to observe all the rules formerly given for the composition of the fundamental bass.—These are the principle observations to be made for finding one under any given air; for there are sometimes several different ones which may be investigated. But, whatever may be said to the contrary, if the air has accent and character, there is only one just fundamental bass which can be adapted to it.

After having given a summary explication of the manner in which a fundamental bass should be composed, it should remain to suggest the means of transforming it into a continued bass; and this would be easy, if it were only necessary to regard the diatonic procedure and the agreeable air of this bass. But let us not imagine, that the bass, which is the guide and support of the harmony, the soul, and as it were the interpreter, of the air, should be limited to rules so simple: there are others which depend upon principles more certain and more radical; fruitful, but latent principles, which have been felt by every artist of genius, without having been detected by any one. Rousseau hopes, that in his letter upon French music he insinuated this principle. For those who understand him, he imagines he has said enough concerning it, and can never say enough of it for those who do not. See *Rousseau's Miscellanies*, Vol. II. p. 1.

He does not here mention the ingenious system by M. Serre of Geneva, nor his double fundamental bass; because the principles, which, with a sagacity meritorious of praise, he had half detected, have afterwards been unfolded by M. Tartini, in a work of which Rousseau has given an account in his article SYSTEM.

FUNDY-BAY, a bay seated between New-England and Acadia or New-Scotland, in which there is an excellent fishery.

FUNEN, or FIONIA, a considerable island in Denmark, seated on the Baltic sea, and separated from Jutland by a strait called the *Lesser Belt*, and from the island of Zealand by another called the *Great Belt*. It is fertile in wheat and barley; and abounds in cattle, horses, game of all sorts, and fish. Odensee is the capital town.

FUNERAL RITES, ceremonies accompanying the interment or burial of any person.

These rites differed among the ancients according to the different genius and religion of each country. The Egyptians, among the rest of their funeral rites, embalmed their dead.

Among the ancient Greeks it was usual sometimes, before the interment, to put a piece of money into the mouth of the deceased, which was thought to be Charon's fare for waiving the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neigh-

Funeral:

bourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake, composed of flour, honey, &c. which was designed to appease the fury of Cerberus the door-keeper of hell, and to procure the ghost a safe and quiet entrance.

During the time the corpse continued in the house, there stood before the door a vessel of water: the design of which was, that those concerned about the body might purify themselves by washing; it being the opinion of the Greeks, as well as of the Jews, that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends, were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground, and rolled in the dust, or covered their head with ashes; they beat their breasts, and even tore their flesh with their nails, upon the loss of a person they much lamented. When persons of rank, such as public magistrates or great generals, died, the whole city put on a face of mourning; all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse, were shut up.

Interring or laying the dead on the ground, seems to have been the most ancient practice among the Greeks; though burning came afterwards to be generally used among them. It was customary to throw into the funeral pile, those garments the deceased usually wore. The pile was lighted by one of the deceased's nearest relations or friends, who made prayers and vows to the winds to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead person's friends stood by it, pouring libations of wine, and calling upon the deceased.

When Numa reformed the religion of Rome, he ordered that the pontiffs should have the care of the funeral ceremonies; which, in most respects, were like those of the Greeks already described.

The funeral rites among the Hebrews were solemn and magnificent. When any person was dead, his relations and friends rent their cloths; which custom is but faintly imitated by the modern Jews, who only put off a bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string; because the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a speech to the dead in the following terms: "Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life, &c." Then they spoke the eulogium, or funeral oration, of the deceased; after which they said a prayer, called the *righteousness of judgment*; then turning the face of the deceased towards heaven, they called out, "Go in peace."

The ancient Christians testified their abhorrence of the Pagan custom of burning the dead ; and always deposited the body entire in the ground : and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral attire. The exportation or carrying forth of the body was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Palmody, or singing of psalms, was the great ceremony used in all funeral processions among the ancient Christians.

In the Romish church, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the *miserere*, and some other psalms; and at the end of each psalm a *requiem*. We learn from Alex's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers: after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the Greek church, are much the same with those of the Latin. It needs only be observed, that, after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased : after which each of the company eats a bit of bread and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

FUNERAL-Games, a part of the ceremony of the ancient funerals.

It was customary for persons of quality, among the ancient Greeks and Romans, to institute games, with all sorts of exercises, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus's funeral games take up the greatest part of one of Homer's *Iliads*; and Agamemnon's ghost is introduced by the same poet telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks, mostly consisted of horse-races; the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The garlands, given to victors on this occasion, were usually of parsley, which was thought to have some particular relation to the dead.

Those games, among the Romans, consisted chiefly of processions; and sometimes of mortal combats of gladiators around the funeral pile. They, as well as the Greeks, had also a custom, though very ancient, of cutting the throats of a number of captives, before

Funeral.

before the pile, as victims to appease the manes of the deceased. Cæsar relates, that the Gauls had this custom.

The funeral games were abolished by the emperor Claudius.

FUNERAL-Oration, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

This custom is very ancient, both among the Greeks and Romans. Before the company departed from the sepulchre, they were often entertained with a panegyric upon the dead person, always pronounced by a near relation, or one of the public magistrates.

FUNGI (from *fungus*; fungus), one of the seven families or tribes of the vegetable kingdom, according to Linnæus, comprehending all those who are of the mushroom kind, and which in Tournefort constitute the 2d, 3d, 4th, 5th, 6th, 7th, and 8th genera of the first section in the class xvii.

FUNGI, an order of plants in the *fragmenta methodi naturalis* of Linnæus. See **BOTANY**, p. 1317.

FUNGIBLES, in Scots law, are such things as are estimated by number, weight, or measure; as, coin, butter, ale, &c.

FUNGITÆ, in natural history, a kind of fossil coral, of a conic figure, though sometimes flattened and striated longitudinally.

FUNGUS, in surgery, denotes any spongy excrescence. See **SURGERY**.

FUNNEL of a CHIMNEY, the shaft or finallest part of the waste, where it is gathered into its least dimensions.

Palladio directs, that the funnels of chimneys be carried through the roof four or five feet at least, that they may carry the smoke clear from the house into the air. See the article CHIMNEY.

He also advises, that chamber-chimneys be not made narrower than 10 or 11 inches, nor broader than 15: for if too narrow, the smoke will not be able to make its way; and, if too wide, the wind will drive it back into the room.

FUR, or **FURR**, in commerce. See **FURR**.

FURBISHER, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c.; which is chiefly performed with emery. See the article **EMERY**.

FURCA, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced a servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor having his head fastened on the furca, was whipped to death.

FURCHE, in heraldry, a cross forked at the ends.

FURIES, in Pagan antiquity, certain goddesses whose office it was to punish the guilty after death. They were three in number: *Alæto*, *Megara*, and *Tiphone*; who were described with snakes instead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish, the guilty: and they were supposed to be constantly hovering over such persons as had been guilty of any

enormous crime.

Mythologists suppose, that *Tiphone* punished the crimes which sprang from hatred or anger; *Megara*, those from envy; and *Alæto*, those from an insatiable pursuit after riches and pleasure. They were worshipped at *Casina* in *Arcadia*, and at *Carmia* in *Peloponnesus*. They had a temple at *Athens*, near the *Areopagus*, and their priests were chosen from amongst the judges of that court. At *Telphusia*, a city in *Arcadia*, a black ewe was sacrificed to them.

FURIUS (*Bibaculus*), a Latin Poet, flourished about 103 B. C. He wrote annals in verse, of which *Macrobius* recites some fragments. *Suetonius* also relates some verses of his on *Valerius Cato*, in his *Illustrious Grammarians*.

FURLING, in the sea language, signifies the wrapping up and binding any sail close to the yard; which is done by hauling upon the clew-lines, buntlines, &c. which wraps the sail close together, and being bound fast to the yard the sail is furled.

FURLONG, a long measure, equal to one eighth of a mile, or 40 poles.

It is also used in some law-books, for the eighth part of an acre.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, an utensil, or vessel, proper to contain fire, or to raise and maintain a vehement fire in, whether of coal or wood.—Of these there are a great variety, according to the different uses to which they are applied.

An *Essay on Cupelling FURNACE* is made in the following manner. 1. Make with iron plates a hollow quadrangular prism, eleven inches broad and nine inches high (*aa, bb*), ending at top in a hollow quadrangular pyramid (*bb, cc*) seven inches high, terminating in an aperture at top seven inches square. This prism must be closed at bottom with another iron plate, which serves as a basis or bottom to it (*a a*).

2. Near the bottom make a door (*c*), three inches high, and five inches broad, that leads to the ash-hole. 3. Above this door, and at the height of six inches from the basis, make another door (*f*), of the figure of a segment of a circle, four inches broad at its basis, and three inches and a half high in the middle. 4. Then fasten three iron plates on the forepart of this furnace. Let the first of them (*gg*), eleven inches long and half an inch high, be fastened, so that its lower edge shall rest against the bottom of the furnace, with three or four rivets; and in such a manner, that there may be between the upper edge of the said plate and the side of the furnace a groove so wide, as that the sliders of the lower door (*h h*) may be put into it, and freely move backwards and forwards therein: these must be made of a thicker iron-plate. The second iron-plate (*h h*), eleven inches long, three inches high, and perfectly parallel to the foregoing plate, must be fastened in the space between the two doors, in such manner that both the upper and the lower edges of it may form a hollow groove with the side of the furnace. One of these grooves, which is turned downwards, serves to receive the upper edge of the sliders that shut the lower door (No. 2). The other, that turns upwards, is to receive the inferior edges of the sliders of the

Plate

Assaying.

Furnace.

small door above (No. 3). The third plate (*ii*), which is like the first, must be rivetted close above the upper door, in such manner, that it may form a groove turning downwards, and contiguous to the upper edge of the upper door (No. 3.) 5. In order to shut both doors (No. 2, 3.), you must adapt to each of them two sliders made of iron-plates, that may move within the above-mentioned grooves (*kk*, *ll*). But the two sliders belonging to the upper door (No. 3.) must have each a hole near the top; that is, one a small hole one fifth part of an inch broad, and one inch and a half long (*m*); and the other a semicircular aperture, one inch high and two inches broad (*n*). Let, besides, each slider have a handle, that they may be laid hold of when they are to be moved. 6. Moreover, let five round holes, one inch broad, be bored in the furnace; two of which must be made in the fore-part of the furnace (*oo*), two others in the back part; all at the height of five inches from the bottom, but three inches and a half distant from each side, of the furnace; and, finally, a fifth hole (*p*), at the height of one inch above the upper edge of the upper door (*f*). 7. In short, let the inside of the furnace be armed with iron-hooks, jetting out half an inch, and about three inches distant from each other, to fasten the lute with which the furnace is to be covered over within. 8. Let then an iron, moveable, hollow, quadrangular pyramid (*q*), three inches high, be adapted to the upper aperture (*d*) of the furnace, at the basis seven inches broad, ending upwards in a hollow tube (*r*), three inches in diameter, two inches high, almost cylindrical, though somewhat convergent at top. This prominent tube serves to support a funnel or flue, which is almost cylindrical, hollow, made of iron-plates, and two foot high; and which, when a very strong fire is required, is put perpendicularly upon the shorter tube, in such a manner, that it enters close into it, one inch and a half or two inches deep, and may again be taken off at pleasure, when there is no need of so strong a fire. But this pyramidal cover (*q*) must besides have two handles (*ss*) adapted to it, that it may be laid hold of, and thus be taken away or put on again: and that this, being put on the aperture (*d*) of the furnace, may not be easily thrown down, let an iron plate be rivetted to the right and left upper edge of the furnace (*cc*), and be turned down towards the inside, so as to make a furrow open before and behind, into which the lateral edges of the cover may enter and be fastened, and at pleasure be moved backwards and forwards, whenever it must be put on, or moved. 9. Let a square ledge, made of a thick iron-plate, be fastened at top of the upper edge of the lower door (*r*): this is designed to support the grate and the lute; but it must be made of two pieces, that it may be easily introduced into the cavity of the furnace. Thus you will have an assay-oven, which must afterwards be covered over on the inside with lute. This you are to do as follows:

That the fire may be better confined, and that the iron may not be destroyed by growing red-hot, the whole inside of the furnace must be covered over with lute, one finger or one finger and a half thick. The lute fit for this is described under the article *ЧЕМИСТКА*, n° 73, 81. But before you cover the inside of your furnace with this lute, you must first put within

Furnace.

the furnace small iron bars, equal in length to the diameter of the oven, quadrangular, prismatical, half an inch thick, having their extremities supported by a square iron ledge, and three fourths of an inch distant from each other; and you must fasten them so, that their flat sides may be oblique with regard to the transverse section of the furnace, and that the two opposite angles may look one upwards and the other downwards: the bars must not be laid flat, but edge-wise; by which situation you hinder the ashes of the fuel of the fire from being detained too long between the interstices of the said iron-bars, and from making an obstruction that would oppose the free draught of the air. The furnace being then covered over with lute, and dried up by a gentle heat, is at last fit for doctrinal operations, and especially for such as must be performed in the assay-oven.

If then an operation is to be made in the furnace hitherto described, you must let through the four lower holes above described of the furnace (*oo*) placed before and behind, and directly opposite to each other, two iron-bars one inch thick, and long enough that their extremities on every side may jut out of the holes a small matter. These serve to support the muffle and its bottom. You then introduce the muffle through the upper aperture of the furnace (*d*), and place it upon the above described iron-bars, in such a manner, that the open fore-side of it be contiguous to the inward border of the upper door (*f*). The fuel of the fire is introduced through the top of the furnace (*d*); the cover of which (*q*), on this account, must be moveable and not very heavy. The best fuel for the fire is charcoal made of the hardest wood, especially of beech, broken into small pieces of the bigness of an inch, wherewith the muffle must be covered over some inches high. We then reject larger bits of coals, because they cannot fall thro' the narrow interstices, between the sides of the muffle and those of the furnace, and cannot of course sufficiently surround the circumference of the muffle. Whence it happens, that there are on every side places void of fuel, and the fire is either not strong enough or unequal. But if, on the contrary, you use coals too small, then a great part fall immediately through the interstices of the grate into the ash-hole; and the tenderest particles of them turn too soon into ashes, and, by increasing the heap of ashes, obstruct the free draught of the air, which is here greatly requisite.

A perfect management of the fire is most commonly necessary in the performing of operations in this furnace; therefore the chemical reader must give attention to what follows. If the door of the ash-hole (*e*) is quite open; and the sliders of the upper door (*r*) drawn towards each other, so as to touch one another in the middle of the door; and if, besides, the cover (*q*), and the funnel adapted to its tube (*r*), is upon the top (*q*) of the furnace; the fire will be then in the highest degree possible; though, in the mean time, it is hardly ever necessary to put the funnel on, except in a very cold season: but if, after having disposed the furnace in the manner just described, you put red burning coals into the open upper door (*f*) of it, the fire is still more increased thereby: however, this artifice is never, or very seldom, necessary. When you shut the upper door with only that slider that has a narrow ob-

long

long hole in it (*m*), then the heat becomes a little less; but it diminishes still more when you shut the door with the other slider that has in it the semicircular hole (*n*), which is larger than that of the first slider: nay, the heat again is less when you take away the funnel put at the top of the cover: finally, the door of the ash-hole being either in part or totally shut, the heat is still diminished; because the draught of air so necessary to excite the fire, is thereby hindered: but if, besides all these, you likewise open the upper door quite, then the cold air, rushing into the muffle, cools the bodies put under it, that are to be changed, to a degree never required in any operation, and such as will entirely hinder the boiling of lead. If, during the operation, the fire begins to decay, or to grow unequal, it is a sign that there are places void of coals between the sides of the furnace and those of the muffle: therefore, in this case, you must stir your coals on every side with an iron-rod, which is to be introduced through the upper hole (*p*) of the furnace, that they may fall together, and thus act in a proper manner and equality.

However, you are to observe concerning the regimen of the fire just described, that though the apparatus is made with all the exactness mentioned, nevertheless the effect does not always answer it. The cause of which difference has most commonly its origin in the various dispositions of the air: for as every fire is more excited by coals in proportion as the air, more condensed, and more quickly agitated, strikes them more violently (which the effect of the bellows plainly shews); it thence appears, that in warm and wet weather, when the atmosphere is light, the fire must be less efficacious in furnaces; that likewise, when several furnaces, situated near each other, are burning at the same time, the fire is in part suffocated, because the ambient air is thereby rendered more rare and lighter. The same effect is produced by the sun, especially in summer-time, when it shines upon the place where the furnace is situated. The atmosphere, on the contrary, being heavier in cold dry weather, excites a very great fire.

The heat of the fire acts the stronger upon the bodies to be changed, as the muffle put in the furnace is less; as the said muffle has more and larger segments cut out of it; as the sides of this muffle are thinner; in short, as there are more vessels placed in the hinder part of the muffle; and on the contrary. In this case, when many of the conditions requisite for the exciting of fire are wanting, then indeed the artificer, with all his skill, will hardly be able to excite the fire to a sufficient degree, in order to perform operations well, in common assay-ovens, even though he uses bellows, and puts coals into the upper door of the furnace. For this reason, the grate ought to be put almost three inches below the muffle, lest the air, rushing through the ash-hole, should cool the bottom of the muffle, which happens in common assay-ovens; and again, that the smaller coals, almost already consumed, and the ashes, may more easily fall through the interstices of the grate, and the larger coals still fit to keep up the fire be retained. Lastly, The above-mentioned funnel is added, that the blowing of the fire being, by means of it, increased as much as possible, this might at last be carried to the requisite degree; for the fire may always be

diminished, but not always be increased at pleasure, without the assistance of a proper apparatus.

Fig. 5. Represents a longitudinal section of a *Reverberatory FURNACE* used in the smelting of ores. 1. The masonry. 2. The ash-hole. 3. A channel for the evaporation of the moisture. 4. The grate. 5. The fire-place. 6. The inner part of the furnace. 7. A basin formed of sand. 8. The cavity where the melted metal is. 9. A hole through which the scoria is to be removed. 10. The passage of the flame and smoke, or the lower part of the chimney; which is to be carried up to a height of about 30 feet. 11. A hole in the roof, through which the ore is thrown into the furnace. This furnace is 18 feet long, 12 feet broad, and 9½ high.

Fig. 6. Represents a longitudinal section of the *Refining FURNACE*. 1. The masonry of the pillars and walls surrounding the furnace. 2. The channels for carrying off the moisture. 3. Other small channels which join in the middle of the basin. 4. The basin made of bricks. 5. A bed of ashes. 6. The hollow or basin in which the metal is melted and refined. 7. Lamp FURNACE. *Ibid.* 2^d 102.

Machines for Blowing Air into FURNACES. The earliest method of animating large fires in the furnaces where ores were smelted, seems to have been by exposing them to the wind. Such was the practice of the Peruvians before the arrival of the Spaniards among them. Alonso Barba relates, that their furnaces, called *guairas*, were built on eminences, where the air was freest; that they were perforated on all sides with holes, through which the air was driven in when the wind blew, which was the only time when the work could be carried on; that under each hole was made a projection of the stone-work, on which were laid burning coals, to heat the air before it entered the furnace. Some authors speak of several thousands of these *guairas* burning at once on the sides and tops of the hills of Potosi; and several remains of this practice are to be found in different parts of Great Britain.

This method of supplying air being found excessively ineffectual and precarious, the instruments called *bellows* succeeded. These were at first worked by the strength of men; but as this was found to be very laborious and expensive, the force of running water was employed to give motion to these machines. Thus a much greater quantity of metal could be procured than formerly, and the separation was likewise more complete; inasmuch, that in many places the slags or cinders from which the iron had formerly been extracted were again used as fresh ore, and yielded plenty of metal.

But, though this method was found to be greatly preferable to the others, yet great improvements were still wanted. In order to melt very large quantities of ore at a time, it was necessary to use bellows of an immense size; and in proportion to their size they stood in need of the more frequent and expensive repairs.

Furnace.

The oil, also, which the bellows required in large quantity, becoming rancid, was found to generate a kind of inflammable vapour, which sometimes burst the bellows with explosion, and thus rendered them totally useless. A new method, therefore, of blowing up fire, by means altogether free from the abovementioned inconveniences was fallen upon by means of water. It depends on the following principle, viz. That a stream of water, running through a pipe, if by any means it is mixed with air at its entrance into the pipe, will carry that air along with it, and part with it again as soon as it comes out of the pipe; and if the air is then collected by a proper apparatus, it may with success be used for exciting the most violent degrees of heat.

Machines of this kind are represented on Plate CXIV. fig. 4. In the right-hand machine, AB represents a stream of water falling into the funnel, whose throat is contracted at B; after which the stream runs thro' the perpendicular pipe EF, in the upper part of which there are some small holes represented by *cdef*. Through these holes the air has access to mix itself with the descending water, which being dashed against the sides of the pipe is reduced to froth, and thus fills the whole cavity of the pipe EF, which is considerably larger than the throat of the funnel B. When this frothy stream enters the vessel C, the air extricates itself from the water; and as it cannot return through the pipe EF because it is continually filled with a stream of liquid matter, it flies off with considerable force through the smaller pipe D, by which it is conveyed to the furnace.

From this description, it is evident that the principal thing to be kept in view in the construction of these machines is, to mix the descending stream of water with as great a quantity of air as possible. For this purpose the contrivance represented in the left-hand machines answers much better than the former. By this the water descending from the reservoir A, falls into a kind of cullender B, perforated with a great number of holes in its sides. Thus the water being forced out in a number of small streams is very effectually dashed against the sides of the wide descending pipe, when it enters the condensing vessel C, and is sent off by the pipe D, as in the former.

In some machines of this kind the constructors seem to have been of opinion, that a great height was required in the water-fall: but Dr Lewis, who hath made a great number of experiments upon the subject, shews, that an excess in height can never make up for a deficiency in the quantity of the water. Four or five feet, he thinks, is a sufficient height for the water-fall; where there is a greater height, however, it may be rendered useful, by joining two or more machines together in the manner represented in the plate; where the water, after having once emitted its air in the condensing vessel C, flows out into a new reservoir E. From thence it descends through another cullender F, and descending from it into a condensing vessel G, the air is extricated, and carried off through the pipe H. The upper figure represents the cullender, with the shapes of the holes and their proportional distances, according to Dr Lewis.

Thus, with very little expence, where there is a sufficient quantity of water, as strong a blast of air as can be desired may be readily obtained; for several ma-

chines may be constructed, and joined together in a manner somewhat similar to that above mentioned, until all the quantity of water is employed. It is proper to observe, however, that as by this method the air is loaded with moisture, it is proper to make the condensing vessel as high as conveniently may be, that the air may arrive at the furnace in as dry a state as possible.—The long slender pipes in the left-hand machines represent a glass filled with mercury or water, by which the strength of the blast may be determined.

FUROR UTERINUS, a disorder peculiar to women. See (the *Index* subjoined to) MEDICINE.

FURR, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on; and used as a part of drefs, by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, coney, &c.

FURSTENBURGH, a town and castle of Germany, the capital of a county of the same name, 30 miles north-west of Constance. E. Long. 8. 30. N. Lat. 47. 50.

FURTHCOMING, in law, the name of an action competent to any person who has used arrestment in the hands of his debtor's creditor, for having the subject arrested declared his property.

FURUNCLE, or BOIL, in surgery, a small resisting tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin. See SURGERY.

FURZE, in botany. See ULEX; AGRICULTURE, n° 46.; and FENCE.

FUSAROLE, in architecture, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSE, or FUZE, in artillery. See FUSEE.

FUSEE, in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see CLOCK and WATCH.

FUSER, or FIRELOCK. See MUSQUET.

FUSEE, Fuze, or Fufe, of a bomb or granado, is that which makes the whole powder or composition in the shell take fire, to do the designed execution.

Fuzes are chiefly made of very dry beech-wood, and sometimes of hornbeam, taken near the root. They are turned rough, and bored at first, and then kept for several years in a dry place; the diameter of the hole is about $\frac{1}{2}$ of an inch; the hole does not come quite through, leaving about $\frac{1}{2}$ of an inch at the bottom; and the head is made hollow, in the form of a bowl.

The composition for fuzes is saltpetre 3, sulphur 1, and mealed powder 3, 4, and sometimes 5. This composition is drove in with an iron driver, (whose ends are capped with copper to prevent the composition from taking fire), and equally hard as possible; the last shovel-full being all mealed powder, and two stands of quickmatch laid across each other being drove in with it, the ends of which are folded up into the hollow top, and a cap of parchment tied over it till used.

When these fuzes are driven into the loaded shell, the lower end is cut off in a slope, so that the composition may inflame the powder in the shell: the fuze must have such a length as to continue burning all the time the shell is in its range, and to set fire to the powder as soon as it touches the ground, which instantly bursts into many pieces. When the distance of

Furor

Diſ. voce
Laboratory.

the battery from the object is known, the time of the shell's flight may be computed to a second or two; which being known, the fuze may be cut accordingly, by burning two or three, and making use of a watch or a string by way of a pendulum to vibrate seconds.

FUSIBILITY, in natural philosophy, that quality of bodies which renders them fusible.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in Latin *fusus*, "a spindle," from its shape.

FUSILIERS, FUSILEERS, or *Fuzileers*, in the military art, are soldiers armed as the rest of the infantry, but wearing caps like the grenadiers, though somewhat shorter. There are three regiments in the British service: the royal regiment of Scots fuzileers, raised in 1678; the royal regiment of English fuzileers, raised in 1685; and the royal regiment of Welsh fuzileers, raised in 1688-9.

FUSION, the state of a body rendered fluid by fire. See FLUIDITY; and CHEMISTRY, n° 35.

FUST, or FAUSTUS, a citizen of Mentz, and one of the earliest printers. He had the policy to conceal his art; and to this policy we are indebted for the tradition of "The Devil and Dr Faustus," handed down to the present times. Fuft, about 1460, associated with John of Gottenburgh: their types were cut in wood, and fixed, not moveable as at present. Having printed off a considerable number of copies of the Bible, to imitate those which were commonly sold in MS, Fuft undertook the sale of them at Paris, where the art of printing was then unknown. As he sold his printed copies for 60 crowns, while the scribes demanded 500, this created universal astonishment; but when

he produced copies as fast as they were wanted, and lowered the price to 30 crowns, all Paris was agitated. The uniformity of the copies increased the wonder; informations were given into the police against him as a magician; his lodgings were searched; and a great number of copies being found, they were seized: the red ink with which they were embellished was said to be his blood; it was seriously adjudged that he was in league with the devil; and if he had not fled, most probably he would have shared the fate of those, whom ignorant and superstitious judges condemned, in those days, for witchcraft. Fuft died at Mentz in 1466. See (History of) PRINTING.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as it were whaled on one side.

Right fustians should be altogether made of cotton-yarn, both woof and warp; but a great many are made, the warp of which is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse; with flag or nap, and without it.

FUSTIAN, is also used for a bombast style, or a high swelling kind of writing made up of heterogeneous parts.

FUSTICK, or FUSTOCK, a yellow wood, that grows in all the Caribbee islands, used in dying yellow. It pays no duty on importation.

FUSTIGATIO, in the Roman customs, a punishment inflicted by beating with a cudgel. This punishment was peculiar to freemen: for the slaves were scourged or lashed with whips.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

FUZES, or FUSEES, in artillery. See FUSEE.
FUZILEERS. See FUSILEERS.
