On a PLAN entirely New:

BY WHICH,
THE DIFFERENT SCIENCES AND ARTS
Are digested into the Form of Distinct
TREATISES OR SYSTEMS,

COMPREHENDING

The HISTORY, THEORY, and PRACTICE, of each,
according to the Latest Discoveries and Improvements;

AND FULL EXPLANATIONS ARE GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,

WHETHER RELATING TO

NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.

TOGETHER WITH

A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c. throughout
the World; a General HISTORY, *Ancient* and *Modern*, of the different Empires, Kingdoms,
and States; and an Account of the LIVES of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

THE WHOLE COMPILED FROM
THE WRITINGS OF THE BEST AUTHORS, IN SEVERAL LANGUAGES; THE MOST APPROVED DICTIONARIES,
AS WELL OF GENERAL SCIENCE AS OF PARTICULAR BRANCHES; THE TRANSACTIONS, JOURNALS, AND MEMOIRS, OF LEARNED
SOCIETIES, BOTH AT HOME AND ABROAD; THE MS. LECTURES OF EMINENT PROFESSORS ON DIFFERENT SCIENCES;
AND A VARIETY OF ORIGINAL MATERIALS, FURNISHED BY AN EXTENSIVE CORRESPONDENCE.

The SECOND EDITION; greatly Improved and Enlarged.

ILLUSTRATED WITH ABOVE TWO HUNDRED COPPERPLATES.

VOL. V.

INDOCTI DISCANT, ET AMEN MEMINISSE PERITI.

G.

G A B

G, THE seventh letter, and fifth consonant, of our alphabet; tho' in the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, *G* is the third letter. See **LETTER**.

The Hebrews call it *ghimel*, or *gimel*, *q. d.* "camel;" by reason it resembles the neck of that animal; and the same appellation it bears in the Samaritan, Phœnician, and Chaldee; in the Syriac it is called *gamel*, in Arabic *gimm*, and in Greek *gamma*.

The letter *G* is of the mute kind, and cannot be any way founded without the help of a vowel. It is formed by the reflexion of the air against the palate, made by the tongue as the air passes out of the throat: which Martianus Capella expresses thus, *G spiritus cum palato*; so that *G* is a palatal letter.

The form of our *G* is taken from that of the Latins, who borrowed it from the Greeks; the Latin *G* being certainly a corruption of the Greek gamma, *γ*, as might easily be shewn, had our Printers all the characters and forms of this letter which we meet withal in the Greek and Latin MSS thro' which the letter passed from *γ* to *G*.

In English it has a hard and soft sound: hard, as in the words *game*, *gun*, &c.; and soft, as in the words *gesture*, *giant*, &c. At the end of words, *gh* is pronounced like *ff*, as in the words *rough*, *tough*, &c. The letter *g* is also used in many words where the sound is not perceived, as in *sign*, *reign*, &c.

As a numeral, *G* was anciently used to denote 400; and with a dash over it thus *Ḡ*, 40,000. In music, it is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound, in Guido's scale, the whole scale took the name *gamut*. See the articles **CLEFF** and **GAMUT**.

As an abbreviation, *G*. stands for *Gaius*, *Gellius*, *gens*, *genius*, &c. *G. G.* for *gemina*, *gestit*, *gesserunt*, &c. *G. C.* for *genio civitatis* or *Cesaris*. *G. L.* for *Gaius libertus*, or *genio loci*. *G. V. S.* for *genio urbis sacrum*. *G. B.* for *genio bono*. And *G. T.* for *genio tutelari*.

GABARA, or **GABBARA**, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses, especially those of such of their friends as

G A B

died with the reputation of great piety and holiness, or as martyrs. See **EMBALMING**, and **MUMMY**.

GABEL, (*Gabella*, *Gabulum*, *Gablagium*), in French *Gabelle*, i. e. *Vedtigal*, hath the same signification among the ancient English writers, that *gabelle* hath in France. It is a tax; but hath been variously used, as for a rent, custom, service, &c. And where it was a payment of rent, those who payed it were termed *gablatores*. When the word *gabel* was formerly mentioned without any addition to it, it signified the tax on salt, though afterwards it was applied to all other taxes.

GABIONS, in fortification, baskets made of ozier-twigs, of a cylindrical form, six feet high, and four wide; which, being filled with earth, serve as a shelter from the enemy's fire.

GABLE, or **GABLE-End** of a house (from *gaval*, *Welsh*), is the upright triangular end, from the cornice or eaves, to the top of the house.

GABRIEL, the name of one of the principal angels in heaven. It signifies *the strength of God*. There are a few events, in which this exalted being was concerned, recorded in scripture. He was sent to the prophet Daniel, to explain to him the vision of the ram and goat, and the mystery of the seventy weeks, which had been revealed to him. He was sent to Zecharias, to declare to him the future birth of John the baptist. Six months after, he was sent to Nazareth, to the Virgin Mary, to warn her of the birth of Jesus Christ.

The Orientalists add several particulars to what the scriptures inform us concerning the angel Gabriel. The Mahometans call him the *faithful spirit*; and the Persians, by way of metaphor, the *peacock of heaven*. We read, in the second chapter of the Koran, that *whosoever is an enemy to Gabriel, shall be confounded*. It was Gabriel, they believe, who brought to Mahomet, their false prophet, the revelations which he published; and it was he, who conducted him to heaven mounted upon the animal Borak.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

Gad,
Gadus.

GAD-Bee, or *Gad-fly*, in natural history, the common name for a winged insect, called also the *dun-fly* or *ox-fly*; a creature very troublesome to cows, horses, &c. This creature examined by the microscope hath some peculiarities worthy of observation. It has, like the gnat, a long proboscis, with a sharp dart or two darts sheathed within it; the tip of these darts is to penetrate the flesh of animals for the sucking their blood, whereas the proboscis can only serve to suck the dews from flowers, &c.

The eggs of this fly are laid in the waters, and there produce a very remarkable sort of maggot. It is a brown one of a long flattened figure, with a pencil of down-hairs at its tail, which it spreads into a circular form on the surface of the water, while its head is sunk down in search of food. When the creature would descend towards the bottom, these hairs are made to approach one another in an oval form; and in this state they inclose a bubble of air, by means of which it is able to rise again; and if this bubble by any accident escapes, the creature immediately squeezes out of its own body another to supply its place. The finout of this maggot hath three divisions; whence are thrust out three little pointed bodies like serpents tongues. These maggots are very common on the surface of ditch-water; and the motion of their intestines is very singular and observable.

GADUS, in ichthyology, a genus of fishes belonging to the order of jugulares. The head is smooth; there are seven cylindrical rays in the branchiostegic membrane; the body is oblong, with deciduous scales; the whole fins are covered with the common skin of the fish; the rays of the back-fins are blunt, and those of the breast are sharp. There are 17 species, principally distinguished by their cirri and the number of back-fins. The most remarkable are,

1. *The morhua*, or common cod, is found only in the northern parts of the world; it is, as Rondeletius calls it, an ocean fish, and never met with in the Mediterranean sea. It affects cold climates, and seems confined between the latitudes 66° and 50°: what are caught north and south of those degrees being either few in quantity or bad in quality. The Greenland fish are small, and emaciated through want of food; being very voracious, and having in those seas a scarcity of provision. This locality of situation is common to many other species of this genus, most of them being inhabitants of the cold seas, or such as lie within regions that can just claim the title of *temperate*. There are nevertheless certain species found near the Canary-islands, called *cherry*, of which we know no more than the name; but which, according to Captain Glas, are better tasted than the Newfoundland kind.

The great rendezvous of the cod-fish is on the banks of Newfoundland, and the other sand-banks that lie off the coasts of Cape Breton, Nova Scotia, and New England. They prefer those situations, by reason of the quantity of worms produced in those sandy bottoms, which tempt them to resort there for food: but another cause of the particular attachment the fish have to these spots, is their vicinity to the polar seas, where they return to spawn: there they deposit their roes in full security; but want of food forces them, as soon as the first more southern seas are open, to repair thither for subsistence. Few are taken north of Iceland, but on

the south and west coasts they abound; they are again found to swarm on the coasts of Norway, in the Baltic, off the Orkney and the Western isles; after which their numbers decrease, in proportion as they advance towards the south, when they seem quite to cease before they reach the mouth of the Straits of Gibraltar.

Before the discovery of Newfoundland, the greater fisheries of cod were on the seas of Iceland, and off our Western Isles, which were the grand resort of ships from all the commercial nations; but it seems that the greatest plenty was met with near Iceland. The English resorted thither before the year 1415: for we find that Henry V. was disposed to give the king of Denmark satisfaction for certain irregularities committed on those seas by his subjects. In the reign of Edward IV. the English were excluded from the fishery by treaty; and forbidden to resort there under pain of forfeiture of life and goods. Notwithstanding this, that monarch afterwards gave licence to a ship of Hull to sail to Iceland, and there relapse fish and other goods, without regard to any restrictions to the contrary. The right of the English in latter times was far from being confirmed: for we find queen Elizabeth condescending to ask permission to fish in those seas from Christian IV. of Denmark; yet afterwards she so far repented her request, as to instruct her ambassadors at that court to insist on the right of a free and universal fishery. In the reign of her successor, however, they had not fewer than 150 ships employed in the Iceland fishery; which indulgence might arise from the marriage of James with a princess of Denmark. But the Spanish, the French, and the Bretons, had much the advantage of the English in all fisheries at the beginning, as appears by the state of that in the seas of Newfoundland in the year 1578, when the number of ships belonging to each nation stood thus:

Spaniards, 100; besides 20 or 30 that came from Biscay to take whale for train, being about five or six thousand tons.

Portuguese 50, or three thousand tons.

French and Bretons 150, or seven thousand tons.

English, from 30 to 50.

The increase of shipping that resort to those fertile banks, is now unspeakable. Britain still enjoys the greatest share; which ought to be esteemed our chiefest treasure, as it brings wealth to individuals, and strength to the state. See **FISHERY**.

All this immense fishery is carried on by the hook and line only. We have been informed that they fish from the depth of 16 to 60 fathoms, according to the inequality of the bank, which is represented as a vast mountain, under water, above 500 miles long, and near 300 broad; and that seamen know when they approach it by the great swell of the seas and the thick mists that impend over it. The bait is herring, a small fish called a *capelin*, a shell-fish called *clam*, and bits of sea-fowl; and with these are caught fish sufficient to find employ for near 15,000 British seamen, and to afford subsistence to a much more numerous body of people at home, who are engaged in the various manufactures which so vast a fishery demands.

The food of the cod is either small fish, worms, testaceous or crustaceous animals, such as crabs, large welks, &c.; and their digestion is so powerful, as to

dissolve

Gadus.

The Cod.

Gadus. dissolve the greatest part of the shells they swallow. They are very voracious, and catch at any small body they perceive moved by the water, even stones and pebbles, which are often found in their stomachs.

The Cod. Fishermen are well acquainted with the use of the air-bladder or found of the cod; and are very dexterous in perforating this part of a live fish with a needle, in order to disengage the inclosed air: for without this operation it could not be kept under water in the well-boats, and brought fresh to market. The sounds of the cod salted is a delicacy often brought from Newfoundland. Lingslafs is also made of this part by the Iceland fishermen: a process which deserves the attention of the natives of the north of Scotland, where these fish are plentiful. It is given under the article *ICHTHYOCOLLA*.

Providence hath kindly ordained, that this fish, so useful to mankind, should be so very prolific as to supply more than the deficiencies of the multitudes annually taken. Leuwenhoeck counted 9,384,000 eggs in a cod-fish of a middling size; a number, sure, that will baffle all the efforts of man, or the voracity of the inhabitants of the ocean, to exterminate, and which will secure to all ages an inexhaustible supply of grateful provision.

In our seas they begin to spawn in January, and deposit their eggs in rough ground, among rocks. Some continue in roe till the beginning of April. The cod-fish in general recover quicker after spawning than any other fish, therefore it is common to take some good ones all the summer. When they are out of season, they are thin-tailed and bony; and the lice chiefly fix themselves on the inside of their mouths.

The fish of a middling size are most esteemed for the table; and are chosen by their plumpness and roundness, especially near the tail, by the depth of the sulcus or pit behind the head, and by the regular undulated appearance of the sides, as if they were ribbed. The glutinous parts about the head lose their delicate flavour after it has been 24 hours out of the water, even in winter, in which these and other fish of this genus are in highest season.

The largest that we ever heard of taken on our coasts, weighed 78 pounds: the length was five feet eight inches; and the girth round the shoulders, five feet. It was taken at Scarborough in 1755, and was sold for one shilling. But the general weight of these fish in the Yorkshire seas, is from 14 to 40 pounds. This species is short in proportion to its bulk, the belly being very large and prominent.

The jaws are of an equal length, and at the end of the lower is a small beard; the teeth are disposed in the palate as well as in the jaws.

The colour of this fish is cinereous on the back and sides, and commonly spotted with yellow: the belly is white; but they vary much, not only in colour but in shape, particularly that of the head. The side line is white and broad, straight till it reaches opposite the vent, when it bends towards the tail. Codlings are often taken of a yellow, orange, and even red colour, while they remain among the rocks; but, on changing their place, assume the colour of other cod-fish.

2. The *Eglefinus*, or *Haddock*. Large haddocks begin to be in roe in the middle of November, and continue so till the end of January; from that time

till May they are very thin tailed, and much out of season. In May they begin to recover; and some of the middling-sized fish are then very good, and continue improving till the time of their greatest perfection. The small ones are extremely good from May till February, and some even in February, March, and April, viz. those which are not old enough to breed.

The fishermen assert, that in rough weather haddocks sink down into the sand and ooze in the bottom of the sea, and shelter themselves there till the storm is over; because in stormy weather they take none, and those that are taken immediately after a storm are covered with mud on their backs.

In summer they live on young herrings and other small fish; in winter, on the stone-coated worms*, * a species of *Serpula*.

The grand shoal of haddocks comes periodically on the Yorkshire coasts. It is remarkable that they appeared in 1766 on the 10th of December, and exactly on the same day in 1767: these shoals extended from the shore near three miles in breadth, and in length from Flamborough-head to Timmouth-castle, and perhaps much farther northwards. An idea may be given of their numbers by the following fact: Three fishermen, within the distance of a mile from Scarborough harbour, frequently loaded their coble or boat with them twice a-day, taking each time about a ton of fish: when they put down their lines beyond the distance of three miles from the shore, they caught nothing but dog-fish, which shows how exactly these fish keep their limits.

The best haddocks were sold from eightpence to a shilling *per score*; and the poor had the smaller sort at a penny and sometimes a halfpenny *per score*.

The large haddocks quit the coast as soon as they go out of season, and leave behind great plenty of small ones. It is said that the large ones visit the coasts of Hamburg and Jutland in the summer.

It is no less remarkable than providential, that all kinds of fish (except mackrel) which frequent the Yorkshire coast, approach the shore, and as it were offer themselves to us, generally remaining there as long as they are in high season, and retire from us when they become unfit for use. It is the commonest species in the London markets. They do not grow to a great bulk, one of 14 pounds being of an uncommon size, but those are extremely coarse; the best for the table weighing from two to three pounds.

The body of the haddock is long: the head slopes down to the nose: the space between the hind-part of the first dorsal-fin is rigid: on the chin is a short beard. On the back are three fins resembling those of the common cod-fish: on each side beyond the gills is a large black spot. Superstition assigns this mark to the impression St Peter left with his finger and thumb when he took the tribute out of the mouth of a fish of this species, which has been continued to the whole race of haddocks ever since that miracle. The lateral line is black: the tail is forked. The colour of the upper part of the body is dusky or brown; the belly and lower part of the sides silvery.

3. The *Barbatius*, or *ROUT*, never grows to a large size, seldom exceeding a foot in length. It is distinguished from all others by its great depth; one of the size abovementioned being near four inches deep

Gadus.

in the broadest part. The back is very much arched, and carinated: the colour of the fins and tail are black: at the bottom of the pectoral fins is a black spot. The lateral line is white, broad, and crooked. The tail is even at the end, and of a dusky colour. The colour of the body is white, but more obscure on the back than the belly, and tinged with yellow.—It is called at Scarborough a *kleg*, and is a very delicate fish.

4. The *Minutus*, or *POOR*, is the only species of cod-fish with three dorsal fins that we (at this time) are assured is found in the Mediterranean sea. It is taken near Marseilles, and sometimes in such quantities as to become a nuisance; for no other kinds of fish are taken during their season. It is esteemed good, but incapable of being salted or dried: Belon says, that when it is dried in the sun, it grows as hard as horn. It is the smallest species yet discovered, being little more than six inches long. On the chin is a small beard: the eyes are covered with a loose membrane: on the gill-covers and the jaws, there are, on each side, nine punctures. The colour on the back is a light brown; on the belly a dirty white.—We owe the discovery of this kind in our seas to the Reverend Mr Jago.

The Poor-fish.

5. The *Carbonarius*, or *COAL-FISH*, takes its name from the black colour that it sometimes assumes. Belon calls it the *colfish*, imagining that it was so named by the English, from its producing the Ichthyocolla; but Gesner gives the true etymology. These fish are common on most of our rocky and deep coasts, but particularly those of the north of Great Britain. They swarm about the Orkneys, where the fry are the great support of the poor. The young begin to appear on the Yorkshire coast the beginning of July in vast shoals, and are at that time about an inch and an half long. In August they are from three to five inches in length, and are taken in great numbers with the angling rod: they are then esteemed a very delicate fish; but grow so coarse when they are a year old, that few people will eat them. Fish of that age arc from eight to fifteen inches long, and begin to have a little blackness near the gills and on the back, and the blackness increases as they grow older.

The fry is known by different names in different places: they are called at Scarborough *parrs*, and when a year old, *billets*. About nine or ten years ago such a glut of parrs visited that part, that for several weeks it was impossible to dip a pail into the sea without taking some.

Though this fish is so little esteemed when fresh, yet it is salted and dried for sale. It is of a more elegant form than the cod-fish: they generally grow to the length of two feet and an half, and weigh about 28 or 30 pounds at most. The head is small; the under-jaw a little longer than the upper: the tail is broad and forked. They vary in colour: some have their back, nose, dorsal fins, and tail, of a deep black: the gill-covers, silver and black; the ventral and anal fins, white; the belly of the same colour. Others are dusky, others brown; but, in all, the lateral line is straight and white, and the lower part of the ventral and anal fins white.

6. The *Pollachiur*, or *POLLACK*, is common on many of our rocky coasts: during summer they are seen in great shoals frolicking on the surface of the water, and

flinging themselves into a thousand forms. They are at that time so wanton as to bite at any thing that appears on the top of the waves, and are often taken with a goose-feather fixed to the hook. They are very strong, being observed to keep their station at the feet of the rocks in the most turbulent and rapid sea. They are a good eating fish. They do not grow to a very large size; at least the biggest seldom exceed six or seven pounds: but some have been taken in the sea near Scarborough, which they frequent during winter, that weighed near 28 pounds. They are there called *lects*.

The under jaw is longer than the upper; the head and body rises pretty high, as far as the first dorsal fin. The side line is incurved, rising towards the middle of the back, then sinking and running straight to the tail; it is broad, and of a brown colour. The colour of the back is dusky, sometimes inclining to green: the sides beneath the lateral line marked with lines of yellow; the belly white.

7. The *merlangus*, or *WHITING*. These fish appear in vast shoals in our seas in the spring, keeping at the distance of about half a mile to that of three from the shore. They are caught in vast numbers by the line, and afford excellent diversion. They are the most delicate, as well as the most wholesome, of any of the genus: but they do not grow to a large size, the biggest not exceeding 20 inches; and even that is very uncommon, the usual length being 10 or 12; tho' it is said, that whittings, from four to eight pounds in weight, have been taken in the deep water at the edge of the Dogger-Bank.—It is a fish of an elegant make: the upper jaw is the longest; the eyes large, the nose sharp; the teeth of the upper jaw long, and appear above the lower when closed. The colour of the head and back is a pale brown; the lateral line white, and crooked; the belly and sides silvery, the last streaked lengthwise with yellow.

8. The *merlucius*, or *HAKE*, is found in vast abundance on many of our coasts, and of those of Ireland. There was formerly a vast stationary fishery of hake on the Nymph Bank off the coast of Waterford, immense quantities appearing there twice a year; the first shoal coming in June, during the mackerel-season; the other in September, at the beginning of the herring-season, probably in pursuit of those fish: it was no unusual thing for six men with hooks and lines to take a thousand hake in one night, besides a considerable quantity of other fish. These were salted and sent to Spain, particularly to Bilbao. We are at this time uninformed of the state of this fishery; but find that Mr Smith, who wrote the history of the county of Waterford, complains even in his time (1746) of its decline. Many of the gregarious fish are subject to change their situations, and desert their haunts for numbers of years, and then return again. Mr Smith instances the loss of the haddock on the Waterford shores, where they used to swarm; and we can bring the capriciousness of the herrings, which so frequently quit their stations, as another example.—Sometimes the irregular migration of fish is owing to their being followed and harassed by an unusual number of fish of prey, such as the shark-kind; sometimes to deficiency of the smaller fish, which served them as food; and lastly, in many places to the custom of trawling, which not only demolishes a quantity of

Gadus.

The Pollack.

The Whiting.

The Hake.

Gadus.

their spawn, which is deposited in the sand, but also detroys or drives into deeper waters numberless worms and insects, the repast of many fish.—The hake is in England esteemed a very coarse fish, and is seldom admitted to table either fresh or salted. When cured, it is known by the name of *Poor John*. These fish are from a foot and an half to near twice that length: they are of a slender make, of a pale ash-colour on their backs, and of a dirty white on their bellies.

The Ling.

10. The *molva*, or *ling*, takes its English name from its length, being corrupted from the word *long*. It abounds about the Scilly Isles, on the coasts of Scarborough, and those of Scotland and Ireland, and forms a considerable article of commerce. This branch of trade was considerable so long ago as the reign of Edward III. an act for regulating the price of lob, *ling*, and cod, being made in his 31st year.

In the Yorkshirc seas they are in perfection from the beginning of February to the beginning of May, and some till the end of that month. In June they spawn, depositing their eggs in the soft oozy ground of the mouth of the Tees: at that time the males separate from the females, and resort to some rocky ground near Flamborough-head, where the fishermen take great numbers without ever finding any of the female or roed fish among them.

While a ling is in season its liver is very white, and abounds with a fine-flavoured oil; but as soon as the fish goes out of season, the liver becomes red as that of a bullock, and affords no oil. The same happens to the cod and other fish in a certain degree, but not so remarkably as in the ling. When the fish is in perfection, a very large quantity of oil may be melted out of the liver by a slow fire; but if a violent sudden heat be used for that purpose, they yield very little. The oil, which nature hoards up in the cellular membraes of the fishes, returns into their blood, and supports them in the engendering season, when they pursue the business of generation with so much eagerness as to neglect their food.

Vast quantities of ling are salted for exportation, as well as for home-consumption. When it is cut or split for curing, it must measure 26 inches or upwards from the shoulder to the tail: if less than that, it is not reckoned a sizeable fish, and consequently not entitled to the bounty on exportation; such are called *drizzles*, and are in season all summer.

The usual size of a ling is from three to four feet; but they have been heard of seven feet long. The body is very slender; the head flat; the upper jaw the longest; the teeth in that jaw small and very numerous; in the lower, few, slender, and sharp: on the chin is a small beard. They vary in colour, some being of an olive hue on the sides and back, others cinereous; the belly white. The ventral fins white: the dorsal and anal edged with white. The tail marked near the end with a transverse black bar, and tipped with white.

The Burbot.

11. The *lota*, or *burbot*, is found in the Trent; but in greater plenty in the river Witham, and in the great east fen in Lincolnshire. It is a very delicate fish for the table, though of a disgusting appearance when alive. It is very voracious, and preys on the fry and lesser fish. It does not often take a bait, but is generally caught in weels. It abounds in the lake of Ge-

neva, where it is called *lota*; and it is also met with in the Lago Maggiore, and Lugano. The largest taken in our waters weigh between two and three pounds, but abroad they are sometimes found of double that weight. Their body has some resemblance to that of an eel, only shorter and thicker; and its motions also resemble those of that fish: they are besides very smooth, slippery, and slimy. The head is very ugly, being flat, and shaped like that of a toad: the teeth are very small, but numerous. On the end of the nose are two small beards; on the chin another. The colour varies: some are dusky, others are of a dirty green, spotted with black, and oftentimes with yellow; and the belly in some is white; but the real colours are frequently concealed by the slime.

12. The *myxela*, or *five-bearded cod*, very much resembles the former.

The beards on the upper jaw are four, viz. two at the very end of the noses and two a little above them: on the end of the lower jaw is a single one. The fish are of a deep olive brown, their belly whitish. They grow to the same size as the former.—The Cornish fishermen are said to whistle, and make use of the words *bod, bod, vean*, when they are desirous of taking this fish, as if by that they facilitated the capture. In the same manner the Sicilian fishermen repeat their *manassa di paganu*, &c. when they are in pursuit of the sword-fish.

13. The *torax*, or, as it is called in the Shetlands, The *Tusk*, *tusk* and *brismak*, is a northern fish; and as yet undiscovered lower than about the Orkneys, and even there it is rather scarce. In the seas about Shetland, it swarms, and forms (barrelled or dried) a considerable article of commerce. The length is about 20 inches, the greatest depth four and a half. The head is small; the upper jaw a little longer than the lower; both jaws furnished with multitudes of small teeth: on the chin is a small single beard: from the head to the dorsal fin is a deep furrow. The colour of the head is dusky: the back and sides yellow; belly white; edges of the dorsal, anal, and caudal fins, white; the other parts dusky; the pectoral-fins brown.

GAFF, a sort of boom or pole, frequently used in small ships, to extend the upper edge of the mizen; and always employed for the same purpose on those sails whose foremost edges are joined to the mast by hoops or lacing, and which are usually extended by a boom below. Such are the main-sails of all sloops, brigs, and schooners.

GAFFAREL (James), a French divine, and very learned writer, born about 1601. He acquired great skill in the oriental and several other languages; and was particularly versant in the cabalistic and occult sciences, which he learnedly exposed and refuted. Cardinal Richieu made choice of him for his library-keeper, and sent him into Italy to collect the best manuscripts and books. He published a book, intitled *Curiositez Inuueies*, i. e. Unheard-of Curiosities. It is said the cardinal designed to employ him in his grand project for the re-union of religions. He died in 1681, aged 80. He had been labouring for many years, and had almost finished, a history of the subterranean world; containing an account of the caves, grottoes, vaults, catacombs, and mines, he had met with in 30 years travels.

Gadus

Gaffarel.

Gagates

Gage.

GAGATES, or JET. See JET.

GAGE, in our ancient customs, signifies a pledge, or pawn, given by way of security. The word is only properly used in speaking of moveables; for immoveables, *hypotheca* is used.

If the gage perish, the person who received it is not to answer for it, but only for extreme negligence. &c.

GAGE, is also used for a challenge, to combat: See CARTEL. In which sense, it was a pledge, which the accuser or challenger cast on the ground, and the other took up as accepting the challenge: it was usually a glove, gauntlet, chaperoon, or the like. See COMBAT, and DUEL.

GAGE is only now retained as a substantive. As a verb, the G is changed into H, and of *gage* is formed *wage*; as, to wage law; to wage deliverance, *q. d.* to give security a thing shall be delivered. See WAGE.

If a person who has distrained be sued for not having delivered what he had taken by distress, he should wage, or gage, or gager, deliverance; that is, put in surety that he will deliver them.

Mort-GAGE, is that which is left in the hands of the proprietor, so that he reaps the fruits thereof.

In opposition to *viv-gage*, where the fruits or revenues are reaped by the creditor, and reckoned on the foot of the debt, which diminishes in proportion thereto. The second acquits or discharges itself; the first does not.

GAGE, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's *gage*: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water, is the ship's *gage*.

GAGE, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See FOUNDRY.

Sliding-GAGE, a tool used by mathematical instrument-makers, for measuring and setting off distances.

Sea-GAGE, an instrument invented by Dr Hales and Dr Desaguliers, for finding the depth of the sea; the description whereof is this. AB (Plate CXV. fig. 1. n^o 1.) is the gage-bottle, in which is cemented the gage-tube *Ff* in the brass cap at G. The upper end of tube *F* is hermetically sealed, and the open lower end *f* is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass HG, pierced with several holes to admit the water into the bottle AB. The body K is a weight hanging by its shank L, in a socket N, with a notch on one side at *m*, in which is fixed the catch *l* of the spring S, and, passing through the hole L, in the shank of the weight K, prevents its falling out when once hung on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full-blown bladder, I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument, thus constructed, is used in the following manner. The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom: the socket N is somewhat longer than the shank

L; and therefore, after the weight K comes to the bottom, the gage will continue to descend, till the lower part of the socket strikes against the weight: this gives liberty to the catch to fly out of the hole L, and let go the weight K: when this is done, the ball or bladder I, instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube *Ff*, and the height to which it has been forced by the greatest pressure, viz. that at the bottom, will be shewn by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shews into what space the whole air in the tube *Ff* is compressed; and consequently the height or depth of the water which by its weight produced that compression, which is the thing required.

If the gage-tube *Ff* be of glass, a scale might be drawn on it with the point of a diamond, shewing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is no more than 634 feet, which is not half a quarter of a mile.

If, to remedy this, we make use of a tube 50 inches long, which for strength may be a musket-barrel, and suppose the air compressed into an hundredth part of half an inch; then by saying, as 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the doctor contrived a new form for his sea-gage, or rather for the gage-tube in it, as follows. BCDF (*ibid.* n^o 2.) is a hollow metalline globe communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will receive the mark of the treacle, and shew it when taken out.

If the tube AB be 50 inches long, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. 2½ inches, which correspond to 6600, which is a mile and a quarter. Again, half that space, or 1½ inch, will shew double the former depth, viz. 13200 feet, or 2½ miles; which is probably very nearly the greatest depth of the sea.

Wind-GAGE, an instrument for measuring the force of the wind upon any given surface. It was invented by Dr Lind, who gives the following description of it

Gage.

of it, Phil. Trans. Vol. LXV.

Pl. CXLI. fig. 1. This instrument consists of two glass tubes AB, CD, of five or six inches in length. Their bores, which are so much the better for being equal, are about four tenths of an inch in diameter. They are connected together like a siphon by a small bent glass-tube ab , the bore of which is about one tenth of an inch in diameter. On the upper end of the leg AB there is a tube of latten brads, which is kneed, or bent perpendicularly outwards, and has its mouth open towards F. On the other leg CD, is a cover with a round hole G in the upper part of it, two tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brads ed , which not only gives strength to the whole instrument, but also serves to hold the scale HI. The kneed tube and cover, are fixed on with hard cement or sealing wax. To the same tube is foldered a piece of brads e , with a round hole in it to receive the steel spindle KL; and at f there is just such another piece of brads foldered to the brads-hoop gb , which surrounds both legs of the instrument. There is a small shoulder on the spindle at f , upon which the instrument rests, and a small nut at i , to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it; by which it may be screwed into the top of a post or a stand made on purpose. It has also a hole at L, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brads k is foldered to the kneed tube, about half an inch above the round hole G, so as to prevent rain from falling into it. There is likewise a crooked tube AB (fig. 2.) to be put occasionally upon the mouth of the kneed tube F; in order to prevent rain from being blown into the mouth of the wind-gage when it is left out all night, or exposed in the time of rain.

The force or momentum of the wind may be ascertained by the assistance of this instrument, by filling the tubes half full of water, and pushing the scale a little up or down, till the o of the scale, when the instrument is held up perpendicularly, be on a line with the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and, turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water, which the wind is capable of sustaining at that time; and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water, having its base equal to the altitude of the column of water sustained by the wind in the wind-gage. Hence the force of the wind upon any body where the surface opposed to it is known, may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind and that of another.

The force of the wind may be likewise measured with this instrument, by filling it until the water runs out at the hole G. For if we then hold it up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the

same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. But the true height may be obtained by the following formulæ.

Suppose that after a gale of wind which had blown the water from A to B (fig. 3.) forcing it at the same time through the other tube out at E, the surface of the water should be found standing at some level DG, and it were required to know what was the height of the column EF or AB, which the wind sustained. In order to obtain this, it is only necessary to find the height of the columns DB or GF, which are constantly equal to one another; for either of these added to one of the equal columns AD, EG, will give the true height of the column of water which the wind sustained.

1. Let the diameters AC, EH, of the tubes, be respectively represented by cd ; and let $a=AD$, or EG, and $x=DB$, or GF: Then it is evident that the column DB, is to the column EG, as c^2x to d^2a . But these columns are equal. Therefore $c^2x = d^2a$; and consequently, $x = \frac{d^2a}{c^2}$.

2. But if at any instant of time whilst the wind was blowing, it was observed, that, when the water stood at E, the top of the tube out of which it is forced, it was depressed in the other to some given level BF, the altitude at which it would have stood in each had it immediately subsided, may be found in the following manner.—Let $b=AB$ or EF. Then it is evident that the column DB, is equal to the difference of columns EF, GF. But the difference of these columns is as $d^2b - d^2x$; and consequently $x = \frac{d^2b}{c^2 + d^2}$.

For the cases when the wind blows in at the narrow leg of the instrument: Let $AB=EF=b$, EG, or AD= a , GF=DB= x , and the diameters EH, GA, respectively = d , c , as before. Then it is evident, that the column AD, is to the column GF as c^2a to d^2x . But these columns are equal; therefore $d^2x = ac^2$; and consequently $x = \frac{ac^2}{d^2}$. It is also evident, that the column AD is equal to the difference of the columns AB, DB; but the difference of these columns is as $b^2 - c^2x$. Therefore $d^2x = b^2 - c^2x$. Whence we get $x = \frac{b^2}{a + c^2}$.

The use of the small tube of communication ab (fig. 1.), is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude, than the true height of the column which the wind is able at that time to sustain, from its receiving a sudden impulse whilst it is vibrating either in its ascent or descent. As in some cases the water in this instrument might be liable to freeze, and thus break the tubes, Dr Lind recommends a saturated solution of sea-salt to be used instead of it, which does not freeze till Fahrenheit's thermometer falls to o.

Gaieta
||
Galatia.

GAIIETA, an ancient, handsome, and strong town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, with a fort, citadel, harbour, and bishop's see. It was taken by the Austrians in 1707, and by the Spaniards in 1734. It is seated at the foot of a mountain near the sea, in E. Long. 13. 37. N. Lat. 41. 30.

GAINSBOROUGH, a town of Lincolnshire in England, seated on the river Trent near the sea. It is a large well built town, with a pretty good trade, and has the title of an earldom. W. Long. 0. 40. N. Lat. 53. 26.

GALACTITES, in the history of fossils, a substance much resembling the morochthus or French chalk, in many respects; but different from it in colour. The ancients found it in the Nile, and in some rivers in Greece, and used it in medicine as an astringent, and for defluxions and ulcers of the eyes. At present it is common in Germany, Italy, and some parts of France, and is wholly overlooked, being esteemed a worse kind of morochthus. See **MOROCOTHUS**.

GALANGALS, in the materia medica. See **KÆMPFERIA**.

GALANTHUS, the **SNOW-DROP**; a genus of the monogynia order, belonging to the hexandria class of plants. There is but one species, viz. the *valis*; which is a bulbous-rooted flowery perennial, rising but a few inches in height, and adorned at top with small tripetaloid flowers of a white colour. There are three varieties, viz. the common single flowered snow-drop, the semi-double snow-drop, and the double snow-drop. They are beautiful little plants; and are much valued on account of their early appearance, often adorning the gardens in January or February, when scarce any other flower is to be seen. They frequently burst forth when the ground is covered with snow, and continue very often till the beginning of March, making a very ornamental appearance, especially when disposed in clusters towards the fronts of the borders, &c. The single kind comes first into bloom, then the semi-double, and after that the double. They will succeed any where, and multiply exceedingly by off-sets from the roots.

GALATA, a great suburb belonging to Constantinople, opposite to the seraglio, on the other side of the harbour. It is here the Greeks, Armenians, Franks, Christians, and Jews inhabit, and are allowed the exercise of their respective worships.

GALATEA, in fabulous history, a nymph and marine deity, the daughter of Nereus and Doris. She was beloved by Polyphemus, whom she despised for the shepherd *Acis*; at which that Cyclops was so enraged, that he crushed *Acis* to pieces with a rock. See *ACIS*.

GALATIA, the ancient name of a province of Asia Minor, now called *Amasia*. It was bounded on the east by Cappadocia, on the west by Bithynia, on the south by Pamphylia, and on the north by the Euxine Sea. It was reduced under the subjection of the Romans in the time of Augustus, and is now in the hands of the Turks. Here St. Paul founded a church, to which he directed that epistle which is still known by the name of the *Epistle to the Galatians*, and was

written to reclaim them from the observation of Jewish ordinances, into which they had been seduced by some false teachers.

GALAXY, in astronomy, that long, white, luminous track, which seems to encompass the heavens like a swath, scarf, or girdle: and which is easily perceivable in a clear night, especially when the moon does not appear. The Greeks call it *Γαλαξίας*, *Galaxy*, of *Γάλα, γαλακτός*, *Milk*; on account of its colour and appearance: the Latins, for the same reasons, call it *via lactea*; and we, the *milky way*. It passes between Sagittary and Gemini, and divides the sphere into two parts; it is unequally broad; and in some parts is single, in others double.

The ancient poets, and even philosophers, speak of the *Galaxy*, as the road, or way, by which the heroes went to heaven.

Aristotle makes it a kind of meteor, formed of a crowd of vapours, drawn into that part by certain large stars disposed in the region of the heavens answering hereto.

Others, finding that the *Galaxy* was seen all over the globe, that it always corresponded to the same fixed stars, and that it transcended the height of the highest planets, set aside Aristotle's opinion, and placed the *Galaxy* in the firmament, or region of the fixed stars, and concluded it to be nothing but an assemblage of an infinite number of minute stars.

Since the invention of the telescope, this opinion has been abundantly confirmed. By directing a good telescope to any part of the milky way; where, before, we only saw a confused whiteness, we now descry an innumerable multitude of little stars, so remote, that a naked eye confounds them. See **ASTRONOMY**, n° 28.

GALBANUM, in pharmacy, a gum issuing from the stem of an umbelliferous plant growing in Persia and many parts of Africa.

It is sometimes met with in the shops, in loose granules, called *drops* or *tears*; and sometimes in large masses, formed of a number of these blended together; but in these masses some accidental foulness is often mixed with the gum. The single drops usually approach to a roundish, oblong, pear-like form. Galbanum is soft like wax, and, when fresh drawn, white; but it afterwards becomes yellowish or reddish: it is of a strong smell, of an acrid and bitterish taste; it is inflammable in the manner of a resin, and soluble in water like a gum.

In medical virtue, and sensible qualities, it resembles the gum ammoniacum; but is less efficacious than it in asthma, though more efficacious in hystERIC disorders. When assa fetida is too strong, galbanum may be tried; and, if it disagrees, give ammoniacum.

A mixture of spirit of wine two parts, with one part water, dissolves all but the impurities, which are commonly in considerable quantities.

Great part of the virtue of galbanum consists in its essential oil, and is carried up in distillation either with water or with spirit, whence great care is required in purifying it. For making of plasters, and such like inferior purposes, the best method is to expose it in winter to a sharp frost, and whilst it is brittle to powder it; thus the impurities may in some measure be separated.

Galaxy,
Galbanum.

Gale.

rated in the searce: for internal uses, it is best managed by including it in a bladder, and keeping it in hot water, until it is soft enough to be strained by preasure through an hempen cloth.

Besides the essential oil yielded by distillation with water, an empyreumatic oil is obtained by distilling in a retort without mixture. This empyreumatic oil is of a fine blue colour, but changes in the air to a purple.

GALE, in the sea language, a term of various import. When the wind blows not so hard but that a ship may carry her top-sails a-trip, (that is, hoisted up to the highest) then they say it is a loom-gale. When it blows very strong, they say it is a stiff, strong, or fresh gale. When two ships are near one another at sea, and there being but little wind blowing, one of them finds more of it than the other, they say that the one ship gales away from the other.

GALE (Dr John), an eminent and learned minister among the Baptists, was born at London in 1680. He studied at Leyden, where he distinguished himself very early, and afterwards at Amsterdam, under Dr Limborch. He was chosen minister of the Baptist congregation at Barbican; where his preaching, being chiefly practical, was greatly resorted to by people of all persuasions. Four volumes of his sermons were published after his death, which happened in 1721. His *Reflections on Dr Wall's History of Infant-baptism*, is the best defence of the Baptists ever published, and the reading of that performance induced the learned Mr William Whiston and Dr Foster to become Baptists.

GALE (Theophilus), an eminent nonconformist minister, born in 1628. He was invited to Winchester in 1657; and continued a stated preacher there, until the re-establishment of the church by Charles II. when he rather chose to suffer the penalties of the act of conformity, than submit to it contrary to his conscience. He was afterwards engaged by Philip lord Wharton as tutor to his sons, whom he attended to an academy at Caen in Normandy; and when this duty was fulfilled, he became pastor over a congregation of private conventiclers in Holborn. He died in 1678; and is principally known by an elaborate work, entitled, *the Court of the Gentiles*, calculated to shew, that the Pagan philosophers derived their most sublime sentiments from the Scriptures.

GALE (Dr Thomas), a learned divine, born at Scruton in Yorkshire, in the year 1636, was educated at Cambridge, and at length became professor of the Greek language in that university. He was afterwards chosen head master of St Paul's school, London; and was employed by the city in writing those elegant inscriptions on the monument erected in memory of the conflagration in 1666. In 1676 he was collated to a prebend in the cathedral of St Paul's; and was likewise elected a fellow of the Royal Society, to which he presented a Roman urn with its ashes. About the year 1697, he gave to the new library of Trinity college, in Cambridge, a great number of Arabic manuscripts; and in 1697, was admitted dean of York. He died in that city, in 1702; and was interred in the cathedral, where a monument, with a Latin inscription, was erected to his memory. He was a learned divine, a great historian, one of the best Greek scholars of his age, and maintained a correspondence with the most

learned men abroad as well as at home. He published, 1. *Historie Poetice Antiqui Scriptores*, octavo. 2. *Opuscula Mythologica, Ethica, & Physica*, in Greek and Latin, octavo. 3. *Herodoti Historia*, folio. 4. *Historie Anglicanae Scriptores quinque*, in folio. *Historie Britannicae, Saxonicae, Anglo-Danicae, Scriptores quindecim*, in folio. 6. *Rhetores Selecti*, &c.

GALEASSE, a large low built vessel, using both sails and oars, and the biggest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down. It has also thirty-two benches of rowers; and to each bench six or seven slaves, who sit under cover. This vessel is at present used only by the Venetians.

GALEN (CLAUDIUS), in Latin, *Galenus*, prince of the Greek physicians, after Hippocrates, was born at Pergamus in the Lesser Asia, about the year 131. His father was possessed of a considerable fortune; was well-versed in polite literature, philosophy, astronomy, and geometry; and was also well skilled in architecture. He himself instructed his son in the first rudiments of learning, and afterwards procured him the greatest masters of the age in philosophy and eloquence. Galen having finished his studies under their care, chose physic for his profession, and chiefly studied the works of Hippocrates. Having at length exhausted all the sources of literature that were to be found at home, he resolved to travel, in order to converse with the most able physicians in all parts, intending at the same time to take every opportunity of inspecting on the spot the plants and drugs of the countries through which he passed. With this view he went to Alexandria, and staid some years in that metropolis of Egypt: from thence he travelled through Cilicia; passed through Palestine; visited the isles of Crete and Cyprus; and made two voyages to Lemnos, in order to examine the Lemnian earth, which was then esteemed an admirable medicine. With the same view he went into the Lower Tyria, in order to obtain a thorough insight into the nature of the opobalsamum, or balm of Gilead; and having completed his design, returned home by the way of Alexandria.

Galen had been four years at Pergamus, where his practice was attended with extraordinary applause, when some seditious commotions induced him to go to Rome, where he resolved to settle: but the proofs he gave of his superior skill, added to the respect shewn him by several persons of very high rank, created him so many enemies among his brethren of the faculty, that he was obliged to quit the city, after having resided there four or five years. But he had not long returned to Pergamus, when he was recalled by the emperors Aurelius and Verus. After their death, he retired to his native country; where he died, about the year 200. He wrote in Greek; and is said to have composed two hundred volumes, which were unhappily burnt in the temple of Peace. The best editions of those that remain, are, that printed at Basil, in 1538, in five volumes, and that of Venice, in 1625, in seven volumes. Galen was of a weak and delicate constitution, as he himself asserts: but he nevertheless, by his temperance and skill in physic, arrived to a great age; for it was his maxim, always to rise from table with

Galeasie,
Galen.

some degree of appetite. He is justly considered as the greatest physician of antiquity, next to Hippocrates; and he performed such surprising cures, that he was accused of magic.

GALENIC, or **GALENICAL**, in pharmacy; a manner of treating diseases, founded on the principles of Galen.

The distinction of *galenical* and *chemical*, was occasioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine. Then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice. And though this division into the two sects of galenists and chemists has long ceased, yet the distinction of medicines, which resulted from it, is still retained.

Galenical medicines are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

GALEON. See **GALLION**.

GALICIA, a province of Spain, bounded on the north and west by the ocean, on the south by Portugal, and on the east by Asturias and the kingdom of Leon. The air is temperate along the coast; but, in other places, it is cold and moist. It is but thin of people, and the produce is wine, flax, and citrons; here also are good pastures, copper, and lead; the forests yield wood for building of ships. St. Jago di Compostella is the capital town.

GALILEE, once a province of Judæa, now of Turkey in Asia, was bounded by mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the Chison on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles; but the bounds of the country are not now well known, nor yet the places where many of the towns stood.

GALILEANS, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrolment of all the subjects of the Roman empire.

They pretended that God alone should be owned as Master and Lord, and in other respects were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

GALILEO (Galilei), the famous mathematician and astronomer, was the son of a Florentine nobleman, and born in the year 1564. He had from his infancy a strong inclination to philosophy and the mathematics; and made prodigious progress in these sciences. In 1592, he was chosen professor of mathematics at Padua; and during his abode there he invented, it is said, the telescope; or, according to others, improv-

ved that instrument, so as to make it fit for astronomical observations: (See *ASTRONOMY*, p. 749, col. 1.) In 1611, Cosmo II. grand duke of Tuscany sent for him to Pisa, where he made him professor of mathematics, with a handsome salary; and soon after inviting him to Florence, gave him the office and title of *principal philosopher and mathematician to his highness*.

He had been but a few years at Florence, before he was convinced by sad experience, that Aristotle's doctrine, however ill-grounded, was held too sacred to be called in question. Having observed some solar spots in 1612, he printed that discovery the following year at Rome; in which, and in some other pieces, he ventured to assert the truth of the Copernican system, and brought several new arguments to confirm it. For these he was cited before the inquisition; and, after some months imprisonment, was released upon a simple promise, that he would renounce his heretical opinions, and not defend them by word or writing. But having afterwards, in 1632, published at Florence his "Dialogues of the two greatest systems of the world, the Ptolemaic and Copernican," he was again cited before the inquisition, and committed to the prison of that ecclesiastical court at Rome. In June 32d N. S. that year, the congregation convened; and in his presence pronounced sentence against him and his books, obliging him to abjure his errors in the most solemn manner; committed him to the prison of their office during pleasure; and enjoined him, as a saving penance, for three years to come and repeat once a-week the seven penitential psalms: referring to themselves, however, the power of moderating, changing, or taking away altogether or in part, the abovementioned punishment and penance. On this sentence, he was detained a prisoner till 1634; and his "Dialogues of the system of the world" were burnt at Rome.

He lived ten years after this, seven of which were employed in making still further discoveries with his telescope. But by the continual application to that instrument, added to the damage he received in his sight from the nocturnal air, his eyes grew gradually weaker, till he became totally blind in 1639. He bore this calamity with patience and resignation, worthy of a great philosopher. The loss neither broke his spirit, nor hindered the course of his studies. He supplied the defect by constant meditation; whereby he prepared a large quantity of materials, and began to dictate his own conceptions; when, by a distemper of three months continuance, wasting away by degrees, he expired at Arcetti near Florence, in January 1642, N. S. in the 78th year of his age.

Among various useful inventions of which Galileo was the author, is that of the simple pendulum, which he had made use of in his astronomical experiments. He had thoughts of applying it to clocks; but did not execute it: the glory of that invention was reserved for Vicenzio his son, who made the experiment at Venice in 1649; and M. Huygen's afterwards carried this invention to perfection.—He wrote a great number of treatises, several of which were published in a collection by Signor Mendessi, under the title of *L'opera di Galileo Galilei Lyncea*. Some of these, with others of his pieces, were translated into English and published by Thomas Salisbry, Esq; in his mathema-
ti-

tical collections, &c. in two volumes folio. A volume also of his letters to several learned men, and solutions of several problems, were printed at Bologna in quarto. Besides these, he wrote many others, which were unfortunately lost through his wife's devotion; who, solicited by her confessor, gave him leave to peruse her husband's manuscripts, of which he tore and took away as many as he said were not fit to be published.

GALL, in the animal economy. See BILE.

A great number of experiments have been made upon the gall of different animals, but few conclusions can be drawn from them with any certainty. Dr Percival, however, hath shewn, that putrid bile may be perfectly corrected and sweetened by an admixture of the vegetable acids, vinegar and juice of lemons. These, he observes, have this effect much more completely than the mineral ones: and hence, he thinks, arises the great usefulness of the vegetable acids in autumnal diseases; which are always attended with a putrescent disposition of the bile, owing to the heat of the preceding summer. On this occasion he takes notice of a common mistake among physicians, who frequently prescribe elixir of vitriol in those diseases, where vinegar or lemon juice would be much more effectual.

From this effect of acids on the gall, he also thinks, we may see why the immoderate use of acids is so pernicious to digestion. It is necessary to health that the gall should be in some degree acrid and alkalescent: but as acids have the property of rendering it perfectly mild and sweet, they must be proportionably pernicious to the due concoction and assimilation of the food; which without an acrid bile cannot be accomplished. Hence the body is deprived of its proper nourishment and support, the blood becomes vapid and watery, and a fatal cachexy unavoidably ensues. This hath been the case with many unfortunate persons, who, in order to reduce their excessive corpulency, have indulged themselves in the too free use of vinegar. From the mild state of the gall in young children, Dr Percival also thinks it is, that they are so much troubled with acidities.

GALL-Bladder. See ANATOMY, n° 358.

GALL, in natural history, denotes any protuberance or tumour produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed *gall-nuts*, and the latter *berry-galls* or *apple-galls*.

The general history of the gall is this. An insect of the fly kind is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the leaves or tender branches of a tree; and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The external coat of this excrescence is dried by the air; and grows into a figure which bears some resemblance to the bow of an arch, or the roundness of a kernel. This little ball receives its nutriment, growth, and vegetation, as the other parts of

the tree, by slow degrees, and is what we call the *gall-nut*. The worm that is hatched under this spacious vault, finds in the substance of the ball, which is as yet very tender, a subsistence suitable to its nature; gnaws and digests it till the time comes for its transformation to a nymph, and from that state of existence changes into a fly. After this, the insect, perceiving itself duly provided with all things requisite, disengages itself soon from its confinement, and takes its flight into the open air. The case, however, is not similar with respect to the gall-nut that grows in autumn. The cold weather frequently comes on before the worm is transformed into a fly, or before the fly can pierce through its inclosure. The nut falls with the leaves: and although you may imagine that the fly which lies within is lost, yet in reality it is not so; on the contrary, its being covered up so close, is the means of its preservation. Thus it spends the winter in a warm house, where every crack and cranny of the nut is well stopped up; and lies buried as it were under a heap of leaves, which preserves it from the injuries of the weather. This apartment, however, though so commodious a retreat in the winter, is a perfect prison in the spring. The fly, roused out of its lethargy by the first heats, breaks its way through, and ranges where it pleases. A very small aperture is sufficient, since at this time the fly is but a diminutive creature. Besides, the ringlets whereof its body is composed, dilate and become pliant in the passage.

Oak-galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour: which, as it grows stronger, becomes black; and on this property depends the art of making our writing-ink, as also the arts of dying and dressing leather, and other manufactures. See INK.

GALLS are very strong astringents, and give out their astringent virtue very readily both to water and spirit. From two ounces of galls, 14 drachms of astringent extract were obtained by water, and between 12 and 13 with spirit. In medicine they are rarely used.

GALL (St), a considerable town in Switzerland, and in the Upper Thurgow, with a rich and celebrated abbey, whose abbot is a prince of the empire. This place has for some time been a republic, in alliance with the Cantons. It is not very large; but is well built, neat, populous. It contains about 10,000 inhabitants, who are chiefly employed in the linen-manufacture; and make annually, it is said, 40,000 pieces of linen, of 200 ells each; which renders it one of the richest towns in Switzerland. The inhabitants are Protestants; for which reason there are often great contentions between them and the abbey, about religious affairs. It is seated in a narrow barren valley, between two mountains, and upon two small streams. E. Long. 29. 5. N. Lat. 47. 38.

GALLAND (Aithony), a learned antiquarian, member of the Academy of Inscriptions, and professor of Arabic in the Royal College of Paris, was born of poor parents at Rollo, a village in Picardy. Having studied at the Sorbonne and other universities, he travelled into the east; where he acquired great skill in the Arabic tongue, and in the manners of the Mahometans. He wrote several works; the principal of which are, 1. An account of the death of Sultan Of-

man, and the coronation of the sultan Mustapha. 2. A collection of maxims, drawn from the works of the Orientals. 3. A treatise on the origin of coffee. 4. The Arabian nights entertainments, &c.

GALLANT, or **GALANT**, a French term adopted into our language, and signifying polite, civil, and well-bred, with a disposition to please, particularly the ladies. It also signifies brave or courageous.

GALLERY, in architecture, a covered place in a house, much longer than broad, and usually in the wings of a building; its use being chiefly to walk in.

GALLERIES, in gardening, are certain ornaments made with trees of different kinds; which are very common in all the French gardens, but are seldom introduced into the British ones, especially since the taste for clipped trees has been exploded. For those, however, who may still choose to have them, Mr Miller gives the following directions.

In order to make a gallery in a garden with porticoes and arches, a line must first be drawn of the length you design the gallery to be; which being done, it is to be planted with hornbeam, as the foundation of the gallery. The management of galleries is not difficult. They require only to be digged round about; and sheared a little when there is occasion. The chief curiosity required is in the ordering the forepart of the gallery, and in forming the arches. Each pillar of the porticoes or arches ought to be four feet distant from another, and the gallery 12 feet high and 10 feet wide, that there may be room for two or three persons to walk abreast. When the hornbeams are grown to the height of three feet, the distance of the pillars well regulated, and the ground-work of the gallery finished, the next thing to be done is to form the frontispiece; to perform which, you must stop the hornbeam between two pillars for that purpose, which forms the arch. As it grows, you must with your sheers cut off those boughs which outshoot the others. In time they will grow strong, and may be kept in form by the sheers. Portico-galleries may be covered with lime-trees.

GALLERY, in fortification, a covered walk a-cross the ditch of a town, made of strong beams, covered over with planks, and loaded with earth: sometimes it is covered with raw hides, to defend it from the artificial fires of the besieged.

GALLERY of a Mine, is a narrow passage or branch of a mine carried on under ground to a work designed to be blown up. See **MINE**.

GALLERY, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

GALLEY, a kind of low flat-built vessel, furnished with one deck, and navigated with sails and oars, particularly in the Mediterranean. By the Greek authors under the eastern empire, this kind of vessel was called γαλῆρα and γαλῆρα; and by the Latin authors of the same time, *galeas*; whence, according to some, the modern denomination. Some say it was called *galea*, on account of a calk or helmet which it carried on its prow, as Ovid attests, *de Trifolii*. The French call it *galere*; by reason, they say, that the top of the masts is usually cut in the form of a hat, which the Italians call *galero*. Others derive both *galea*, and *galere*, from a fish by

the Greeks called γαλῆρα, or *egalea*, and by us the *sword-fish*, which this vessel resembles. Lastly, others derive the *galley*, *galea*, *galere*, *galeasse*, &c. from the Syriac and Chaldean *gaul*, and *gallin*, a man exposed on the water in a vessel of wood.

The largest sort of these vessels is employed only by the Venetians. They are commonly 162 feet long above, and 133 feet by the keel; 32 feet wide, with 23 feet length of stern-post. They are furnished with three masts, and 32 banks of oars; every bank containing two oars, and every oar being managed by six or seven slaves, who are usually chained thereto. In the fore part they have three little batteries of cannon, of which the lowest is of two 36 pounders, the second of two 24 pounders, and the uppermost of two 2 pounders: three 18 pounders are also planted on each quarter. The complement of men for one of these galleys is 1000 or 1200. They are esteemed extremely convenient for bombarding or making a descent upon an enemy's coast, as drawing but little water; and having by their oars frequently the advantage of a ship of war, in light winds or calms, by cannonading the latter near the surface of the water; by scouring her whole length with their shot, and at the same time keeping on her quarter or bow, so as to be out of the direction of her cannon.

The galleys next in size to these, which are also called *half-galleys*, are from 120 to 130 feet long, 18 feet broad, and 9 or 10 feet deep. They have two masts, which may be struck at pleasure; and are furnished with two large lateen sails, and five pieces of cannon. They have commonly 25 banks of oars, as described above. A size still less than these are called *quarter-galleys*, carrying from 12 to 16 banks of oars. There are very few galleys now besides these in the Mediterranean, which are found by experience to be of little utility except in fine weather; a circumstance which renders their service extremely precarious. They generally keep close under the shore, but sometimes venture out to sea to perform a summer cruise.

GALLEY-Worm, in zoology, an insect known by most writers under the name of *Lulus*. It is a land-insect, with a long body, composed of a great number of rings, and furnished with many feet. It is found very frequently in gardens; and, when touched, has the power of rolling itself up into a ball. This animal is very common among us, and is by some referred to the scolopendræ, but improperly: for though they agree in the great number of legs, ours is a harmless animal; whereas the scolopendræ are mischievous creatures, armed with dangerous forceps. It is supposed by Lister, that this sort of animal, common with us, would on distillation yield the same sort of animal-acid that is procured from the ant. The reason of the conjecture is, that the ant and this creature agree in emitting a sharp and pungent smell on being bruised; but these are not easily procured in sufficient plenty to make the experiment, as they are not gregarious like the ants.

GALLI, in antiquity, the priests of the goddess Cybele. They were eunuchs; and took their name from Gallus, a river in Phrygia.

When a youth was to be initiated into this order, the custom was to throw off his cloaths, to run crying aloud into the midst of the troop, and then drawing a sword to castrate himself: after this, he ran about the

street,

streets, carrying in his hands the marks of his mutilation; which he was to throw into a house, and in that house to put on a woman's dress.

GALLICAN, any thing belonging to France: thus the term *Gallican church* denotes the church of France, or the assembly of the clergy of that kingdom.

GALLICISM, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages.

GALLINÆ, in ornithology, an order of birds. See **ZOOLOGY**.

GALLINACIOUS, an appellation given to the birds of the order of the gallinæ.

GALLING, or **EXCORIATION**, in medicine. See **EXCORIATION**.

GALLING of a *horse's back*; a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and sit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel: anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for want of that, with grease: wash the swelling, or hurt, every evening with cold water and soap; and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLION, or **GALLEON**, in naval affairs, a sort of ships employed in the commerce of the West Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the *flota*; and the other for Peru, which they call the *gallions*. See **FLOTA**.

By a general regulation made in Spain, it has been established, that there should be twelve men of war, and five tenders, annually fitted out for the armada or galleons; eight ships of six hundred tons burden each, and three tenders, one of an hundred tons, for the island Margarita, and two of eighty each, to follow the armada; for the New Spain fleet, two ships of six hundred tons each, and two tenders of eighty each; and for the Honduras fleet, two ships of five hundred tons each: and, in case no fleet happened to fail any year, three galleons and a tender should be sent to New Spain for the plate.

They are appointed to sail from Cadiz in January, that they may arrive at Porto-Bello about the middle of April; where, the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June; where they are joined by the *flota*, that they may return to Spain with the greater safety.

GALLIOT, a small galley designed only for chace, carrying but one mast and two patereroes; it can both sail and row, and has 16 or 20 oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

GALLIPOLI, a sea-port town of Italy, in the kingdom of Naples, and in the Terra-di-Otrante, with a bishop's see, a fort, and a harbour. It is seated on a rock, surrounded by the sea, and which is joined to

the firm land by a bridge. E. Long. 18. 10. N. Lat. 40. 20.

GALLIPOLI, a sea-port town of Turkey in Europe, in the province of Romania, seated at the mouth of the sea of Marmora, with a good harbour, and a bishop's see. It contains about 10,000 Turks, 3500 Greeks, besides a great number of Jews. The bazar, or bezelestin, the place where merchandizes are sold, is a handsome structure, with domes covered with lead. It is an open place, and has no other defence than a paltry square castle. The houses of the Greeks and Jews have doors not above three feet and a half high, to prevent the Turks riding into their houses. E. Long. 26. 59. N. Lat. 40. 30.

GALLIUM, **LADY'S BED-STRAW**; a genus of the monogynia order, belonging to the tetrandria class of plants. There are a great many species, of which the most remarkable is the verum, or yellow lady's bed-straw. It grows commonly in dry ground, and on road-sides. The flowers will coagulate boiling milk; and the best Cheshire cheese is said to be prepared with them. The French prescribe them in hysteric and epileptic cases. Boiled in alum-water, they tinge wool yellow. The roots dye a red not inferior to madder; for which purpose they are used in the island of Jura.—In the Edinburgh medical commentaries we have accounts of some violent scorbutic complaints being cured by the juice of this plant.—Sheep and goats eat the plant; horses and swine refuse it; cows are not fond of it.

GALLO, an island of the South Sea, near the sea-coast of Peru, in South America, which was the first place possessed by the Spaniards when they attempted the conquest of Peru; it is also the place where the bucaners used to come for wood and water, and to refit their vessels, when they were in these parts. W. Long. 50. 0. N. Lat. 2. 30.

GALLOIS (John), born at Paris in 1632, was an universal scholar; but chiefly noted for having been, in conjunction with M. de Sallo who formed the plan, the first publisher of the *Journal des Sçavans*. The first journal was published January 5th 1665; but these gentlemen criticized new works so rigorously, that the whole tribe of authors united and cried it down. De Sallo declined entirely after the publication of the third number: but Gallois ventured to send out a fourth, on January 4th 1666; though not without a most humble advertisement at the beginning, wherein it was declared, that the author "would not presume to criticize, but simply give an account of the books." This, with the protection of Mr Colbert, who was greatly taken with the work, gradually reconciled the public to it: and thus began literary journals, which have been continued from that time to this, under various titles, and by various writers. Gallois continued his journal to the year 1674, when more important occupations obliged him to turn it over to other hands. M. Colbert had taken him into the house to teach him Latin; and when he lost his patron in 1683, he was first made librarian to the king, and then Greek professor in the royal college. He died in 1707.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts. But these quarts, and consequently the gallon itself, are different, according

Galloway
||
Gama.

cording to the quality of the thing measured: For instance, the wine-gallon contains 231 cubic inches, and holds eight pounds averdupois of pure water; the beer and ale gallon contains 281 solid inches, and holds ten pounds three ounces and a quarter averdupois of water; and the gallon for corn, meal, &c. 272½ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOWAY, a county of Scotland, which gives the title of earl to a branch of the noble family of Stuart. It is divided into two districts; the western, called *Upper Galloway*, being the same with Wigtonshire; and the eastern, or stewartry of Kirkcubright, called *Lower Galloway*. See KIRCUDBRIGHT and WIGTONSHIRE.

GALWAY, or **GALLOWAY**, a county of Ireland, which is 82 miles in length, and 42 in breadth, bounded by the counties of Clare, Tipperary, King's County, Roscommon, and the sea. The river Shannon washes the frontiers of the east and south-east, and forms a lake several miles in length. There is another great lake, called *Corrib*, or *Carib*, which is near 20 miles long, and five broad. The county contains 15,420 houses, 136 parishes, 17 baronies, and 13 boroughs; and sends eight members to parliament. The capital town is of the same name.

GALWAY, a town of Ireland, in the county of the same name, and province of Connaught, of which it is the capital. It is surrounded with strong walls, has large straight streets, and the houses are generally well built with stone. It has a good trade into foreign parts, on account of its harbour, which is defended by a fort. It is seated on the bay of Galway on the western ocean, 30 miles west of Athlone, and 100 west of Dublin. W. Long. 9. 10. N. Lat. 53. 12.

GALLOWES, an instrument of punishment, whereon persons convicted capitally of felony, &c. are executed by hanging.

Among our ancestors it was called *furca*, "fork;" a name by which it is still denominated abroad, particularly in France and Italy. In this latter country, the reason of the name still subsists; the gallows being a real fork drove into the ground, across the legs whereof is laid a beam, to which the rope is tied. See **FURCA**.

GALLUS (Cornelius), an ancient Roman poet, born at Forum Julium, now called *Frejus*, in France. He was a particular favourite with Augustus Cæsar, who made him governor of Egypt: but his maladministration there occasioned his banishment, and the loss of his estate; for grief of which he put an end to his own life. He wrote four books of love-elegies; and Virgil has complimented him in many places.

GALLUS, or *Cock*, in ornithology. See **PHASIANUS**.

GALLY, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom called a *gally-slice*.

GAMA (Valco de), a Portuguese admiral, celebrated for his discovery of the East Indies by the Cape of Good Hope, was born at Synes; and, in 1497,

was sent to the Indies by king Emanuel: he returned in 1502, and sailed thither again with 13 vessels richly laden. He was made viceroy of the Indies by king John III.; and died at Cochín, on the 24th of December 1525. Don Stephen and Don Christopher de Gama, his sons, were also viceroys of the Indies, and celebrated in history.

GAMBIA, a large river of Negroeland in Africa, generally supposed to be a branch of the Niger. See **NILE**, **NIGER**, and **SENEGAL**.

GAMBOGE, is a concentered vegetable juice, the produce of two trees, both called by the Indians *caracapulli*, and is partly of a gummy and partly of a resinous nature. It is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes; and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East Indies, called also *Cambodja*, and *Cambogia*; and from thence it has obtained its names of *cambadium*, *cambogium*, and *gambogium*.

As a pigment, it makes a beautiful yellow, which is much used by the painters. Dr Lewis says, that it makes a beautiful and durable citron-yellow stain upon marble, whether rubbed in substance on the hot stone, or applied, as dragon's-blood sometimes is, in form of a spirituous tincture. When it is applied on cold marble, the stone is afterwards to be heated, to make the colour penetrate.

Gamboge is commonly called a *gum*, but improperly. It appears to be wholly resinous or sulphureous; since spirit of wine dissolves it almost entirely, and water, though it separates its parts and keeps them suspended, yet does not dissolve them at all, nor is by any means a solvent for it. It is also very inflammable, and melts with a very gentle heat. If mixed with an equal quantity of salt of tartar, it readily dissolves in common water by a few hours digestion. This solution, if kept over the fire, soon becomes a sort of smooth glue or jelly. This is sometimes done with a view to correct the deleterious qualities of gamboge taken inwardly, in which case it occasions violent vomitings and purgings. But the most effectual method of correcting this and other resinous purgatives, is by triturating them well with three or four times their weight of white sugar, by which means they are rendered fusible in water, and incapable of adhering to the villous coats of the intestines.

GAME, in general, signifies any diversion, or sport, that is performed with regularity, and restrained to certain rules. See **GAMING**.

Games are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, &c. and to the latter those performed with cards or dice, as back-gammon, ombre, picquet, whist, &c. See **BACK-GAMMON**, &c.

GAMES, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See **OLYMPIC**, **PYTHIAN**, &c.

GAME, in law, signifies birds, or prey, taken or killed by fowling or hunting.

The property of such animals *sera natura* as are known under the denomination of *game*, with the right of

Gambia

of pursuing, taking, and destroying them, is vested in the king alone; and from him derived to such of his subjects as have received the grants of a chase, a park, or a free warren.

Black.
Comment.

By the law of nature, indeed, every man, from the prince to the peasant, has an equal right of pursuing, and taking to his own use, all such creatures as are *feræ naturæ*, and therefore the property of nobody, but liable to be seized by the first occupant. But it follows from the very end and constitution of society, that this natural right, as well as many others belonging to man as an individual, may be restrained by positive laws enacted for reasons of state, or for the supposed benefit of the community. This restriction may be either with respect to the *place* in which this right may, or may not, be exercised; with respect to the *animals* that are the subjects of this right; or with respect to the *persons* allowed or forbidden to exercise it. And, in consequence of this authority, we find that the municipal laws of many nations have exerted such power of restraint; have in general forbidden the entering on another man's grounds, for any cause, without the owner's leave; have extended their protection to such particular animals as are usually the objects of pursuit; and have invested the prerogative of hunting and taking such animals, in the sovereign of the state only, and such as he shall authorize. Many reasons have concurred for making these constitutions: as, 1. For the encouragement of agriculture and improvement of lands, by giving every man an exclusive dominion over his own soil. 2. For the preservation of the several species of these animals, which would soon be extirpated by a general liberty. 3. For prevention of idleness and dissipation in husbandmen, artificers, and others of lower rank; which would be the unavoidable consequence of universal licence. 4. For prevention of popular insurrections and resistance to the government, by disarming the bulk of the people: which last is a reason oftener meant than avowed, by the makers of forest or game laws. Nor, certainly, in these prohibitions is there any *natural* injustice, as some have weakly enough supposed: since, as Puffendorf observes, the law does not hereby take from any man his present property, or what was already his own; but barely abridges him of one means of acquiring a future property, that of occupancy; which indeed the law of nature would allow him, but of which the laws of society have in most instances very justly and reasonably deprived him.

Yet, however defensible these provisions in general may be, on the footing of reason, or justice, or civil policy, we must, notwithstanding, acknowledge, that, in their present shape, they owe their immediate original to slavery. It is not till after the irruption of the northern nations into the Roman empire, that we read of any other prohibitions, than that natural one of not sporting on any private grounds without the owner's leave.

With regard to the rise and original of our present civil prohibitions, it will be found, that all forest and game laws were introduced into Europe at the same time, and by the same policy, as gave birth to the feudal system; when those swarms of barbarians issued from their northern hive, and laid the foundation of most of the present kingdoms of Europe, on the ruins

VOL. V.

of the western empire. For when a conquering general came to settle the *economy* of a vanquished country, and to partit out among his soldiers or feudatories, who were to render him military service for such donations; it behoved him, in order to secure his new acquisitions, to keep the *russici* or natives of the country, and all who were not his military tenants, in as low a condition as possible, and especially to prohibit them the use of arms. Nothing could do this more effectually than a prohibition of hunting and sporting: and therefore it was the policy of the conqueror to reserve this right to himself, and such on whom he should bestow it; which were only his capital feudatories, or greater barons. And, accordingly, we find, in the feudal constitutions, one and the same law prohibiting the *russici* in general from carrying arms, and also proscribing the use of nets, snares, or other engines for destroying the game. This exclusive privilege well suited the martial genius of the conquering troops, who delighted in a sport which in its pursuit and slaughter bore some resemblance to war. *Vita omnis* (says Cæsar, speaking of the ancient Germans) in *venationibus atque in studiis rei militaris consistit*. And Tacitus in like manner observes, that *quoties bella non inuent, multum venatibus, plus per otium transigunt*. And indeed, like some of their modern successors, they had no other amusement to entertain their vacant hours; they despising all arts as effeminate, and having no other learning, than was couched in such rude ditties as were sung at the solemn carousals which succeeded these ancient huntings. And it is remarkable, that, in those nations where the feudal policy remains the most uncorrupted, the forest or game laws continue in their highest rigour. In France, all game is properly the king's; and in some parts of Germany it is death for a peasant to be found hunting in the woods of the nobility.

With us in Britain, also, hunting has ever been esteemed a most princely diversion and exercise. The whole island was replenished with all sorts of game in the times of the Britons; who lived in a wild and pastoral manner, without inclosing or improving their grounds; and derived much of their subsistence from the chase, which they all enjoyed in common. But, when husbandry took place under the Saxon government, and lands began to be cultivated, improved, and enclosed, the beasts naturally fled into the woody and desert tracts; which were called the *forests*, and, having never been disposed of in the first distribution of lands, were therefore held to belong to the crown. These were filled with great plenty of game, which our royal sportsmen reserved for their own diversion, on pain of a pecuniary forfeiture for such as interfered with their sovereign. But every freeholder had the full liberty of sporting upon his own territories, provided he abtained from the king's forests.

However, upon the Norman conquest, a new doctrine took place; and the right of pursuing and taking all beasts of chase or *venary*, and such other animals as were accounted *game*, was then held to belong to the king, or to such only as were authorized under him. And this, as well upon the principles of the feudal law, that the king is the ultimate proprietor of all the lands in the kingdom, they being all held of him as the chief lord, or lord paramount of the fee;

18 G

and

and that therefore he has the right of the universal soil, to enter thereon, and to chase and take such creatures at his pleasure: so also upon another maxim of the common law, that these animals *sunt bona vacantia*, and, having no other owner, belong to the king by his prerogative. As therefore the former reason was held to vest in the king a right to pursue and take them any where; the latter was supposed to give the king, and such as he should authorize, a *sole and exclusive* right.

This right, thus newly vested in the crown, was exerted with the utmost rigour, at and after the time of the Norman establishment; not only in the ancient forests, but in the new ones which the conqueror made, by laying together vast tracts of country, depopulated for that purpose, and reserved solely for the king's royal diversion; in which were exercised the most horrid tyrannies and oppressions, under colour of forest-law, for the sake of preserving the beasts of chase; to kill any of which, within the limits of the forest, was as penal as the death of a man. And, in pursuance of the same principle, king John laid a total interdict upon the winged as well as the fourfooted creation: *capturam avium per totam Angliam interdixit* *. The cruel and insupportable hardships, which these forest-laws created to the subject, occasioned our ancestors to be as zealous for their reformation, as for the relaxation of the feudal rigours and the other exactions introduced by the Norman family; and accordingly we find the immunities of *carta foresta* as warmly contended for, and extorted from the king with as much difficulty, as those of *magna carta* itself. By this charter, confirmed in parliament †, many forests were disafforested, or stripped of their oppressive privileges, and regulations were made in the regimen of such as remained; particularly killing the king's deer was made no longer a capital offence, but only punished by a fine, imprisonment, or abjuration of the realm. And by a variety of subsequent statutes, together with the long acquiescence of the crown without exerting the forest-laws, this prerogative is now become no longer a grievance to the subject.

But, as the king reserved to himself the forests for his own exclusive diversion, so he granted out from time to time other tracts of lands to his subjects under the names of *chases* or *parks*; or gave them licence to make such in their own grounds; which indeed are smaller forests in the hands of a subject, but not governed by the forest-laws; and by the common law no person is at liberty to take or kill any beasts of chase, but such as hath an ancient chase or park; unless they be also beasts of pvey.

As to all inferior species of game, called *beasts and fowls of warren*; the liberty of taking or killing them is another franchise or royalty, derived likewise from the crown, and called *free-warren*; a word which signifies preservation or custody: as the exclusive liberty of taking and killing fish in a public stream or river is called a *free fishery*; of which, however, no new franchise can at present be granted, by the express provision of *magna carta*, c. 16. The principal intention of granting a man these franchises or liberties was in order to protect the game, by giving him a sole and exclusive power of killing it himself, provided he prevented other persons. And no man, but he who has

a chase or free warren, by grant from the crown, or prescription, which supposes one, can justify hunting or sporting upon another man's soil; nor indeed, in thorough strictness of common law, either hunting or sporting at all.

However novel this doctrine may seem, it is a regular consequence from what has been before delivered; that the sole right of taking and destroying game belongs exclusively to the king. This appears, as well from the historical deduction here made, as because he may grant to his subjects an exclusive right of taking them; which he could not do, unless such a right was first inherent in himself. And hence it will follow, that no person whatever, but he who has such derivative right from the crown, is by common law entitled to take or kill any beasts of chase, or other game whatsoever. It is true, that, by the acquiescence of the crown, the frequent grants of free-warren in ancient times, and the introduction of new penalties of late by certain statutes for preserving the game, this exclusive prerogative of the king is little known or considered; every man, that is exempted from these modern penalties, looking upon himself as at liberty to do what he pleases with the game: whereas the contrary is strictly true, that no man, however well qualified he may vulgarly be esteemed, has a right to encroach on the royal prerogative by the killing of game, unless he can shew a particular grant of free-warren; or a prescription, which presumes a grant; or some authority under an act of parliament. As for the latter, there are but two instances wherein an express permission to kill game was ever given by statute; the one by 1 Jac. I. c. 27. altered by 7 Jac. I. c. 11. and virtually repealed by 22 and 23 Car. II. c. 25. which gave authority, so long as they remained in force, to the owners of free-warren, to lords of manors, and to all freeholders having 40*l.* *per annum* in lands of inheritance, or 80*l.* for life or lives, or 400*l.* personal estate, (and their servants), to take partridges and pheasants upon their own, or their master's, free-warren, inheritance, or freehold: the other by 5 Ann. c. 14. which empowers lords and ladies of manors to appoint gamekeepers, to kill game for the use of such lord or lady; which with some alteration still subsists; and plainly supposes such power not to have been in them before. The truth of the matter is, that these game-laws do indeed *qualify* nobody, except in the instance of a gamekeeper, to kill game: but only to save the trouble and formal process of an action by the person injured, who perhaps too might remit the offence, these statutes inflict *additional* penalties, to be recovered either in a regular or summary way, by any of the king's subjects, from certain persons of inferior rank who may be found offending in this particular. But it does not follow that persons, excused from these additional penalties, are therefore *authorized* to kill game. The circumstance of having 100*l.* *per annum*, and the rest, are not properly qualifications, but exemptions. And these persons, so exempted from the penalties of the game-statutes, are not only liable to actions of trespass by the owners of the land; but also, if they kill game within the limits of any royal franchise, they are liable to the actions of such who may have the right of chase or free-warren therein.

Upon the whole, it appears, that the king, by his pre-

articles.

prerogative, and such persons as have, under his authority, the royal franchise of CHACE, PARK, or FREE-WARREN *, are the only persons who may acquire any property, however fugitive and transitory, in these animals *feræ nature*, while living; which is said to be vested in them *propter privilegium*. And it must also be observed, that such persons as may thus lawfully hunt, fish, or fowl, *ratione privilegii*, have only a qualified property in these animals: it not being absolute or permanent, but lasting only so long as the creatures remain within the limits of such respective franchise or liberty, and ceasing the instant they voluntarily pass out of it. It is held indeed, that if a man starts any game within his own grounds, and follows it into another's, and kills it there, the property remains in himself. And this is grounded on reason and natural justice: for the property consists in the possession; which possession commences by the finding it in his own liberty, and is continued by the immediate pursuit. And so, if a stranger starts game in one man's chace or free-warren, and hunts it into another liberty, the property continues in the owner of the chace or warren; this property arising from privilege, and not being changed by the act of a mere stranger. Or if a man starts game on another's private grounds, and kills it there, the property belongs to him in whose ground it was killed, because it was also started there; this property arising *ratione soli*. Whereas if, after being started there, it is killed in the grounds of a third person, the property belongs not to the owner of the first ground, because the property is local; nor yet to the owner of the second, because it was not started in his soil; but it vests in the person who started and killed it, tho' guilty of a trespass against both the owners. See the article *Game-Laws*.

GAME-COCK, a fighting cock, or one kept for sport; a barbarous practice, which is a disgrace to any civilized nation. See *Cock-Fighting*.

GAMELIA, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage; thus called, from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing 29 days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazard; as cards, dice, tables, &c.

Gaming has at all times been looked upon as a thing of pernicious consequence to the commonwealth; and is therefore severely prohibited by law. It is considered as a practice generally intended to supply, or retrieve, the expences occasioned by *LUXURY*: it being a kind of tacit confession, that the company engaged therein do, in general, exceed the bounds of their respective fortunes; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer. But, taken in any light, it is an offence of the most alarming nature; tending, by necessary consequence, to promote public

idleness, theft, and debauchery, among those of a lower class; and, among persons of a superior rank, it hath frequently been attended with the sudden ruin and desolation of ancient and opulent families, an abandoned prostitution of every principle of honour and virtue, and too often hath ended in self-murder. To restrain this pernicious vice among the inferior sort of people, the statute 33 Hen. VIII. c. 9. was made; which prohibits, to all but gentlemen, the games of tennis, tables, cards, dice, bowls, and other unlawful diversions there specified, unless in the time of Christmas, under pecuniary pains and imprisonment. And the same laws, and also the statute 30 Geo. II. c. 24. inflict pecuniary penalties, as well upon the master of any public house wherein servants are permitted to game, as upon the servants themselves who are found to be gaming there. But this is not the principal ground of modern complaint: it is the gaming in high life, that demands the attention of the magistrate; a passion to which every valuable consideration is made a sacrifice, and which we seem to have inherited from our ancestors the ancient Germans; whom Tacitus describes to have been bewitched with the spirit of play to a most exorbitant degree. "They addict themselves, (says he,) to dice (which is wonderful) when sober, and as a serious employment; with such a mad desire of winning or losing, that, when strip of every thing else, they will stake at last their liberty, and their very selves. The loser goes into a voluntary slavery; and, though younger and stronger than his antagonist, suffers himself to be bound and sold. And this perseverance in so bad a cause they call the point of honour: *ea est in re prava perniciosa, ipsi fidem vocant*." One would almost be tempted to think Tacitus was describing a modern Englishman. When men are thus intoxicated with so frantic a spirit, laws will be of little avail: because the same false sense of honour, that prompts a man to sacrifice himself, will deter him from appealing to the magistrate. Yet it is proper that laws should be, and be known publicly, that gentlemen may consider what penalties they wilfully incur, and what a confidence they repose in sharpers; who, if successful in play, are certain to be paid with honour, or, if unsuccessful, have it in their power to be still greater gainers by informing. For, by stat. 16 Car. II. c. 7. if any person by playing or betting shall lose more than 100 l. at one time, he shall not be compellable to pay the same; and the winner shall forfeit treble the value, one moiety to the king, the other to the informer. The statute 9 Ann. c. 14. enacts, that all bonds and other securities, given for money won at play, or money lent at the time to play withal, shall be utterly void; that all mortgages and incumbrances of lands, made upon the same consideration, shall be and enure to the heir of the mortgagor; that, if any person at one time loses 10 l. at play, he may sue the winner, and recover it back by action of debt at law; and, in case the loser does not, any other person may sue the winner for treble the sum so lost; and the plaintiff in either case may examine the defendant himself upon oath: and that in any of these suits no privilege of parliament shall be allowed. The statute farther enacts, that if any person cheats at play, and at one time wins more than 10 l. or any valuable thing, he may be indicted thereupon, and shall forfeit five times the value, shall

Gaming.

be deemed infamous, and suffer such corporal punishment as in case of wilful perjury. By several statutes of the reign of king George II. all private lotteries by tickets, cards, or dice, (and particularly the games of faro, ballet, ace of hearts, hazard, passage, rolly polly, and all other games with dice, except back-gammon) are prohibited under a penalty of 200*l*. for him that shall erect such lotteries, and 50*l*. a-time for the players. Public lotteries, unless by authority of parliament, and all manner of ingenious devices, under the denomination of *sales* or otherwise, which in the end are equivalent to lotteries, were before prohibited by a great variety of statutes under heavy pecuniary penalties. But particular descriptions will ever be lame and deficient, unless all games of mere chance are at once prohibited; the invention of sharpers being swifter than the punishment of the law, which only hunts them from one device to another. The stat. 13 Geo. II. c. 19. to prevent the multiplicity of horse-races, another fund of gaming, directs, that no plates or matches under 50*l*. value shall be run, upon penalty of 200*l*. to be paid by the owner of each horse running, and 100*l*. by such as advertise the plate. By statute 18 Geo. II. c. 34. the statute 9 Ann. is farther enforced, and some deficiencies supplied: the forfeitures of that act may now be recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or losing at any sitting 10*l*. or 20*l*. within 24 hours, he shall forfeit five times the sum. Thus careful has the legislature been to prevent this destructive vice: which may shew that our laws against gaming are not so deficient, as ourselves and our magistrates in putting those laws in execution.

Chance, or Hazard, in GAMING. Hazard, or chance, is a matter of mathematical consideration, because it admits of more and less. Gamblers either set out upon an equality of chance, or are supposed to do so. This equality may be altered in the course of the game, by the greater good-fortune or address of one of the gamblers, whereby he comes to have a better chance, so that his share in the stakes is proportionably better than at first. This more and less runs thro' all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinite great one, whereby the game is determined. The whole game, therefore, with regard to the issue of it, is a chance of the proportion the two shares bear to each other.

The probability of an event is greater or less, according to the number of chances by which it may happen, compared with the number of all the chances by which it may either happen or fail.

M. de Moivre, in a treatise de *Mensura Sortis*, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose *p* the number of cases in which an event may happen, and *q* the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as *p* to *q*.

If two gamblers, A and B, engage on this footing, that, if the cases *p* happen, A shall win; but if *q* happen, B shall win, and the stake be *a*; the chance of

A will be $\frac{p \cdot a}{q + p}$, and that of B $\frac{q \cdot a}{p + q}$; consequently, if

they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that, if A throw two or more aces at eight throws, he shall win; otherwise B shall win; What is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let $a=1$, and $b=5$. And, again, since there are eight throws of the die, let $n=8$; and, you will have $a^n + b^n - b^n - nab^n - 1$, to $b^n + nab^n - 1$: that is, the chance of A will be to that of B, as 663991 to 1015625, or nearly as 2 to 3.

A and B are engaged at single quoits; and, after playing some time, A wants 4 of being up, and B 6; but B is so much the better gambler, that his chance against A upon a single throw would be as 3 to 2; What is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise $a=b$ to the ninth power, and it will be $a^9 + 9 a^8 b + 36 a^7 b^2 + 84 a^6 b^3 + 126 a^5 b^4 + 126 a^4 b^5$, to $84 a^3 b^6 + 36 a^2 b^7 + 6 a b^8 + b^9$: call *a* 3, and *b* 2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at single quoits, and A is the best gambler, so that he can give B 2 in 3: What is the ratio of their chances at a single throw? Suppose the chances as 2 to 1, and raise $x+1$ to its cube, which will be $x^3 + 3x^2 + 3x + 1$. Now since A could give B 2 out of 3, A might undertake to win three throws running; and, consequently, the chances in this case will be as x^3 to $3x^2 + 3x + 1$. Hence $x^3 = 3x^2 + 3x + 1$; or $2x^3 = 3x^2 + 3x + 1$. And, therefore, $x^{\frac{3}{2}} = x + 1$; and, consequently, $x = \sqrt[3]{\frac{1}{2x-1}}$. The chances,

therefore, are $\sqrt[3]{\frac{1}{2x-1}}$ and 1, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4; What is the probability I win both wagers?

1. The probability of winning the first is $\frac{3}{5}$, that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is $\frac{7}{11}$: therefore, multiplying these two fractions together, the product will be $\frac{3}{5} \cdot \frac{7}{11}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{14}{55}$, which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$: therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$, the product $\frac{12}{55}$ will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: The probability of winning the second is $\frac{7}{11}$; the probability of losing the first is $\frac{2}{5}$: therefore, multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second, and also lose the first.

Gaming.

Gaming.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{1}{2}$, and the probability of losing the second $\frac{1}{2}$; therefore the probability of losing them both is $\frac{1}{4}$; which, being subtracted from 1, there remains $\frac{3}{4}$; therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is $\frac{5}{6}$, the second is also $\frac{5}{6}$, the third $\frac{5}{6}$, and the fourth $\frac{5}{6}$; therefore the probability of missing it four times together is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$; which being subtracted from 1, there will remain $\frac{671}{1296}$ for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of missing it three times would be $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$; which being subtracted from 1, there will remain $\frac{91}{216}$ for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is $\frac{1}{4}$, and of missing it the other three times, is $\frac{3}{4} \times \frac{3}{4} \times \frac{3}{4}$, it follows, that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{1}{4} \times \frac{3}{4} \times \frac{3}{4} \times \frac{3}{4} = \frac{27}{256}$; but because it is possible to hit it every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing it the other three, is $\frac{4 \times 125}{1296} = \frac{500}{1296}$; which being subtracted from 1, there will remain $\frac{796}{1296}$ for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other; what is the probability, that the event, which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances is as 2 to 1, the probability of the first happening before the second is $\frac{2}{3}$, the probability of its happening twice before it is but $\frac{2}{3} \times \frac{2}{3}$ or $\frac{4}{9}$; therefore it is 5 to 4 seven does not come up twice before four once.

But, if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is, 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{12}{17}$, and the probability of throwing it twice is $\frac{12}{17} \times \frac{12}{17}$, or $\frac{144}{289}$; therefore the probability of not doing it is $\frac{145}{289}$; therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour; What is the probability, that, taking one card

at a venture out of each heap, I shall take out the two aces?

The probability of taking the ace out of the first heap is $\frac{1}{13}$, the probability of taking the ace out of the second heap is $\frac{1}{13}$; therefore the probability of taking out both aces is $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$, which being subtracted from 1, there will remain $\frac{168}{169}$; therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of thirteen cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be $\frac{1}{13}$, and the probability of taking out the two be likewise $\frac{1}{13}$; yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be $\frac{2}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13} \times \frac{2}{12}$.

In this last question the two events have a dependence on each other, which consists in this, that one of the events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

If the events in question be n in number, and be such as have the same number a of chances by which they may happen, and likewise the same number b of chances by which they may fail, raise $a+b$ to the power n . And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of

A's winning will be $\frac{a+b^n - b^n}{a+b^n}$; and that of B's

winning will be $\frac{b^n}{a+b^n}$; for when $a+b$ is actually raised to the power n , the only term in which a does not occur is the last b^n : therefore all the terms but the last are favourable to A.

Thus if $n=3$, raising $a+b$ to the cube $a^3+3a^2b+3ab^2+b^3$, all the terms but b^3 will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3+3a^2b+3ab^2}{a^3+3a^2b+3ab^2+b^3}$, or $\frac{a^3+b^3}{a+b}$; and the proba-

bility of B's winning will be $\frac{b^3}{a+b^3}$. But if A and B

play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be $\frac{a+b^n - n \cdot a^{n-1}b - b^n}{a+b^n}$; for

the only two terms in which a does not occur, are the two last, viz. $n \cdot a^{n-1}b$ and b^n .

GAMMONING, among seamen, denotes several turns of rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT, in music, a scale whereon we learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders and dispositions. See MUSIC.

GANDER, in ornithology, the male of the goose-kind; one of which, it is said, will serve five geese.* * See ANAT.

GANG-

Gaming

Gander.

Gang
Gaol.

GANG-WAY, is the several passages or ways from one part of the ship to the other; and whatsoever is laid in any of those passages, is said to lie in the gaugeway.

GANGANELLI. See **CLEMENT XIV.**

GANGES, a large and celebrated river of India. It has its source in the mountains which border on Little Thibet, in 96 degrees of longitude, and 35. 45. of latitude. It crosses several kingdoms, running from north to south; and falls into the bay of Bengal, by several mouths. The waters are lowest in April and May, and highest before the end of September. It overflows yearly like the Nile; and renders the kingdom of Bengal as fruitful as that of the Delta in Egypt. The people in these parts hold the water of this river in high veneration; and it is visited annually by a prodigious number of pilgrims from all parts of India. The English have several settlements on this river, which will be taken notice of in their proper places. The greatest happiness that many of the Indians has for, is to die in this river.

GANGLION, in anatomy, denotes a knot frequently found in the course of the nerves, and which is not morbid; for wherever any nerve sends out a branch, or receives one from another, or where two nerves join together, there is generally a ganglion or plexus, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other places of the body.

GANGLION, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part; usually without any pain to the patient.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. See (the *Index* subjoined to) **MEDICINE**, and **SURGERY**.

GANNET, or **SOLAND GOSSE**, in ornithology. See **PELICANUS**.

GANTLET, or **GAUNTLET**, a large kind of glove made of iron, and the fingers covered with small plates. It was formerly worn by the cavaliers, when armed at all points.

GANYMEDE, in the ancient mythology, son of a king of Troy, was the most beautiful boy in the world. Jupiter was charmed with him, and made him his cup-bearer in the room of Hebe. Some say that he caused him to be carried away by an eagle, and others affirm he was himself the ravisher under the form of that bird. He defied this youth; and, to comfort his father, made a present to him of some of those very swift horses that the gods rode upon.

GAOL (*Gaola*, Fr. *Geole*, i. e. *Caveola*, "a cage for birds"), is used metaphorically for a prison. It is a strong place or house for keeping of debtors, &c. and wherein a man is restrained of his liberty to answer an offence done against the laws; and every county hath two gaols, one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county gaol.

If a gaol be out of repair, or insufficient, &c. justices of peace, in their quarter sessions, may contract with workmen for the rebuilding or repairing it; and by their warrant order the sum agreed on for that

purpose, to be levied on the several hundreds, and other divisions in the county by a just rate, 11 & 12 Will. III. c. 19. See **PRISON**.

GAOL-DELIVERY. The administration of justice being originally in the crown, in former times our kings in person rode through the realm once in seven years, to judge of and determine crimes and offences; afterwards *justices in eyre* were appointed; and since, *justices of assize and gaol-delivery*, &c. A commission of gaol-delivery, is a patent in nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorizing them to deliver his *gaol*, at such a place, of the prisoners in it: for which purpose it commands them to meet at such a place, at the time they themselves shall appoint; and informs them, that, for the same purpose, the king hath commanded his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed.

The justices of gaol-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order to execution or reprieve: they may likewise discharge such prisoners, as on their trials are acquitted, and those against whom, on proclamation being made, no evidence has appeared: they have authority to try offenders for treason, and to punish many particular offences, by statute 2 *Hawk.* 24. 2 *Hale's hist. Placit. Cor.* 35.

GAOLER, the keeper of a gaol or prison. Sheriffs are to make such gaolers for whom they will be answerable: but if there be any default in the gaoler, an action lies against him for an escape, &c. yet the sheriff is most usually charged; 2 *Inst.* 592. Where a gaoler kills a prisoner by hard usage, it is felony; 3 *Inst.* 52. No fee shall be taken by gaolers, but what is allowed by law, and settled by the judges, who may determine petitions against their extortions, &c. 2 *Geo.* II. c. 22.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the talmud. The word *Gaons* signifies Excellent, Sublime; as in the divinity-schools we formerly had Irrefragable, Sublime, Resolute, Angelic, and Subtle doctors. The Gaons succeeded the Sazarans, or Opinars, about the beginning of the sixth century. Chanan Meisichtia was the head, and first of the excellents. He reformed the academy of Pandebita, which had been shut up for 30 years.

GAR-FISH, *HORN-fish*, or *Sea-needle*. See **ESOX**.

GARAMOND (Claude), a very ingenious letter-founder, was born at Paris; where he began, in the year 1510, to found his printing types free from all the remains of the Gothic, or (as it is generally called) the *black letter*, and brought them to such perfection, that he had the glory of surpassing all who went before him, and of being scarcely ever excelled by his successors in that useful art. His types were prodigiously multiplied; both by the great number of matrices he struck, and the types formed in resemblance of his in all parts of Europe. Thus in Italy, Germany, England, and Holland, the booksellers, by way of recommending their books, distinguished the type by his name; and in particular the small Roman was, by way of excellence, known among the printers of these nations by the name of *Garamond's small Roman*.

Gaol
Garamond

By the special command of king Francis I. he founded three sizes of Greek types for the use of Robert Stephens, who with them printed all his beautiful editions of the New Testament, and other Greek authors. He died at Paris, in 1561.

GARASSE (Francis), a remarkable jesuitical writer, the first author of that irreconcilable enmity that fill subsists between the Jesuits and Janfenists in the church of Rome, was born at Angoulême in 1585; and entered the Jesuits college in 1600. As he had a quick imagination, a strong voice, and a peculiar turn to wit, he became a popular preacher in the chief cities of France; but not content with this honour, he distinguished himself still more by his writings, which were bold, licentious, and produced much controversy. The most considerable in its consequences, was intitled *La somme theologique des veritez capitales de la religion Chretienne*; which was first attacked by the abbot of St Cyran, who, observing in it a prodigious number of falsifications of the Scriptures and of the fathers, beside many heretical and impious opinions, conceived the honour of the church required him to undertake a refutation. Accordingly he published a full answer to it; while Garasse's book was also under examination of the doctors of the Sorbonne, by whom it was afterwards condemned. Garasse replied to St Cyran; but the two parties of Jesuits and Janfenists, of whom these were respectively the champions, grew to an implacable animosity against each other, that is not even now likely to subside. The Jesuits were forced to remove their brother to a distance from Paris; where, probably weary of his inactive obscurity, when the plague raged at Poitiers in 1631, he begged leave of his superior to attend the sick, in which charitable office he caught the disorder, and died.

GARBE, in heraldry, a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

GARBLE, a word used to signify the action of separating the dross and dunt from spice, drugs, &c. *Garbling* is the cleansing and purifying the good from the bad; and may come from the Italian *garbo*, i. e. finery or neatness: and hence, probably, we say, when we see a man in a neat habit, that he is in handsome *garb*.

GARCILASSO (de la Vega), a celebrated Spanish poet, born of a noble family at Toledo, in 1500. He was educated near the emperor Charles V. who had a particular regard for him, and whom he attended in all his military expeditions; acquiring as much renown by his courage as by his poetry. In Provence he commanded a battalion; and was killed in the 36th year of his age, by a stone thrown at his head by a country-man from a turret. He had strong natural talents for poetry; and not only extended the bounds, but introduced new beauties, into that of the Spanish language.—We must not confound this poet with another person of the same name, a native of Cusco, who wrote in Spanish, a History of Florida, and of Peru and the Incas.

GARDANT, or GWARDANT, in heraldry, denotes any beast full-faced, and looking right forward.

GARDEN, a plot of ground, cultivated, and properly ornamented with a variety of plants, flowers,

fruits, &c. See GARDENING.

Gardens are usually distinguished into flower-garden, fruit-garden, and kitchen-garden: the first of which, being designed for pleasure and ornament, is to be placed in the most conspicuous part, that is, next to the back-front of the house; and the two latter, being designed for use, should be placed less in sight. But though the fruit and kitchen-gardens are here mentioned as two distinct gardens, yet they are now usually in one; and that with good reason, since they both require a good soil and exposure, and equally require to be placed out of the view of the house. See KITCHEN-Garden.

In the choice of a place proper for a garden, the most essential points to be considered are the situation, the soil, the exposure, water, and prospect.

1st, As to the situation, it ought to be such a one as is wholesome, and in a place neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; and if it be too low, the dampness, the vermin, and the venomous creatures that breed in ponds and marshy places, add much to their insalubrity. The most happy situation is on the side of a hill, especially if the slope be easy, and in a manner imperceptible; if a good deal of level ground be near the house; and if it abounds with springs of water: for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades for ornament, but, when it has performed its office, will water the adjacent valleys, and, if it be not suffered to stagnate, will render them fertile and wholesome. Indeed, if the declivity of the hill be too steep, and the water be too abundant, a garden on the side of it may frequently suffer, by having trees torn up by torrents and floods; and by the tumbling down of the earth above, the walls may be demolished, and the walks spoiled. It cannot, however, be denied, that the situation on a plain or flat has several advantages which the higher situation has not: for floods and rain commit no damage; there is a continued prospect of champaigns, intersected by rivers, ponds, and brooks, meadows, and hills covered with woods or buildings; besides, the level surface is less tiresome to walk on, and less chargeable than that on the side of an hill, since terrace-walks and steps are not there necessary: but the greatest disadvantage of flat gardens, is the want of those extensive prospects which rising grounds afford.

2^{dly}, A good earth or soil is next to be considered; for it is scarce possible to make a fine garden in a bad soil. There are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bellowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom. To judge of the quality of the soil, observe whether there be any heath, thistles, or such-like weeds growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe, whether they grow crooked, ill-shaped, and grubby, and whether they are of a faded green, and full of

moths, or infested with vermin; if this be the case, the place is to be rejected: but, on the contrary, if it be covered with good grafs fit for pasture, you may then be encouraged to try the depth of the soil. To know this, dig holes in several places, six feet wide, and four deep; and if you find three feet of good earth, it will do very well; but less than two will not be sufficient. The quality of good ground is, neither to be stony, nor too hard to work; neither too dry, too moist, nor too sandy and light; nor too strong and clayey, which is the worst of all for gardens.

3dly, The next requisite is water; the want of which is one of the greatest inconveniences that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains, canals, cascades, &c. which are the greatest ornaments of a garden.

4thly, The last thing to be considered, is the prospect of a fine country; and though this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable, but unwholesome.

In the laying out and planting of gardens the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. The area of a handsome garden, may take up thirty or forty acres, but not more; and the following rules should be observed in the disposition of it. There ought always to be a descent of at least three steps from the house to the garden; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive. The first thing that ought to present itself to view, should be an open lawn of grafs, which ought to be considerably broader than the front of the building; and if the depth be one half more than the width, it will have a better effect: if on the sides of the lawn there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel walk, on the outside of which should be borders three or four feet wide, for flowers; and from the back of these the prospect will be agreeably terminated by a slope of ever-green shrubs; which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead through the different plantations, gently winding about in an easy natural manner; which

will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings, that are twisted about into so many short turns, as to render it difficult to walk in them: and as no garden can be pleasing where there is a want of shade and shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind. Where the borders of the gardens are fenced with walls or pales, they should be concealed with plantations of flowering shrubs, intermixed with laurels and other ever-greens; which will have a good effect, and at the same time conceal the fences, which are disagreeable when left naked and exposed to the sight. Groves are the most agreeable parts of a garden, so that there cannot be too many of them; only that they must not be too near the house, nor be suffered to block up agreeable prospects. To accompany parterres, groves opened in compartments, quincunxes, and arbour-work with fountains, &c. are very agreeable. Some groves of ever-greens should be planted in proper places, and some squares of trees of this kind may also be planted among the other wood.

Narrow rivulets, if they have a constant stream, and are judiciously led about a garden, have a better effect than many of the large stagnating ponds or canals, so frequently made in large gardens. When wildernesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design appear trifling. Buildings, statues, and vases, appear very beautiful; but they should never be placed too near each other: magnificent fountains are also very ornamental; but they ought never to be introduced, except there be water to keep them constantly running. The same may also be observed of cascades and other falls of water.

In short, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In the business of designs, the aim should be always at what is natural, great, and noble. The general disposition of a garden, and of its parts, ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number and sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. And before a garden is planned out, it ought ever to be considered, what it will be when the trees have had 20 years growth.—But for a more extended view of this subject, see the next article.

G A R D E N I N G;

THE art of cultivating or planning gardens.—Gardening, in the perfection to which it has been lately brought in Britain, is entitled to a place of considerable rank among the liberal arts. It is as superior to landscape-painting, as a reality to a representation: it is an exertion of fancy; a subject for taste; and being released now from the restraints of regularity, and enlarged beyond the purposes of domestic convenience, the most beautiful, the most simple, the most noble

scenes of nature, are all within its province. For it is no longer confined to the spots from which it takes its name; but regulates also the disposition and embellishments of a park, a farm, or a riding: and the business of a gardener is to select and apply whatever is great, elegant, or characteristic, in any of them; to discover and to shew all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties. For all these operations,

Subjects
and materials
of gardening.

perations, the objects of nature are still his only materials. His first inquiry, therefore, must be into the means by which those effects are attained in nature,

which he is to produce; and into those properties in the objects of nature, which should determine him in the choice and arrangement of them.

PART I. OF THE CONSTITUENT PARTS OF THE SCENES OF NATURE.

NATURE, always simple, employs but four materials in the composition of her scenes; *ground, wood, water, and rocks*. The cultivation of nature has introduced a fifth species, the *buildings* requisite for the accommodation of men. Each of these again admits of varieties in figure, dimensions, colour, and situation. Every landscape is composed of these parts only; every beauty in a landscape depends on the application of their several varieties.

SECT. I. Of Ground.

THE shape of ground must be either a *convex*, a *concave*, or a *plane*; in terms less technical called a *swell*, a *hollow*, and a *level*. By combinations of these are formed all the irregularities of which ground is capable; and the beauty of it depends on the degrees and the proportions in which they are blended.

Both the convex and the concave are forms in themselves of more variety, and may therefore be admitted to a greater extent than a plane. But levels are not totally inadmissible. The preference unjustly shewn to them in the old gardens; where they prevailed almost in exclusion of every other form, has raised a prejudice against them. It is frequently reckoned an excellence in a piece of made ground, that every the least part of it is uneven; but then it wants one of the three great varieties of ground, which may sometimes be intermixed with the other two. A gentle concave declivity falls and spreads easily on a flat; the channels between several swells degenerate into mere gutters, if some breadth be not given to the bottoms by flattening them; and in many other instances, small portions of an inclined or horizontal plane may be introduced into an irregular composition. Care only must be taken to keep them down as subordinate parts, and not to suffer them to become principal.

There are, however, occasions on which a plane may be principal: a hanging level often produces effects not otherwise attainable. A large dead flat, indeed, raises no other idea than of safety: the eye finds no amusement, no repose on such a level: it is fatigued, unless timely relieved by an adequate termination; and the strength of that termination will compensate for its distance. A very wide plain, at the foot of a mountain, is less tedious than one of much less compass surrounded only by hillocks. A flat therefore of considerable extent may be hazarded in a garden, provided the boundaries also be considerable in proportion; and if, in addition to their importance, they become still more interesting by their beauty, then the facility and distinctness with which they are seen over a flat make the whole an agreeable composition. The greatness and the beauty of the boundary are not, however, alone sufficient; the form of it is of still more consequence. A continued range of the noblest wood, or the finest hill, would not cure the insipidity of a flat: a less important, a less pleasing

boundary, would be more effectual, if it traced a more varied outline; if it advanced sometimes boldly forward, sometimes retired into deep recesses; broke all the sides into parts, and marked even the plain itself with irregularity.

At Moor Park, on the back-front of the house, is a lawn of about thirty acres, absolutely flat; with falls below it on one hand, and heights above it on the other. The rising ground is divided into three great parts, each so distinct and so different, as to have the effect of several hills. That nearest to the house shelves gently under an open grove of noble trees which hang on the declivity, and advance beyond it on the plain. The next is a large hill pressing forward, and covered with wood from the top to the bottom. The third is a bold steep, with a thicket falling down the steepest part, which makes it appear still more precipitate: but the rest of the slope is bare; only the brow is crowned with wood, and towards the bottom is a little groupe of trees. These heights, thus finely characterised in themselves, are further distinguished by their appendages. The small, compact groupe near the foot, but still on the descent, of the farther hill, is contrasted by a large straggling clump, some way out upon the lawn, before the middle eminence. Between this and the first hill, under two or three trees which cross the opening, is seen to great advantage a winding glade, which rises beyond them, and marks the separation. This deep recess, the different distances to which the hills advance, the contrast in their forms, and their accompaniments, cast the plain on this side into a most beautiful figure. The other side and the end were originally the flat edge of a descent; a harsh, offensive termination: but it is now broken by several hillocks, not diminutive in size, and considerable by the fine clumps which distinguish them. They recede one beyond another, and the outline waves agreeably amongst them. They do more than conceal the sharpness of the edge; they convert a deformity into a beauty, and greatly contribute to the embellishment of this most lovely scene: a scene, however, in which the flat is principal; and yet a more varied, a more beautiful landscape, can hardly be desired in a garden.

A plain is not, however, in itself interesting; and the least deviation from the uniformity of its surface changes its nature: as long as the flat remains, it depends on the objects around for all its variety, and all its beauty. But convex and concave forms are generally pleasing, and the number of degrees and combinations into which they may be cast is infinite: those forms only in each which are perfectly regular must be avoided. A semicircle can never be tolerable: small portions of large circles blended together, or lines gently curved which are not parts of any circle, a hollow sinking but little below a level, a swell very much flattened at the top, are commonly the most agreeable figures.

³ Description of a lawn at Moor Park, (the seat of Sir J. Laur. Dundas, near Rickmansworth in Hertfordshire.)

² Of a level.

⁴ Of convex or concave shapes of ground.

Section I.
GROUND.

In ground which lies beautifully, the concave will generally prevail; within the same compass it shews more surface than a swell. All the sides of the latter, are not visible at the same time, except in a few particular situations: but it is only in a few particular situations, that any part of a hollow is concealed; earth seems to have been accumulated to raise the one, and taken away to sink the other. The concave, therefore, appears the lighter, and for the most part it is the more elegant shape: even the slopes of a swell can hardly be brought down, unless broken now and then into hollows, to take off from the heaviness of the mass. There are, however, situations where the convex form should be preferred: a hollow just below the brow of a hill reduces it to a narrow ridge, which has a poor meagre appearance; and an abrupt fall will never seem to join with a concave form immediately above it: a sharp edge divides them; and to connect them, that edge must be rounded, or at least flattened; which is, in fact, to interpose a convex or a level.

5
Of the connection between the parts in ground.

Is made ground, the connection is, perhaps, the principal consideration. A swell which wants it is but a heap, a hollow but a hole, and both appear artificial: the one seems placed upon a surface to which it does not belong; the other, dug into it. On the great scale of nature, indeed, either may be so considerable in itself, as to make its relation to any other almost a matter of indifference: but, on the smaller scale of a garden, if the parts are disjointed, the effect of the whole is lost; and the union of all is not more than sufficient to preserve an idea of greatness and importance, to spots which must be varied, and cannot be spacious. Little inequalities are besides in nature usually well blended together: all lines of separation have, in a course of time, been filled up; and therefore, when in made ground they are left open, that ground appears artificial.

Even where artifice is avowed, a breach in the connection offends the eye. The use of a fosse is merely to provide a fence, without obstructing the view. To blend the garden with the country is no part of the idea: the cattle, the objects, the culture, without the sunk fence, are discordant to all within, and keep up the division. A fosse may open the most polished lawn to a corn-field, a road, or a common, though they mark the very point of separation. It may be made on purpose to shew objects which cannot, or ought not to be in the garden; as a church, or a mill, a neighbouring gentleman's seat, a town, or a village; and yet no consciousness of the existence can reconcile us to the sight of this division. The most obvious disguise is to keep the hither above the further bank all the way; so that the latter may not be seen at a competent distance. But this alone is not always sufficient: for a division appears, if an uniformly continued line, however faint, be discernible; that line, therefore, must be broken. Low but extended hillocks may sometimes interrupt it; or the shape on one side may be continued, across the sunk fence, on the other; as when the ground sinks in the field, by beginning the declivity in the garden. Trees too without, connected with those within, and seeming part of a clump or a grove there, will frequently obliterate every trace of an interruption. By such, or other means, the line may be, and should be,

hid or disguised; not for the purpose of deception, (when all is done, we are seldom deceived), but to preserve the continued surface entire.

If, where no union is intended, a line of separation is disagreeable, it must be disgusting when it breaks the connection between the several parts of the same piece of ground. That connection depends on the *junction of each part to those about it, and on the relation of every part to the whole*. To complete the former, such shapes should be contiguous as most readily unite; and the actual division between them should be anxiously concealed. If a swell descends upon a level; if a hollow sinks from it, the level is an abrupt termination, and a little rim marks it distinctly. To cover that rim, a short sweep at the foot of the swell, a small rotundity at the entrance of the hollow, must be interposed. In every instance, when ground changes its direction, there is a point where the change is effected, and that point should never appear; some other shapes, uniting easily with both extremes, must be thrown in to conceal it. But there must be no uniformity even in these connections: if the same sweep be carried all round the bottom of a swell, the same rotundity all round the top of a hollow, though the junction be perfect, yet the art by which it is made is apparent, and art must never appear. The manner of concealing the separation should itself be disguised: and different degrees of cavity and rotundity; different shapes and dimensions to the little parts thus distinguished by degrees; and those parts breaking, in one place more in another less, into the principal forms which are to be united; produce that variety with which all nature abounds, and without which ground cannot be natural.

THE relation of all the parts to the whole, when clearly marked, facilitates their junction with each other: for the common bond of union is then perceived, before there has been time to examine the subordinate connections; and if these should be deficient in some niceties, the defect is lost in the general impression. But any part which is at variance with the rest, is not barely a blemish in itself: it spreads disorder as far as its influence extends; and the confusion is in proportion as the other parts are more or less adapted to point out *any particular direction*, or to mark any *peculiar character* in the ground.

If, in ground all descending one way, a piece is twisted another, the general fall is obstructed by it; but if all the parts incline in the same direction, it is hardly credible how small a declivity will seem to be considerable. An appearance even of steepness may be given to a very gentle descent, by raising hillocks upon it, which shall lean to the point, whither all the rest are tending: for the eye measures from the top of the highest, to the bottom of the lowest ground; and when the relation of the parts is well preserved, such an effect from one is transfused over the whole.

But they should not, therefore, all lie exactly in the same direction: some may seem to point to it directly, others to incline very much, others but little, some partially, some entirely. If the direction be strongly marked on a few principal parts, great liberties may be taken with the others, provided none of them are turned the contrary way. The general idea must, however, be preserved, clear even of a doubt. A hillock which only intercepts the sight, if it does not contribute

6
Of the relation of the parts to the whole.

tribute to the principal effect, is at the best an unnecessary excess; and even an interruption in the general tendency, tho' it hide nothing, is a blemish. On a descent, any hollow, any fall, which has not an outlet to lower ground, is a hole: the eye skips over it, instead of being continued along it; it is a gap in the composition.

There may indeed be occasions, when we should rather wish to check, than to promote, the general tendency. Ground may proceed too hastily towards its point; and we have equal power to retard, or to accelerate, the fall. We can slacken the precipitancy of a steep, by breaking it into parts, some of which shall incline less, than the whole before inclined, to the principal direction; and by turning them quite away, we may even change the course of the descent. These powers are of use in the larger scenes, where the several great parts often lie in several directions; and if they are thereby too strongly contrasted, or led towards points too widely asunder, every art should be exerted to bring them nearer together, to assimilate, and to connect them. As scenes increase in extent, they become more impatient of controul: they are not only less manageable, but ought to be less restrained; they require more variety and contrast. But still the same principles are applicable to the least, and to the greatest, tho' not with equal severity: neither ought to be rent to pieces; and tho' a small neglect, which would distract the one, may not disturb the other, yet a total disregard of all the principles of union is alike productive of confusion in both.

THE *style* also of every part, must be accommodated to the character of the whole. For every piece of ground is distinguished by certain properties: it is either tame or bold, gentle or rude, continued or broken; and if any variety, inconsistent with those properties, be obtruded, it has no other effect than to weaken one idea without raising another. The insipidity of a flat is not taken away by a few scattered hillocks; a continuation of uneven ground can alone give the idea of inequality. A large, deep, abrupt break, among easy swells and falls, seems at the best but a piece left unfinished, and which ought to have been softened: it is not more natural, because it is more rude; nature forms both the one and the other, but seldom mixes them together. On the other hand, a small fine polished form, in the midst of rough, misshapen ground, though more elegant than all about it, is generally no better than a patch, itself disgraced, and disfiguring the scene. A thousand instances might be adduced to shew, that the prevailing idea ought to pervade every part, so far at least indispensably as to exclude whatever distracts it, and as much further as possible to accommodate the character of the ground to that of the scene it belongs to.

On the same principle, the *proportion* of the parts may often be adjusted. For though their size must be very much governed by the extent of the place, and a feature which would fill up a small spot may be lost in a large one; though there are forms of a particular cast, which appear to advantage only within certain dimensions, and ought not therefore to be applied where they have not room enough, or where they must occupy more space than becomes them; yet, independent of these considerations, a character of greatness

belongs to some scenes, which is not measured by their extent, but raised by other properties, sometimes only by the proportional largeness of their parts. On the contrary, where elegance characterises the spot, the parts should not only be small, but diversified besides with subordinate inequalities, and little delicate touches with every where scattered about them. Striking effects, forcible impressions, whatever seems to require effort, disturb the enjoyment of a scene intended to amuse and to please.

In other instances, similar considerations will determine rather the *number* than the proportion of the parts. A place may be distinguished by its simplicity, which many divisions would destroy; another spot, without any pretensions to elegance, may be remarkable for an appearance of richness: a multiplicity of objects will give that appearance, and a number of parts in the ground will contribute to the profusion. A scene of gaiety is improved by the same means; the objects and the parts may differ in style, but they must be numerous in both. Sameness is dull: the purest simplicity can at the most render a place composed of large parts placid; the sublimest ideas only make it striking: it is always grave; to enliven it, numbers are wanting.

BUT ground is seldom beautiful or natural without *variety*, or even without contrast; and the precautions which have been given, extend no farther than to prevent variety from degenerating into inconsistency, and contrast into contradiction. Within the extremes, nature supplies an inexhaustible fund; and variety thus limited, so far from destroying, improves the general effect: Each distinguished part makes a separate impression; and all bearing the same stamp, all concurring to the same end, every one is an additional support to the prevailing idea: that is multiplied, it is extended, it appears in different shapes, it is shewn in several lights, and the variety illustrates the relation.

BUT variety wants not this recommendation; it is always desirable where it can be properly introduced; and an accurate observer will see in every form several circumstances by which it is distinguished from every other. If the scene be mild and quiet, he will place together those which do not differ widely; and he will gradually depart from the similitude. In ruder scenes, the succession will be less regular, and the transitions more sudden. The character of the place must determine the degree of difference between forms which are contiguous. Besides distinctions in the shapes of ground, differences in their *situations* and their *dimensions* are sources of variety. The position will alter the effect, though the figure be the same; and for particular effects, a change only in the distance may be striking. If that be considerable, a succession of similar shapes sometimes occasions a fine perspective; but the diminution will be less marked, that is, the effect will be less sensible, if the forms are not nearly alike: we take more notice of one difference, when there is no other. Sometimes a very disagreeable effect, produced by too close a resemblance of shapes, may be remedied only by an alteration in the size. If a steep descends in a succession of abrupt falls, nearly equal, they have the appearance of steps, and are neither pleasing nor wild; but if they are made to differ in height and length, the objection is removed: and at all times a difference

ground.

difference in the dimensions will be found to have a greater effect than in speculation we should be inclined to ascribe to it, and will often disguise a similarity of figure.

It also contributes, perhaps more than any other circumstance, to the perfection of those *lines*, which the eye traces along the parts of a piece of ground, when it glances over several together. No variety of form compensates for the want of it. An undulating line composed of parts all elegant in themselves, all judiciously contralted, and happily united, but equal one to another, is far from the line of beauty. A long straight line has no variety at all; and a little deviation into a curve, if there be still a continued uniformity, is but a trifling amendment. Though ground all falling the same requires every attention to its general tendency, yet the eye must not dart down the whole length immediately in one direction, but should be insensibly conducted towards the principal point with some circuit and delay. The channels between hillocks ought never to run in straight, nor even regularly curved lines; but winding gently among them, and constantly varying in form and in dimensions, should gradually find their way. The beauty of a large hill, especially when seen from below, is frequently impaired by the even continuation of its brow. An attempt to break it by little knoles is seldom successful; they seem separate independent hillocks artificially put on. The intended effect may indeed be produced by a large knole descending in some places lower than in others, and rooted at several points into the hill. The same end may be attained by carrying some channel or hollow on the side upwards, till it cut the continued line; or by bringing the brow forward in one place, and throwing it back in another; or by forming a secondary ridge a little way down the side, and casting the ground above it into a different though not opposite direction to the general descent. Any of these expedients will at least draw the attention off from the defect. But if the break were to divide the line into equal parts, another uniformity would be added, without removing the former: for regularity always suggests a suspicion of artifice; and artifice detected, no longer deceives. Our imaginations would indolently join the broken parts, and the idea of the continued line would be restored.

10
Of contrast.

WHATEVER break be chosen, the position of it must be oblique to the line which is to be broken. A rectangular division produces sameness; there is no *contrast* between the forms it divides: but if it be oblique, while it diminishes the part on one side, it enlarges that on the other. Parallel lines are liable to the same objection as those at right angles: though each by itself be the perfect line of beauty; yet if they correspond, they form a shape between them, whose sides want contrast. On the same principle, forms will sometimes be introduced, less for their intrinsic than their occasional merit in contrasting happily with those about them: each sets off the other; and together they are a more agreeable composition than if they had been more beautiful, but at the same time more similar.

One reason why tame scenes are seldom interesting, is, that though they often admit of many varieties, they allow of few, and those only faint, contrasts. We may be pleased by the number of the former, but we

can be struck only by the force of the latter. These ought to abound in the larger and bolder scenes of a garden, especially in such as are formed by an assemblage of many distinct and considerable parts thrown together: as when several rising grounds appear one beyond another; a fine swell seen above a sloping sweep which runs before it, has a beautiful effect, which a nearer resemblance would destroy: and (except in particular instances) a close similarity between lines which either cross, or face, or rise behind one another, makes a poor, uniform, disagreeable composition.

THE application of any of the foregoing observations to the still greater scenes of nature, would carry us at present too far; nor could it well be made, before the other constituent parts of those scenes, wood, water, rocks, and buildings, have been taken into consideration. The rules which have been given, are chiefly applicable to ground which may be managed by a spade; and even there they are only general, not universal: few of them are without exception; very few, which, on particular occasions, may not be dispensed with. Many of the above remarks are, however, so far of use in scenes the farthest from our reach, as they may assist in directing our choice of those parts which are in our power to shew, or to conceal, though not to alter. But in converting them to this purpose, a caution, which has more than once been alluded to, must always be had in remembrance; never to suffer general considerations to interfere with *extraordinary great effects*, which rise superior to all regulations, and perhaps owe part of their force to their deviation from them. Singularity causes at least surprise, and surprise is allied to astonishment. These effects are not, however, attached merely to objects of enormous size; they frequently are produced by a greatness of style and character, within such an extent as ordinary labour may modify, and the compass of a garden include. The caution therefore may not be useless within these narrow bounds: but nature proceeds still further, beyond the utmost verge to which art can follow; and, in scenes licentiously wild, not content with contrast, forces even contradictions to unite. The grotesque discordant shapes which are often there confusedly jumbled together, might sufficiently justify the remark. But the caprice does not stop here: to mix with such shapes a form perfectly regular, is still more extravagant; and yet the effect is sometimes so wonderful, that we cannot with the extravagance corrected. It is not unusual to see a conical hill standing out from a long, irregular, mountainous ridge, and greatly improving the view: but at Ilam such a hill is thrown into the midst of the rudest scene, and almost fills up an abyss, sunk among huge, bare, misshapen hills, whose unwieldy parts, and uncouth forms, cut by the tapering lines of the cone, appear more savage from the opposition: and the effect would evidently be stronger, were the figure more complete; for it does not rise quite to a point, and the want of perfect regularity seems a blemish. Whether such a mixture of contraries would for a length of time be engaging, can be known only to those who are habituated to the spot. It certainly at first sight rivets the attention. But the conical hill is the most striking object. In such a situation it appears more strange, more fantastic, than

11
Of extraordinary effects.

12
Description of a hill at Ilam, near Athbourne in Derbyshire.

the

the rude shapes which are heaped about it: and together they suit the character of the place, where nature seems to have delighted to bring distances together; where two rivers, which are ingulphed many miles asunder, issue from their subterraneous passages, the one often muddy when the other is clear, within a few paces of each other: but they appear only to lose themselves again; for they immediately unite their streams, just in time to fall together into another current, which also runs through the garden. Such whimsical wonders, however, lose their effect, when represented in a picture, or mimicked in ground artificially laid. They there want that vastness which constitutes their force; that reality which ascertains the caprice. As accidents they may surprize; but they are not objects of choice.

To determine the choice to its proper objects is the purpose of the foregoing observations. Some of the principles upon which they are founded will be applicable also, and perhaps without further explanation, to the other constituent parts of the scenes of nature: they will there be often more obvious than in ground. But this is not a place for the comparison; the subject now is ground only. It is not, however, foreign to that subject to observe, that the effects which have been recommended, may sometimes be produced by wood alone, without any alteration in the ground itself: a tedious continued line may by such means be broken. It is usual for this purpose to place several little clumps along a brow; but if they are small and numerous, the artifice is weak and apparent: an equal number of trees collected into one or two large masses, and dividing the line into very unequal parts, is less suspicious, and obliterates the idea of sameness with more certainty. Where several similar lines are seen together, if one be planted, and the other bare, they become contrails to each other. A hollow in certain situations, has been mentioned as a disagreeable interruption in a continued surface: but, filled with wood, the heads of the trees supply the vacancy; the irregularity is preserved; even the inequalities of the depth are in some measure shewn; and a continuation of surface is provided. Raising ground may, on the other hand, be in appearance raised still higher, by covering it with wood, of humble growth towards the bottom, and gradually taller as it ascends. An additional mark of the inclination of falling ground may also be obtained, by placing a few trees in the same direction, which will strongly point out the way; whereas plantations athwart a descent, bolster up the ground, and check the fall: but obliquely crossing it, they will often divert the general tendency; the ground will in some measure assume their direction, and they will make a variety, not a contradiction. Hedges, or continued plantations, carried over uneven ground, render the irregularity more conspicuous, and frequently mark little inequalities, which would otherwise escape observation; or if a line of trees run close upon the edge of an abrupt fall, they give it depth and importance. By such means a view may be improved; by similar means, in more confined spots, very material purposes may be answered.

SECT. II. Of Wood.

In the above instances the ground is the principal consideration: but previous to any inquiry into the greater

effects of wood, when it is itself an object, an examination of the *characteristic differences* of trees and shrubs is necessary. We do not mean botanical distinctions; we mean apparent, not essential varieties; and these must be obvious and considerable, to merit regard in the disposition of the objects they distinguish.

Trees and shrubs are of different *shapes, greens, and growths*.

The varieties in their shapes may be reduced to the following heads.

Some thick with branches and foliage have almost an appearance of *solidity*; as the beech and the elm, the lilac and syringa. Others thin of boughs and of leaves seem *light and airy*; as the ash and the arbutus, the common arbutus vitæ and the tamarisk.

There is a mean *betwixt the two extremes*, very distinguishable from both; as in the bladder-nut, and the alden-leaved maple.

They may again be divided into those whose *branches begin from the ground*, and those which *shoot up in a stem before their branches begin*. Trees which have some, not much clear stem, as several of the firs, belong to the former class; but a very short stem will rank a shrub, such as the althæa, in the latter.

Of those whose branches begin from the ground, some rise in a *conical figure*, as the larch, the cedar of Lebanon, and the holly; some *swell out in the middle of their growth, and diminish at both ends*, as the Weymouth pine, the mountain ash, and the lilac: and some are *irregular and bushy* from the top to the bottom, as the evergreen oak, the Virginian cedar, and Guelder rose.

There is a great difference, between one whose *base is very large*, and another whose *base is very small*, in proportion to its height: the cedar of Lebanon, and the cypress, are instances of this difference; yet in both the branches begin from the ground.

The heads of those which shoot up into a stem before their branches begin, sometimes are *slender cones*, as of many firs: sometimes are *broad cones*, as of the horse-chestnut; sometimes they are *round*, as of the stone-pine, and most sorts of fruit-trees; and sometimes *irregular*, as of the elm. Of this last kind there are many considerable varieties.

The branches of some grow *horizontally*, as of the oak. In others they *tend upwards*, as in the almond, and in several sorts of broom and of willows. In others they *fall*, as in the lime, and the acacia: and in some of these last they *incline obliquely*, as in many of the firs; in some they *hang directly down*, as in the weeping willow.

These are the most obvious great distinctions in the shapes of trees and shrubs. The differences between shades of green cannot be so considerable; but these also will be found well deserving of attention.

Some are of a *dark green*, as the horse-chestnut and the yew; some of a *light green*, as the lime and the laurel; some of a *green tinged with brown*, as the Virginian cedar; some of a *green tinged with white*, as the arbutus and the sage tree; and some of a *green tinged with yellow*, as the alden-leaved maple and the Chinese arbutus vitæ. The variegated plants also are generally entitled to be classed with the white, or the yellow, by the strong tincture of the one or the other of those colours on their leaves.

Other

Section II.
Wood.

Other considerations concerning colours will soon be suggested: the present inquiry is only into great fixed distinctions. Those in the shapes and the greens of trees and shrubs have been mentioned: there are others, as great and as important, in their growths; but they are too obvious to deserve mentioning. Every gradation, from the most humble to the most lofty, has, in certain situations, particular effects: it is unnecessary to divide them into stages.

15
Variety arising from those differences.

ONE principal use in settling these characteristic distinctions, is to point out the stores whence varieties may at all times be readily drawn, and the causes by which sometimes inconsistencies may be accounted for. Trees which differ but in one of these circumstances, whether of shape, of green, or of growth, though they agree in every other, are sufficiently distinguished for the purpose of variety: if they differ in two or three, they become contrasts; if in all, they are opposites, and seldom groupe well together. But there are intermediate degrees, by which the most distant may be reconciled: the upright branches of the almond mix very ill with the falling boughs of the weeping willow; but an interval filled with other trees, in figure between the two extremes, renders them at least not unsightly in the same plantation. Those, on the contrary, which are of one character, and are distinguished only as the characteristic mark is strongly or faintly impressed upon them, as a young beech and a birch, an acacia and a larch, all pendant, though in different degrees, form a beautiful mass, in which unity is preserved without sameness; and still finer groupings may often be produced by greater deviations from uniformity into contrast.

Occasions to shew the effects of particular shapes in certain situations will hereafter so frequently occur, that a further illustration of them now would be needless. But there are besides, sometimes in trees, and commonly in shrubs, still *more minute varieties*,—in the turn of the branches, in the form and the size of the foliage, which generally catch, and often deserve attention. Even the texture of the leaves frequently occasions many different appearances: some have a stiffness, some an agility, by which they are more or less proper for several purposes; on many there is a gloss, very useful at times to enliven, at other times too glittering for the hue of the plantation. But all these inferior varieties are below our notice in the consideration of great effects: they are of consequence only where the plantation is near to the sight; where it skirts a home-scene, or borders the side of a walk: and in a shrubbery, which in its nature is little both in style and in extent, they should be anxiously sought for. The noblest wood is not indeed disguised by them; and when a wood, having served as a great object to one spot, becomes in another the edge of a walk, little circumstances, varying with ceaseless change along the outline, will then be attended to: but where-ever these minute varieties are sitting, the grossest taste will feel the propriety, and the most curious observation will suggest the distinctions: a detail of all would be endless; nor can they be reduced into classes. To range the shrubs and small trees so that they may mutually set off the beauties, and conceal the blemishes, of each other; to aim at no effects which depend on a nicety for their success, and which the soil,

the exposure, or the season of the day, may destroy; to attend more to the groupes than to the individuals; and to consider the whole as a plantation, not as a collection of plants; are the best general rules which can be given concerning them.

16
Of the mixture of greens.

THE different tints of greens may seem at first sight to be rather minute varieties than characteristic distinctions: but upon experience it will be found, that from small beginnings they lead to material consequences; that they are more important on the broad expanse, than along the narrow outline of a wood; and that by their union, or their contrast, they produce effects not to be disregarded in scenes of extent and of grandeur.

A hanging wood in autumn is enriched with colours, whose beauty cheers the approaches of the inclement season they forebode: but when the trees first droop, while the verdure as yet only begins to fade, they are no more than stronger tints of those colours with which the greens in their vigour are shaded; and which now are succeeded by a paler white, a brighter yellow, or a darker brown. The effects are not different; they are only more faintly impressed at one time than another; but when they are strongest, they are most observable. The fall of the leaf, therefore, is the time to learn the species, the order, and the proportion of tints, which blended will form *beautiful masses*; and, on the other hand, to distinguish those which are *incompatible* near together.

The peculiar beauty of the tints of red cannot then escape observation, and the want of them throughout the summer-months must be regretted: but that want, though it cannot perfectly, may partially be supplied; for plants have a *permanent* and an *accidental* colour. The permanent is always some shade of green; but any other may be the accidental colour; and there is none which so many circumstances concur to produce as a red. It is assumed in succession by the bud, the blossom, the berry, the bark, and the leaf. Sometimes it profusely overpreads, at other times it dimly tinges the plant; and a *reddish green* is generally the hue of those plants, on which it lasts long, or frequently returns.

Admitting this, at least for many months in the year, among the characteristic distinctions, a large piece of red green, with a narrow edging of dark green along the further side of it, and beyond that a piece of light green larger than the first, will be found to compose a beautiful mass. Another, not less beautiful, is a yellow green nearest to the eye, beyond that a light green, then a brown green, and lastly a dark green. The dark green must be the largest, the light green the next in extent, and the yellow green the least of all.

From these combinations, the agreements between particular tints may be known. A light green may be next either to a yellow or a brown green, and a brown to a dark green, all in considerable quantities; and a little rim of dark green may border on a red or a light green. Further observations will shew, that the yellow and the white greens connect easily; but that a large quantity of the light, the yellow, or the white greens, does not mix well with a large quantity also of the dark green; and that to form a pleasing mass, either the dark green must

must be reduced to a mere edging, or a brown or an intermediate green must be interposed: that the red, the brown, and the intermediate greens, agree among themselves: and that any of them may be joined to any other tint; but that the red green will bear a larger quantity of the light than of the dark green near it, nor does it seem for proper a mixture with the white green as with the rest.

In massing these tints, an attention must be constantly kept up to their *forms*, that they do not lie in large stripes one beyond another; but that either they be quite intermingled, or, which is generally more pleasing, that considerable pieces of different tints, each a beautiful figure, be, in different proportions, placed near together. Exactness in the shapes must not be attempted, for it cannot be preserved; but if the great outlines be well drawn, little variations, afterwards occasioned by the growth of the plants, will not spoil them.

17
Effects arising from the disposition of the greens.

A *SMALL* thicket is generally most agreeable, when it is one fine mass of well-mixed greens: that mass gives to the whole a *unity*, which can by no other means be so perfectly expressed. When more than one is necessary for the extent of the plantation, still if they are too much contrasted, if the gradations from one to another are easy, the unity is not broken by the variety.

While the union of tints is productive of pleasing effects, strong effects may, on the other hand, be sometimes produced by their *disagreements*. Opposites, such, for instance, as the dark and light greens, in large quantities close together, break to pieces the surface upon which they meet; and an outline which cannot be sufficiently varied in form, may be in appearance, by the management of its shades: every opposition of tints is a break in a continued line: the depth of recesses may be deepened by darkening the greens as they retire; a tree which stands out from a plantation may be separated by its tint as much as by its position; the appearance of solidity or airiness in plants depends not solely on the thickness or thinness, but partly on the colour of the leaves; clumps at a distance, may be rendered more or less distinct by their greens; and the fine effect of a dark green tree, or groupe of trees, with nothing behind it but the splendor of a morning or the glow of an evening sky, cannot be unknown to any who was ever delighted with a picture of Claude, or with the more beautiful originals in nature.

Another effect attainable by the aid of the different tints, is founded on the first principles of *perspective*. Objects grow faint as they retire from the eye; a detached clump, or a single tree, of the lighter greens, will, therefore, seem farther off than one equidistant of a darker hue; and a regular gradation from one tint to another will alter the apparent length of a continued plantation, according as the dark or light greens begin the gradation. In a straight line this is obvious; in a broken one, the fallacy in the appearance is seldom detected, only because the real extent is generally unknown; but experiments will support the principle, if they are made on plantations not very small, nor too close to the eye: the several parts may then be shortened or lengthened, and the variety of the outline be improved by a judicious arrangement of greens.

OTHER effects arising from mixtures of greens will occasionally present themselves in the *disposition* of a wood, which is the next consideration. Wood, as a general term, comprehends all trees and shrubs in whatever disposition; but it is specifically applied in a more limited sense, and in that sense we shall now use it.

Every plantation must be either a *wood*, a *grove*, a *clump*, or a *single tree*.

A wood is composed both of trees and underwood, covering a considerable space. A grove consists of trees without underwood. A clump differs from either only in extent: it may be either close or open: when close, it is sometimes called a *thicket*; when open, a *groupe of trees*; but both are equally clumps, whatever may be the shape or situation.

ONE of the noblest objects in nature is the *surface* of a large thick wood, commanded from an eminence, or seen from below, hanging on the side of a hill. The latter is generally the more interesting object. Its aspiring situation gives it an air of greatness; its termination is commonly the horizon: and, indeed, if it is deprived of that splendid boundary, if the brow appears above it, (unless some very peculiar effect characterizes that brow), it loses much of its magnificence: it is inferior to a wood which covers a less hill from the top to the bottom; for a whole space filled is seldom little: but a wood commanded from an eminence is generally no more than a part of the scene below; and its boundary is often inadequate to its greatness. To continue it, therefore, till it winds out of sight, or loses itself in the horizon, is generally desirable: but then the varieties of its surface grow confused as it retires; while those of a hanging wood are all distinct; the furthest parts are held up to the eye; and none are at a distance, though the whole be extensive.

The varieties of a surface are essential to the beauty of it: a continued smooth shaven level of foliage is neither agreeable nor natural; the different growths of trees commonly break it in reality, and their shadows still more in appearance. These shades are so many tints, which, undulating about the surface, are its greatest embellishment; and such tints may be produced with more effect, and more certainty, by a judicious mixture of greens; at the same time an additional variety may be introduced, by grouping and contrasting trees very different in shape from each other: and whether variety in the greens or in the forms be the design, the execution is often easy, and seldom to a certain degree impossible. In raising a young wood, it may be perfect. In old woods, there are many spots which may be either thinned or thickened: and there the characteristic distinctions should determine what to plant, or what to leave; at the least will often point out those which, as blemishes, ought to be taken away; and the removal of two or three trees will sometimes accomplish the design. The number of beautiful forms, and agreeable masses, which may decorate the surface, is so great, that where the place will not admit of one, another is always ready; and as no delicacy of finishing is required, no minute exactness is worth regarding, great effects will not be disconcerted by small obstructions and little disappointments.

The contrasts, however, of masses and of groupes must not be too strong, where *greatness* is the character.

19
Of the surface of a wood distinguished by its greatness.

ter of the wood; for unity is essential to greatness; and if direct opposites be placed close together, the wood is no longer one object; it is only a confused collection of several separate plantations. But if the progress be gradual from the one to the other, shapes and tints widely different may assemble on the same surface; and each should occupy a considerable space: a single tree, or a small cluster of trees, in the midst of an extensive wood, is in size but a speck, and in colour but a spot; the groupings and the masses must be large to produce any sensible variety.

Yet single trees in the midst of a wood, though seldom of use to diversify a surface, often deserve particular regard as individuals, and are important to the greatness of the whole. The superficies of a shrubby thicket, how extensive soever, does not convey the same ideas of magnificence, as that of a hanging wood: and yet, at first sight, the difference is not always very discernible. It often requires time to collect the several circumstances in the latter, which suggest the elevation to which that broad expanse of foliage is raised, the vastness of the trunks which support it so high, the extent of the branches which spread it so far. When these circumstances, all of grandeur, crowd together upon the mind, they dignify the space; which, without them, might, indifferently, be the superficies of a thicket or the surface of a wood: but a few large trees, not eminent above all about them, but distinguished by some slight separation, and obvious at a glance, immediately resolve the doubt. They are noble objects in themselves; become the situation; and serve as a measure to the rest. On the same principle, trees which are thin of boughs and of leaves, those whose branches tend upwards, or whose heads rise in slender cones, have an appearance more of airiness than of importance; and are blemishes in a wood, where greatness is the prevailing idea. Those, on the contrary, whose branches hang directly down, have a breadth of head, which suits with such a situation, though their own peculiar beauty be lost in it.

These decorations are natural graces, which never derogate from greatness; and a number of shades playing on the surface, over a variety of those beautiful forms into which it may be cast, enliven that sameness, which, while it prevails, reduces the merit of one of the noblest objects in nature to that of mere space. To fill that space with objects of beauty, to delight the eye after it has been struck, to fix the attention where it has been caught, and to prolong astonishment into admiration, are purposes not unworthy of the greatest designs; and, in the execution, productive of embellishments, which in style are not unequal to scenes of richness and magnificence.

WHEN, in a romantic situation, very broken ground is overspread with wood, it may be proper, on the surface of the wood, to mark the inequalities of the ground. *Rudeness*, not greatness, is the prevailing idea; and a choice directly the reverse of that which is productive of unity, will produce it. Strong contrasts, even oppositions, may be eligible; the aim is rather to disjoint than to connect: a deep hollow may sink into dark greens; an abrupt bank may be shewn by a rising stage of aspiring trees, a sharp ridge by a narrow line of conical shapes; firs are of great use

upon such occasions; their tint, their form, their singularity, recommend them.

A hanging wood of thin forest-trees, and seen from below, is seldom pleasing: those few trees, are by the perspective brought nearer together; it loses the beauty of a thin wood, and is defective as a thick one: the most obvious improvement, therefore, is to thicken it. But, when seen from an eminence, a thin wood is often a lively and elegant circumstance in a view; it is full of objects; and every separate tree shews its beauty. To increase that vivacity, which is the peculiar excellence of a thin wood, the trees should be characteristically distinguished both in their tints and their shapes; and such as for their airiness have been proscribed in a thick wood, are frequently the most eligible here. Differences also in their growths are a further source of variety; each should be considered as a distinct object, unless where a small number are grouped together; and then all that compose the little cluster must agree: but the groups themselves, for the same reason as the separate trees, should be strongly contrasted; the continued underwood is their only connection, and that is not affected by their variety.

THOUGH the surface of a wood, when commanded, deserves all these attentions, yet the outline more frequently calls for our regard: it is also more in our power; it may sometimes be great, and may always be beautiful. The first requisite is irregularity. That a mixture of trees and underwood should form a long straight line, can never be natural; and a succession of easy sweeps and gentle rounds, each a portion of a greater or less circle, composing all together a line literally serpentine, is, if possible, worse. It is but a number of regularities put together in a disorderly manner, and equally distant from the beautiful both of art and of nature. The true beauty of an outline consists more in breaks than in sweeps; rather in angles than in rounds; in variety, not in succession.

The outline of a wood is a continued line, and small variations do not save it from the insipidity of sameness: one deep recess, one bold prominence, has more effect than twenty little irregularities. That one divides the line into parts, but no breach is thereby made in its unity; a continuation of wood always remains; the form of it only is altered, and the extent is increased. The eye, which hurries to the extremity of whatever is uniform, delights to trace a varied line through all its intricacies, to pause from stage to stage, and to lengthen the progress. The parts must not, however, on that account be multiplied till they are too minute to be interesting, and so numerous as to create confusion. A few large parts should be strongly distinguished in their forms, their directions, and their situations; each of these may afterwards be decorated with subordinate varieties; and the mere growth of the plants will occasion some irregularity; on many occasions, more will not be required.

Every variety in the outline of a wood must be a prominence, or a recess. Breadth in either is not so important as length to the one, and depth to the other. If the former ends in an angle, the latter diminishes to a point; they have more force than a shallow dent, or a dwarf excrescence, how wide soever. They are greater deviations from the continued line which they are intended to break; and their effect is to enlarge

19
Of the surface of a romantic, and of a thin wood.

21
Of the outline of a wood.

Section II.
Wood.Section II.
Wood.

the wood itself, which seems to stretch from the most advanced point, back beyond the most distant to which it retires. The extent of a large wood on a flat, not commanded, can by no circumstance be so manifestly shewn, as by a deep recess; especially if that recess wind so as to conceal the extremity, and leave the imagination to pursue it. On the other hand, the poverty of a shallow wood might sometimes be relieved by here and there a prominence, or clumps, which by their apparent junction should seem to be prominences from it. A deeper wood with a continued outline, except when commanded, would not appear so considerable.

An inlet into a wood seems to have been cut, if the opposite points of the entrance tally; and that show of art depreciates its merit; but a difference only in the situation of those points, by bringing one more forward than the other, prevents the appearance, though their forms be similar. Other points, which distinguish the great parts, should in general be strongly marked: a short turn has more spirit in it than a tedious circuit; and a line broken by angles has a precision and firmness, which in an undulated line are wanting: the angles should indeed commonly be a little softened; the rotundity of the plant which forms them is sometimes sufficient for the purpose; but if they are mellowed down too much, they lose all meaning. Three or four large parts thus boldly distinguished, will break a very long outline; more may be, and often ought to be, thrown in, but seldom are necessary: and when two woods are opposed on the sides of a narrow glade, neither has so much occasion for variety in itself as if it were single; if they are very different from each other, the contrast supplies the deficiency to each, and the interval between them is full of variety. The form of that interval is indeed of as much consequence as their own: though the outlines of both the woods be separately beautiful, yet if together they do not cast the open space into an agreeable figure, the whole scene is not pleasing; and a figure is never agreeable, when the sides too closely correspond; whether they are exactly the same, or exactly the reverse of each other, they equally appear artificial.

Every variety of outline hitherto mentioned, may be traced by the *underwood* alone; but frequently the same effects may be produced with more ease, and with much more beauty, by a *few trees* standing out from the thicket, and belonging, or seeming to belong, to the wood, so as to make a part of its figure. Even where they are not wanted for that purpose, detached trees are such agreeable objects, so distinct, so light, when compared to the covert about them, that skirting along it in some parts, and breaking it in others, they give an unselected grace, which can no otherwise be given to the outline. They have a still further effect, when they stretch across the whole breadth of an inlet, or before part of a recess into the wood; they are themselves shewn to advantage by the space behind them, and that space, seen between their stems, they in return throw into an agreeable perspective. An inferior grace of the same kind may be often introduced, only by distinguishing the boles of some trees in the wood itself, and keeping down the thicket beneath them. Where even this cannot be well executed, still the outline may be filled with such trees and shrubs as swell out in the middle of their growth,

Vol. V.

and diminish at both ends; or with such as rise in a slender cone; with those whose branches tend upwards; or whose base is very small in proportion to their height; or which are very thin of boughs and of leaves. In a confined garden-scene, which wants room for the effect of detached trees, the outline will be heavy, if these little attentions are disregarded.

THE prevailing character of a wood is generally grandeur; the principal attention therefore which it requires, is to prevent the excesses of that character, to diversify the uniformity of its extent, to lighten the unwieldiness of its bulk, and to blend graces with greatness. But the character of a grove is *beauty*. Fine trees are lovely objects: a grove is an assemblage of them; in which every individual retains much of its own peculiar elegance, and whatever it loses is transferred to the superior beauty of the whole. To a grove, therefore, which admits of endless variety in the disposition of the trees, differences in their shapes and their greens are seldom very important, and sometimes they are detrimental. Strong contrasts scatter trees which are thinly planted, and which have not the connection of underwood; they no longer form one plantation; they are a number of single trees. A thick grove is not indeed exposed to this mischief, and certain situations may recommend different shapes and different greens for their effects upon the *surface*; but in the *outline* they are seldom much regarded. The eye attracted into the depth of the grove, passes by little circumstances at the entrance; even varieties in the form of the line do not always engage the attention: they are not so apparent as in a continued thicket, and are scarcely seen if they are not considerable.

BUT the surface and the outline are not the only circumstances to be attended to. Though a grove be beautiful as an object, it is besides delightful as a spot to walk or to sit in; and the choice and the disposition of the trees for effects *within*, are therefore a principal consideration. Mere irregularity alone will not please: strict order is there more agreeable than absolute confusion; and some meaning better than none. A regular plantation has a degree of beauty; but it gives no satisfaction, because we know that the same number of trees might be more beautifully arranged. A disposition, however, in which the lines only are broken, without varying the distances, is less natural than any; for though we cannot find straight lines in a forest, we are habituated to them in the hedge-rows of fields; but neither in wild nor in cultivated nature do we ever see trees equi-distant from each other: that regularity belongs to art alone. The distances, therefore, should be strikingly different: the trees should gather into groupes, or stand in various irregular lines, and describe several figures: the intervals between them should be contrasted both in shape and in dimensions: a large space should in some places be quite open; in others the trees should be so close together, as hardly to leave a passage between them; and in others as far apart as the connection will allow. In the forms and the varieties of these groupes, these lines, and these openings, principally consists the interior beauty of a grove.

The force of them is most strongly illustrated at Claremont; where the walk to the cottage, though destitute of many natural advantages, and eminent for

none; though it commands no prospect; though the water below it is a trifling pond; though it has nothing, in short, but inequality of ground to recommend it; is yet the finest part of the garden: for a grove is there planted in a gently curved direction, all along the side of a hill, and on the edge of a wood, which rises above it. Large recesses break it into several clumps, which hang down the declivity; some of them approaching, but none reaching quite to the bottom. These recesses are so deep as to form great openings in the midst of the grove; they penetrate almost to the covert: but the clumps being all equally suspended from the wood; and a line of open plantation, though sometimes narrow, running constantly along the top; a continuation of grove is preserved, and the connection between the parts is never broken. Even a groupe, which near one of the extremities stands out quite detached, is still in style so similar to the rest, as not to lose all relation. Each of these clumps is composed of several others still more intimately united: each is full of groupes, sometimes of no more than two trees, sometimes of four or five, and now and then in larger clusters: an irregular waving line, issuing from some little crowd, loses itself in the next; or a few scattered trees drop in a more distant succession from the one to the other. The intervals, winding here like a glade, and widening there into broader openings, differ in extent, in figure, and direction; but all the groupes, the lines, and the intervals, are collected together into large general clumps, each of which is at the same time both compact and free, identical and various. The whole is a place wherein to tarry with secure delight, or fainter with perpetual amusement.

25
Grove at
Esher-place,
(contiguous
to Clare-
mont.)

The grove at Esher-place was planted by the same masterly hand; but the necessity of accommodating the young plantation to some large trees which grew there before, has confined its variety. The groupes are few and small; there was not room for larger or for more: there were no opportunities to form continued narrow glades between opposite lines; the vacant spaces are therefore chiefly irregular openings spreading every way, and great differences of distance between the trees are the principal variety; but the grove winds along the bank of a large river, on the side and at the foot of a very sudden ascent, the upper part of which is covered with wood. In one place, it presses close to the covert; retires from it in another; and stretches in a third across a bold recess, which runs up high into the thicket. The trees sometimes overspread the flat below; sometimes leave an open space to the river; at other times crown the brow of a large knole, climb up a steep, or hang on a gentle declivity. These varieties in the situation more than compensate for the want of variety in the disposition of the trees; and the many happy circumstances which concur

—In Esher's peaceful grove,
Where Kent and nature vie for Pelham's love,

render this little spot more agreeable than any at Claremont. But though it was right to preserve the trees already standing, and not to sacrifice great present beauties to still greater in futurity; yet this attention has been a restraint; and the grove at Claremont, considered merely as a plantation, is in delicacy of taste, and fertility of invention, superior to that at Esher.

Both were early essays in the modern art of garden-

ing: and, perhaps from an eagerness to shew the effect, the trees in both were placed too near together: though they are still far short of their growth, they are run up into poles, and the groves are already past their prime; but the temptation to plant for such a purpose no longer exists, now that experience has justified the experiment. If, however, we still have not patience to wait, it is possible to secure both a present and a future effect, by fixing first on a disposition which will be beautiful when the trees are large, and then intermingling another which is agreeable while they are small. These occasional trees are hereafter to be taken away; and must be removed in time, before they become prejudicial to the others.

The consequence of variety in the disposition, is variety in the light and shade of the grove; which may be improved by the choice of the trees. Some are impenetrable to the fiercest sun-beam; others let in here and there a ray between the large masses of their foliage; and others, thin both of boughs and of leaves, only chequer the ground. Every degree of light and shade, from a glare to obscurity, may be managed, partly by the number, and partly by the texture, of the trees. Differences only in the manner of their growths have also corresponding effects: there is a closeness under those whose branches descend low, and spread wide; a space and liberty where the arch above is high; and frequent transitions from the one to the other are very pleasing. These still are not all the varieties of which the interior of a grove is capable: trees indeed, whose branches nearly reach the ground, being each a sort of thicket, are inconsistent with an open plantation: but though some of the characteristic distinctions are thereby excluded, other varieties more minute succeed in their place; for the freedom of passage throughout brings every tree in its turn near to the eye, and subjects even differences in foliage to observation. These, slight as they may seem, are agreeable when they occur: it is true, they are not regretted when wanting; but a defect of ornament is not necessarily a blemish.

It has been already observed, that clumps differ only in extent from woods, if they are close; or from groves, if they are open: they are small woods, and small groves, governed by the same principles as the larger, after allowances made for their dimensions. But besides the properties they may have in common with woods or with groves, they have others peculiar to themselves, which require examination.

They are either *independent* or *relative*: when independent, their beauty, as single objects, is solely to be attended to; when relative, the beauty of the individuals must be sacrificed to the effect of the whole, which is the greater consideration.

The least clump that can be, is of two trees; and the best effect they can have is, that their heads united should appear one large tree: two therefore of different species, or seven or eight of such shapes as do not easily join, can hardly be a beautiful groupe, especially if it have a tendency to a circular form. Such clumps of firs, though very common, are seldom pleasing; they do not compose one mass, but are only a confused number of pinnacles. The confusion is however avoided, by placing them in succession, not in clusters; and a clump of such trees is therefore more agreeable when it is ex-

teached

tended rather in length than in breadth.

Three trees together must form either a right line, or a triangle: to disguise the regularity, the distances should be very different. Distinctions in their shapes contribute also to the same end; and a variety in their growths still more. When a straight line consists of two trees nearly similar, and of a third much lower than they are, the even direction in which they stand is hardly discernible.

If humbler growths at the extremity can discompose the strictest regularity, the use of them is thereby recommended upon other occasions. It is indeed the variety peculiarly proper for clumps: every apparent artifice affecting the objects of nature, disguises; and clumps are such distinguished objects, so liable to the suspicion of having been left or placed on purpose to be so distinguished, that, to divert the attention from these symptoms of art, irregularity in the composition is more important to them than to a wood or to a grove: being also less extensive, they do not admit so much variety of outline: but variety of growths is most observable in a small compass; and the several gradations may often be cast into beautiful figures.

The extent and the outline of a wood or a grove engage the attention more than the extremities; but in clumps the last are of the most consequence: they determine the form of the whole; and both of them are generally in sight: great care should therefore be taken to make them agreeable and different. The ease with which they may be compared, forbids all similarity between them: for every appearance of equality suggests an idea of art; and therefore a clump as broad as it is long, seems less the work of nature than one which stretches into length.

Another peculiarity of clumps, is the facility with which they admit a mixture of trees and of shrubs, of wood and of grove; in short, of every species of plantation. None are more beautiful than those which are so composed. Such compositions are, however, more proper in compact than in straggling clumps: they are most agreeable when they form one mass: if the transitions from very lofty to very humble growths, from thicket to open plantations, be frequent and sudden, the disorder is more suited to rude than to elegant scenes.

The occasions on which independent clumps may be applied, are many. They are often desirable as beautiful objects in themselves; they are sometimes necessary to break an extent of lawn, or a continued line, whether of ground or of plantation; but on all occasions a jealousy of art constantly attends them, which irregularity in their figure will not always alone remove. Though elevations shew them to advantage, yet a hillock evidently thrown up on purpose to be crowned with a clump, is artificial to a degree of disgust: some of the trees should therefore be planted on the sides, to take off that appearance. The same expedient may be applied to clumps placed on the brow of a hill, to interrupt its sameness: they will have less ostentation of design, if they are in part carried down either declivity. The objection already made to planting many along such a brow, is on the same principle: a single clump is less suspected of art; if it be an open one, there can be no finer situation for it, than just at the point of an abrupt hill, or on a promontory into a

lake or a river. It is in either a beautiful termination, distinct by its position, and enlivened by an expanse of sky or of water about and beyond it. Such advantages may balance little defects in its form: but they are lost if other clumps are planted near it; art then intrudes, and the whole is displeasing.

But though a multiplicity of clumps, when each is an independent object, seldom seems natural; yet a number of them may, without any appearance of art, be admitted into the same scene, if they bear a relation to each other: if by their succession they diversify a continued outline of wood, if between them they form beautiful glades, if all together they cast an extensive lawn into an agreeable shape, the effect prevents any scrutiny into the means of producing it. But when the reliance on that effect is so great, every other consideration must give way to the beauty of the whole. The figure of the glade, of the lawn, or of the wood, are principally to be attended to: the finest clumps, if they do not fall easily into the great lines, are blemishes; their connections, their contrals, are more important than their forms.

A line of clumps, if the intervals be closed by others beyond them, has the appearance of a wood, or of a grove; and in one respect the semblance has an advantage over the reality. In different points of view, the relations between the clumps are changed, and a variety of forms is produced, which no continued wood or grove, however broken, can furnish. These forms cannot all be equally agreeable; and too anxious a solicitude to make them every where pleasing, may, perhaps, prevent their being ever beautiful. The effect must often be left to chance; but it should be studiously consulted from a few principal points of view; and it is easy to make any recess, any prominence, any figure in the outline, by clumps thus advancing before, or retreating behind one another.

But amidst all the advantages attendant on this species of plantation, it is often exceptional when commanded from a neighbouring eminence: clumps below the eye lose some of their principal beauties, and a number of them betray the art of which they are always liable to be suspected; they compose no surface of wood, and all effects arising from the relations between them are entirely lost. A prospect spotted with many clumps can hardly be great: unless they are so distinct as to be objects, or so distant as to unite into one mass, they are seldom an improvement of a view.

The proper situations for single trees are frequently the same as for clumps: the choice will often be determined, solely by the consideration of proportion between the object, and the spot it is intended to occupy; and if the desired effect can be attained by a single tree, the simplicity of the means recommends it. Sometimes it will be preferred merely for variety; and may be used to mark one point in a scene in which two or three points are already distinguished by clumps. It may occasionally be applied to most of the purposes for which clumps are used: may be an independent object; may interrupt a continued line, or decorate an extent of space. There is but one effect resulting from clumps which may not to a certain degree be produced by single trees: a number of them will never unite into one large mass; but more distant relations may be observed between them. Scattered about a lawn, they

Of single trees.

27
Uses and situations of independent clumps.

may cast it into an agreeable shape; and to produce that shape, each must be placed with an attention to the rest: they may stand in particular directions, and collectively form agreeable figures; or between several straggling trees little glades may open, full of variety and beauty. The lines they trace are fainter than those which larger plantations describe; but then their forms are their own: they are therefore absolutely free from all appearance of art; any disposition of them, if it be but irregular, is sure to be natural.

The situations of single trees is the first consideration, and differences in the distances between them their greatest variety. In shape, they admit of no choice but that which their species affords: greatness often, beauty often, sometimes mere solidity, and now and then peculiarity alone, recommends them. Their situations will also frequently determine the species. If they are placed before a continued line of wood only to break it, they should commonly be similar to the trees in that wood; they will else lose their connection, and not affect the outline which they are intended to vary; but if they are designed to be independent objects, they are as such more discernible when distinguished, both in their shapes and their greens, from any plantations about them. After all, the choice, especially in large scenes, is much confined to the trees on the spot. Young clumps from the first have some, and soon produce a considerable effect: but a young single tree for many years has none at all: and it is often more judicious to preserve one already growing, though not exactly such as might be wished, either in itself, or in its situation, than to plant in its stead another, which may be a finer object, and better placed, in a distant futurity.

SECT. III. *Of Water.*

30
Effects and
species of
water.

In considering the subjects of gardening, ground and wood first present themselves: water is the next; which, though not absolutely necessary to a beautiful composition, yet occurs so often, and is so capital a feature, that it is always regretted when wanting; and no large place can be supposed, a little spot can hardly be imagined, in which it may not be agreeable. It accommodates itself to every situation; is the most interesting object in a landscape, and the happiest circumstance in a retired recess; captivates the eye at a distance, invites approach, and is delightful when near: it refreshes an open exposure; it animates a shade; cheers the dreariness of a waste, and enriches the most crowded view. In form, in style, and in extent, it may be made equal to the greatest compositions, or adapted to the least: it may spread in a calm expanse to soothe the tranquillity of a peaceful scene; or, hurrying along a devious course, add splendor to a gay, and extravagance to a romantic, situation. So various are the characters which water can assume, that there is scarcely an idea in which it may not concur, or an impression which it cannot enforce. A deep stagnated pool, dank and dark with shades which it dimly reflects, befits the seat of melancholy; even a river, if it be sunk between two dismal banks, and dull both in motion and colour, is like a hollow eye, which deadens the countenance; and over a sluggish, silent stream, creeping heavily along all together, a gloom hangs, which no art can dissipate, nor even the sunshine disperse. A gently

murmuring rill, clear and shallow, just gurgling, just dimpling, imposes silence, suits with solitude, and leads to meditation: a brisker current, which wanders in little eddies over a bright sandy bottom, or babbles among pebbles, spreads cheerfulness all around: a greater rapidity, and more agitation, to a certain degree are animating; but in excess, instead of awakening, they alarm the senses: the roar and the rage of a torrent, its force, its violence, its impetuosity, tend to inspire terror; that terror which, whether as cause or effect, is so nearly allied to sublimity.

Abstracted, however, from all these ideas, from every sensation, either of depression, composure, or exertion; and considering water merely as an object; no other is so apt soon to catch, and long to fix, the attention. But it may want beauties of which we know it is capable, or the marks may be confused by which we distinguish its species; and these defects displease: to avoid them, the properties of each species must be determined.

All water is either *running*, or *stagnated*: when stagnated, it forms a *lake* or a *pool*, which differ only in extent; and a *pool* and a *pond* are the same. Running waters are either a *rivulet*, a *river*, or a *rill*; and these differ only in breadth: a *rivulet* and a *brook* are synonymous terms; a *stream* and a *current* are general names for all.

In a garden, the water is generally imitative. That which in the open country would be called a *great pond*, there assumes the name, and should be shaped as if it had the extent, of a lake; for it is large in proportion to the other parts of the place. Though sometimes a real river passes thro' a garden, yet still but a small portion of it is seen; and more frequently the semblance only of such a portion is substituted instead of the reality. In either case, the imitation is lost, if the characteristic distinctions between a lake and a river be not scrupulously preserved.

THE characteristic property of running water is *progress*; of stagnated, is *circuity*: the one stretches into length, the other spreads over space. But it is necessary that the whole circumference of a lake be seen, or that no bounds be set to the prospect of a river: on the contrary, the latter is never more beautiful than when it is lost in a wood, or retires behind a hill from the view: the former never appears so great as when its termination is concealed; the *shape*, not the *close*, denotes the character: if the opposite shores are both concave, they seem intended to surround, and to meet; if they are nearly parallel, they shew no tendency to come together, but suggest the idea of continuation.

To make both the banks of a river in concave forms is to sin against this first principle; and yet the fault is often committed, in order to increase the expanse. But when the bold sweep of a river is thus converted into an insignificant pool, more is lost to the imagination in length, than is gained to the view in breadth; and, paradoxical as the assertion may seem, it is certainly true, that the water would appear more important were it narrower. When one bank, therefore, retires, the other, if it does not advance, should, at the least, continue its former direction; or if that should be convex, it may be straitened; but both must not together depart from the appearance of progress.

Particular occasions may, however, justify a seeming

31
Differences
between a
lake and a
river.

ing deviation from the rule. To make room for an island, it may be proper to widen the river every way; for there the water is, in fact, intended to surround, and to meet; while the currents on each side preserve the principal character. The same liberty may also be allowed on the influx of a collateral stream; and the accession will account for both the breadth and for the shape: but the licence must here be used with moderation, lest the wide place become principal, and divide the river into two streams, the one falling into a pool, and the other issuing from it. Both the sides of a lake may at all times retire; but on such an accession, the increase should be chiefly on the shore opposite to the collateral stream, that it may appear to be a real enlargement of the lake, and not merely the mouth of a river.

A collateral stream should, in general, keep, or seem to keep, for some way, to nearly the same breadth: if it diminishes very fast, it must soon come to an end, and has more the appearance of a creek than of a stream. Whether it be the one or the other, may be matter of indifference when it falls into a lake; but a creek is seldom agreeable in a river; it diverts the current, its waters seem stagnated, it weakens the idea of progress.

All recesses in which the current is lost, are blemishes in a river. A bay is as exceptionable as a creek. Whatever be the form, if it be a receptacle, not a passage, it is a symptom that the water rather spreads than proceeds, and hurts the character of the river. But a head-land, which only turns or contracts the stream, though it make a sort of bay, is not liable to the same objection. Such a bay has a vent; such an obstruction only strengthens the current; they do not suggest the most distant idea of stagnation: It is almost needless to add, that in a lake, just the reverse of a river, creeks, bays, recesses of every kind, are always in character, sometimes necessary, and generally beautiful: the objections to them in the one, are recommendations of them to the other.

32
Of a lake.

Besides the circumstances, which have been mentioned, and in which a river and a lake essentially differ; besides those in which they agree, and which are too obvious to require illustration; there are some peculiar to each character, and which, though common in the one, can hardly occur in the other; at least, not so often, nor to that degree, as to become subjects of comparison.

Space is essential to a lake; it may spread to any extent; and the mind, always pleased to expand itself on great ideas, delights even in its vastness. A lake cannot be too large as a subject of description or of contemplation: but the eye receives little satisfaction when it has not a form on which to rest: the ocean itself hardly atones by all its grandeur for its infinity; and a prospect of it is, therefore, always most agreeable, when in some part, at no great distance, a reach of shore, a promontory, or an island, reduces the immensity into shape. If the most extensive view which can be the object of vision, must be restrained in order to be pleasing; if the noblest ideas, which the creation can suggest, must be checked in their career, before they can be reconciled to the principles of beauty; an offence against those principles, a transgression of that restraint, will not easily be forgiven on a subject less

than infinite: a lake whose bounds are out of sight, is circumscribed in reality, not in appearance; at the same time that it disappoints the eye, it confines the imagination; it is but a waste of waters, neither interesting nor agreeable.

A distant flat coast, dimly and doubtfully seen, does not obviate the objection; but it may be the means of removing it; for elevation and distinctness give an appearance of proximity, and contract the space they limit. This is the constant effect of a high shore: a low one, covered with wood, is in reality raised; and marked by buildings, becomes more conspicuous; it acquires an artificial elevation and distinctness.

These observations, though immediately relative to very large bodies of water, are still applicable to imitative lakes in parks and gardens. The principles upon which they are founded are equally true in both; and though an artificial lake cannot be supposed, which shall be absolutely, yet comparatively it may be extravagant. It may be so, out of proportion to its appendages, as to seem a waste of water; for all size is in some respects relative: if this exceeds its due dimensions, and if a flatness of shore beyond it adds still to the dreariness of the scene, wood to raise the banks, and objects to distinguish them, will, from the same cause, produce the same effects as on a larger scale. If the length of a piece of water be too great for its breadth, so as to destroy all idea of circuitry, the extremities should be considered as too far off, and made important, to give them proximity; while at the same time the breadth may be favoured, by keeping down the banks on the sides. On the same principle, if the lake be too small, a low shore will, in appearance, increase the extent.

But it is not necessary that the whole scene be bounded: if form be impressed on a considerable part, the eye can, without disgust, permit a large reach to stretch beyond its ken; it can even be pleased to observe a tremulous motion in the horizon, which shews that the water has not there yet attained its termination. Still short of this, the extent may be kept in uncertainty; a hill or a wood may conceal one of the extremities, and the country beyond it, in such a manner as to leave room for the supposed continuation of so large a body of water. Opportunities to choose this shape are frequent, and it is the most perfect of any; the scene is closed, but the extent of the lake is undetermined; a complete form is exhibited to the eye, while a boundless range is left open to the imagination.

But mere form will only give content, not delight: that depends upon the outline, which is capable of exquisite beauty; and the *bays*, and the *creeks*, and the *promontories*, which are ordinary parts of that outline, together with the accidents of *islands*, of *inlets* and of *outlets* to rivers, are in their shapes and their combinations an inexhaustible fund of variety.

A straight line of considerable length may find a place in that variety; and it is sometimes of singular use to prevent the semblance of a river in a channel formed between islands and the shore. But no figure perfectly regular ought ever to be admitted; it always seems artificial, unless its size absolutely forbid the supposition. A semicircular bay, though the shape be beautiful, is not natural; and any rectilinear figure is

abso-

absolutely ugly: but if one line be curved, another may sometimes be almost straight: the contrast is agreeable; and to multiply the occasions of shewing contrasts, may often be a reason for giving several directions to a creek, and more than two sides to a promontory.

Bays, creeks, and promontories, though extremely beautiful, should not, however, be very numerous: for a shore broken into little points and hollows has no certainty of outline; it is only ragged, not diversified; and the distinctness and simplicity of the great parts are hurt by the multiplicity of subdivisions. But islands, though the channels between them be narrow, do not so often derogate from greatness: they intimate a space beyond them whose boundaries do not appear; and remove to a distance the shore which is seen in perspective between them. Such partial interruptions of the sight suggest ideas of extent to the imagination.

The inlets and the outlets of rivers have similar effects: fancy pursues the course of the stream far beyond the view; no limits are fixed to its excursions. The greatest composition therefore of water is that which is in part a lake, and in part a river; which has all the expanse of the one, and all the continuation of the other, each being strongly characterised to the very point of their junction. If that junction break into a side of the lake, the direction of the river should be oblique to the line it cuts; rectangular bifurcations are in this, as in all other instances, formal: but when the conflux is at an angle, so that the bank of the river coincides with one shore of the lake, they should both continue for some way in the same direction; a deviation from that line immediately at the outlet detaches the lake from the river.

THOUGH the windings of a river are proverbially descriptive of its course; yet without being perpetually wreathed, it may be natural. Nor is the character expressed only by the turnings. On the contrary, if they are too frequent and sudden, the current is reduced into a number of separate pools, and the idea of progress is obscured by the difficulty of tracing it. Length is the strongest symptom of continuation: long reaches are, therefore, characteristic of a river; and they conduce much to its beauty: each is a considerable piece of water; and variety of beautiful forms may be given to their outlines; but a straight one can very seldom be admitted: it has the appearance of a cut canal, unless great breadth, a bridge across it, and strong contrasts between the objects on the banks, disguise the formality. A very small curvature obliterates every idea of art and stagnation; and a greater is often mischievous: for an excess of deviation from a straight towards a circular line, shortens the view, weakens the idea of continuation, and tho' not chargeable with stiffness, yet approaches to regularity; whereas the line of beauty keeps at a distance from every figure which a rule can determine or a compass describe.

A considerable degree of roundness is, however, often becoming, where the stream changes its direction: and if the turn be effected by a sharp point of land on one side, there is the more occasion for circuitry on the other. The river should also be widened under that other bank: for it is the nature of water thus driven out of its course, to dash and encroach up-

on the opposite shore. Where this circumstance has been attended to, the bend appears natural; and the view ending in space, gives scope to the imagination. The turn, therefore, ought generally to be larger than a right angle: if it be less, it closes immediately, and checks the idea of progress.

To further that idea is one use of bridges. Though they cross, they do not close the view: the water is seen to run through them, and is supposed to continue far beyond them: such a communication between the opposite banks implies the want of any other, and gives both length and depth to the stream. The form of a lake, on the contrary, intimates, that all the several shores are, by making a certain circuit, accessible. Bridges, therefore, are inconsistent with the nature of a lake, but characteristic of a river: they are on that account used to disguise a termination: but the deception has been so often practised, that it no longer deceives; and a bolder aim at the same effect will now be more successful. If the end can be turned just out of sight, a bridge at some distance raises a belief, while the water beyond it removes every doubt, of the continuation of the river: the supposition immediately occurs, that if a disguise had been intended, the bridge would have been placed further back; and the disregard thus shewn to one deception, gains credit for the other.

To give to bridges their full effect, the connection between them and the river must be attended to: from the want of it, the single wooden arch, now much in fashion, seems to us generally misplaced. Elevated, without occasion, so much above, it is totally detached from the river: it is often seen straddling in the air, without a glimpse of the water to account for it: and the ostentation of it as an ornamental object, diverts all that train of ideas which its use as a communication might suggest. The wateness of Walton bridge cannot without affectation be mimicked in a garden, where the magnificent idea of including the Thames under one arch is wanting, and where the structure itself reduced to a narrow scale retains no pretensions to greatness. Unless the situation make such a height necessary, or the point of view be greatly above it, or wood or rising ground instead of sky behind it, fill up the vacancy of the arch, it seems an effort without a cause, forced and preposterous.

The vulgar foot-bridge, of planks only, guarded on one hand by a common rail, and supported by a few ordinary piles, is often more proper. It is perfect as a communication, because it pretends to nothing further: it is the utmost simplicity of cultivated nature: and if the banks from which it starts be of a moderate height, its elevation preserves it from meanness. No other species so effectually characterises a river: it seems too plain for an ornament, too obscure for a disguise: it must be for use; it can be a passage only: it is therefore spoiled, if adorned; it is disguised, if only painted of any other than a dusky colour.

But being thus incapable of all decoration and importance, it is often too humble for a great, and too simple for an elegant, scene. A stone bridge is generally more suitable to either: but in this also, an extraordinary elevation is seldom becoming, unless the grandeur compensate for the distance at which it leaves the

Section III.
WATER.

A gentle rise, and easy sweep, more closely preserve the relation : a certain degree of union should also be formed between the banks and the bridge ; that it may seem to rise out of the banks, not barely to be imposed upon them. ' It ought not generally to swell much above their level ; the parapet wall should be brought down near to the ground, or end against some swell ; and the size and the uniformity of the abutments should be broken by hillocks or thickets about them : every expedient should be used to mark the connection of the building both with the ground from which it starts, and the water which it crosses.

In wild and romantic scenes may be introduced a ruined stone-bridge, of which some arches may be still standing, and the loss of those which are fallen may be supplied by a few planks, with a rail, thrown over the vacancy. It is a picturesque object ; it suits the situation ; and the antiquity of the passage, the care taken to keep it still open though the original building is decayed, the apparent necessity which thence results for a communication, give it an imposing air of reality.

In every scene of magnificence, in some where elegance chiefly prevails, a bridge with a colonnade, or other ornamental structure upon it, is characteristically proper, and it has a peculiarity which recommends it to many situations. The colonnade is alone a perfect independent object, which may belong to several species of buildings : it may, therefore, embellish a scene where no water is visible : but the sight must not be let down below the balustrade. If the arches appear, this is like other bridges shown by themselves : they may now and then be of use to mark a continuation of water, which would otherwise be doubtful ; but in general they only remind us of what is wanting to the view.

In some situations, two or three bridges may be admitted into one scene ; a collateral stream always, the turnings of the same stream often, afford opportunities to place them in several directions ; and a greater distinction between objects is seldom required, than that between two bridges, in construction exactly alike, one of which presents the passage over it, and the other that under it, to the eye. Such a variety of beautiful forms have besides been invented for them, that, in similar positions, they may be objects in very different styles : and collateral circumstances occasion still further distinctions. A bridge, which, by means of a bend in the river, is backed with wood or rising grounds, has, in the effect, little similarity to one through which nothing can be seen but the water and the sky : and if the accident which distinguishes, immediately groups with the bridge ; if, for instance, a tree, or a little cluster of trees, stand so that the stems appear beneath, the heads above the arches ; the whole is but one picturesque object, which retains no more than a distant resemblance to a bridge quite simple and unaccompanied. Amidst all this variety, two or three may easily be chosen, which, in the same landscape, so far from assimilating, will diversify the parts ; and, if properly disposed, neither in a confused crowd nor in a formal succession, will not encumber the view.

A RIVER requires a number of *accompaniments*. The

changes in its course furnish a variety of situations ; while the fertility, convenience, and amenity, which attend it, account for all appearances of inhabitants and improvement. Profusion of ornament on a fictitious river, is a just imitation of cultivated nature. Every species of building, every stile of plantation, may abound on the banks ; and whatever be their characters, their proximity to the water is commonly the happiest circumstance in their situation. A lustre is from thence diffused on all around ; each derives an importance from its relation to this capital feature : those which are near enough to be reflected, immediately belong to it ; those at a greater distance still share in the animation of the scene ; and objects totally detached from each other, being all attracted towards the same interesting connexion, are united into one composition.

In the front of Blenheim was a deep broad valley, which abruptly separated the cattle from the lawn and the plantations before it ; even a direct approach could not be made, without building a monstrous bridge over the vast hollow : but this forced communication was only a subject of railery ; and the scene continued broken into two parts, absolutely distinct from each other. This valley has been lately flooded : it is not filled ; the bottom only is covered with water : the sides are still very high ; but they are no longer the steep slopes of a chasm, they are the bold shores of a noble river. The same bridge is standing without alteration : but no extravagance remains ; the water gives it propriety. Above it the river first appears, winding from behind a small thick wood, in the valley ; and soon taking a determined course, it is then broad enough to admit an island filled with the finest trees : others, corresponding to them in growth and disposition, stand in groups on the banks, intermixed with younger plantations. Immediately below the bridge, the river spreads into a large expanse : the sides are open lawn. On that forthright from the house formerly stood the palace of Henry the Second, celebrated in many an ancient ditty by the name of Fair Rosamond's Bower. A little clear spring, which rises there, is by the country people still called Fair Rosamond's Well. The spot is now marked by a single willow. Near it, is a fine collateral stream, of a beautiful form, retaining its breadth as far as it is seen, and retiring at last behind a hill from the view. The main river, having received this accession, makes a gentle bend ; then continues for a considerable length in one wide direct reach ; and, just as it disappears, throws itself down a high cascade, which is the present termination. On one of the banks of this reach is the garden : the steep is there diversified with thickets and with glades ; but the covert prevails, and the top is crowned with lofty trees. On the other side is a noble hanging wood in the park : it was depreciated when it sunk into a hollow, and was poorly lost in the bottom ; but it is now a rich appendage to the river, falling down an easy slope quite to the water's edge, where, without overshadowing, it is reflected on the surface. Another face of the same wood borders the collateral stream, with an outline more indented and various ; while a very large irregular clump adorns the opposite declivity. This clump is at a considerable distance from the principal river : but the stream is

Section I.
WATER.

belongs to, brings it down to connect with the rest; and the other objects, which were before dispersed, are now, by the interest of each in a relation which is common to all, collected into one illustrious scene. The castle is itself a prodigious pile of building; which, with all the faults in its architecture, will never seem less than a truly princely habitation; and the confined spot where it was placed, on the edge of an abyss, is converted into a proud situation, commanding a beautiful prospect of water, and open to an extensive lawn, adequate to the mansion, and an emblem of its domain. In the midst of this lawn stands a column, a lately trophy, recording the exploits of the Duke of Marlborough, and the gratitude of Britain. Between this pillar and the castle is the bridge, which now, applied to a subject worthy of it, is established in all the importance due to its greatness. The middle arch is wider than the Rialto, but not too wide for the occasion; and yet this is the narrowest part of the river: but the length of the reaches is every where proportioned to their breadth: each of them is alone a noble piece of water: and the last, the finest of all, loses itself gradually in a wood, which, on that side, is also the boundary of the lawn, and rises into the horizon. All is great in the front of Blenheim: but in that vast space no void appears; so important are the parts, so magnificent the objects. The plain is extensive, the valley is broad, the wood is deep. Tho' the intervals between the buildings are large, they are filled with the grandeur which buildings of such dimensions and so much pomp diffuse all around them; and the river, in its long varied course, approaching to every object, and touching upon every part, spreads its influence over the whole. Notwithstanding their distances from each other, they all seem to be assembled about the water, which is every where a fine expanse, whose extremities are undetermined. In size, in form, and in style, it is equal to the majesty of the scene; and is designed in the spirit, is executed with the liberality, of the original donation, when this residence of a mighty monarch was bestowed by a great people, as a munificent reward on the hero who had deserved best of his country.

35
Of a river
flowing
through a
wood.

In the composition of this scene, the river, both as a part itself, and as uniting the other parts, has a principal share. But water is not lost, though it be in so confined or so concealed a spot as to enter into no view; it may render that spot delightful. It is capable of the most exquisite beauty in its form; and though not in space, may yet in disposition have pretensions to greatness: for it may be divided into several branches, which will form a cluster of islands all connected together, make the whole place irriguous, and, in the stead of extent, supply a quantity of water. Such a sequestered scene usually owes its retirement to the trees and the thickets with which it abounds; but in the disposition of them, one distinction should be constantly attended to. A river flowing through a wood which overpreads one continued surface of ground, and a river between two woods, are in very different circumstances. In the latter case, the woods are separate; they may be contrasted in their forms and their characters, and the outline of each should be forcibly marked. In the former, no outline ought to be discernible; for the river passes between trees, not

between boundaries; and though, in the progress of its course, the style of the plantations may be often changed, yet on the opposite banks a similarity should constantly prevail, that the identity of the wood may never be doubtful.

A river between two woods may enter into a view; and then it must be governed by the principles which regulate the conduct and the accompaniments of a river in an open exposure. But, when it runs through a wood, it is never to be seen in prospect: the place is naturally full of obstructions; and a continued opening, large enough to receive a long reach, would seem an artificial cut. The river must therefore necessarily wind more than in crossing a lawn, where the passage is entirely free; but its influence will never extend so far on the sides: the buildings must be near the banks; and, if numerous, will seem crowded, being all in one track, and in situations nearly alike. The scene, however, does not want variety: on the contrary, none is capable of more. The objects are not indeed so different from each other as in an open view; but they are very different, and in much greater abundance; for this is the interior of a wood, where every tree is an object, every combination of trees a variety, and no large intervals are requisite to distinguish the several dispositions; the grove, the thicket, or the groupes, may prevail, and their forms and their relations may be constantly changed, without restraint of fancy, or limitation of number.

Water is so universally and so deservedly admired in a prospect, that the most obvious thought in the management of it, is to lay it as open as possible, and purposely to conceal it would generally seem a severe self-denial: yet so many beauties may attend its passage through a wood, that larger portions of it might be allowed to such retired scenes, than are commonly spared from the view, and the different parts in different styles would be fine contrasts to each other. If the water at Wotton were all exposed, a walk of near two miles along the banks would be of a tedious length, from the want of those changes of the scene, which now supply through the whole extent a succession of Grenville's perpetual variety. That extent is so large as to admit of a division into four principal parts, all of them great in style and in dimensions, and differing from each other both in character and situation. The two first are the least. The one is a reach of a river, about the third of a mile in length, and of a competent breadth, flowing through a lovely mead, open in some places to views of beautiful hills in the country, and adorned in others with clumps of trees, so large, that their branches stretch quite across, and form a high arch over the water. The next seems to have been once a formal basin, encompassed with plantations, and the appendages on either side still retain some traces of regularity; but the shape of the water is free from them: the size is about 14 acres; and out of it issue two broad collateral streams, winding towards a large river, which they are seen to approach, and supposed to join. A real junction is however impossible, from the difference of the levels; but the terminations are so artfully concealed, that the deception is never suspected, and when known is not easily explained. The river is the third great division of the water; a lake into which it falls, is the fourth. These two do actually

36

usually join: but their characters are directly opposite; the scenes they belong to are totally distinct; and the transition from the one to the other is very gradual: for an island near the conflux, dividing the breadth, and concealing the end of the lake, moderates for some way the space; and permitting it to expand but by degrees, raises an idea of greatness, from uncertainty accompanied with increase. The reality does not disappoint the expectation; and the island, which is the point of view, is itself equal to the scene: it is large, and high above the lake; the ground is irregularly broken; thickets hang on the sides; and towards the top is placed an Ionic portico, which commands a noble extent of water, not less than a mile in circumference, bounded on one side with wood, and open on the other to two sloping lawns, the least of an hundred acres, diversified with clumps, and bordered by plantations. Yet this lake, when full in view, and with all the importance which space, form, and situation can give, is not more interesting than the sequestered river, which has been mentioned as the third great division of the water. It is just within the verge of a wood, three quarters of a mile long, every where broad, and its course is such as to admit of infinite variety without any confusion. The banks are cleared of underwood; but a few thickets still remain, and on one side an impenetrable covert soon begins: the interval is a beautiful grove of oaks, scattered over a green sward of extraordinary verdure. Between these trees and these thickets the river seems to glide gently along, constantly winding, without one short turn, or one extended reach, in the whole length of the way. This even temper in the stream suits the scenes through which it passes; they are in general of a very sober cast; not melancholy, but grave; never exposed to a glare; never darkened with gloom; nor, by strong contrasts of light and shade, exhibiting the excess of either. Undisturbed by an extent of prospects without, or a multiplicity of objects within, they retain at all times a mildness of character; which is still more forcibly felt when the shadows grow faint as they lengthen, when a little rustling of birds in the spray, the leaping of the fish, and the fragrant of the woodbine, denote the approach of evening; while the setting sun shoots its last gleams on a Tuscan portico, which is close to the great basin, but which from a seat near this river is seen at a distance, through all the obscurity of the wood glowing on the banks, and reflected on the surface of the water. In another still more distinguished spot is built an elegant bridge, with a colonnade upon it, which not only adorns the place where it stands, but is also a picturesque object to an octagon building near the lake, where it is shewn in a singular situation, over-arched, encompassed, and backed with wood, without any appearance of the water beneath. This building in return is also an object from the bridge; and a Chinese room, in a little island just by, is another: neither of them are considerable, and the others which are visible are at a distance, but more or greater adventitious ornaments are not required in a spot so rich as this in beauties peculiar to its character. A profusion of water pours in from all sides round upon the view; the opening of the lake appears; a glimpse is caught of the large basin; one of the collateral streams is full in sight, and the

bridge itself is in the midst of the finest part of the river: all seem to communicate the one with the other. Though thickets often intercept, and groupes perplex, the view, yet they never break the connection between the several pieces of water: each may still be traced along large branches, or little catches; which in some places are over-shadowed and dim; in others glitten through a glade, or glimmer between the boles of trees in a distant perspective; and in one, where they are quite lost to the view, some arches of a stone-bridge, but partially seen among the wood, preserve their connection. However interrupted, however varied, they still appear to be parts of one whole, which has all the intricacy of number, and the greatness of unity; the variety of a stream, and the quantity of a lake; the solemnity of a wood, and the animation of water.

If a large river may sometimes, a smaller current undoubtedly may often, be conducted through a wood: it seldom adorns, it frequently disfigures a prospect, where its course is marked, not by any appearance of water, but by a confused line of clotted grass, which disagrees with the general verdure. A rivulet may, indeed, have consideration enough for a home scene, though it be open; but a rill is always most agreeable when most retired from public view. Its characteristic excellencies are vivacity and variety, which require attention, leisure, and silence, that the eye may pore upon the little beauties, and the ear listen to the low murmurs of the stream without interruption. To such indulgence a confined spot only is favourable; a close copse is, therefore, often more acceptable than a high wood, and a sequestered valley at all times preferable to any open exposure: a single rill at a very little distance is a mere water-course; it loses all its charms; it has no importance in itself, and bears no proportion to the scene. A number of little streams have, indeed, an effect in any situation, but not as objects; they are interesting only on account of the character they express, the irrisuous appearance which they give to the whole.

The full tide of a large river has more force than activity, and seems too unwieldy to allow of very quick transitions. But in a rill, the agility of its motion accounts for every caprice: frequent windings disguise its insignificance: short turnings shew its vivacity: sudden changes in the breadth are a species of its variety: and however fantastically the channel may be wreathed, contracted, and widened, it still appears to be natural. We find an amusement in tracing the little stream through all the intricacies of its course, and in seeing it force a passage through a narrow freight, expatiate on every opportunity, struggle with obstructions, and puzzle out its way. A rivulet, which is the mean betwixt a river and a rill, partakes of the character of both: it is not licensed to the extravagance of the one, nor under the same restraints as the other: it may have more frequent bends than the river; longer reaches than a rill: the breadth of a stream determines whether the principal beauty results from extent or from variety.

The murmurs of a rill are amongst the most pleasing circumstances which attend it. If the bed of the stream be rough, mere declivity will occasion a constant rippling noise: when the current drops down a

37

a rivulet.

Section III.
WATER.Section IV.
ROCKS.

descent, though but of a few inches, or forcibly bubbles up from a little hollow, it has a deep gurgling tone, not uniformly continued, but incessantly repeated, and therefore more engaging than any. The flattest of all, is that found rather of the splashing than the fall of water, which an even gentle slope, or a tame obdruftion, will produce: this is less pleasing than the others; but none should be entirely excluded: all in their turns are agreeable; and the choice of them is much in our power: by observing their causes, we may often find the means to strengthen, to weaken, or to change them; and the addition or removal of a single stone, or a few pebbles, will sometimes be sufficient for the purpose.

39
Of cascades.

A rill cannot pretend to any sound beyond that of a little water-fall: the roar of a cascade belongs only to larger streams; but it may be produced by a rivulet to a considerable degree, and attempts to do more have generally been unsuccessful. A vain ambition to imitate nature in her great extravagancies betrays the weakness of art. Though a noble river, throwing itself headlong down a precipice, be an object truly magnificent, it must however be confessed, that in a single sheet of water there is a formality, which its vastness alone can cure; but the height, not the breadth, is the wonder: when it falls no more than a few feet, the regularity prevails; and its extent only serves to expose the vanity of affecting the style of a cataract in an artificial cascade. It is less exceptionable if divided into several parts: for then each separate part may be wide enough for its depth; and in the whole, variety, not greatness, will be the predominant character. But a structure of rough, large, detached stones, cannot easily be contrived of strength sufficient to support a great weight of water: it is sometimes from necessity almost smooth and uniform; and then it loses much of its effect: several little falls in succession are preferable to one great cascade which in figure or in motion approaches to regularity.

When greatness is thus reduced to number, and length becomes of more importance than breadth, a rivulet vies with a river; and it more frequently runs in a continued declivity, which is very favourable to such a succession of falls. Half the expence and labour which are sometimes bestowed on a river, to give it, at the best, a forced precipitancy, in one spot only, would animate a rivulet through the whole of its course: and, after all, the most interesting circumstance in falling waters is their animation. A great cascade fills us with surprise: but all surprise must cease; and the motion, the agitation, the rage, the froth, and the variety of the water, are finally the objects which engage the attention: for these a rivulet is sufficient; and they may there be produced without that appearance of effort which raises a suspicion of art.

To obviate such a suspicion, it may be sometimes expedient to begin the descent out of sight; for the beginning is the difficulty: if that be concealed, the subsequent falls seem but a consequence of the agitation which characterises the water at its first appearance; and the imagination is, at the same time, left loose to give ideal extent to the cascades. When a stream issues from a wood, such management will have a great effect: the bends of its course in an open expanse may afford frequent opportunities for it; and sometimes a

low broad bridge may furnish the occasion: a little fall hid under the arch will create a disorder; in consequence of which, a greater cascade below will appear very natural.

SECT. IV. Of Rocks.

RILLS, rivulets, and cascades, abound among rocks: they are natural to the scene; and such scenes commonly require every *accompaniment* which can be procured for them. Mere rocks, unless they are peculiarly adapted to certain impressions, may surprise, but can hardly please: they are too far removed from common life, too barren, and inhospitable; rather desolate than solitary, and more horrid than terrible. So austere a character cannot be long engaging, if its rigour be not softened by circumstances which may belong either to these or to more cultivated spots: and when the dreariness is extreme, little streams and water-falls are of themselves insufficient for the purpose; an intermixture of vegetation is also necessary, and on some occasions even marks of inhabitants are proper.

Middleton-dale is a cleft between rocks, ascending gradually from a romantic village, till it emerges, at about two miles distance, on the vast moor-lands of the Peake. It is a dismal entrance to a desert: the hills above it are bare; the rocks are of a grey colour; their surfaces are rugged, and their shapes savage; frequently terminating in craggy points, sometimes resembling vast unwieldy bulwarks, or rising in heavy buttresses one above another; and here and there a misshapen mass bulging out hangs lowering over its base. No traces of men are to be seen, except in a road which has no effect on such a scene of desolation, and in the lime-kilns constantly smoking on the side; but the labourers who occasionally attend them live at a distance; there is not a hovel in the dale; and some scanty withering bushes are all its vegetation: for the soil between the rocks produces as little as they do; it is disfigured with all the tinges of brown and red, which denote barrenness; in some places it has crumbled away, and strata of loose dark stones only appear; and in others, long lines of drofs and rubbish shoveled out of mines, have fallen down the steep. In these mines, the veins of lead on one side of the dale, are observed always to have corresponding veins, in exactly the same direction, on the other: and the rocks, though differing widely in different places, yet always continue in one style for some way together, and seem to have a relation to each other. Both these appearances make it probable, that Middleton-dale is a chasm rent in the mountain by some convulsion of nature, beyond the memory of man, or perhaps before the island was peopled: the scene, though it does not prove the fact, yet justifies the supposition; and it gives credit to the tales of the country people, who, to aggravate its horrors, always point to a precipice, down which they say that a poor girl of the village threw herself headlong, in despair, at the neglect of the man whom she loved; and shew a cavern, where a skeleton was once discovered, and of what wretch is unknown, his bones were the only memorial left of him. All the dreariness however of the place, which accords so well with such traditions, abates upon the junction of another valley, the sides of which are still of rock, but mixed and crowned with fine wood; and Middleton-dale becomes

39
Of the accompaniments of rocks.40
Description of Middleton-dale, (near Chatsworth.)

more

more mild by sharing in its beauties : near this junction a clear stream issues from under the hill, and runs down the dale, receiving as it proceeds many rills and springs, all as transparent as itself. The principal rivulet is full of little water-falls : they are sometimes continued in succession along a reach of considerable length, which is whitened with froth all the way ; at other times the brook wreathes in frequent windings, and drops down a step at every turn ; or slopes between tufts of grass, in a brisk, though not a precipitant descent ; when it is most quiet, a thousand dimples still mark its vivacity ; it is every where active, sometimes rapid, seldom silent, but never furious or noisy : the first impressions which it makes are of sprightliness and gaiety, very different from those which belong to the scene all around ; but by dwelling upon both, they are brought nearer together ; and a melancholy thought occurs, that such a stream should be lost in watering a walle ; the wilderness appears more forlorn which to much vivacity cannot enliven ; as the idea of desolation is heightened by reflecting that the

Flower is born to blith unseen,
And waste its sweetness on the desert air ;
and that

The nightingale attunes her notes,
Where none are left to hear.

If such a scene occurs within the precincts of a park or a garden, no expense should be spared to meliorate the soil, wherever any soil can be found. Without some vegetation among the rocks, they are only an object of curiosity, or a subject of wonder : but verdure alone will give some relief to the dreariness of the scene ; and shrubs or bushes, without trees, are a sufficiency of wood : the thickets may also be extended by the creeping plants, such as pyracantha, vines, and ivy, to wind up the sides, or cluster on the tops of the rocks. And to this vegetation may be added some symptoms of inhabitants, but they must be slight and few : the use of them is only to cheer, not to destroy, the solitude of the place ; and such therefore should be chosen as are sometimes found in situations retired from public resort ; a cottage may be lonely, but it must not here seem ruinous and neglected ; it should be tight and warm, with every mark of comfort about it, to which its position in some sheltered recess may greatly contribute. A cavity also in the rocks, rendered easy of access, improved to a degree of convenience, and maintained in a certain state of preservation, will suggest similar ideas of protection from the bitterest inclemencies of the sky, and even of occasional refreshment and repose. But we may venture still further : a mill is of necessity often built at some distance from the town which it supplies ; and here it would at the same time apply the water to a use, and increase its agitation. The dale may besides be made the haunt of those animals, such as goats, which are sometimes wild, and sometimes domestic ; and which accidentally appearing, will divert the mind from the sensations, natural to the scene, but not agreeable if continued long without interruption. These and such other expedients will approximate the severest retreat to the habitations of men, and convert the appearance of a perpetual banishment into that of a temporary retirement from society.

But too strong a force on the nature of the place al-

ways fails. A winding-path, which appears to be worn, not cut, has more effect than a high road, all artificial and level, which is too weak to overbear, and yet contradicts, the general idea. The objects therefore to be introduced must be those which hold a mean between solitude and population ; and the inclination of that choice towards either extreme, should be directed by the degree of wildness which prevails : for tho' that runs sometimes to an excess which requires correction, at other times it wants encouragement, and at all times it ought to be preferred : it is the predominant character of rocks, which mixes with every other, and to which all the appendages must be accommodated ; and they may be applied to as greatly to increase it : a licentious irregularity of wood and of ground, and a fantastic conduct of the streams, neither of which would be tolerated in the midst of cultivation, become and improve romantic spots ; even buildings, partly by their style, but still more by their position, in strange, difficult, or dangerous situations, distinguishing and aggravate the native extravagancies of the scene.

In the choice and the application of these accompaniments, consists all our power over rocks ; they are themselves too vain and too stubborn to submit to our controul ; but by the addition or removal of appendages, which we can command, parts may be shewn or concealed, and the characters with their impressions may be weakened or enforced : to adapt the accompaniments accordingly, is the utmost ambition of art when rocks are the subject.

Their most distinguished characters are, *dignity, terror, and fancy* : the expressions of all are constantly wild : and sometimes a rocky scene is only wild, without pretensions to any particular character.

THAT which inspires ideas of greatness, as distinguished from those of terror, has less wildness in it than any. There is a composure in dignity, which is disconcerted by quick transitions and the flutter of variety. A succession, therefore, of nearly the same forms, a repetition of them one above the other, do not derogate from an effect, which depends more on the extent than the changes of the scene : the dimensions which are necessary to produce that effect, contract the room for variety ; the parts must be large : if the rocks are only high, they are but stupendous, not majestic ; breadth is equally essential to their greatness ; and every slender, every grotesque shape, is excluded.

Art may interpose to shew these large parts to the eye, and magnify them to the imagination, by taking away thickets which stretch quite across the rocks, so as to disguise their dimensions ; or by filling with wood the small intervals between them, and thus, by concealing the want, preserving the appearance of continuation.

When rocks retire from the eye down a gradual declivity, we can, by raising the upper ground, deepen the fall, lengthen the perspective, and give both height and extent to those at a distance : this effect may be still increased by covering that upper ground with a thicket, which shall cease, or be lowered, as it descends.

A thicket, on other occasions, makes the rocks which rise out of it seem larger than they are. If they stand upon a bank overpread with shrubs, their beginning is at the least uncertain ; and the presumption is,

18 K 2 that

42

characteri-
sed by dig-
nity.

Section IV. that they start from the bottom.

ROCKS.

Another use of this brushy underwood is to conceal the fragments and rubbish which have fallen from the sides and the brow, and which are often unsightly. Rocks are seldom remarkable for the elegance of their forms; they are too vast, and too rude, to pretend to delicacy: but their shapes are often agreeable; and we can affect those shapes to a certain degree, at least we can cover many blemishes in them, by conducting the growth of shrubby and creeping plants about them.

For all these purposes mere underwood suffices: but for greater effects larger trees are requisite: they are worthy of the scene; and not only improvements, but accessions to its grandeur: we are used to rank them among the noblest objects of nature; and when we see that they cannot aspire to the midway of the heights around them, the rocks are raised by the comparison. A single tree is, therefore, often preferable to a clump: the size, though really less, is more remarkable: and clumps are besides generally exceptionable in a very wild spot, from the suspicion of art which attends them; but a wood is free from that suspicion, and its own character of greatness recommends it to every scene of magnificence.

On the same principle, all the consideration which can be, should be given to the streams. No number of little rills are equal to one broad river; and in the principal current, some varieties may be sacrificed to importance: but a degree of strength should always be preserved: the water, though it needs not be furious, should not be dull; for dignity, when most serene, is not languid; and space will hardly atone for want of animation.

The character, however, of greatness, when divested of terror, is placid. It does not, therefore, exclude marks of inhabitants, though it never requires them to tame its wildness: and without inviting, it occasionally admits an intermixture of vegetation. It even allows of buildings intended only to decorate the scene: but they must be adequate to it, both in size and in character. And if cultivation is introduced, that too should be conformable to the rest: not a single narrow patch cribbed out of the waste; but the confines of a country shelving into the vale, and suggesting the idea of extent: nothing trivial ought to find admittance. But, on the other hand, the character is not violated by a mixture of agreeableness with its grandeur; and far less is extravagance required to support it: strange shapes in extraordinary positions, enormous weights unaccountably sustained, trees rooted in the sides, and torrents raging at the foot of the rocks, are, at the best, needless excesses. There is a temperance in dignity, which is rather hurt by a wanton violence on the common order of nature. Great objects alone, great in their dimensions and in their style, are amply sufficient to satisfy and to fill the mind: when these fail, then, and then only, we are apt to have recourse to wonder, in order to excite admiration.

Many of the circumstances which have been mentioned concur at Matlock Bath, which is situated in a vale near three miles long, shut up at one end by a rising moor, and at the other end by vast cliffs of rock: the entrance into it is hewn through one of them, and is indeed a noble rude portal to a scene of romantic

magnificence. One side of the valley is a very high range of hill, rough with bushes, and great blocks or ledges of stone. The other side is washed by the Derwent, and consists chiefly of rocks; which, however, are often interrupted by steep declivities of green sward, large thickets, and gentle descents of fine fields from the adjacent country. The rocks sometimes form the brow, sometimes they fix the foot, and sometimes they break the sides, of the hill. At the high Tor they are 123 yards above the water: in other places they are no more than an abrupt bank of a few feet to the river: for the most part they are nearly perpendicular, falling in several stages, or in one vast precipice, from the top to the bottom. But though similar in shape, they are widely different in their construction: in one place they are irregularly jointed, in another, more uniformly ribbed, in a third they form a continued surface from the summit to the base, and frequently they are composed of enormous masses of stone heaped upon each other. From some such scene probably was conceived the wild imagination in ancient mythology of the giants piling Pelion upon Ossa: in this, all is vast; height, breadth, solidity, boldness of idea, and unity of style, combine to form a character of greatness, consistent throughout, not uniform, unmixed with any littleness, unallayed with any extravagance. The colour of the rocks is almost white; and their splendour is enhanced in many places by ivy and single yew-trees appearing amongst them: the intervals between them are generally filled with a brushy underwood, which diversifies and embellishes the scene very beautifully, but for want of large trees adds nothing to its grandeur; there are few of any note through out the vale: the best are in a small wood near the bath; but they are not adequate to the objects around them, to the steepness of the hill, the loftiness of the rocks, and the character of the Derwent. That character is, indeed, rather too strong for the place: in size, and in the direction of its course, the river is exactly such as might be wished; but it is a torrent, in which force and fury prevail: the cascades in it are innumerable; before the water is recovered from one fall, it is hurried down another; and its agitation being thus increased by repeated shocks, it pushes on with restless violence to the next, where it dashes against fragments of rocks, or foams among heaps of stones which the stream has driven together. The colour all along is of a reddish brown; even the foam is tinged with a dusky hue: and where there are no cascades, still the declivity of the bed preserves the rapidity, and a quantity of little breakers continue the turbulence of the current. Many of these circumstances are certainly great: but a more temperate river, rolling its full tide along with strength and activity, without rage; falling down one noble cascade, instead of many; and if animated sometimes by resistance, yet not constantly struggling with obstructions; would have been more consistent with the sedate steady dignity of these noble piles of rock, whose brightness, together with the verdure of a vigorous and luxuriant, though humble vegetation, and some appearances of culture, give to the whole an air of cheerful serenity, which is disturbed by the impetuosity of the Derwent.

This river would be better suited to a scene characterized by that terror, which the combination of greatness with force inspires, and which is animating and in-

43

ized by ter-
ror.

interesting, from the exertion and anxiety attending it. The terrors of a scene in nature are like those of a dramatic representation: they give an alarm; but the sensations are agreeable, so long as they are kept to such as are allied only to terror, unmixed with any that are horrible and disgusting. Art may therefore be used to heighten them, to display the objects which are distinguished by greatness, to improve the circumstances which denote force, to mark those which intimate danger, and to blend with all here and there a cast of melancholy.

Greatness is as essential to the character of terror as to that of dignity: vast efforts in little objects are but ridiculous; nor can force be supposed upon trifles incapable of resistance. On the other hand, it must be allowed, that exertion and violence supply some want of space. A rock wonderfully supported, or threatening to fall, acquires a greatness from its situation, which it has not in dimensions; so circumstanced, the size appears to be monstrous: a torrent has a consequence which a placid river of equal breadth cannot pretend to: and a tree, which would be inconsiderable in the natural soil, becomes important when it bursts forth from a rock.

Such circumstances should be always industriously sought for; it may be worth while to cut down several trees, in order to exhibit one apparently rooted in the stone. By the removal perhaps of only a little brush-wood, the alarming disposition of a rock, strangely undermined, rivetted, or suspended, may be shewn; and if there be any soil above its brow, some trees planted there, and impending over it, will make the object still more extraordinary. As to the streams, great alterations may generally be made in them: and therefore it is of use to ascertain the species proper to each scene, because it is in our power to enlarge or contract their dimensions; to accelerate or retard their rapidity; to form, increase, or take away obstructions; and always to improve, often to change, their characters.

Inhabitants furnish frequent opportunities to strengthen the appearances of force, by giving intimations of danger. A house placed at the edge of a precipice, any building on the pinnacle of a crag, makes that situation seem formidable, which might otherwise have been unnoticed: a steep, in itself not very remarkable, becomes alarming, when a path is carried almost up the side: a rail on the brow of a perpendicular fall, shews that the height is frequented and dangerous: and a common foot-bridge thrown over a cleft between rocks has a still stronger effect. In all these instances, the imagination immediately transports the spectator to the spot, and suggests the idea of looking down such a depth: in the last, that depth is a chasm, and the situation is directly over it.

In other instances, exertion and danger seem to attend the occupations of the inhabitants:

—Half way down

Hangs one that gathers sapphires; dreadful trade!

is a circumstance chosen by the great master of nature, to aggravate the terrors of the scene he describes. Mines are frequent in rocky places: and they are full of ideas suited to such occasions. To these may sometimes be added the operations of engines: for machinery, especially when its powers are stupendous or its effects formidable, is an effort of art which may be ac-

commodated to the extravagancies of nature.

A scene at the New Weir on the Wye, which in itself is truly great and awful, so far from being disturbed, becomes more interesting and important, by the business to which it is destined. It is a chasm between two high ranges of hill, which rise almost perpendicularly from the water; the rocks on the sides are mostly heavy masses, and their colour is generally brown: but here and there a pale craggy shape starts up to a vast height above the rest, unconnected, broken, and bare: large trees frequently force out their way amongst them: and many of them stand far back in the covert, where their natural dusky hue is deepened by the shadow which overhangs them. The river too, as it retires, loses itself in woods, which close immediately above, then rise thick and high, and darken the water. In the midst of all this gloom is an iron forge, covered with a black cloud of smoke, and surrounded with half-burned ore, with coal, and with cinders: the fuel for it is brought down a path, worn into steps narrow and steep, and winding among precipices: and near it is an open space of barren moor, about which are scattered the huts of the workmen. It stands close to the cascade of the Weir; where the agitation of the current is increased by large fragments of rocks, which have been swept down by floods from the banks, or shivered by tempests from the brow: and the sudden found, at stated intervals, from the strokes of the great hammers in the forge, deadens the roar of the waterfall. Just below it, while the rapidity of the stream still continues, a ferry is carried across it: and lower down the fishermen use little round boats, called *truckles*, the remains, perhaps, of the ancient British navigation, which the least motion will overset, and the slightest touch may destroy. All the employments of the people seem to require either exertion or caution: and the ideas of force or of danger which attend them, give to the scene an animation unknown in a solitary, though perfectly compatible with the wildest romantic situations.

But marks of inhabitants must not be carried to the length of cultivation, which is too mild for the ruggedness of the place, and has besides an air of cheerfulness inconsistent with the character of terror: a little inclination towards melancholy is generally acceptable, at least to the exclusion of all gaiety; and beyond that point, so far as to throw just a tinge of gloom upon the scene. For this purpose, the objects whose colour is obscure should be preferred; and those which are too bright may be thrown into shadow: the wood may be thickened, and the dark greens abound in it: if it is necessarily thin, yews and shabby firs should be scattered about it: and sometimes to shew a withering or a dead tree, it may for a space be cleared entirely away. All such circumstances are acquisitions, if they can be had without detriment to the principal character: for it must ever be remembered, that where terror prevails, melancholy is but a secondary consideration.

The different species of rocks often meet in the same place, and compose a noble scene, which is not distinguished by any particular character: it is only when one eminently prevails, that it deserves such a preference as to exclude every other. Sometimes a spot, remarkable for nothing but its wildness, is highly romantic: and when this wildness rises to fancy, when

the most singular, the most opposite forms and combinations are thrown together, then a mixture also of several characters adds to the number of instances which there concur to display the inexhaustible variety of nature.

So much variety, so much fancy, are seldom found within the same extent as in Dove-dale. It is about two miles in length, a deep, narrow, hollow valley: both the sides are of rock; and the Dove in its passage between them is perpetually changing its course, its motion, and appearance. It is never less than ten, nor so much as twenty yards wide, and generally about four feet deep; but transparent to the bottom, except when it is covered with a foam of the purest white; under water-falls which are perfectly lucid. These are very numerous, but very different. In some places they stretch straight across, or assant the stream: in others, they are only partial; and the water either dashes against the stones, and leaps over them, or, pouring along a steep, rebounds upon those below; sometimes it rushes through the several openings between them; sometimes it drops gently down; and at other times it is driven back by the obstruction, and turns into an eddy. In one particular spot, the valley almost closing, leaves hardly a passage for the river, which pent up, and struggling for a vent, rages and roars and foams, till it has extricated itself from the confinement. In other parts, the stream, though never languid, is often gentle; flows round a little desert island, glides between bits of bulrushes, disperses itself among tufts of grass or of moss, bubbles about a water-dock, or plays with the slender threads of aquatic plants which float upon the surface. The rocks all along the dale vary as often in their structure, as the stream in its motion. In one place, an extended surface gradually diminishes from a broad base almost to an edge; in another, a heavy top hanging forwards, overhangs all beneath: sometimes many different shapes are confusedly tumbled together; and sometimes they are broken into slender sharp pinnacles, which rise upright, often two or three together, and often in more numerous clusters. On this side of the dale, they are universally bare; on the other, they are intermixed with wood; and the vast height of both the sides, with the narrowness of the interval between them, produces a further variety: for whenever the sun shines from behind the one, the form of it is distinctly and completely cast upon the other; the rugged surface on which it falls diversifies the tints; and a strong reflected light often glares on the edge of the deepest shadow. The rocks never continue long in the same figure or situation, and are very much separated from each other: sometimes they form the sides of the valley, in precipices, in steep, or in stages; sometimes they seem to rise in the bottom, and lean back against the hill; and sometimes they stand out quite detached, heaving up in cumbrous piles, or starting into conical shapes, like vast spars, an 100 feet high; some are firm and solid throughout, some are cracked, and some, split and undermined, are wonderfully upheld by fragments apparently unequal to the weight they sustain. One is placed before, one over another, and one fills, at some distance behind, an interval between two. The changes in their disposition are infinite; every step produces some new combination;

they are continually crossing, advancing, and retiring: the breadth of the valley is never the same 40 yards together: at the narrow pafs which has been mentioned, the rocks almost meet at the top, and the sky is seen as through a chink between them: just by this gloomy abyss, is a wider opening, more light, more verdure, more cheerfulness, than any where else in the dale. Nor are the forms and the situations of the rocks their only variety: many of them are perforated by large natural cavities, some of which open to the sky, some terminate in dark recesses, and through some are to be seen several more uncouth arches, and rude pillars, all detached, and retiring beyond each other, with the light shining in between them, till a rock far behind them closes the perspective: the noise of the cascades in the river echoes amongst them; the water may often be heard at the same time gurgling near, and roaring at a distance; but no other sounds disturb the silence of the spot: the only trace of men is a blind path, but lightly and but seldom trodden, by those whose curiosity leads to see the wonders they have been told of Dove-dale. It seems, indeed, a fitter haunt for more ideal beings: the whole has the air of enchantment. The perpetual shifting of the scenes; the quick transitions, the total changes; then the forms all around, grotesque as chance can cast, wild as nature can produce, and various as imagination can invent; the force which seems to have been exerted to place some of the rocks where they are now fixed immovable, the magic by which others appear still to be suspended; the dark caverns, the illuminated recesses, the fleeting shadows, and the gleams of light glancing on the sides, or trembling on the stream; and the loneliness and the stillness of the place, all crowding together on the mind, almost realize the ideas which naturally present themselves in this region of romance and of fancy.

The solitude of such a scene is agreeable, on account of the endless entertainment which its variety affords, and in the contemplation of which both the eye and the mind are delighted to indulge: marks of inhabitants and cultivation would disturb that solitude; and ornamental buildings are too artificial in a place to absolutely free from restraint. The only accompaniments proper for it are wood and water; and by these sometimes improvements may be made. When two rocks similar in shape and position are near together, by skirting one of them with wood, while the other is left bare, a material distinction is established between them: if the streams be throughout of one character, it is in our power, and should be our aim, to introduce another. Variety is the peculiar property of the spot, and every accession to it is a valuable acquisition. On the same principle, endeavours should be used, not only to multiply, but to aggravate differences, and to increase distinctions into contrasts: but the subject will impose a caution against attempting too much. Art must almost despair of improving a scene, where nature seems to have exerted her invention.

SECT. V. Of Buildings.

BUILDINGS are the very reverse of rocks. They ⁴⁷ are absolutely in our power, both the species and the situation; and hence arises the excess in which they ^{often} often

Section IV.
BUILD-
INGS.

often abound. The desire of doing something, is stronger than the fear of doing too much: these may always be procured by expence, and bought by those who know not how to choose; who consider profusion as ornament, and confound by number instead of distinguishing by variety.

Buildings probably were first introduced into gardens merely for convenience, to afford refuge from a sudden shower, and shelter against the wind; or, at the most, to be seats for a party; or for retirement. They have since been converted into objects, and now the original use is too often forgotten in the greater purposes to which they are applied: they are considered as objects only; the inside is totally neglected, and a pompous edifice frequently wants a room barely comfortable. Sometimes the pride of making a lavish display to a visitor, without any regard to the owner's enjoyments, and sometimes too scrupulous an attention to the style of the structure, occasions a poverty and dulness within, which deprives the buildings of part of their utility. But in a garden they ought to be considered both as beautiful objects, and as agreeable retreats: if a character becomes them, it is that of the scene they belong to; not that of their primitive application. A Grecian temple or Gothic church, may adorn spots where it would be affectation to preserve that solemnity within, which is proper for places of devotion: they are not to be exact models, subjects only of curiosity or study; they are also seats: and such seats will be little frequented by the proprietor; his mind must generally be indisposed to so much simplicity, and so much gloom, in the midst of gaiety, richness, and variety.

But though the interior of buildings should not be disregarded, it is by their exterior that they become objects; and sometimes by the one, sometimes by the other, and sometimes by both, they are entitled to be considered as characters.

As objects, they are designed either to *distinguish*, or to *break*, or to *adorn*, the scenes to which they are applied.

The differences between one wood, one lawn, one piece of water, and another, are not always very apparent; the several parts of a garden would, therefore, often seem similar, if they were not distinguished by buildings: but these are so observable, so obvious at a glance, so easily retained in the memory, they mark the spots where they are placed with so much strength, they attract the relation of all around with so much power, that parts thus distinguished can never be confounded together. Yet it by no means follows, that therefore every scene must have its edifice: the want of one is sometimes a variety; and other circumstances are often sufficiently characteristic: it is only when these too nearly agree, that we must have recourse to buildings for differences: we can introduce, exhibit, or contrast them as we please: the most striking object is thereby made a mark of distinction; and the force of this first impression prevents our observing the points of resemblance.

The uniformity of a view may be broken by similar means, and on the same principle: when a wide heath, a dreary moor, or a continued plain, is in prospect, objects which catch the eye supply the want of variety: none are so effectual for this purpose as build-

ings. Plantations or water can have no very sensible effect, unless they are large or numerous, and almost change the character of the scene: but a small single building diverts the attention at once from the sameness of the extent; which it breaks, but does not divide; and diversifies, without altering, its nature. The design, however, must not be apparent. The merit of a cottage applied to this purpose, consists in its being free from the suspicion; and a few trees near it will both enlarge the object, and account for its position. Ruins are a hackneyed device immediately detected, unless their style be singular, or their dimensions extraordinary. The semblance of an ancient British monument might be adapted to the same end, with little trouble, and great success. The materials might be brick, or even timber plastered over, if stone could not easily be procured: whatever they were, the fallacy would not be discernible; it is an object to be seen at a distance, rude, and large, and in character agreeable to a wild open view. But no building ought to be introduced, which may not in reality belong to such a situation: no Grecian temples, no Turkish mosques, no Egyptian obelisks or pyramids; none imported from foreign countries, and unusual here. The apparent artifice would destroy an effect; which is so nice as to be weakened, if objects proper to produce it are displayed with too much ostentation; if they seem to be contrivances, not accidents; and the advantage of their position appear to be more laboured than natural.

But in a garden, where objects are intended only to adorn, every species of architecture may be admitted, from the Grecian down to the Chinese; and the choice is so free, that the mischief most to be apprehended, is an abuse of this latitude in the multiplicity of buildings. Few scenes can bear more than two or three; in some, a single one has a greater effect than any number: and a careless glimpse, here and there, of such as belong immediately to different parts, frequently enliven the landscape with more spirit than those which are indistinctly shewn. If the effect of a partial sight, or a distant view, were more attended to, many scenes might be filled, without being crowded; a greater number of buildings would be tolerated, when they seemed to be casual, not forced; and the animation, and the richness of the objects, might be had without pretence or display.

Too fond an ostentation of buildings, even of those which are principal, is a common error; and when all is done, they are not always shewn to the greatest advantage. Though their symmetry and their beauties ought in general to be distinctly and fully seen, yet an oblique is sometimes better than a direct view: and they are often less agreeable objects when entire, than when a part is covered, or their extent is interrupted; when they are bosomed in wood, as well as backed by it; or appear between the stems of trees which rise before or above them: thus thrown into perspective, thus grouped and accompanied, they may be as important as if they were quite exposed, and are frequently more picturesque and beautiful.

But a still greater advantage arises from this management, in connecting them with the scene: they are considerable, and different from all around them; inclined therefore to separate from the rest; and yet

they are sometimes still more detached by the pains taken to exhibit them: that very importance which is the cause of the distinction, ought to be a reason for guarding against the independence to which it is naturally prone, and by which an object, which ought to be a part of the whole, is reduced to a mere individual. An elevated is generally a noble situation. When it is a point or a pinnacle, the structure may be a continuation of the ascent; and on many occasions, some parts of the building may descend lower than others, and multiply the appearances of connection: but an edifice in the middle of an extended ridge, commonly seems naked alone, and imposed upon the brow, not joined to it. If wood, to accompany it, will not grow there, it had better be brought a little way down the declivity; and then all behind, above, and about it, are so many points of contact, by which it is incorporated into the landscape.

Accompaniments are important to a building; but they lose much of their effect, when they do not appear to be casual. A little mount just large enough for it: a small piece of water below, of no other use than to reflect it; and a plantation close behind, evidently placed there only to give it relief; are as artificial as the structure itself, and alienate it from the scene of nature into which it is introduced, and to which it ought to be reconciled. These appendages therefore should be so disposed, and so connected with the adjacent parts, as to answer other purposes, tho' applicable to this; that they may be bonds of union, not marks of difference; and that the situation may appear to have been chosen, at the most, not made, for the building.

In the choice of a situation, that which shews the building best ought generally to be preferred: eminence, relief, and every other advantage which can be, ought to be given to an object of so much consideration: they are for the most part desirable; sometimes necessary; and exceptionable only when, instead of rising out of the scene, they are forced into it, and a contrivance to procure them at any rate is avowed without any disguise. There are, however, occasions, in which the most tempting advantages of situation must be waved; the general composition may forbid a building in one spot, or require it in another; at other times, the interest of the particular groupe it belongs to, may exact a sacrifice of the opportunities to exhibit its beauties and importance; and at all times, the pretensions of every individual object must give way to the greater effect of the whole.

THE same structure which adorns as an object, may also be expressive as a character. Where the former is not wanted, the latter may be desirable: or it may be weak for one purpose, and strong for the other; it may be grave, or gay; magnificent, or simple; and, according to its style, may or may not be agreeable to the place it is applied to. But mere consistency is not all the merit which buildings can claim: their characters are sometimes strong enough to *determine, improve, or correct*, that of the scene; and they are so conspicuous, and so distinguished, that whatever force they have is immediately and sensibly felt. They are fit therefore to make a first impression; and when a scene is but faintly characterised, they give at once a cast which spreads over the whole, and which the weaker

parts concur to support, though perhaps they were not able to produce it.

Nor do they stop at fixing an uncertainty, or removing a doubt; they raise and enforce a character already marked: a temple adds dignity to the noblest, a cottage simplicity to the most rural, scenes; the lightness of a spire, the airiness of an open rotunda, the splendor of a continued colonnade, are less ornamental than expressive; others improve cheerfulness into gaiety, gloom into solemnity, and richness into profusion: a retired spot, which might have been passed unobserved, is noticed for its tranquillity, as soon as it is appropriated by some structure to retreat; and the most unfrequented place seems less solitary than one which appears to have been the haunt of a single individual, or even of a sequestered family, and is marked by a lonely dwelling, or the remains of a deserted habitation.

The means are the same, the application of them only is different, when buildings are used to correct the character of the scene; to enliven its dulness, mitigate its gloom, or to check its extravagance; and, on a variety of occasions, to soften, to aggravate, or to counteract, particular circumstances attending it. But care must be taken that they do not contradict too strongly the prevailing idea: they may lessen the dreariness of a waste, but they cannot give it amenity; they may abate horrors, but they will never convert them into graces; they may make a tame scene agreeable, and even interesting, not romantic; or turn solemnity into cheerfulness, but not into gaiety. In these, and in many other instances, they correct the character, by giving it an inclination towards a better, which is not very different; but they can hardly alter it entirely: when they are totally inconsistent with it, they are at the best nugatory.

The great effects which have been ascribed to buildings, do not depend upon those trivial ornaments and appendages, which are often too much relied on; such as the furniture of a hermitage, painted glass in a Gothic church, and sculpture about a Grecian temple; grotesque or bacchanalian figures to denote gaiety, and death's-heads to signify melancholy. Such devices are only descriptive, not expressive, of character; and must not be substituted in the stead of those superior properties, the want of which they acknowledge, but do not supply. They besides often require time to trace their meaning, and to see their application; but the peculiar excellence of buildings is, that their effects are instantaneous, and therefore the impressions they make are forcible. In order to produce such effects, the general style of the structure, and its position, are the principal considerations: either of them will sometimes be strongly characteristic alone; united, their powers are very great; and both are so important, that if they do not concur, at least they must not contradict one another. The colour also of the buildings is seldom a matter of indifference: that excessive brightness which is too indiscriminately used to render them conspicuous, is apt to disturb the harmony of the whole, sometimes makes them too glaring as objects, and is often inconsistent with their characters. When these essential points are secured, subordinate circumstances may be made to agree with them; and though minute, they may not

not be improper, if they are not affected; they frequently mark a correspondence between the outside and the inside of a building: in the latter they are not inconsiderable; they may there be observed at leisure, and there they explain in detail the character which is more generally expressed in the air of the whole.

To enumerate the several buildings which may be used for convenience, or distinction, as ornaments, or as characters, would lead us far from our subject into a treatise of architecture: for every branch of architecture furnishes, on different occasions, objects proper for a garden; and different species may meet in the same composition: no analogy exists between the age and the country whence they are borrowed, and the spot they are applied to, except in some particular instances; but, in general, they are naturalized to a place of the most improved cultivated nature by their effects: beauty is their life; and they are consistent with each other, if all are conformable to the style of the scene, proportioned to its extent, and agreeable to its character. On the other hand, varieties more than sufficient for any particular spot, enough for a very extensive view, may be found in every species; to each also belong a number of characters; the Grecian architecture can lay aside its dignity in a rustic building; and the caprice of the Gothic is sometimes not incompatible with greatness: our choice therefore may be confined to the variations of one species, or range through the contrails of many, as circumstances, taste, or other considerations, shall determine.

The choice of situations is also very free. Circumstances which are requisite to particular structures, may often be combined happily with others, and enter into a variety of compositions: even where they are appropriated, they may still be applied in several degrees, and the same edifice may thereby be accommodated to very different scenes. Some buildings which have a just expression when accompanied with proper appendages, have none without them; they may therefore be characters in one place, and only objects in another. On all these occasions, the application is allowable, if it can be made without inconsistency: a hermitage must not be close to a road; but whether it be exposed to view on the side of a mountain, or concealed in the depth of a wood, is almost a matter of indifference; that it is at a distance from public resort, is sufficient. A castle must not be sunk in a bottom; but that it should stand on the utmost pinnacle of a hill, is not necessary: on a lower knole, and backed by the rise, it may appear to greater advantage as an object, and be much more important to the general composition. A tower,

"Bosom'd high in tufted trees,"

has been selected by one of our greatest poets as a singular beauty; and the justness of his choice has been so generally acknowledged, that the description is become almost proverbial: and yet a tower does not seem designed to be surrounded by a wood; but the appearance may be accounted for: it does sometimes occur; and we are easily satisfied of the propriety, when the effect is so pleasing. Many buildings, which from their splendor best become an open exposure, will yet be sometimes not ill bestowed on a more se-

Vol. V.

questered spot, either to characterize or adorn it; and others, for which a solitary would in general be preferred to an eminent situation, may occasionally be objects in very conspicuous positions. A Grecian temple, from its peculiar grace and dignity, deserves every distinction; it may, however, in the depth of a wood, be so circumstanced, that the want of those advantages to which it seems entitled, will not be regretted. A happier situation cannot be devised, than that of the temple of Pan at the fourth lodge on Enfield chace. It is of the usual oblong form, encompassed by a colonnade; in dimensions, and in style, it is equal to a most extensive landscape: and yet by the antique and rustic air of its Doric columns without bases; by the chastity of its little ornaments, a crook, a pipe, and a serip, and those only over the doors; and by the simplicity of the whole both within and without; it is adapted with so much propriety to the thickets which conceal it from the view, that no one can wish it to be brought forward, who is sensible to the charms of the Arcadian scene which this building alone has created. On the other hand, a very spacious field, or sheep-walk, will not be disgraced by a cottage, a Dutch barn, or a hay-stack; nor will they, though small and familiar, appear to be inconsiderable or insignificant objects. Numberless other instances might be adduced to prove the impossibility of restraining particular buildings to particular situations, upon any general principles: the variety in their forms is hardly greater than in their application.

To this great variety must be added the many changes ⁵¹Of ruins. which may be made by the means of ruins. They are a class by themselves, beautiful as objects, expressive as characters, and peculiarly calculated to connect with appendages into elegant groupes. They may be accommodated with ease to irregularity of ground, and their disorder is improved by it. They may be intimately blended with trees and thickets; and the interruption is an advantage: for imperfection and obscurity are their properties; and to carry the imagination to something greater than is seen, is their effect. They may for any of these purposes be separated into detached pieces; contiguity is not necessary, nor even the appearance of it, if the relation be preserved; but straggling ruins have a bad effect; when the several parts are equally considerable. There should be one large mass to raise an idea of greatness, to attract the others about it, and to be a common centre of union to all: the smaller pieces then mark the original dimensions of one extensive structure; and no longer appear to be the remains of several little buildings.

All remains excite an inquiry into the former state of the edifice, and fix the mind in a contemplation of the use it was applied to; besides the characters expressed by their style and position, they suggest ideas which would not arise from the buildings if entire. The purposes of many have ceased: an abbey, or a castle, if complete, can now be no more than a dwelling; the memory of the times, and of the manners to which they are adapted, is preserved only in history, and in ruins; and certain sensations of regret, of veneration, or compassion, attend the recollection. Nor are these confined to the remains of buildings which are now in disuse: those of an old mansion raise

Section I.
ART.

reflections on the domestic comforts once enjoyed, and the ancient hospitality which reigned there. Whatever building we see in decay, we naturally contrast its present to its former state, and delight to ruminate on the comparison. It is true that such effects properly belong to real ruins; they are however produced in a certain degree by those which are fictitious: the impressions are not so strong, but they are exactly similar; and the representation, though it does not present facts to the memory, yet suggests subjects to the imagination. But, in order to affect the fancy, the supposed original design should be clear, the use obvious, and the form easy to be traced: no fragments should be hazarded without a precise meaning, and an evident connection; none should be perplexed in their construction, or uncertain as to their application. Conjectures about the form, raise doubts about the existence of the ancient structure: the mind must not be allowed to hesitate; it must be hurried away from examining into the reality, by the exactness and the force of the resemblance.

52
Description
of Tintern
abbey, [between
Chepstowe
and Monmouth.]

In the ruins of Tintern abbey, the original construction of the church is perfectly marked; and it is principally from this circumstance that they are celebrated as a subject of curiosity and contemplation. The walls are almost entire; the roof only is fallen in, but most of the columns which divided the aisles are still standing: of those which have dropped down, the bases remain, every one exactly in its place; and in the middle of the nave four lofty arches, which once supported the steeple, rise high in the air above all the rest, each reduced now to a narrow rim of stone, but completely preserving its form. The shapes even of the windows are little altered: but some of them are quite obscured, others partially shaded, by tufts of ivy; and those which are most clear, are edged with its slender tendrils, and lighter foliage, wreathing about the sides and the divisions: it winds round the pillars; it clings to the walls; and in one of the aisles clusters at the top in bunches, so thick and so large, as to darken the space below. The other aisles, and the great nave, are exposed to the sky: the floor is entirely overgrown with turf; and to keep it clear from weeds and bushes, is now its highest preservation. Monkish tomb-stones, and the monuments of benefactors long since forgotten, appear above the green sward; the

bases of the pillars which have fallen, rise out of it; Section I. ART. and maimed effigies, and sculpture worn with age and weather, Gothic capitals, carved cornices, and various fragments, are scattered about, or lie in heaps piled up together. Other shattered pieces, though disjointed and mouldering, still occupy their original places; and a stair-case much impaired, which led to a tower now no more, is suspended at a great height, uncovered and inaccessible. Nothing is perfect; but memorials of every part still subsist; all certain, but all in decay; and suggesting, at once, every idea which can occur in a seat of devotion, solitude, and desolation. Upon such models, fictitious ruins should be formed; and if any parts are entirely lost, they should be such as the imagination can easily supply from those which are still remaining. Distinct traces of the building which is supposed to have existed, are less liable to the suspicion of artifice, than an unmeaning heap of confusion. Precision is always satisfactory, but in the reality it is only agreeable; in the copy, it is essential to the imitation.

A material circumstance to the truth of the imitation, is, that the ruin appear to be very old. The idea is besides interesting in itself: a monument of antiquity is never seen with indifference; and a semblance of age may be given to the representation, by the hue of the materials, the growth of ivy and other plants, and cracks and fragments seemingly occasioned rather by decay than by destruction. An appendage evidently more modern than the principal structure will sometimes corroborate the effect: the shed of a cottager amidst the remains of a temple, is a contrast both to the former and to the present state of the building; and a tree flourishing among ruins, shews the length of time they have lain neglected. No circumstance so forcibly marks the desolation of a spot once inhabited, as the prevalence of nature over it:

“*Campes ubi Troja fuit,*”

is a sentence which conveys a stronger idea of a city totally overthrown, than a description of its remains; but in a representation to the eye, some remains must appear; and then the perversion of them to an ordinary use, or an intermixture of a vigorous vegetation, intimates a settled despair of their restoration.

PART II. OF THOSE PROPERTIES IN THE OBJECTS OF NATURE WHICH SHOULD DETERMINE THE CHOICE AND ARRANGEMENT OF THEM IN GARDENING.

SECT. I. *Of Art.*

THE several constituent parts of the scenes of nature having now been considered, the next inquiry is into the particular principles and circumstances which may affect them when they are applied to the subjects of gardening.

It has always been supposed, that *art* must then interfere: but art was carried to excess, when from accessory it became principal, and the subject upon which it was employed was brought under regulations less applicable to that than to any other; when ground, wood, and water, were reduced to mathema-

tical figures, and similarity and order were preferred to freedom and variety. These mischiefs, however, were occasioned, not by the use, but the perversion of art; it excluded, instead of improving upon nature, and thereby destroyed the very end it was called in to promote.

So strange an abuse probably arose from an idea of some necessary correspondence between the mansion, and the scene it immediately commanded: the forms, therefore, of both were determined by the same rules; and terraces, canals, and avenues, were but so many variations of the plan of the building. The regularity thus established spread afterwards to more distant

54
Of the appearance of art near the house.

distant quarters: there, indeed, the absurdity was acknowledged as soon as a more natural disposition appeared; but a prejudice in favour of art, as it is called, *just about the house*, still remains. If, by the term, *regularity* is intended, the principle is equally applicable to the vicinity of any other building; and every temple in the garden ought to have its concomitant formal slopes and plantations: or the conformity may be reversed, and we may as reasonably contend, that the building ought to be irregular, in order to be consistent with the scene it belongs to. The truth is, that both propositions are erroneous: architecture requires symmetry; the objects of nature freedom; and the properties of the one cannot with justice be transferred to the other. But if, by the term, no more is meant than merely *design*, the dispute is at an end: choice, arrangement, composition, improvement, and preservation, are so many symptoms of art, which may occasionally appear in several parts of a garden, but ought to be displayed without reserve near the house: nothing there should seem neglected; it is a scene of the most cultivated nature; it ought to be enriched, it it ought to be adorned; and design may be avowed in the plan, and expence in the execution.

Even regularity is not excluded: so capital a structure may extend its influence beyond its walls: but this power should be exercised only over its immediate appendages. The platform upon which the house stands, is generally continued to a certain breadth on every side; and, whether it be pavement or gravel, may undoubtedly coincide with the slope of the building. The road which leads up to the door may go off from it in an equal angle, so that the two sides shall exactly correspond: and certain ornaments, though detached, are yet rather within the province of architecture than of gardening. Works of sculpture are not, like buildings, objects familiar in scenes of cultivated nature; but vases, statues, and termini, are usual appendages to a considerable edifice: as such, they may attend the mansion, and trespass a little upon the garden, provided they are not carried so far into it as to lose their connection with the structure. The platform and the road are also appurtenances to the house; all these may therefore be adapted to its form, and the environs will thereby acquire a degree of regularity: but to give it to the objects of nature, only on account of their proximity to others which are calculated to receive it, is, at the best, a refinement.

§§
Of the approach.

UPON the same principles regularity has been required in the *approach*; and an additional reason has been assigned for it, that the idea of a seat is thereby extended to a distance. But that may be done by other means than by an avenue. A private road is easily known. If carried through grounds, or a park, it is commonly very apparent: even in a lane, here and there a bench, a painted gate, a small plantation, or any other little ornament, will sufficiently denote it: if the entrance only be marked, simple preservation will retain the impression along the whole progress. Or the road may wind through several scenes distinguished by objects, or by an extraordinary degree of cultivation; and then the length of the way, and the variety of improvements through which it is conducted, may extend the appearance of domain, and the idea of a seat, beyond the reach of any direct avenue.

An avenue being confined to one termination, and excluding every view on the sides, has a tedious sameness throughout: to be great, it must be dull; and the object to which it is appropriated, is after all seldom shown to advantage. Buildings, in general, do not appear so large, and are not so beautiful, when looked at in front, as when they are seen from an angular situation, which commands two sides at once, and throws them both into perspective. But a winding lateral approach is free from these objections; it may besides be brought up to the house without disturbing any of the views from it: but an avenue cuts the scenery directly in two, and reduces all the prospect to a narrow vista. A mere line of perspective, be the extent what it may, will seldom compensate for the loss of that space which it divides, and of the parts which it conceals.

The approach to Caversham, though a mile in length, and not once in sight of the house till close upon it, yet can never be mistaken for any other way than it is; a passage only through a park is not introduced with so much distinction, so precisely marked, or kept in such preservation. On each side of the entrance is an elegant lodge: the interval between them is a light open pallisade, crossing the whole breadth of a lovely valley: the road is conducted along the bottom, continually winding in natural easy sweeps, and presenting at every bend some new scene to the view: at last it gently slants up the side of a little rise to the mansion, where the eminence, which seemed considerable, is found to be a very elevated situation, to which the approach, without once quitting the valley, had been insensibly ascending all the way. In its progress, it never breaks the scenes through which it passes: the plantations and the glades are continued without interruption, quite across the valley: the opposite sides have a relation to each other, not answering, not contrasted, but connected: nor does the disposition ever seem to have been made with any attention to the road; but the scenes fill belong purely to the park; each of them is preserved entire, and avails itself of all the space which the situation will allow. At the entrance the slopes are very gentle, with a few large hawthorns, beeches, and oaks, scattered over them: these are thickened by the perspective as the valley winds; and just at the bend, a large clump hangs on a bold ascent, from whence different groups, growing gradually less and less till they end in single trees, stretch quite away to a fine grove which crowns the opposite brow. The road passes between the groups, under a light and lofty arch of ash; and then opens upon a glade, broken on the left only by a single tree, and on the right by several beeches standing so close together as to be but one in appearance. This glade is bounded by a beautiful grove, which in one part spreads a perfect gloom, but in others divides into different clusters, which leave openings for the gleams of light to pour in between them. It extends to the edge, and borders for some way the side of a collateral dale, which retires slowly from the view; and in which the falls of the ground are more tame, the bottom more flattened, than in the principal valley; the banks of this also, near the junction, are more gentle than before: but on the opposite side, the steep and the clumps still continue; and amongst them is a fine knole, from

Section I.
Art.

which descend two or three groups of large trees, feathering down to the bottom, and by the tendency of their branches favouring the declivity. To these succeeds an open space, diversified only by a few scattered trees; and in the midst of it, some magnificent beeches crowding together, overshadow the road, which is carried through a narrow darksome passage between them: soon after it rises under a thick wood in the garden up to the house, where it suddenly bursts out upon a rich and extensive prospect, with the town and the churches of Reading in full sight, and the hills of Windsor-forest in the horizon. Such a view at the end of a long avenue, would have been, at the best, but a compensation for the tediousness of the way; but here the approach is as delightful as the termination. Yet even in this, a similarity of style may be said to prevail. But it has every variety of open plantations; and these are not confusedly thrown together, but formed into several scenes, all of them particularly marked: one is characterized by a grove, the next by clumps, and others by little groups or single trees: the plantations sometimes cover only the brow, and retire along the top from the view; sometimes they seem to be suspended on the edge or the sides of the descents; in one place they leave the bottom clear, in another they overpread the whole valley: the intervals are often little less than lawns; at other times they are no more than narrow glades between the groves, or only small openings in the midst of a plantation. The ground, without being broken into diminutive parts, is cast into an infinite number of elegant shapes, in every gradation from the most gentle slope, to a very precipitate fall: the trees also are of several kinds, and their shadows of various tints; those of the horse-chestnuts are dark; the beeches spread a broader but less gloomy obscurity; and they are often so vast, they swell out in a succession of such enormous masses, that, though contiguous, a deep shade sinks in between them, and distinguishes each immense individual: such intervals are in some places filled up with other species; the maples are of so extraordinary a size, that they do not appear inconsiderable, when close to the forest-trees; large hawthorns, some oaks, and in one part many, perhaps too many limes, the remains of former avenues, are intermixed; and amongst all these often rise the tallest ash, whose lighter foliage only chequers the turf beneath, while their peculiar hue diversifies the greens of the groups they belong to.

If regularity is not entitled to a preference in the environs or approach to a house, it will be difficult to support its pretensions to a place in any more distant parts of a park or a garden. Formal slopes of ground are ugly: right or circular lines bounding water, do not indeed change the nature of the element; it still retains some of its agreeable properties; but the shape given to it is disgusting. Regularity in plantations is less offensive; we are habituated, as has been already observed, to straight lines of trees, in cultivated nature; a double row, meeting at the top, and forming a complete arched vista, has a peculiar effect; other regular figures have a degree of beauty: and to alter or to dissolve such a disposition, without destroying a number of fine trees, which cannot well be spared, may sometimes be difficult; but it hardly ever ought to be chosen in the arrangement of a young plantation.

Regularity was, however, once thought essential to every garden, and every approach; and it yet remains in many. It is still a character, denoting the neighbourhood of a gentleman's habitation; and an avenue, as an object in a view, gives to a house, otherwise inconsiderable, the air of a mansion. Buildings which answer one another at the entrance of an approach, or on the sides of an opening, have a similar effect; they distinguish at once the precincts of a seat from the rest of the country. Some pieces of sculpture also, such as vases and termini, may perhaps now and then be used, to extend the appearance of a garden beyond its limits, and to raise the mead in which they are placed above the ordinary improvements of cultivated nature. At other times they may be applied as ornaments to the most polished lawns; the traditional ideas we have conceived of Arcadian scenes, correspond with such decorations: and sometimes a solitary urn, inscribed to the memory of a person now no more, but who once frequented the shades where it stands, is an object equally elegant and interesting. The occasions, however, on which we may, with any propriety, trespass beyond the bounds of cultivated nature, are very rare; the force of the character can alone excuse the artifice avowed in expressing it.

SECT. II. Of Picturesque Beauty.

BUT regularity can never attain to a great share of beauty, and to none of the species called *picturesque*; a denomination in general expressive of excellence, but which, by being too indiscriminately applied, may be sometimes productive of errors. That a subject is recommended at least to our notice, and probably to our favour, if it has been distinguished by the pencil of an eminent painter, is indisputable: we are delighted to see those objects in the reality, which we are used to admire in the representation; and we improve upon their intrinsic merit, by recollecting their effects in the picture. The greatest beauties of nature will often suggest the remembrance; for it is the business of a landscape painter to select them: and his choice is absolutely unrestrained; he is at liberty to exclude all objects which may hurt the composition; he has the power of combining those which he admits in the most agreeable manner; he can even determine the season of the year, and the hour of the day, to shew his landscape in whatever light he prefers. The works therefore of a great master, are fine exhibitions of nature, and an excellent school wherein to form a taste for beauty: but still their authority is not absolute; they must be used only as studies, not as models; for a picture and a scene in nature, though they agree in many, yet differ in some particulars, which must always be taken into consideration, before we can decide upon the circumstances which may be transferred from the one to the other.

In their *dimensions* the distinction is obvious; the same objects on different scales have very different effects; those which seem monstrous on the one, may appear diminutive on the other; and a form, which is elegant in a small object, may be too delicate for a large one. Besides, in a canvas of a few feet, there is not room for every species of variety which in nature is pleasing. Though the characteristic distinction of trees may be marked, their more minute differences,

58
Of the different effects from the same objects in a scene and a picture.

57
Of regularity in the several parts of a garden.

which

which however enrich plantations, cannot be expressed: and a multiplicity of enclosures, catches of water, cottages, cattle, and a thousand other circumstances, which enliven a prospect, are, when reduced into a narrow compass, no better than a heap of confusion. Yet, on the other hand, the principal objects must often be more diversified in a picture than in a scene: a building which occupies a considerable portion of the former, will appear small in the latter when compared to the space all around it; and the number of parts which may be necessary to break its sameness in one, will aggravate its insignificance in the other. A tree which presents one rich mass of foliage, has sometimes a fine effect in nature; but when painted, is often a heavy lump, which can be lightened only by separating the boughs, and shewing the ramifications between them. In several other instances the object is frequently affected by the proportion it bears to the actual, not the ideal, circumjacent extent.

Painting, with all its powers, is still more unequal to some subjects, and can give only a *faint, if any, representation* of them: but a gardener is not therefore to reject them: he is not debarred from a view down the sides of a hill, or a prospect where the horizon is lower than the station, because he never saw them in a picture. Even when painting exactly imitates the appearances of nature, it is often weak in conveying the *ideas* which they excite, and on which much of their effect sometimes depends. This however is not always a disadvantage; the appearance may be more pleasing than the idea which accompanies it, and the omission of the one may be an improvement of the other. Many beautiful tints denote disagreeable circumstances: the hue of a barren heath is often finely diversified; a piece of bare ground is sometimes overpread with a number of delicate shades; and yet we prefer a more uniform verdure to all their variety. In a picture, the several tints which occur in nature may be blended, and retain only their beauty, without suggesting the poverty of the soil which occasions them: but in the reality, the cause is more powerful than the effect: we are less pleased with the sight, than we are hurt by the reflection; and a most agreeable mixture of colours may prevent no other idea than of dreariness and sterility.

On the other hand, *utility* will sometimes supply the want of beauty in the reality, but not in a picture. In the former, we are never totally inattentive to it; we are familiarised to the marks of it; and we allow a degree of merit to an object which has no other recommendation. A regular building is generally more agreeable in a scene than in a picture, and an adjacent platform, if evidently convenient, is tolerable in the one; it is always a right line too much in the other. Utility is at the least an excuse, when it is real; but it is an idea never included in the representation.

Many more instances might be alleged to prove, that the subjects for a painter and a gardener are not always the same. Some which are agreeable in the reality, lose their effect in the imitation; and others, at the best, have less merit in a scene than in a picture. The term *picturesque* is therefore applicable only to such objects in nature, as, after allowing for the differences between the arts of painting and of gardening, are fit to be formed into groupes, or to enter into a composition where the several parts have a relation

to each other, and in opposition to those which may be spread abroad in detail, and have no merit but as individuals.

SECT. III. *Of Character.*

CHARACTER is very reconcilable with beauty; and, even when independent of it, has attracted so much regard, as to occasion several frivolous attempts to produce it: statues, inscriptions, and even paintings, history and mythology, and a variety of devices, have been introduced for this purpose. The heathen deities and heroes have therefore had their several places assigned to them in the woods and the lawns of a garden: natural cascades have been disfigured with rivers; and columns erected only to receive quotations: the compartments of a summer-house have been filled with pictures of gambols and revels, as significant of gaiety: the cypresses, because it was once used in funerals, has been thought peculiarly adapted to melancholy: and the decorations, the furniture, and the environs of a building, have been crowded with puerilities under pretence of propriety. All these devices are rather *emblematical* than expressive: they may be ingenious contrivances, and recall absent ideas to the recollection; but they make no immediate impression: for for they must be examined, compared, perhaps explained, before the whole design of them is well understood: and though an allusion to a favourite or well-known subject of history, of poetry, or of tradition, may now and then animate or dignify a scene; yet as the subject does not naturally belong to a garden, the allusion should not be principal: it should seem to have been suggested by the scene; a transitory image, which irresistibly occurred; not fought for, not laboured; and have the force of a metaphor, free from the detail of an allegory.

ANOTHER species of character arises from direct *imitation*; when a scene or an object, which has been celebrated in description, or is familiar in idea, is represented in a garden. Artificial ruins, lakes, and rivers, fall under this denomination. The air of a seat extended to a distance, and scenes calculated to raise ideas of Arcadian elegance or of rural simplicity, with many more which have been occasionally mentioned or will obviously occur, may be ranked in this class. They are all representations. But the materials, the dimensions, and other circumstances, being the same in the copy and the original, their effects are similar in both: and if not equally strong the defect is not in the resemblance; but the consciousness of an imitation checks that train of thought which the appearance naturally suggests. Yet an over-anxious solicitude to disguise the fallacy is often the means of exposing it: too many points of likeness sometimes hurt the deception; they seem studied and forced; and the affectation of resemblance destroys the supposition of a reality. A hermitage is the habitation of a recluse; it should be distinguished by its solitude, and its simplicity: but if it is filled with crucifixes, hour-glasses, beads, and every other trinket which can be thought of, the attention is diverted from enjoying the retreat to examining the particulars: all the collateral circumstances which agree with a character, seldom meet in one subject; and when they are indistinctly brought together, though each be natural, the collection is artificial.

59
Of emblematical
characters.

60
Of imitative
characters.

The peculiar advantages which gardening has over other imitative arts, will not, however, support attempts to introduce, they rather forbid the introduction of characters, to which the space is not adequate. A plain simple field, unadorned but with the common rural appendages, is an agreeable opening; but if it is extremely small, neither a hay-stack, nor a cottage, nor a stile, nor a path, nor much less all of them together, will give it an air of reality. A harbour or an artificial lake is but a conceit: it raises no idea of refuge or security; for the lake does not suggest an idea of danger: it is detached from the large body of water; and yet it is in itself but a poor inconsiderable basin, vainly affecting to mimic the majesty of the sea. When imitative characters in gardening are egregiously defective in any material circumstance, the truth of the other things exposes and aggravates the failure.

61
Of original
characters.

BUT the art of gardening aspires to more than imitation: it can create *original* characters, and give expressions to the several scenes superior to any they can receive from allusions. Certain properties, and certain dispositions, of the objects of nature, are adapted to excite particular ideas and sensations: many of them have been occasionally mentioned; and all are very well known. They require no discernment, examination, or discussion; but are obvious at a glance, and instantaneously distinguished by our feelings. Beauty alone is not so engaging as this species of character: the impressions it makes are more transient and less interesting; for it aims only at delighting the eye, but the other affects our sensibility. An assemblage of the most elegant forms in the happiest situations is to a degree indiscriminate, if they have not been selected and arranged with a design to produce certain expressions; an air of magnificence, or of simplicity, of cheerfulness, tranquillity, or some other general character, ought to pervade the whole; and objects pleasing in themselves, if they contradict that character, should therefore be excluded: those which are only indifferent, must sometimes make room for such as are more significant; many will often be introduced for no other merit than their expression; and some, which are in general rather disagreeable, may occasionally be recommended by it. Barrenness itself may be an acceptable circumstance in a spot dedicated to solitude and melancholy.

The power of such characters is not confined to the ideas which the objects immediately suggest; for these are connected with others, which insensibly lead to subjects, far distant, perhaps, from the original thought, and related to it only by a similitude in the sensations they excite. In a prospect, enriched and enlivened with inhabitants and cultivation, the attention is caught at first by the circumstances which are gayest in their season, the bloom of an orchard, the festivity of a hay-field, and the carols of harvest-home: but the cheerfulness which these infuse into the mind, expands afterwards to other objects than those immediately presented to the eye; and we are thereby disposed to receive, and delighted to pursue, a variety of pleasing ideas, and every benevolent feeling. At the sight of a ruin, reflections on the change, the decay, and the desolation before us, naturally occur; and they introduce a long succession of others, all tinged with that melancholy which these have inspired:

or if the monument revive the memory of former times, we do not stop at the simple fact which it records, but recollect many more coeval circumstances, which we see, not perhaps as they were, but as they are come down to us, venerable with age, and magnified by fame. Even, without the assistance of buildings, or other adventitious circumstances, nature alone furnishes materials for scenes which may be adapted to almost every kind of expression: their operation is general, and their consequences infinite: the mind is elevated, depressed, or composed, as gaiety, gloom, or tranquillity, prevail in the scene; and we soon lose sight of the means by which the character is formed: we forget the particular objects it presents; and giving way to their effects, without recurring to the cause, we follow the track they have begun, to any extent which the disposition they accord with will allow. It suffices that the scenes of nature have a power to affect our imagination and our sensibility: for such is the constitution of the human mind, that if once it is agitated, the emotion often spreads far beyond the occasion; when the passions are roused, their course is unrestrained; when the fancy is on the wing, its flight is unbounded; and, quitting the inanimate objects which first gave them their spring, we may be led by thought above thought, widely differing in degree, but still corresponding in character, till we rise from familiar subjects up to the sublimest conceptions, and are rapt in the contemplation of whatever is great or beautiful, which we see in nature, feel in man, or attribute to divinity.

SECT. IV. Of the General Subject.

THE scenes of nature are also affected by the general subject to which they are applied, whether that be a *farm*, a *garden*, a *park*, or a *riding*. These may all indeed be parts of one place; they may border on each other; they may, to a degree, be intermixed; but each is still a character of such force, that, whichever prevails, the propriety of all other characters, and of every species of beauty, must be tried by their conformity to this. And circumstances necessary to one, may be incongruities in the rest: *elegance* is the peculiar excellence of a garden, *greatness* of a park, *simplicity* of a farm, and *pleasantness* of a riding. These distinguishing properties will alone exclude from the one, many objects which are very acceptable in the others; but these are not the only properties in which they essentially differ.

A garden is intended to walk or to sit in, which are circumstances not considered in a riding; a park comprehends all the uses of the other two; and these uses determine the *proportional extent* of each. A large garden would be but a small park; and the circumference of a considerable park but a short riding. A farm is in some measure denominated from its size: if it greatly exceed the dimensions of a garden, so that its bounds are beyond the reach of a walk, it becomes a riding. A farm and a garden hence appear to be calculated for indolent, a riding for active amusements, and a park for both: seats, therefore, and buildings for refreshment or indulgence, should be frequent in a garden or a farm; should sometimes occur in a park; but are unnecessary in a riding.

Within the narrow compass of a garden, there is
not

62

den, a park
and a ri-
ding.

Section IV.
GENERAL
SUBJECT

Section V.
GARDEN.

not room for *distant effects*. On the other hand, it allows of objects which are striking only in a *single point of view*; for we may stop there to contemplate them: and an obscure catch, or a partial glimpse of others, are also acceptable circumstances, in the leisure of a seat, or even in the course of a loitering walk. But these are lost in a riding, where the pleasantness of the road, not the spot, is the principal consideration; and its greatest improvement is a distant object, which may be seen from several points, or along a considerable part of the way. *Minute beauties* in general may abound in a garden; they may be frequent in a farm; in both we have opportunities to observe and to examine them: in a park, they are below our notice; in a riding, they escape it.

Prospects are agreeable to either of the four general subjects, but not equally necessary to all. In a garden, or in a farm, scenes within themselves are often satisfactory; and, in their retired spots, an opening would be improper. A park is defective, if confined to its inclosure: a perpetual succession of home-scenes, through so large an extent, wants variety; and fine prospects are circumstances of greatness: but they are not required in every part. The place itself supplies many noble views; and these are not much improved by a distant rim, or a little peep of the country, which is inadequate to the rest of the composition. A riding has seldom much beauty of its own; it depends on objects without for its pleasantness: if it only leads now and then to a striking point, and is dull all the rest of the way, it will not be much frequented; but very moderate views are sufficient to render its progress agreeable.

By concealing, therefore, much of the prospects, we destroy the amusement of a riding. The view of the country should not be hurt by the improvements of the road. In a garden, on the contrary, continuation of shade is very acceptable; and if the views be sometimes interrupted, they may still be caught from many points: we may enjoy them there whenever we please; and they would pass if constantly in sight. The best situation for a house is not that which has the greatest command; a cheerful look-out from the windows is all that the proprietor desires. He is more sensible to the charms of the greater prospects, if he sees them only occasionally, and they do not become insipid by being familiar: for the same reason he does not wish for them in every part of his garden; and temporary concealments give them fresh spirit whenever they appear. But the views of a riding are not visited so often, as thereby to lose any of their effect. Plantations, therefore, in a country, should be calculated rather for objects to look at, than for shades to pass through. In a park, they may answer both purposes: but in a garden, they are commonly considered as places to walk or to sit in. As such, too, they are most welcome in a farm: but still the distinction between an improved and an ordinary farm being, by no circumstance, so sensibly marked, as by the arrangement of the trees, they are more important, as objects, there than in a garden.

Though a farm and a garden agree in many particulars connected with extent, yet, in *style*, they are the two extremes. Both, indeed, are subjects of cultivation: but cultivation in the one is *husbandry*, and

in the other *decoration*; the former is appropriated to *profit*, the latter to *pleasure*. Fields profusely ornamented do not retain the appearance of a farm; and an apparent attention to produce, obliterates the idea of a garden. A park is sometimes not much hurt by being turned to account. The use of a riding is to lead from one beauty to another, and be a scene of pleasure all the way: made avowedly for that purpose only, it admits more embellishment and distinction than an ordinary road through a farm. See the articles FARM, PARK, and RIDING.

SECT. V. Of a Garden.

THE gravel paths have been mentioned † as contributing to the appearance of a garden: they are unusual elsewhere; they constantly present the idea of a walk; and the correspondence between their sides, the exactness of the edges, the nicety of the materials and of the preservation, appropriate them to spots in the highest state of improvement. Applied to any other subject than a park, their effect is the same. A field, surrounded by a gravel-walk, is, to a degree, bordered by a garden; and many ornaments may be introduced as appendages to the latter, which would otherwise appear to be inconsistent with the former. When these accompaniments occupy a considerable space, and are separated from the field, the idea of a garden is complete as far as they extend; but if the gravel be omitted, and the walk be only of turf, a greater breadth to the border, and more richness in the decorations, are necessary to preserve that idea.

Many gardens are nothing more than such a *walk round a field*; that field is often raised to the character of a lawn: and sometimes the inclosure is, in fact, a paddock. Whatever it be, the walk is certainly garden: it is a spot set apart for pleasure; it admits on the sides a profusion of ornament; it is fit for the reception of every elegance, and requires the nicest preservation: it is attended also with many advantages; may be made and kept without much expence; leads to a variety of points; and avails itself, in its progress, of the several circumstances which belong to the inclosure it surrounds, whether they be the rural appurtenances of a farm, or those more refined which distinguish a paddock.

But it has at the same time its inconveniences and defects. Its approach to the several points is always circuitous, and they are thereby often thrown to a distance from the house and from each other: there is no access to them across the open exposure: the way must constantly be the same: the view all along is into one opening, which must be peculiarly circumstanced, to furnish within itself a sufficient variety: and the embellishments of the walk are seldom important; their number is limited; and the little space allotted for their reception admits only of those which can be accommodated to the scale, and will conform to the character. This species of garden, therefore, reduces almost to a sameness all the places it is applied to: the subject seems exhausted: no walk round a field can now be very different from several others already existing. At the best too it is but a walk: the fine scenery of a garden is wanting: and that in the field, which is substituted in its stead, is generally of an inferior character; and often defective in connection with the spot which com-

GARDEN.

mands it, by the intervention of the fence, or the visible difference in the preservation.

This objection, however, has more or less force according to the character of the inclosure. If that be a paddock or a lawn, it may exhibit scenes not unworthy of the most elegant garden; which agreeing in style, will unite in appearance, with the walk. The other objections also are stronger or weaker in proportion to the space allowed for the appendages; and not applicable at all to a broad circuit of garden, which has room within itself for scenery, variety, and character: but the common narrow walk, too indiscriminately in fashion, if continued to a considerable extent, becomes very tiresome; and the points it leads to must be more than ordinarily delightful, to compensate for the fatigue of the way.

This tediousness may, however, be remedied, without any extravagant enlargement of the plan, by taking in, at certain intervals, an additional breadth, sufficient only for a little scene to interrupt the uniformity of the progress. The walk is then a communication, not between points of view, through all which it remains unaltered; but between the several parts of a garden, in each of which it is occasionally lost; and, when resumed, it is at the worst a repetition, not a continuation of the same idea; the eye and the mind are not always confined to one track; they expatiate at times, and have been relieved before they return to it. Another expedient, the very reverse of this, may now and then be put in practice: it is to contract, instead of enlarging, the plan; to carry the walk, in some part of its course, directly into the field, or at the most to secure it from cattle; but, to make it quite simple, omit all its appendages, and drop every idea of a garden. If neither of these, nor any other means, be used to break the length of the way, though the inclosure should furnish a succession of scenes, all beautiful, and even contrasted to each other, yet the walk will introduce a similarity between them. This species of garden, therefore, seems proper only for a place of a very moderate extent; if it be stretched out to a great length, and not mixed with other characters, its sameness hurts that variety, which it is its peculiar merit to discover.

64
Of a garden which occupies the whole inclosure.

BUT the advantages attending it upon some, and the use of it on so many, occasions, have raised a partiality in its favour; and it is often carried round a place, where *the whole inclosure is garden*: the interior openings and communications furnish there a sufficient range; and they do not require that number and variety of appendages, which must be introduced to disguise the uniformity of the circuitous walk, but which often interfere with greater effects. It is at the least unnecessary in such a garden; but plain gravel-walks to every part are commonly deemed to be indispensable: they undoubtedly are convenient; but it must also be acknowledged, that though sometimes they adorn, yet at other times they disfigure, the scenes through which they are conducted. The proprietor of the place, who visits these scenes at different seasons, is most anxious for their beauty in fine weather; he does not feel the restraint to be grievous, if all of them be not at all times equally accessible; and a gravel-walk perpetually before him, especially when it is useless, must be irksome. It ought not, therefore, to be ostentatiously

shewn; on many occasions it should be industriously concealed: that it lead to the capital points is sufficient: it can never be requisite along the whole extent of every scene: it may often skirt a part of them, without appearing; or just touch upon them, and without hurting them, it ought commonly to be omitted.

The sides of a gravel-walk must correspond, and its course be in sweeps gently bending all the way. It preserves its form, though conducted through woods, or along glades, of the most licentious irregularity. But a grass walk is under no restraint; the sides of it may be perpetually broken, and the direction frequently changed: sudden turns, however, are harsh; they check the idea of progress; they are rather disappointments than varieties; and if they are similar, they are in the worst style of affectation. The line must be curved, but it should not be too wretched; if it be truly serpentine, it is the most unnatural of any. It ought constantly to proceed; and wind only just so much, that the termination of the view may differ at every step, and the end of the walk never appear: the thickets which confine it should be diversified with several mixtures of greens; no distinctions in the forms of the shrubs or the trees will be lost, when there are opportunities to observe them so nearly; and combinations and contrasts without number may be made, which will be there truly ornamental. Minute beauties are proper in a spot precluded from great effects: and yet such a walk, if it be broad, is by no means insignificant; it may have an importance which will render it more than a mere communication.

BUT the peculiar merit of that species of garden which occupies the whole inclosure, consists in the larger scenes: it can make room for them both in breadth and in length; and being dedicated entirely to pleasure, free from all other considerations, those scenes may be in any style which the nature of the place will allow: a number of them is expected; all different; sometimes contrasted; and each distinguished by its beauty. If the space be divided into little slips, and made only a collection of walks, it forfeits all its advantages, loses its character, and can have no other excellence than such as it may derive from situation; whereas, by a more liberal disposition, it may be made independent of whatever is external; and though prospects are no where more delightful than from a point of view which is also a beautiful spot, yet if in such a garden they should be wanting, the elegant, picturesque, and various scenes within itself, almost supply the deficiency.

This is the character of the gardens at Stowe: for there the views in the country are only circumstances of the views in the garden; and the principal advantage of the situation is the variety of the ground within the inclosure. The house stands on the brow of a gentle ascent; part of the gardens lie on the declivity, and spread over the bottom beyond it: this eminence is separated by a broad winding valley from another which is higher and steeper; and the descents of both are broken by large dips and hollows, sloping down the sides of the hills. The whole space is divided into a number of scenes, each distinguished with taste and fancy; and the changes are so frequent, so sudden, and complete, the transitions so artfully conducted, that

65
Description of the gardens at Stowe.

that the same ideas are never continued or repeated to fatyety.

These gardens were begun when regularity was in fashion; and the original boundary is still preserved, on account of its magnificence: for round the whole circuit, of between three or four miles, is carried a very broad gravel walk, planted with rows of trees, and open either to the park or the country; a deep-funk fence attends it all the way, and comprehends a space of near four hundred acres. But in the interior scenes of the garden, few traces of regularity appear: where it yet remains in the plantations, it is generally disguised: every symptom, almost, of formality is obliterated from the ground; and an octagon basin in the bottom, is now converted into an irregular piece of water, which receives on one hand two beautiful streams, and falls on the other down a cascade into a lake.

In the front of the house is a considerable lawn, open to the water: beyond which are two elegant Doric pavilions, placed in the boundary of the garden, but not marking it, though they correspond to each other; for still further back, on the brow of some rising grounds without the inclosure, stands a noble Corinthian arch, by which the principal approach is conducted, and from which all the gardens are seen, reclining back against their hills: they are rich with plantations; full of objects; and, lying on both sides of the house almost equally, every part is within a moderate distance, notwithstanding the extent of the whole.

On the right of the lawn, but concealed from the house, is a perfect garden-scene, called the *queen's amphitheatre*, where art is avowed, though formality is avoided. The fore ground is scooped into a gentle hollow. The plantations on the sides, though but just rescued from regularity, yet in style are contrasted to each other: they are, on one hand, chiefly thickets, standing out from a wood; on the other, they are open groves, through which a glimpse of the water is visible. At the end of the hollow, on a little knole, quite detached from all appendages, is placed an open Ionic rotunda: beyond it, a large lawn slopes across the view; a pyramid stands on the brow; the queen's pillar, in a recess on the descent; and all the three buildings, being evidently intended for ornament alone, are peculiarly adapted to a garden-scene. Yet their number does not render it gay: the dusky hue of the pyramid, the retired situation of the queen's pillar, and the solitary appearance of the rotunda, give it an air of gravity; it is encompassed with wood; and all the external views are excluded; even the opening into the lawn is but an opening into an inclosure.

At the king's pillar, very near to this, is another lovely spot; which is small, but not confined; for no termination appears: the ground one way, the water another, retire under the trees out of sight, but nowhere meet with a boundary. The view is first over some very broken ground, thinly and irregularly planted; then between two beautiful clumps, which feather down to the bottom; and afterwards across a glade, and through a little grove beyond it, to that part of the lake, where the thickets, close upon the brink, spread a tranquillity over the surface, in which their shadows are reflected. Nothing is admitted to disturb that quiet: no building obtrudes: for objects

to fix the eye are needless in a scene, which may be comprehended at a glance; and none would suit the pastoral idea it inspires, of elegance too refined for a cottage, and of simplicity too pure for any other edifice.

The situation of the rotunda promises a prospect more enlarged; and in fact most of the objects on this side of the garden are there visible: but they want both connection and contrast; each belongs peculiarly to some other spot: they are all blended together in this, without meaning; and are rather shewn on a map, than formed into a picture. The water only is capital; a broad expanse of it is so near as to be seen under the little groups on the bank without interruption. Beyond it is a wood, which in one place leaves the lake, to run up behind a beautiful building, of three pavilions joined by arcades, all of the Ionic order: it is called *Kent's Building*. And never was a design more happily conceived: it seems to be characteristically proper for a garden; it is so elegant, so varied, and so purely ornamental: it directly fronts the rotunda, and a narrow rim of the country appears above the trees beyond it. But the effect even of this noble object is fainter here than at other points: its position is not the most advantageous; and it is but one among many other buildings, none of which are principal.

The scene at the temple of Bacchus is in character directly the reverse of that about the rotunda, though the space and the objects are nearly the same in both: but in this, all the parts concur to form one whole. The ground from every side shelves gradually towards the lake; the plantations on the further bank open to shew Kent's building, rise from the water's edge towards the knole on which it stands, and close again behind it. That elegant structure, inclined a little from a front view, becomes more beautiful by being thrown into perspective; and though at a greater distance, is more important than before, because it is alone in the view: for the queen's pillar and the rotunda are removed far aside; and every other circumstance refers to this interesting object: the water attracts, the ground and the plantations direct, the eye thither; and the country does not just glimmer in the offskip, but is close and eminent above the wood, and connected by clumps with the garden. The scene altogether is a most animated landscape: and the splendor of the building; the reflection in the lake; the transparency of the water, and the picturesque beauty of its form, diversified by little groupes on the brink, while on the broadest expanse no more trees cast their shadows than are sufficient to vary the tints of the surface; all these circumstances, vying in lustre with each other, and uniting in the point to which every part of the scene is related, diffuse a peculiar brilliancy over the whole composition.

The view from Kent's building, is very different from those which have been hitherto described. They are all directed down the declivity of the lawn. This rises up the ascent: the eminence being crowned with lofty wood, becomes thereby more considerable; and the hillocks into which the general fall is broken, sloping further out this way than any other, they also acquire an importance which they had not before: that, particularly, on which the rotunda is placed,

seems here to be a profound situation; and the structure appears to be properly adapted to so open an exposure. The temple of Bacchus, on the contrary, which commands such an illustrious view, is itself a retired object, close under the covert. The wood rising on the brow, and descending down one side of the hill, is shewn to be deep; is high, and seems to be higher than it is. The lawn too is extensive; and part of the boundary being concealed, it suggests the idea of a still greater extent. A small portion only of the lake indeed is visible; but it is not here an object: it is a part of the spot; and neither termination being in sight, it has no diminutive appearance: if more water had been admitted, it might have hurt the character of the place, which is sober and temperate; neither solemn nor gay; great and simple, but elegant; above rusticity, yet free from ostentation.

These are the principal scenes on one side of the gardens. On the other, close to the lawn before the house, is the winding valley above-mentioned: the lower part of it is assigned to the Elysian fields. These are watered by a lovely rivulet; are very lightsome, and very airy, so thinly are the trees scattered about them; are open at one end to more water and a larger glade; and the rest of the boundary is frequently broken to let in objects afar off, which appear still more distant from the manner of shewing them. The entrance is under a Doric arch, which coincides with an opening among the trees, and forms a kind of vista, through which a Pembroke bridge just below, and a lodge built like a castle in the park, are seen in a beautiful perspective. That bridge is at one extremity of the gardens; the queen's pillar is at another; yet both are visible from the same station in the Elysian fields: and all these external objects are unaffectedly introduced, divested of their own appurtenances, and combined with others which belong to the spot. The temple of friendship also is in sight, just without the place: and within it, are the temples of ancient virtue, and of the British worthies; the one in an elevated situation, the other low down in the valley, and near to the water: both are decorated with the effigies of those who have been most distinguished for military, civil, or literary merit; and near to the former stands a rostral column, sacred to the memory of captain Grenville, who fell in an action at sea: by placing here the meed of valour, and by filling these fields with the representations of those who have deserved best of mankind, the character intended to be given to the spot is justly and poetically expressed; and the number of the images which are presented or excited, perfectly corresponds with it. Solitude was never reckoned among the charms of Elysium; it has been always pictured as the mansion of delight and of joy: and in this imitation, every circumstance accords with that established idea. The vivacity of the stream which flows through the vale; the glimpses of another approaching to join it; the sprightly verdure of the green sward, and every bust of the British worthies reflected in the water; the variety of the trees: the lightness of the greens; their disposition; all of them distinct objects, and dispersed over gentle inequalities of the ground; together with the multiplicity of objects both within and without, which embellish and enliven the scene; give it a gaiety, which the imagi-

nation can hardly conceive, or the heart wish to be exceeded.

Close by this spot, and a perfect contrast to it, is the alder grove; a deep recess, in the midst of a shade, which the blaze of noon cannot brighten. The water seems to be a stagnated pool, eating into its banks; and of a peculiar colour, not dirty but clouded, and dimly reflecting the dun hue of the horse-chestnuts and alders which press upon the brink: the stems of the latter, rising in clusters from the same root, bear one another down, and slant over the water. Mithapen elms and ragged firs are frequent in the wood which encompasses the hollow; the trunks of dead trees are left standing amongst them; and the uncouth fumach, and the yew, with elder, nut, and holly, compose the underwood: some limes and laurels are intermixt; but they are not many: the wood is in general of the darkest greens; and the foliage is thickened with ivy, which not only twines up the trees, but creeps also over the falls of the ground: these are steep and abrupt: the gravel-walk is covered with moss; and a grotto at the end, faced with broken flints and pebbles, preserves, in the simplicity of its materials, and the duskiness of its colour, all the character of its situation: two little rotundas near it were better away; one building is sufficient for such a scene of solitude as this, in which more circumstances of gloom concur than were ever perhaps collected together.

Immediately above the alder-grove is the principal eminence in the gardens. It is divided by a great dip into two pinnacles; upon one of which is a large Gothic building. The space before this structure is an extensive lawn: the ground on one side falls immediately into the dip; and the trees which border the lawn, sinking with the ground, the house rises above them, and fills the interval: the vast pile seems to be still larger than it is; for it is thrown into perspective, and between and above the heads of the trees, the upper story, the porticoes, the turrets and ballustrades, and all the slated roofs, appear in a noble confusion. On the other side of the Gothic building, the ground slopes down a long-continued declivity into a bottom, which seems to be perfectly irriguous. Divers streams wander about it in several directions: the conflux of that which runs from the Elysian fields with another below it, is full in sight; and a plain wooden bridge thrown over the latter, and evidently designed for a passage, imposes an air of reality on the river. Beyond it is one of the Doric porticoes which front the house; but now it is alone; it stands on a little bank above the water, and is seen under some trees at a distance before it: thus grouped, and thus accompanied, it is a happy incident, concurring with many other circumstances to distinguish this landscape by a character of cheerfulness and amenity.

From the Gothic building a broad walk leads to the Grecian valley, which is a scene of more grandeur than any in the gardens. It enters them from the park, spreading at first to a considerable breadth; then winds; grows narrower, but deeper; and loses itself at last in a thicket, behind some lofty elms, which interrupt the sight of the termination. Lovely woods and groves hang all the way on the declivities: and the open space is broken by detached trees; which, near the park, are cautiously and sparingly introduced.

left the breadth should be contracted by them; but as the valley sinks, they advance more boldly down the sides, stretch across or along the bottom, and cluster at times into groups and forms, which multiply the varieties of the larger plantations. Those are sometimes close coverts, and sometimes open groves: the trees rise in one upon high stems, and feather down to the bottom in another; and between them are short openings into the park or the gardens. In the midst of the scene, just at the bend of the valley, and commanding it on both sides, upon a large, easy, natural rise, is placed the temple of Concord and Victory: at one place its majestic front of six Ionic columns, supporting a pediment filled with bas relief, and the points of it crowned with statues, faces the view; at another, the beautiful colonnade, on the side, of ten lofty pillars, retires in perspective. It is seen from every part; and impressing its own character of dignity on all around, it spreads an awe over the whole: but no gloom, no melancholy attends it: the sensations it excites are rather placid; but full of respect, admiration, and solemnity: no water appears to enliven, no distant prospect to enrich, the view; the parts of the scene are large, the idea of it sublime, and the execution happy; it is independent of all adventitious circumstances, and relies on itself for its greatness.

The scenes which have been described are such as are most remarkable for beauty or character: but the gardens contain many more: and even the objects in these, by their several combinations, produce very different effects, within the distance sometimes of a few paces, from the unevenness of the ground, the variety of the plantations, and the number of the buildings. The multiplicity of the last has indeed been often urged as an objection to Stowe; and certainly, when all are seen by a stranger in two or three hours, twenty or thirty capital structures, mixed with others of inferior note, do seem too many. But the growth of the wood every day weakens the objection, by concealing them one from the other: each belongs to a distinct scene; and if they are considered separately, at different times, and at leisure, it may be difficult to determine which to take away. Yet still it must be acknowledged that their frequency destroys all ideas of silence and retirement. Magnificence and splendor are the characteristics of Stowe: it is like one of those places celebrated in antiquity, which were devoted to the purposes of religion, and filled with sacred groves, hallowed fountains, and temples dedicated to several deities; the resort of distant nations, and the object of veneration to half the heathen world: this pomp is, at Stowe, blended with beauty; and the place is equally distinguished by its amenity and its grandeur.

In the midst of so much embellishment as may be introduced into this species of garden, a plain field, or a sheep-walk, is sometimes an agreeable relief, and even wilder scenes may occasionally be admitted. These indeed are not properly parts of a garden, but they may be comprehended within the verge of it; and their proximity to the more ornamented scenes is at least a convenience, that the transition from the one to the other may be easy, and the change always in our option. For though a spot in the highest state of improvement be a necessary appendage to a seat; yet, in a place which is perfect, other characters will not be

wanting: if they cannot be had on a large scale, they are acceptable on a smaller; and so many circumstances are common to all, that they may often be intermixed; they may always border on each other.

SECT. VI. *Of the Seasons.*

To every view belongs a light which shews it to advantage: every scene and every object is in its highest beauty only at particular hours of the day; and every place is, by its situation or its character, peculiarly agreeable in certain months of the year. The *seasons* thus become subjects of consideration in gardening; and when several of those circumstances which distinguish a spot more at one time than another happen to concur, it will often be worth the while to add to their number, and to exclude such as do not agree with them, for no other purpose than to strengthen their effect at that particular time. Different parts may thus be adapted to different seasons, and each in its turn will be in perfection. But if the place will not allow of such a succession, still *occasional effects* may often be secured and improved, without prejudice to the scene when they are past, and without affectation while they continue.

The temple of Concord and Victory at Stowe has been mentioned as one of the noblest objects that ever adorned a garden: but there is a moment when it appears in singular beauty. The setting sun shines on the long colonnade which faces the west: all the lower parts of the building are darkened by the neighbouring wood: the pillars rise at different heights out of the obscurity; some of them are nearly overspread with it, some are chequered with a variety of tints, and others illuminated almost down to their bases. The light is gently softened off by the rotundity of the columns: but it spreads in broad gleams upon the wall within them; and pours full and without interruption on all the entablature, distinctly marking every dentil. On the statues which adorn the several points of the pediment, a deep shade is contrasted to splendor: the rays of the sun linger on the side of the temple long after the front is overcast with the sober hue of evening; and they tip the upper branches of the trees, or glow in the openings between them, while the shadows lengthen across the Grecian valley.

Such an occasional effect, however transient, is so exquisitely beautiful, that it would be unpardonable to neglect it. Others may be produced at several hours of the day; and the disposition of the buildings, of the ground, the water, and the plantations, may often be accommodated to support them. There are also occasional effects in certain months, or only weeks, of the year, arising from some particular bloom, some occupation then carrying on, or other incident, which may so far deserve attention as to recommend a choice and arrangement of objects, which at that time will improve the composition, though at another they may have no extraordinary merit.

BESIDES these transitory effects, there are others which may be defined and produced with more exactness, which are fixed to stated periods, and have certain properties belonging to them. Some species and situations of objects are in themselves adapted to receive or to make the impressions which characterize

the principal parts of the day: their splendor, their sobriety, and other peculiarities, recommend or prohibit them upon different occasions. The same considerations direct the choice also of their appendages; and in consequence of a judicious assemblage and arrangement of such as are proper for the purpose, the *spirit* of the mornings, the *excess* of noon, or the *temperance* of evening, may be improved or corrected by the application of the scene to the season.

In a *morning*, the freshness of the air allays the force of the fun-beams, and their brightness is free from glare: the most splendid objects do not offend the eye, nor suggest the idea of heat in its extreme; but they correspond with the glitter of the dew which bespangles all the produce of the earth, and with the cheerfulness diffused over the whole face of the creation. A variety of buildings may therefore be introduced to enliven the view: their colour may be the purest white, without danger of excess, though they face the eastern sun; and those which are in other aspects should be so contrived, that their turrets, their pinnacles, or other points, may catch glances of the rays, and contribute to illuminate the scene. The trees ought in general to be of the lightest greens, and so situated as not to darken much of the landscape by the length of their shadows. Vivacity in the streams, and transparency in a lake, are more important at this than at any other hour of the day: and an open exposure is commonly the most delightful, both for the effect of particular objects, and the general character of the scene.

At *noon*, every expedient should be used to correct the excess of the season. The shades are shortened, they must therefore be thick; but open plantations are generally preferable to a close covert: they afford a passage, or at least admittance to the air; which, tempered by the coolness of the place, soft to the touch, and refreshing at once to all the senses, renders the shade a delightful climate, not a mere refuge from heat. Groves, even at a distance, suggest the ideas which they realize on the spot; and, by multiplying the appearances, improve the sensations of relief from the extremity of the weather. Grottos, caves, and cells, are on the same account agreeable circumstances in a sequestered recess; and though the chill within be hardly ever tolerable, the eye catches only an idea of coolness from the sight of them. Other buildings ought in general to be cast into shade, that the glare of the reflection from them may be obscured. The large expanse of a lake is also too dazzling: but a broad river moving gently, and partially darkened with shadow, is very refreshing; more so perhaps than a little rill, for the vivacity of the latter rather disturbs the repose which generally prevails at mid-day. Every breeze then is still; the reflexion of an aspen-leaf scarcely trembles on the water; the animals remit their search of food, and man ceases from his labour: the steam of heat seems to oppress all the faculties of the mind, and all the active powers of the body; and any very lively motion discomposes the languor in which we then delight to indulge. To hear, therefore, the murmurs of a brook purling underneath a thicket, or the echo of falling waters through a wood, is more agreeable than the sight of a current; the idea conveyed by the sound is free from any agitation:

but if no other stream than a rill can be introduced, the refreshment which attends the appearance of water must not be denied to the scene.

In the *evening*, all splendor fades: no buildings glare; no water dazzles. The calmness of a lake suits the quiet of the time: the light hovers there, and prolongs the duration of day. An open reach of a river has a similar, though a fainter, effect; and a continued stream all exposed, preserves the last rays of the sun along the whole length of its course, to beautify the landscape: but a brisk current is not so consistent as a lake with the tranquillity of evening. And other objects should in general conform to the temper of the time. Buildings of a dusky hue are most agreeable to it: but a very particular effect from a setting sun will recommend those of a brighter colour; and they may also be sometimes used, among other means, to correct the uniformity of twilight. No contrast of light and shade can then be produced: but if the plantations, which by their situation are the first to be obscured, be of the darkest greens, if the buildings which have a western aspect be of a light colour, and if the management of the lawns and the water be adapted to the same purpose, a diversity of tints will be preserved long after the greater effects are faded.

THE delights, however, of the morning and evening are confined to a few months of the year; at other times, two or three hours before, and as much after, noon, are all that are pleasant; and even then the heat is seldom so extreme as to require relief from its excess. The distinctions, therefore, between the three parts of the day may in general be reckoned among the characteristics of summer. The occasional effects which by the position of objects may occur at any hour, are common to all the seasons of the year: and such as arise from the accidental colours of plants, though they are more frequent and more beautiful in one season than another, yet exist in all; and very agreeable groupings may be formed by an assemblage of them. A degree of importance may be given even to the flowers of a border, if, instead of being indiscriminately mixed, they are arranged according to their heights, their sizes, and their colours, so as to display their beauties, and to blend or contrast their varieties to the greatest advantage. The bloom of shrubs differs from that of flowers only in the scale; and the tints occasioned by the hue of the berry, the foliage, or the bark, are sometimes little inferior to bloom. By collecting into one spot such plants as have at the same time their accidental colours, considerable effects may be produced from the concurrence of many little causes.

Those which arise from bloom are the most striking, and the most certain; and they abound chiefly in the *spring*. Bloom is a characteristic of the season; and a villa near town, which is designed principally for that time of the year, is not adapted to its use if this property be not amply provided for. In such a place, therefore, shrubberies, with an intermixture of flowers, are peculiarly proper. In the summer-months, a border between the thicket and the greenward, breaks the connexion, and destroys the greater effect: it ought not to be then introduced, except to enliven small spots, and as the best species of parterre. But in the spring, the thicket is hardly formed: its principal

cial beauty is bloom; and flowers before or among the shrubs, are agreeable to the character of the season. An orchard, which, at other times, is unlightful, is then delightful; and, if a farm joins to the garden, should not be forgotten. But evergreens appear in general to great disadvantage. Most of them have a rust or a dark hue, which suffers by being contrasted to the lively verdure of the young shoots on the deciduous trees. That verdure is, however, so light, and so universal, that effects, from a mixture of greens, can seldom be produced; and those which depend on a depth of shade will often be disappointed. But buildings, views of water, and whatever tends to animate the scene, accord with the season; which is full of youth and vigour, fresh and sprightly, brightened by the verdure of the herbage and the woods, gay with blossoms and flowers, and enlivened by the songs of the birds in all their variety, from the rude joy of the sky-lark, to the delicacy of the nightingale.

In *summer*, both the buildings and the water are agreeable, not as objects only, but also as circumstances of refreshment: the pleasantness, therefore, of the rooms in the former, of the seats and the walks near the latter, is to be regarded. The plantations also should be calculated at least as much for places of retreat, as for ornaments of the view; and a continuation of shade be preserved, with very few and short interruptions, through all the parts of the garden. Communications by gravel walks are of less consequence: they do not suggest that idea of utility which attends them in winter or autumn; and their colour, which in spring is a lively contrast to the verdure through which it winds, is in the intemperate blaze of a summer day glaring and painful. They should, therefore, be concealed as much as possible; and the other considerations which belong to the noon-tide hour should be particularly attended to, at the same time that the delights of the morning and the evening are also liberally provided for. But, exclusive of all such incidental circumstances, the scenes of nature in general appear at this season to the greatest advantage: though the bloom of the spring be faded, and the verdure of the herbage may be sometimes affected by drought; yet the richness of the produce of the earth, and the luxuriance of the foliage in the woods; the sensations of refreshment, added to the beauty of water; the ideas of enjoyment which accompany the sight of every grove, of every building, and every delightful spot; the characters of rocks, heightened by their appendages, and unalloyed by any disconsolate reflections; the connexion of the ground with the plantations, the permanency of every tint, and the certainty of every effect; all concur, in summer, to raise the several compositions to their highest state of perfection.

But maturity is always immediately succeeded by decay: flowers bloom and fade; fruits ripen and rot; the grass springs and withers; and the foliage of the woods shoots, thickens, and falls. In the latter months of *autumn*, all nature is on the decline; it is a comfortless season: not a blossom is left on the shrubs or the trees; and the few flowers which still remain in the borders, dripping with wet, and sickening even as they blow, seem hardly to survive the leaves of the plant which are shrivelling beneath them. But

the change of the leaf precedes the fall; and thence results a variety of colours, superior to any which the spring or the summer can boast of. To shew and to improve that variety should be principally attended to, in a place, such as a sporting seat, which is frequented only in autumn. It appears to advantage, whenever the surface of a wood can be commanded; and it may be produced to a considerable degree, even in a shrubbery, if the plants are so disposed as to rise in gradation one behind another. By observing the tints which the leaves assume when they change, the choice may be directed to the improvement of their variety; and by attending to the times when they fall, a succession of these transitory beauties may be provided, from the earliest to the latest in the season. Many shrubs and trees are at this time also covered with berries, which furnish still further varieties of colour; both evergreens and deciduous plants abound with them; and the verdure of the former is besides a welcome substitute to that which is daily fading away. Open buildings, airy groves, views of water, and the other delights of summer, now lose their charms; and more homely circumstances of comfort and convenience are preferable to all their beauties.

A place which is the residence of a family all the year is very defective, if some portion of it be not set apart for the enjoyment of a fine day, for air, and exercise, in *winter*. To such a spot shelter is absolutely essential; and evergreens being the thickest covert, are therefore the best: their verdure also is then agreeable to the eye; and they may be arranged so as to produce beautiful mixtures of greens, with more certainty than deciduous trees, and with almost equal variety: they may be collected into a wood; and through that wood gravel-walks may be led, along openings of a considerable breadth, free from large trees which would intercept the rays of the sun, and winding in such a manner as to avoid any draft of wind, from whatever quarter it may blow. But when a retreat at all times is thus secured, other spots may be adapted only to occasional purposes; and be sheltered towards the north or the east on one hand, while they are open to the sun on the other. The few hours of cheerfulness and warmth which its beams afford are so valuable, as to justify the sacrifice even of the principles of beauty to the enjoyment of them; and therefore no objections of sameness or formality can prevail against the pleasantness of a straight walk, under a thick hedge or a fourth wall. The eye may, however, be diverted from the screen, by a border before it, where the aconite and the snowdrop, the crocus and heptaca, brought forward by the warmth of the situation, will be welcome harbingers of spring; and on the opposite side of the walk, little tufts of laurustinus, and of variegated evergreens, may be planted. The spot thus enlivened by a variety of colours, and even a degree of bloom, may be still further improved by a green-house. The entertainment which exotics afford peculiarly belongs to this part of the year; and if amongst them be interspersed some of our earliest flowers, they will there blow before their time, and anticipate the gaiety of the season which is advancing. The walk may also lead to the stoves, where the climate and the plants are always the same. And the kitchen-garden should not be far off; for that is never quite

Conclusion.

quite destitute of produce, and always an active scene: the appearance of business is alone engaging; and the occupations there are an earnest of the happier seasons to which they are preparative. By these expedients even the winter may be rendered cheerful in a place, where shelter is provided against all but the bitterest inclemencies of the sky, and agreeable objects and interesting amusements are contrived for every hour of tolerable weather.

69
Extent and
study of
gardening.

To conclude: Whatever contributes to render the scenes of nature delightful, is amongst the subjects of gardening; and animate as well as inanimate objects, are circumstances of beauty or character. Several of these have been occasionally mentioned; others will readily occur; and nothing is unworthy of the attention of a gardener, which can tend to improve his compositions, whether by immediate effects, or by suggesting a train of pleasing ideas. The whole range of nature is open to him, from the parterre to the forest; and whatever is agreeable to the senses or the imagination, he may appropriate to the spot he is to improve: it is a part of his business to collect into one place, the delights which are generally dispersed thro' different species of country.

But in this application, the genius of the place must always be particularly considered: to force it, is hazardous; and an attempt to contradict it, is always unsuccessful. The beauties peculiar to one character, cannot be transferred to its opposite: even where the characters are the same, it is difficult to copy directly

from the one into the other; and by endeavouring to produce a resemblance of a scene which is justly admired, the proper advantages of the place are often neglected for an imitation much inferior the original. The excellence of the latter probably depends on the happy application of the circumstances to the subject; and the subjects of both are never exactly alike. The art of gardening, therefore, is not to be studied in those spots only where it has been exercised; though they are in this country very numerous, and very various. Yet all together they contain but a small proportion of the beauties which nature exhibits: and unless the gardener has stored his mind with ideas from the infinite variety of the country at large, he will feel the want of that number which is necessary for choice; he will have none ready to apply to the subject immediately before him; and will be reduced to copy an imitation. But improved places are of singular use to direct the judgment in the choice, and the combinations, of the beauties of nature: an extensive knowledge of them is to be acquired in the country where they casually occur; discernment of their excellencies, and a taste for the disposition of them, is to be formed in places where they have been selected, and arranged with design.

For the particular Operations in GARDENING, see PLANTING, PRUNING, GRAFTING, INOCULATING, KITCHEN-GARDEN, ORCHARD, GREEN-HOUSE, HOT-HOUSE, INARCHING, ESPALIER, &c. and the culture and management of different plants under their respective names.

G A R

Gardiner
Garland.

GARDINER (Stephen), bishop of Winchester, and lord chancellor of England, born at Bury St Edmunds in Suffolk, natural son to Richard Woodville, brother to queen Elizabeth wife to Edward IV. was learned in the canon and civil laws, and in divinity. He signed the divorce of Henry VIII. from Katharine of Spain; abjured the pope's supremacy; and writ *De vera et falsa obedientia*, in behalf of the king: yet in Edward's reign he opposed the reformation, and was punished with imprisonment; but queen Mary coming to the throne, she enlarged him. He drew up the articles of marriage between the queen and Philip of Spain, which were very advantageous to England. He was violent against the reformers; but on his death-bed was dissatisfied with his life, and often repeated these words: *Erravi cum Petro, sed non fleui cum Petro*. He died in 1555.

GARGARISM, (from γαργαρίζω, "to wash the mouth;" a gargle. Its use is for washing the mouth and throat with, when inflammations, ulcerations, &c. are there. A small quantity may be taken into the mouth, and moved briskly about, and then spit out; or if the patient cannot do this to any advantage, the liquor may be injected by a syringe. When gargles are required, their use should be more frequently repeated than is done in common practice.

GARLAND, a sort of chaplet made of flowers, feathers, and sometimes precious stones, worn on the head, in manner of a crown.—The word is formed of the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *ghirlanda*. Menage traces its origin from *gyrus*, through *gyrulus*, to *gyrulare*, *gyrlan-*

G A R

dum, *ghirlandum*, and at length *ghirlanda* and *guirlande*; so that *guirlande* and *garland* are descended in the sixth or seventh degree from *gyrus*.—Hicks rejects this derivation, and brings the word from *garden banda*, which in the northern languages signify a *nosegay* artfully wrought with the hand.

GARLAND also denotes ornaments of flowers, fruits, and leaves, intermixed; anciently much used at the gates of temples, where feasts and solemn rejoicings were held; or at any other place where marks of public joy or gaiety were required, as at triumphal arches, tournaments, &c.

GARLIC. See **ALLIUM**.

GARNET, in natural history, a very beautiful gem, of a red colour, with an admixture of blue.

When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, tho' only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue: this is a very beautiful gem. 3. The *forane* or *ferain* garnet; that of a yet brighter red, approaching to the colour of native cinnamon, with a faint blue tinge. 4. The *almandine*, a garnet only a little paler than that called the

Garland
Garnet.

the rock-ruby.

Garnets are very properly distinguished into the oriental and occidental kinds, as being found in Europe as well as the East Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European ones are common in Italy, Hungary, and Bohemia.

Some authors have supposed the deeper-coloured garnet to be the same with the carbuncle of the ancients; from which it really differs; since, on receiving the sun's beams, it never gives so true a fire-colour as the carbuncle.

GARNET-COLOUR. To give this colour to glass, the workmen take equal quantities of crystal and Rochetta fritt; and to every hundred weight of this mixture they add a pound of manganese, and a pound of prepared zaffre; these are to be powdered separately, then mixed and added by degrees to the fritt while in the furnace: great care is to be taken to mix the manganese and zaffre very perfectly; and when the matter has stood 24 hours in fusion, it may be worked.

To imitate GARNETS. The making the counterfeit garnet in paste is done as follows.—Take prepared crystal two ounces, common red-lead six ounces, manganese 16 grains, zaffre three grains; mix all well, put them into a crucible, cover it with lute, and set it in a potter's kiln for 24 hours. Or take crystal two ounces, minium five ounces and a half, manganese 15 grains, zaffre four grains: mix them well together; and let all be baked, in a pot well luted, in a potter's kiln 24 hours.

GARONNE, a large river of France, which taking its rise in the Pyrenean mountains, runs north-west by the city of Tholouse, divides the provinces of Guienne and Gascony, and, visiting the city of Bourdeaux, falls into the bay of Biscay, about 60 miles below that city. It has also a communication with the Mediterranean, by means of the royal canal of Lewis XIV. The tide flows up this river 20 miles above Bourdeaux.

GARRICK (David), Esq; the great Roscius of this age and country, who for near 40 years hath shone the brightest luminary in the hemisphere of the stage, was born at the Angel Inn at Hereford, in the year 1716. His father, Captain Peter Garrick, was a French refugee, and had a troop of horse which were then quartered in that city. This rank he maintained in the army for several years, and had a majority at the time of his death; that event, however, prevented him from ever enjoying it. Mr Garrick received the first rudiments of his education at the free-school at Litchfield; which he afterwards completed at Rochester, under the celebrated Mr Colson, since mathematical professor at Cambridge. Dr Johnson and he were fellow-students at the same school; and it is a curious fact, that these two celebrated geniuses came up to London, with the intention of pushing themselves into active life, in the same coach. On the 9th of March 1736, he was entered at the honourable society of Lincoln's-Inn. The study of the law, however, he soon quitted; and followed for some time the employment of a wine-merchant: but that too disgusting him, he gave way at last to the irresistible bias of his mind, and joined a travelling company of comedians at Ipswich in Suffolk, where he went by the name of *Lyddel*. Ha-

ving in this poor school of Apollo got some acquaintance with the theatric art, he burst at once upon the world, in the year 1740-1, in all the lustre of perfection, at the little theatre in Goodman's Fields, then under the direction of Henry Giffard.

The character he first performed was Richard the Third; in which, like the sun bursting from behind a cloud, he displayed, in the earliest dawn, a somewhat more than meridian brightness. His excellence dazzled and astonished every one; and the seeing a young man, in no more than his 24th year, and a novice in reality to the stage, reaching at one single step to that height of perfection which maturity of years and long practical experience had not been able to bestow on the then capital performers of the English stage, was a phenomenon that could not but become the object of universal speculation and of as universal admiration. The theatres at the west end of the town were deserted; Goodman's Fields, from being the rendezvous of citizens and citizens wives alone, became the resort of all ranks of men; and Mr Garrick continued to act till the close of the season.

Having very advantageous terms offered him for the performing in Dublin during some part of the summer (1741), he went over thither, where he found the same just homage paid to his merit which he had received from his own countrymen. To the service of the latter, however, he esteemed himself more immediately bound; and therefore, in the ensuing winter, engaged himself to Mr Fleetwood, then manager of Drury-Lane: in which theatre he continued till the year 1745, when he again went over to Ireland, and continued there the whole season, joint manager with Mr Sheridan in the direction and profits of the theatre-royal in Smock-Alley. From thence he returned to England, and was engaged for the season of 1746 with Mr Rich at Covent-Garden. This was his last performance as an hired actor: for in the close of that season, Mr Fleetwood's patent for the management of Drury-Lane being expired, and that gentleman having no inclination further to pursue a design by which, from his want of acquaintance with the proper conduct of it, or some other cause, he had considerably impaired his fortune; Mr Garrick, in conjunction with Mr Lacy, purchased the property of that theatre, together with the renovation of the patent; and in the winter of 1747, opened it with the greatest part of Mr Fleetwood's company, and with the great additional strength of Mr Barry, Mrs Pritchard, and Mrs Cibber, from Covent-Garden.

In this station Mr Garrick continued till his retirement in the spring of 1776; and both by his conduct as a manager, and his unequalled merit as an actor, from year to year added to the entertainment and consulted the taste of the public with the greatest assiduity. They were grateful in their acknowledgments; and by a well-deserved and warm encouragement, raised him to a state of fame, ease, and affluence, which he enjoyed for many years.

Were we to trace Mr Garrick through the several occurrences of his life,—a life so active, so busy, and so full of occurrences as his, we should swell this account to many pages. Suffice it to say, he continued in the unmoiled enjoyment of his fame and unrivalled excellence to the moment of his retirement. His universality

fality of excellence was never once attacked by competition. Tragedy, comedy, and farce, the lover and the hero, the jealous husband who suspects his wife without cause, and the thoughtless lively rake who attacks it without design, were all alike his own. Rage and ridicule, doubt and despair, transport and tenderness, compassion and contempt; love, jealousy, fear, fury, and implicit; all took in turn possession of his features, while each of them in turn appeared to be the sole possessor of his heart. In the several characters of Lear and Hamlet, Richard, Dorilas, Romeo, and Luſignane; in his Ranger, Bayes, Druggier, Kiteley, Brute, and Benedick, you ſaw the muscular conformation that your ideas attached to them all. In ſhort, nature, the miſtreſs from whom alone this great performer borrowed all his leſſons, being in herſelf inexhauſtible, this her darling ſon, marked out for her trueſt repreſentative, found an unlimited ſcope for change and diverſity in his manner of copying from her various productions. There is one part of theatrical conduct which ought unqueſtionably to be recorded to Mr Garrick's honour, ſince the cauſe of virtue and morality, and the formation of public manners, are conſiderably dependent upon it; and that is, the zeal with which he aimed to baniſh from the ſtage all thoſe plays which carry with them an immoral tendency, and to prune from thoſe which do not abſolutely, on the whole, promote the intereſts of vice, ſuch ſcenes of licentiousneſs and liberty, as a redundancy of wit and too great livelineſs of imagination have induced ſome of our comic writers to indulge themſelves in, and which the ſympathetic diſpoſition of our age of gallantry and intrigue has given ſanction to. The purity of the Engliſh ſtage has certainly been much more fully eſtabliſhed during the adminiſtration of this theatrical miniſter, than it had ever been during preceding managements. He ſeems to have carried his model, moral, chaſte, and pious principles with him into the very management of the theatre itſelf, and reſcued performers from that obloquy which ſtuck on the profeſſion. Of thoſe who were accounted blackguards, unworthy the aſſociation of the world, he made gentlemen, united them with ſociety, and introduced them to all the domeſtic comforts of life. The theatre was no longer eſteemed the receptacle of all vice; and the moral, the ſerious, the religious part of mankind did not hesitate to partake of the rational entertainment of a play, and paſs a cheerful evening undiſguſted with the licentiousneſs, and uncorrupted by the immorality, of the exhibition.

Notwithſtanding the numberleſs and laborious avocations attendant on his profeſſion as an actor, and his ſtation as a manager; yet ſtill his active genius was perpetually buſying forth in various little productions in the dramatic and poetical way, whoſe merit cannot but make us regret his want of time for the purſuance of more extenſive and important works. It is certain, that his merit as an author is not of the firſt magnitude: but his great knowledge of men and manners, of ſtage-eſſect, and his happy turn for lively and ſtriking ſatire, made him generally ſucceſſful; and his prologues and epilogues in particular, which are almoſt innumerable, poſſeſs ſuch a degree of happineſs, both in the conception and execution, as to ſtand unequalled. His Ode on the death of Mr Pelham run through four edi-

tions in leſs than fix weeks. His Ode on Shakeſpeare is a maſterly piece of poetry; and when delivered by himſelf, was a moſt capital exhibition. His alterations of Shakeſpeare and other authors have been at times ſucceſſful, and at times exploded. The cutting out the grave-diggers ſcene from Hamlet will never be forgot to him by the inhabitants of the gallery at Drury. Though neceſſary to the chaſteneſs of the ſcene, they cannot bear to loſe ſo much true ſterling wit and humour; and it muſt be owned, that exuberances of that kind, though they hurt the uniformity, yet increaſe the luxuriance of the tree. Among his alterations the following are part: Every Man in his Humour, altered from Ben Johnſon; Romeo and Juliet, Winter's Tale, Catherine and Petruchio, Cymbeline, Hamlet, &c. altered and made up from Shakeſpeare; Gameſters, a comedy, from Shirley; Iſabella, from Southerne. To theſe we add, as original productions, The Farmer's Return, and Linceo's Travels, interludes; Guardian, Lethe, Lying Valet, Miſs in her Teens, Male Coquet, Iriſh Widow, and other comedies in two acts; Enchanter, a muſical entertainment; Lilliput; the Chriſtmas Tale is aſcribed to him, and many others. At this time a complete edition of his works is preparing for the preſs, under the direction of his friends, and in which the whole will be aſcertained.

We now bring him to the period of his retirement in the ſpring of 1776; when, full of fame, with the acquirement of a ſplendid fortune, and growing into years, he thought proper to ſeek the vale of life, to enjoy that dignified and honourable eaſe which was compatible with his public ſituation, and which he had ſo well earned by the activity and the merits of his dramatic reign. But very ſhort, indeed, was the period allotted to him for this precious enjoyment: for on the 20th day of January 1779, he departed this life; leaving no one rival in excellence upon earth to compenſate for his loſs, or a hope of our ever meeting with his like again.

GARRISON, in the art of war, a body of forces, diſpoſed in a fortrefs, to defend it againſt the enemy, or to keep the inhabitants in ſubjection; or even to be ſubſtituted during the winter-ſeaſon: hence, *garrison* and *winter-quarters* are ſometimes uſed, indifferently, for the ſame thing; and ſometimes they denote different things. In the latter caſe, a *garrison* is a place wherein forces are maintained to ſecure it; and where they keep regular guard, as a frontier town, a caſtle, caſtle, tower, &c. The *garrison* ſhould be always ſtronger than the townſmen.

Du Cange derives the word from the corrupt Latin *garniſo*, which the latter writers uſe to ſignify all manner of munition, arms, victuals, &c. neceſſary for the defence of a place, and ſuſtaining of a ſiege.

Winter-quarters ſignify a place where a number of forces are laid up in the winter ſeaſon, without keeping the regular guard.

GARTER, a ligature for tying up the ſtockings; but particularly uſed for the badge of a noble order of knights, hence denominated the

Order of the GARTER, a military order of knighthood, the moſt noble and ancient of any lay-order in the world, inſtituted by Edward III. This order conſiſts of 26 knights-companions, generally princes and peers,

peers, whereof the king of England is the sovereign or chief. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, regifter, king at arms, and usher of the black rod. They have also a dean with 12 canons, and petty canons, vergers, and 26 pensioners or poor knights. The prelate is the head. This office is vefted in the bifhop of Winchester, and has ever been fo. Next to the prelate is the chancellor; which office is vefted in the bifhop of Salifbury, who keeps the feals, &c. The next is the regifter, who by his oath is to enter upon the regiftry, the ferutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is Garter and King-at-arms, being two diftinct offices united in one perfon. Garter carries the rod and fceptre at the feaft of St George, the protector of this order, when the fovereign is prefent. He notifies the elections of new knights, attends the folemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See KING at Arms.

All thefe officers, except the prelate, have fees and penfions. The college of the order is feated in the caftle of Windfor, with the chapel of St George, and the charter-houfe, erected by the founder for that purpofe. The habit and enfign of the order are, a garter, mantle, cape, george, and collar. The four firft were affigned the knights-companions by the founder; and the george and collar by Henry VIII. The garter (Plate CXV. fig. 2. N^o 1.) challenges pre-eminence over all the other parts of the drefs, by reafon that from it the noble order is denominated; that it is the firft part of the habit prefented to foreign princes, and abfent knights, who, and all other knights-eleft, are therewith firft adorned; and it is of fo great honour and grandeur, that by the bare inveftiture with this noble enfign, the knights are e-ftimated companions of the greateft military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QVI MAL Y PENSE; i. e. *Shame to him that thinks evil hereof*: The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that fould dare to think amifs of the juft enterprife he had undertaken, for recovering his lawful right to that crown; and that the bravery of thofe knights whom he had elefted into this order, was fuch as would enable him to maintain the quarrel againft thofe that thought ill of it.

The mantle (*ibid.* N^o 2.) is the chief of thefe veftments made ufe of upon all folemn occafions. The colour of the mantle is by the ftatutes appointed to be blue. The length of the train of the mantle only diftinguifhes the fovereign from the knights-companions. To the collar of the mantle is fixed a pair of long fringes, anciently wove with blue filk only, but now twifted round, and made of Venice gold and filk, of the colour of the robe, with knobs, or buttons, and raffels at the end. The left foulder of the mantle has, from the institution, been adorned with a large garter, with the device, HONI SOIT, &c. Within this is the crofs of the order, which was ordained to be

worn at all times by king Charles I. At length the ftar was introduced, being a fort of crofs irradiated with beams of filver; (*ibid.* N^o 3.)

The collar (*ibid.* N^o 4.) is appointed to be composed of pieces of gold in falhion of garters, the ground enamelled blue, and the motto gold.

The manner of elefting a knight-companion into this moft noble order, and the ceremonies of inveftiture, are as follow. When the fovereign defigns to eleft a companion of the garter, the chancellor belonging to this order draws up the letters, which, paffing both under the fovereign's fign-manual and fignet of the order, are fent to the perfon by Garter principal king at arms; and are in this manner, or to the fame effect: "We, with the companions of our moft noble order of the garter, affembled in chapel, holden this prefent day at our caftle at Windfor, confidering the virtuous fidelity you have fhewn, and the honourable exploits you have done in our fervice, by vindicating and maintaining our right, &c. have elefted and chofen you one of the companions of our order. Therefore, we require you to make your fpeedy repair unto us, to receive the enfigns thereof, and be ready for your installation upon the — day of this prefent month, &c."

The garter, which is of blue velvet bordered with fine gold-wire, having commonly the letters of the motto of the fame, is, at the time of election, buckled upon the left leg, by two of the fenior companions, who receive it from the fovereign, to whom it was prefented upon a velvet cuftion, by Garter king at arms, with the ufual reverence, whilft the chancellor reads the following admonition, enjoined by the ftatutes: "To the honour of God omnipotent, and in memorial of the bleffed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the fymbol of the moft illuftrious order, never to be forgotten or laid afide; that thereby thou mayeft be admonifhed to be courageous; and, having undertaken a juft war, in which thou fhalt be engaged, thou mayeft ftand firm, valiantly fight, and fucceffively conquer."

The princely garter being then buckled on, and the words of its fignification pronounced, the knight-eleft is brought before the fovereign, who puts about his neck, kneeling, a fky-coloured ribbon, (*ibid.* N^o 5.) whereunto is appendant, wrought in gold within the garter, the image of St George on horfeback, with his fword drawn, encountering with the dragon. In the mean time the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the bleffed martyr and foldier of Chrift, St George, by whose imitation provoked, thou mayeft fo overpafs both prosperous and adverfe adventures, that having floutly vanquifhed thy enemies both of body and foul, thou mayeft not only receive the praife of this tranfient combat; but be crowned with the palm of eternal victory."

Then the knight elefted kifles the fovereign's hand; thanks his majefty for the great honour done him; rifes up, and falutes all the companions feverally, who return their congratulations. N^o 2. (*ibid.*) exhibits a view of a knight of the garter in the habit of this order.

Garth.

Since the institution of this order, there have been eight emperors and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related. The common account is, that the countess of Salisbury at a ball happening to drop her garter, the king took it up and presented it to her with these words, "*Honni soit qui mal y pense*;" i. e. Evil to him that evil thinks. This accident, it is said, gave rise to the order and the motto; it being the spirit of the times to mix love and war together: but as in the original statutes of this order there is not the least conjecture to countenance such a feminine institution, credit cannot be given to this tradition: the true motive is therefore attributed by very respectable historians, to a nobler origin; which is, that king Edward III. having issued forth his own garter for the signal of a battle, it ended so fortunately, that he thence took occasion to institute that order, not only as an incentive to honour and martial virtue, but also as a symbol of unity and society.

GARTH (Sir Samuel), an excellent English poet and physician, was descended from a good family in Yorkshire. He was admitted into the college of physicians at London in 1693. He at that time zealously promoted and encouraged the erecting of the dispensary for the relief of the sick poor, by giving them advice gratis, and medicines at low rates. This work of charity having exposed him and many other physicians to the envy and resentment of several persons of the same faculty as well as apothecaries, he ridiculed them, with a peculiar spirit and vivacity, in a poem called the *Dispensary*, in six cantos, highly esteemed. He was one of the most eminent members of the famous society called the *Kit-Kat Club*, which consisted of noblemen and gentlemen distinguished by their excellent parts and affection to the house of Hanover. Upon the accession of George I. he was knighted, and made physician in ordinary to his majesty, and physician-general to the army. Nor were these more than just rewards even of his physical merit. He had gone through the office of censor of the college in 1702; and had practised always with great reputation, and a strict regard to the honour and interest of the faculty, never stooping to prostitute the dignity of his profession, through mean and sordid views of self-interest, to any, even the most popular and wealthy apothecaries. In a steady adherence to this noble principle, he concurred with the much celebrated Dr Radcliffe, with whom he was also often joined in physical consultations. He had a very extensive practice, but was very moderate in his views of advancing his own fortune; his humanity and good-nature inclining him more to make use of the great interest he had with persons in power, for the support and encouragement of other men of letters. He chose to live with the great in that degree of independency and freedom, which became a man possessed of a superior genius, whereof he was daily giving fresh proofs to the public. One of his last performances in polite letters, was his translation of the whole fourteenth book, and the story of Cincinnatus in the fifteenth book, of Ovid's *Metamorphoses*. These, together with an English version of the rest, were published in 1717; and he has prefixed an excellent preface to the whole, wherein

he not only gives an idea of the work, and points out its principal beauties, but shews the uses of the poem, and how it may be read to most profit. The distemper which seized him the ensuing year, and ended not but with his life, caused a general concern; which was particularly testified by lord Landford, brother-poet, though of a different party, in some admirable verses written on the occasion. He died, after a short illness which he bore with great patience, in January 1719.

GAS, the name given by Van Helmont, and after him by other chemists, to those elastic fluids extricated from different terrestrial substances, and which are not condensable by cold. Of these a good number have been observed by Van Helmont: such as, the *gas ventosum*, or atmospheric air; the *gas sylvestre*, or fluid extricated during fermentations and effervescences, called by later authors, *fixed*, *facillitour*, and *fixable* air; *gas pingue*, or the fluid expelled from inflammable substances by heat; *gas flammium*, or the fluid produced in the deflagration of nitre. To these other authors have added *inflammable* air or *gas*, *nitrous acid* *gas*, *marine* *gas*, *alkaline* *gas*, &c.

An account of the most remarkable properties of all these different fluids is given under the articles AIR, CHEMISTRY, DAMPS, &c. Of their composition very little is known with certainty. Dr Priestley some time ago discovered a method of procuring very pure atmospheric air from a mixture of nitrous acid with red lead, or with any dephlogisticated earth, as related under the article AIR, n° 44. Hence he concluded, that the nitrous acid, and likewise earth, entered into the composition of the air we breathe. The proofs of this, however, from subsequent experiments, seem to be but slightly founded. It is certain, that part of the earth, which in Dr Priestley's first experiments was thought to enter into the composition of his dephlogisticated air, was afterwards found to separate from it, and to have been elevated merely by the force of the air extricating itself from the terrestrial substance. With respect to the acid, the case is still more dubious. It was found that dephlogisticated air might be procured from red-lead and oil of vitriol; to which purpose the following experiment is recorded in the Appendix to the Chemical Dictionary. "Forty-eight pennyweights of red-lead were put into a long necked retort, the contents of which were ten cubic inches; and upon this red-lead, 24 pennyweights of oil of vitriol were poured. The nose of the retort was then immersed under water, and over it an inverted jar filled with water was placed. The mixture of oil of vitriol and red-lead became very hot, and ten cubic inches of air were soon thrown into the jar without the application of external heat. Upon applying the flame of a lamp to the bottom of the retort, bubbles of air passed copiously into the jar, which were successively changed, that the air received at different times of the operation might be examined. The quantity of air which had been expelled from the above mixture of red-lead and vitriolic acid, was found to be 36 cubic inches, after the proper allowances for the air contained in the retort had been made; and this air was found to have all the properties of that procured by Dr Priestley from nitrous acid and red lead."

From some late experiments made by Dr Priestley him-

himself, it appears, that very pure air may be obtained by means of the vitriolic acid, or indeed without any acid at all. In the course of his experiments, the doctor found, that dephlogisticated air might be obtained from the green, blue, and white vitriols. Suspecting, however, the purity of these vitriols which were prepared by others, he prepared some green vitriol himself by dissolving clean iron-sfilings in the vitriolic acid diluted with water. Distilling the matter in a retort, he had the same results as before; the dephlogisticated air which came over last, being very turbid, and exceedingly pure.—He now suspected the purity of his oil of vitriol, which at present is generally procured from sulphur with the addition of nitre. He therefore next employed the vitriolic acid prepared in Neumann's manner, in which no nitre is used: but dephlogisticated air was still produced from the combination of iron filings with this purer acid. And lest the mixture of these two substances might be suspected of having attracted pure air, in consequence of their exposure to the atmosphere during their combination, he conducted the experiment in the following scrupulous manner. He dissolved five pennyweights one grain of iron in a sufficient quantity of pure oil of vitriol which had been carefully prepared for this purpose by Mr Winch, so as to be free from any admixture of the nitrous acid. The distillation was performed in the same retort in which the solution had been made, and in the continuation of the same process; so that all communication with the external air was most effectually prevented. Conducting the process with these attentions, and distilling the matter to dryness, the succeeding products were, first, the common air a little phlogisticated; then a little fixed air, and much vitriolic-acid air; and lastly, a considerable quantity of dephlogisticated air. The residuum still weighed more than the iron filings employed; and had the heat been increased, more air might perhaps have been procured.

Adding fresh oil of vitriol to this residuum, and treating it as before, but in a gun-barrel, a still larger quantity of dephlogisticated air was produced; so that the oil of vitriol appeared capable of generating dephlogisticated air as often as it was mixed with iron, as well as the nitrous acid when mixed with red-lead, &c. in his former experiments.

On putting an ounce of manganese into a small retort, with a very long narrow neck, and exposing it to a red sand-heat, 40 ounce-measures of air were expelled in different portions. Part of this, in every portion, was fixed air, and at first almost wholly so: but four-fifths of the last produce was the purest dephlogisticated air. From an ounce of calaminaris without addition, 316 ounce-measures of gas were expelled by a red heat: the whole of this, however, was fixed air, except about four ounce-measures, which were nearly as good as common air.

In making some experiments on vegetation, the doctor discovered, that dephlogisticated air was in some cases produced naturally. Having observed bubbles of air that seemed to issue spontaneously from the roots of several plants growing in water, he was at first led to suspect that this air had percolated through the plant; which had probably seized upon and retained the phlogiston of the air, and then emitted the purer

part. He found this conjecture verified with regard to the purity of the air; for, on examining some of it, he found that one measure of it, and one of nitrous air, occupied the space only of one measure.—Soon after, he found that the plants had no share in the production of this air; for, on taking them out of the vials, the remaining water continued to emit air as plentifully as when they were growing in it. He observed too, that the vials and other vessels in which this pure air had been emitted from the water had their bottoms and sides more or less covered with a green matter, from which the air evidently seemed to proceed. It appeared to him, however, that this green matter could neither be of an animal nor vegetable nature; but that it was a substance *sui generis*; and that neither the external air nor animalcules could have any share in the formation of it: for it was produced in vials closely corked, and in the middle vessel of Mr Parker's apparatus*. But from some experiments made by others, it appears that the green matter will not be deposited in vials closely corked, unless some air is included; and the quantity of the deposit bears some proportion to that of the air left in the vial. In open vials completely filled, and inverted in water, the water contained in the vials has an intermediate communication with the atmosphere, and the process goes on as described above: but if that communication is stopped from the beginning, by inverting the vials in quicksilver (a fluid impermeable to air), no green matter or pure air is produced.

On filling a number of vials with different kinds of water, as river-water, rain-water, pump-water, which contained a considerable quantity of fixed air, he found that no green matter was produced in any of them, except in those which contained the pump-water. Afterwards, however, he found that both the green matter and pure air was produced in great plenty from water strongly impregnated with fixed air.—One measure of the purest air he ever obtained in this way, when mixed with two measures of nitrous air, occupied the space only of 0.44 of a measure; “which (says Dr Priestley) is quite as pure as dephlogisticated air is, at a medium.”

The most remarkable circumstance in this production of air is the instrumentality of the sun's *light* independent of his mere *heat*. Concerning this, the doctor has the following observations:

“Whatever air is naturally contained in water, or in substances dissolved in water, as calcareous matter, &c. becomes, after long standing, but especially when exposed to the sun, depurated, so as at length to become absolutely dephlogisticated; and that this air, being continually emitted by all water exposed to the action of the sun's rays, must contribute to the melioration of the state of the atmosphere in general.

“When water has been long kept in the shade, it has not generally yielded any other kind of air than it would have yielded at first; and though, when kept in an open vessel, the air has been better, it has never been so good as when exposed a much shorter time to the sun.

“No degree of warmth will supply the place of the sun's light: and though, when the water is once prepared by exposure to the sun, warmth will suffice to expel that air; yet, in this case, the air has never

* See Air,
10th S3.

Gas
Gascogne.

been so pure as that which has been yielded spontaneously, without additional heat. The reason of this may be, that, besides the air already depurated, and on that account ready to quit its union with the water, heat expels, together with it, the air that was phlogisticated, and held in a closer union with the water; which air, the *action of light*, whatever that is, would in time have depurated also.

“The quantity of air yielded by water spontaneously, far exceeds that which can be expelled from it by heat. If the water naturally contains fixed air, yet, in consequence of this exposure to the sun’s light, it is all dissipated, and the natural residuum of it becomes pure dephlogisticated air. For no fixed air at all, but the purest dephlogisticated air is at length procured from it; and water impregnated with fixed air yields, after this exposure, the greatest quantity of dephlogisticated air.” From some experiments made by Dr Dobson of Liverpool, and Mr Becket of Bristol, it appears that air purer than the common atmosphere can be extracted from sea-water, and the water of the hot well at Bristol.

A new species of inflammable gas has been discovered by Dr Ingenhousz. This is procured by putting a single drop of vitriolic ether into an inflammable air-pistol, containing about ten cubic inches: it communicates to the common air contained in the pistol, a strong explosive force. It is very remarkable, that the gravity of this inflammable gas exceeds that extracted from iron, in the proportion of 150 to 25. It is even heavier than common air, in the proportion of 150 to 138: so that, if too great a quantity of it contained in the air-pistol, and the consequent exclusion of too much of the common air, prevent it from taking fire, it will fall out, on holding the pistol a few seconds inverted, with its mouth open; and, in consequence of the entrance of a proper quantity of common air in its room, the explosion will take place.—Another very remarkable circumstance is, that though ether itself is so very volatile, and evaporates so quickly; yet this elastic vapour, generated from it, will remain some hours in an open glass, without such diminution from evaporation, or its mixing with the atmosphere, as to destroy its inflammable quality.

From these experiments we cannot conclude any thing with certainty. They only evince, in one case, the transmutation of the *gas sylvestre* of Helmont, our fixed air, into atmospheric air. With regard to this last, it seems also to be pretty plain, that, in some cases, the element of *fire*, in others that of *light*, enters largely into its composition. But whether these elements are, in such cases, combined with any part of the terrestrial matter, or whether they are only new-modelled by some different arrangement of their parts, must be determined by future experiments.

GASCOIGNE (Sir William), chief justice of the court of king’s bench under Henry IV. A most learned and upright judge who, being insulted on the bench by the then prince of Wales, afterwards Henry V. with equal intrepidity and coolness committed the prince to prison; and by this seasonable fortitude, laid the foundation of the future glory of that great monarch, who, from this event, dated his reformation from the licentiousness of his youth. It is not well authenticated that the prince struck Sir William,

as recorded by Shakespeare; but all authors agree, Gascoigne that he interrupted the course of justice, to screen a low servant. Sir William died in 1413.

GASCOIGNE (George), an English poet of some fame in the early part of the reign of Queen Elizabeth, was born at Walthamstow in Essex, of an ancient family, and educated at both universities, but principally at Cambridge. From thence he removed to Gray’s Inn, and commenced student of the law; but, having a genius too volatile for that study, he travelled abroad, and for some time served in the army in the Low Countries. He afterwards went to France; where he became enamoured of a Scottish lady, and married her. Being at length, says Wood, *weary of those vanities*, he returned to England; and settled once more in Gray’s Inn, where he wrote most of his dramatic and other poems. The latter part of his life he spent in his native village of Walthamstow, where he died in the year 1578. He had the character of a polite gentleman, an eloquent and witty companion, *et vir inter poetas sui seculi præstantissimus*. His plays, first printed separately, were afterwards, with several other poems, &c. reprinted in two volumes 4to. the first volume in 1577, the second in 1587.

GASCOIN, or GASCOIGN, denotes the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

GASCONADE, a boast or vaunt of something very improbable. The term has its rise from the Gascons, or people of Gascony in France, who it seems have been distinguished for bragging and rhodomontado.

GASCONY, the most south-west province of France, is bounded by Guienne on the north, by Languedoc on the east, by the Pyrenees which separate it from Spain on the south, and by the bay of Biscay on the west. It had its name from the ancient inhabitants called *Gascones*, or *Vascones*; by the moderns *Basques*, or *Vasques*. After these were subdued by the Franks, they had for some time dukes of their own, who were subject to the dukes of Aquitaine; but both were at last dispossessed by the kings of France. The country produces corn, wine, fruits, tobacco, hemp, brandy, prunes, &c. The inhabitants are noted for a corrupt and vicious pronunciation of the French tongue, as well as their vain-glorious boasting.

GASSENDI (Peter), one of the most celebrated philosophers France has produced, was born at Chanterrier, about three miles from Digne in Provence, in 1592. When a child, he took particular delight in gazing at the moon and stars, as often as they appeared in clear unclouded weather. This pleasure frequently drew him into bye-places, in order to feast his eye freely and undisturbed; by which means his parents had him often to seek, not without many anxious fears and apprehensions. They therefore put him to school at Digne; where, in a short time, he made such an extraordinary progress in learning, that some persons, who have seen specimens of his genius, resolved to have him removed to Aix, in order to study philosophy under Feytaud, a learned minor friar. This proposal was so disagreeable to his father, who intended to breed him up in his own way to country-business, as being more profitable than that of a scholar, that he would consent to it only upon condition that he should

return

return home in two years at farthest. Accordingly young Gassendi, at the end of the appointed time, repaired to Chanterfer: but he had not been long there, when he was invited to be professor of rhetoric at Digne, before he was quite 16 years of age; and he had been engaged in that office but three years, when his master Felay dying, he was made professor in his room at Aix. When he had been there a few years, he composed his *Paradoxical Exercitations*; which, coming to the hands of Nicholas Peirese, that great patron of learning joined with Joseph Walter prior of Valette in promoting him; and he, having entered into holy orders, was first made canon of the church of Digne and doctor of divinity, and then obtained the wardenship or rectorship of that church. Gassendi's fondness for astronomy grew up with his years; and his reputation daily increasing, he was, in 1645, appointed royal professor of mathematics at Paris. This institution being chiefly designed for astronomy, our author read lectures on that science to a crowded audience. However, he did not hold this place long; for a dangerous cough and inflammation of the lungs obliged him, in 1647, to return to Digne for the benefit of his native air.—Gassendi wrote against the metaphysical meditations of Des Cartes; and divided with that great man the philosophers of his time, almost all of whom were Cartesian or Gassendians. He joined to his knowledge of philosophy and the mathematics, an acquaintance with the languages and a profound erudition. He wrote, 1. Three volumes on Epicurus's Philosophy; and six others, which contain his own philosophy. 2. Astronomical works. 3. The lives of Nicholas de Peirese, Epicurus, Copernicus, Tycho Brahe, Peurbachius, and Regiomontanus. 4. Epistles, and other treatises. All his works were collected together, and printed at Lyons in 1658, in six volumes folio. He died at Paris in 1655, aged 63.

GASTEROSTEUS, the STICKLE-BACK, in ichthyology, a genus of fishes belonging to the order of thoracici. There are three rays in the membrane of the gills; the body is carinated; and there are some distinct prickles before the back-fin. There are 11 species distinguished by the number of prickles on the back. One of these species, the aculeatus, stickleback, bankie, or sharpling, is common in many of the British rivers. In the fens of Lincolnshire, and some rivers that proceed from them, they are found in prodigious quantities. At Spalding there are, once in seven or eight years, amazing shoals that appear in the Welland, and come up the river in form of a vast column. They are supposed to be the multitudes that have been washed out of the fens by the floods of several years, and collected in some deep hole, till, overcharged with numbers, they are periodically obliged to attempt a change of place. The quantity is so great, that they are used to manure the land, and trials have been made to get oil from them. A notion may be had of this vast shoal, by being informed, that a man being employed by the farmer to take them, has got for a considerable time four shillings a-day by felling them for a half-penny per bushel.—This species seldom reaches the length of two inches; it hath three sharp spines on the back, that can be raised or depressed at pleasure. The colour of the back and sides is an olive-green; the belly white; but in some the lower jaws and belly are of

a bright crimson.

GAST-HOUND. See GAZE-HOUND.

GASTRELL (Francis), bishop of Chester, was born in 1662, appointed preacher to the society of Lincoln's Inn in 1694, and made bishop of Chester in 1714. He preached a course of sermons for Boyle's lectures; engaged in the Trinitarian controversy with Mr Collins and Dr Clarke; and published two excellent pieces, the one intitled, *Christian Institutes*, and the other, *A moral proof of a future state*. He vindicated the rights of the university of Oxford, against the archbishop of Canterbury, in the appointment of the warden of Manchester college; and opposed the violent proceedings against bishop Atterbury in the house of lords, though he disliked the bishop as a man of arbitrary principles. He died in 1725.

GASTRIC, in general, something belonging to the stomach.

GASTRIC Juice, a thin pellucid liquor, which distills from certain glands in the stomach, for the dilution, &c. of the food.

From some late experiments it appears, that this juice is the chief instrument of digestion; but in what manner this operation is performed by it, remains yet a secret. It is not possessed of any corrosive acrimony, for this would act upon all substances indiscriminately; but the gastric juice is found to act only upon particular substances. The most remarkable particularity of this kind is, that though it very readily dissolves animal substances when deprived of the vital principle, it absolutely refuses to touch those which are alive. This would seem to favour the opinion formerly in vogue, that digestion was performed by means of a kind of fermentation induced into the substances swallowed for food; as very probably the parts of living animals may be capable of resisting those fermentations which readily take place in dead ones. But whether or not this is the case, must be determined by future experiments.

GASTROCNEMIUS, in anatomy. See ANATOMY, *Table of the Muscles*.

GASTROMANCY, a method of divination by water, practised by the ancient Greeks. See DIVINATION.

GASTRORAPHY, in surgery, the operation of sewing up wounds of the abdomen. See SURGERY.

GATE, in architecture, a large door, leading or giving entrance into a city, town, castle, palace, or other considerable building; or a place giving passage to persons, horses, coaches, or waggons, &c. As to their proportion, the principal gates for entrance thro' which coaches and waggons are to pass, ought never to be less than seven feet in breadth, nor more than 12, which last dimension is fit only for large buildings. The height of a gate is to be $\frac{1}{2}$ of the breadth, and somewhat more; but as for common gates in inns, under which waggons go loaded with hay, straw, &c. the height of them may be twice their breadth. See ARCHITECTURE.

GATES of Hell. This expression is used in scripture, to denote figuratively, either the *grave*, or the *powers of darkness*, i. e. the devil and his angels.

The Mahometans use the expression literally, and suppose that hell has seven gates. The first is that where Mussulmans, who incur the guilt of sin, will be tormented. The second is for the Christians. The

Gataker,
Gauden.

third is for the Jews. The fourth for the Sabians. The fifth for the Magians, or worshippers of fire. The sixth for Pagans and idolaters. And the seventh for hypocrites, who make an outward shew of religion, but have none.

GATAKER (Thomas), a learned critic and divine, was born at London in 1574, and studied at St John's college, Cambridge. He was afterwards chosen preacher at Lincoln's Inn; which he quitted in 1611, for the rectory of Rotherhithe in Surry. In 1620, he made a tour through the Low Countries; and, in 1624, published at London a book intitled, "Transubstantiation declared by the confession of the Popish writers to have no necessary foundation in God's word:" he wrote likewise a defence of this discourse. In 1642, he was appointed one of the assembly of divines, and was engaged with them in writing annotations upon the bible. He died in July 1654, in the 80th year of his age. Besides the above works, he published, 1. A dissertation upon the style of the New Testament. 2. *De nomine tetragrammata*. 3. *De diphthongis, five bisocalibus*. 4. An edition and translation of the emperor Marcus Antoninus's meditations. 5. A collection of sermons, in folio; and many other works. His piety and charity were very exemplary; and his modesty so great, that he declined all ecclesiastical dignity and court-preferments. His extensive learning was admired by Salmasius and other great men abroad; his house was a private seminary for young gentlemen of this nation, and many foreigners resorted to him to receive advice in their studies.

GAUDEN (Dr Joseph), son of John Gauden vicar of Mayfield in Essex, was born there in 1605. At the commencement of the civil war, he was chaplain to Robert earl of Warwick; who taking part with the parliament against the king, was followed by his chaplain. Upon the establishment of the presbyterian model of church-government, he complied with the ruling powers, and was nominated one of the assembly of divines who met at Westminster in 1643, and took the covenant; yet having offered some scruples and objections to it, his name was afterward struck out of the list. Nor did he espouse the parliament-cause any longer than they adhered to their first avowed principles of reforming only, instead of destroying, monarchy and episcopacy. In this spirit he was one of those divines who signed a protestation to the army, against the violent proceedings that affected the life of the king; and a few days after his execution published the famous *EVANGELIUM*, *A Portraiture of his sacred Majesty in his solitude and sufferings*; which ran through 50 editions in the course of a year. Upon the return of Charles II. he was promoted to the see of Exeter; and in 1662 was removed to Worcester, much to his regret, having flattered himself with the hopes of a translation to Winchester: and his death happened the same year. He wrote many controversial pieces suited to the circumstances of the times, and to his own views from them.—The *Eikon Basilike* above mentioned he published as the king's private meditations; though on this point there has been a long controversy. After the bishop's death, his widow, in a letter to one of her sons, calls it "The Jewel;" and said, her husband had hoped to make a fortune by it; and that she had a letter of a very great man's, which would

clear up that he writ it. This assertion, as the earl of Clarendon had predicted, was eagerly espoused by the anti-royalists, in the view of disparaging Charles I. But it has been observed, that Gauden had too luxurious an imagination, which betrayed him into a rankness of style in the Abiatic way; and from thence, as bishop Burnet argues with others, it may be certainly concluded, that not he, but the king himself, was the true author of the *EVANGELIUM*; in which there is a nobleness and justness of thought, with a greatness of style, that made it be looked on as the best written book in the English language.

GAVEL, or GABLE, among builders. See GABLE. GAVEL, in law: tribute, toll, custom, or yearly revenue; of which we had in old time several kinds. See GABEL.

GAVEL-Kind, a tenure or custom belonging to lands in the county of Kent. The word is said by Lambard to be compounded of three Saxon words, *gafe, eal, kyn*, "omnibus cognatione proximis data." Verilegan calls it *gavelkind*, quasi "give all kind," that is, to each child his part: and Taylor, in his history of *gavelkind*, derives it from the British *gavel*, i. e. a hold or tenure, and *cenned*, "generatio aut familia;" and so *gavel cenned* might signify *tenura generationis*.—It is universally known what struggles the Kentish men made to preserve their ancient liberties, and with how much success those struggles were attended. And as it is principally here that we meet with the custom of *gavelkind*, (though it was and is to be found in some other parts of the kingdom), we may fairly conclude, that this was a part of these liberties; agreeably to Mr Selden's opinion, that *gavelkind*, before the Norman conquest, was the general custom of the realm. The distinguishing properties of this tenure are various: some of the principal are these. 1. The tenant is of age sufficient to alienate his estate by feoffment, at the age of 15. 2. The estate does not escheat in case of an attainer and execution for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places he had a power of devising lands by will, before the statute for that purpose was made. 4. The lands descend, not to the eldest, youngest, or any one son only, but to all the sons together; which was indeed anciently the most usual course of descent all over England, tho' in particular places particular customs prevailed.

GAVLET; in law, an ancient and special cessavit used in Kent, where the custom of *gavelkind* continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his lands and tenements.

The process of the *gavlet* is thus. The lord is first to seek by the steward of his court, from three weeks to three weeks, to find some distress upon the tenement, till the fourth court; and if at that time he find none, at this fourth court it is awarded, that he take the tenement in his hand in name of a distress, and keep it a year and a day without manuring; within which time, if the tenant pay his arrears, and make reasonable amends for the with-holding, he shall have and enjoy his tenement as before: if he come not before the year and day be past, the lord is to go to the next county-court, with witnesses of what had passed at his own court, and pronounce there his process, to have

Gavel,
Gavelkind.

Gavelet
||
Gaul.

have further witnesses; and then by the award of his own court, he shall enter and manure the tenement as his own: so that if the tenant desired afterwards to have and hold it as before, he must agree with the lord; according to this old saying: "Has he not since any thing given, or any thing paid, then let him pay five pound for his hire, e're he become heilder again." Other copies have the first part with some variation; "Let him nine times pay, and nine times repay."

GAVELET, in London, is a writ used in the hustings, given to lords of rents in the city of London. Here the parties, tenant and demandant, appear by *fire facias*, to shew cause why the one should not have his tenement again on payment of his rent, or the other recover the lands on default thereof.

GAUGAMELA, (anc. geog.), a village of Attica, lying between the rivers Lycus and Tigris; famous for Alexander's victory over Darius. It is said to have been allowed to Darius Hyllaspes for the maintenance of a camel; and hence the name. It was not far from a more considerable place called *Arbela*; whence the latter gave the name to the victory. See **ARBELA**.

GAUGE-POINT of a solid measure, the diameter of a circle whose area is equal to the solid content of the same measure.

GAUGER, a king's officer, who is appointed to examine all tuns, pipes, hogheads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

GAUGING. See **GEOMETRY**.

GAUL, the name given by the Romans to the present kingdom of France.—The original inhabitants were descended from the Celtes or Gomerians, by whom the greatest part of Europe was peopled; the name of *Galli*, or *Gauls*, being probably given them long after their settlement in that country.

The ancient history of the Gauls is entirely wrapped up in obscurity and darkness; all we know concerning them for a long time is, that they multiplied so fast, that, their country being unable to contain them, they poured forth in vast multitudes into other countries, which they generally subdued, and settled themselves in. It often happened, however, that these colonies were so molested by their neighbours, that they were obliged to send for assistance to their native country. This was always very easily obtained. The Gauls were, upon every occasion, ready to send forth great numbers of new adventurers; and as these spread desolation where-ever they came, the very name of *Gauls* proved terrible to most of the neighbouring nations.—The earliest excursion of these people of which we have any distinct account, was into Italy, under a famed leader, named *Bellovesus*, about 622 years before Christ. He crossed the Rhone and the Alps, till then unattempted; defeated the Etrurians; and seized upon that part of their country, since known by the names of *Lombardy* and *Piedmont*.—The second grand expedition was made by the Cœnomani, a people dwelling between the rivers Seine and Loire, under a general named *Eltioin*. They settled in those parts of Italy, now known by the names of *Bresciano*, *Cremonesse*, *Mantuan*, *Carniola*, and *Venetian*.

—In a third excursion, two other Gaulish nations set-

tled on both sides of the river Po; and in a fourth, the Boii and Lingones settled in the country between Ravenna and Bologna. The time of these three last expeditions is uncertain.

The fifth expedition of the Gauls was more remarkable than any of the former, and happened about 200 years after that of *Bellovesus*. The Senones, settled between Paris and Meaux, were invited into Italy by an Etrurian lord, and settled themselves in Umbria. Brennus their king laid siege to Clusium, a city in alliance with Rome: and this produced a war with the Romans, in which the latter were at first defeated, and their city taken and burnt; but at length the whole army was cut off by Camillus, inasmuch that not a single person escaped.

Some other expeditions the Gauls undertook against the Romans: in which, though they always proved unsuccessful, by reason of their want of military discipline; yet their fierceness and courage made them so formidable to the republic, that, on the first news of their march, extraordinary levies of troops were made, sacrifices and public supplications offered to the gods, and the law which granted an immunity from military service to priests and old men, was, for the time, abolished.

Against the Greeks, the expeditions of the Gauls were very little more successful than against the Romans. The first of these we hear of, was about 279 years before Christ, in the year after Pyrrhus had invaded Italy. At this time, the Gauls finding themselves greatly overlooked at home, sent out three great colonies to conquer new countries for themselves. One of these armies was commanded by *Brennus*, another by *Cerethrius*, and the third by *Belgicus*. The first entered Pannonia or Hungary; the second Thrace; and the third marched into Illyricum and Macedonia. Here *Belgicus* at first met with great success; and enriched himself by plunder to such a degree, that *Brennus* envying him, resolved to enter the same countries, in order to share the spoil. In a short time, however, *Belgicus* met with such a total defeat, that his army was almost entirely destroyed; upon which *Brennus* halted to the same place. His army at first consisted of 150,000 foot and 15,000 horse: but two of his principal officers revolted, and carried off 20,000 men, with whom they marched into Thrace; where, having joined *Cerethrius*, they seized on Byzantium and the western coast of Propontis, making the adjacent parts tributary to them.—To retrieve this loss, *Brennus* sent for fresh supplies from Gaul; and having increased his army to 150,000 foot, and upwards of 60,000 horse, he entered Macedonia, defeated the general who opposed him, and ravaged the whole country. He next marched towards the straits of Thermopylæ, with a design to invade Greece; but was stopped by the forces sent to defend that pass against him. He passed the mountains, however, as Xerxes had formerly done; upon which the guards retired, to avoid being surrounded. *Brennus* then, having ordered *Acichærius*, the next to him in command, to follow at a distance with part of his army, marched with the bulk of the forces to Delphi, in order to plunder the rich temple there. This enterprise proved exceedingly unfortunate: a great number of his men were destroyed by a dreadful storm of hail, thunder, and lightning; another

another part of his army was destroyed by an earthquake; and the remainder, some how or other, imagining themselves attacked by the enemy, fought against each other the whole night, so that in the morning scarce one half of them remained. The Greek forces then poured in upon them from all parts; and that in such numbers, that though Acichorius came up in due time with his forces, Brennus found himself unable to make head against the Greeks, and was defeated, with great slaughter. He himself was desperately wounded; and so disheartened by his misfortune, that, having assembled all his chiefs, he advised them to kill all the wounded and disabled, and to make the best retreat they could; after which, he put an end to his own life. On this occasion, it is said that 20,000 of these unhappy people were executed by their own countrymen. Acichorius then set out with the remainder for Gaul; but by being obliged to march through the country of their enemies, the calamities they met with by the way were so grievous, that not one of them reached their own country. A just judgement, say the Greek and Roman authors, for their sacrilegious intentions against Delphi.

The Romans having often felt the effects of the Gaulish ferocity and courage, thought proper at last, in order to humble them, to invade their country. Their first successful attempt was about 118 years before Christ, under the command of Quintus Marcius, surnamed Rex. He opened a way betwixt the Alps and the Pyrenees, which laid the foundation for conquering the whole country. This was a work of immense labour of itself, and rendered still more difficult by the opposition of the Gauls, especially those called the Steni, who lived at the foot of the Alps. These people finding themselves overpowered by the consular army, set fire to their houses, killed their wives and children, and then threw themselves into the flames. After this Marcius built the city of Narbonne, which became the capital of a province. His successor Scaurus also conquered some Gaulish nations; and in order to facilitate the sending troops from Italy into that country, he made several excellent roads between them, which before were almost impassable. These successes gave rise to the invasion of the Cimbri and Teutones; an account of whose unfortunate expedition is given under the articles CIMBRI, ROME, TEUTONES, &c.

From this time, the Gauls ceased to be formidable to the Romans, and even seem to have been for some time on good terms with them. At last, however, the Helvetii kindled a war with the republic, which brought Cæsar over the Alps, and ended in the total subjection of the country. Orgetorix was the first cause of it; who had engaged a vast number of his countrymen to burn their towns and villages, and to go in search of new conquests. Julius Cæsar, to whose lot the whole country of Gaul had fallen, made such haste to come and suppress them, that he was got to the Rhone in eight days; broke down the bridge of Geneva, and, in a few days more, finished the famed wall between that city and mount Jura, now St Claude, which extended seventeen miles in length, was sixteen feet high, fortified with towers and castles at proper distances, and a ditch that ran the whole length of it. If his own account of it may be relied upon, he

did not set out till the beginning of April; and yet this huge work was finished by the ides or 13th of the month: so that, subtracting the eight days he was coming, it must have been all done in about five days: a prodigious work, considering he had but one legion there, or even though the whole country had given him assistance. Whilst this was doing, and the reinforcements he wanted were coming, he amused the Helvetii, who had sent to demand a passage through the country of the Allobroges, till he had got his reinforcements; and then flatly refused it to them: whereupon a dreadful battle ensued; in which they lost one hundred and thirty thousand men, in spite of all their valour; besides a number of prisoners, among whom was the wife and daughter of Orgetorix, the leader of this unfortunate expedition. The rest submitted, and begged they might be permitted to go and settle among the Ædui, from whom they originally sprung; and, at the request of these last, were permitted to go.

The Gauls were constantly in a state of variance with one another; and Cæsar, who knew how to make the most of these intestine broils, soon became the protector of the oppressed, a terror to the oppressor, and the umpire of all their contentions. Among those who applied to him for help, were his allies the Ædui; against whom Ariovistus, king of the Germans, joined with the Arverni, who inhabited the banks of the Loire, had taken the country of the Sequani from them, and obliged them to send hostages to him. Cæsar forthwith sent to demand the restitution of both, and, in an interview which he soon after obtained of that haughty and treacherous prince, was like to have fallen a sacrifice to his perfidy; upon which he bent his whole power against him, forced him out of his strong intrenchments, and gave him a total overthrow. Ariovistus escaped, with difficulty, over the Rhine; but his two wives, and a daughter, with a great number of Germans of distinction, fell into the conqueror's hand. Cæsar, after this signal victory, put his army into winter-quarters, whilst he went over the Alps to make the necessary preparations for the next campaign. By this time all the Belgæ in general were so terrified at his success, that they entered into a confederacy against the Romans, as their common enemy. Of this, Labienus, who had been left in Gaul, sent Cæsar notice; upon which, he immediately left Rome, and made such dispatch, that he arrived upon their confines in about fifteen days. On his arrival, the Rhemi submitted to him; but the rest, appointing Galba, king of the Sueffones, general of all their forces, which amounted to one hundred and fifty thousand men, marched directly against him. Cæsar, who had seized on the bridge of the Axona, now Aisne, led his light horse and infantry over it; and, whilst the others were incumbered in crossing that river, made such a terrible slaughter of them, that the river was filled with their dead, inasmuch that their bodies served for a bridge to those who escaped. This new victory struck such terror into the rest, that they dispersed themselves; immediately after which, the Sueffones, Belovaci, Ambiones, and some others, submitted to him. The Nervii, indeed, joined with the Atrebatas and Veromandui, against them; and, having first secured

their wives and children, made a vigorous resistance for some time; but were at length defeated, and the greatest part of them slain. The rest, with their wives and old men, surrendered themselves, and were allowed to live in their own cities and towns as formerly. The Aduatici were next subdued; and, for their treachery to the conquerors, were sold for slaves, to the number of fifty thousand. Young Crassus, the son of the triumvir, subdued likewise seven other nations, and took possession of their cities; which not only completed the conquest of the Belgæ, but brought several nations from beyond the Rhine to submit to the conqueror. The Veneti, or ancient inhabitants of Vannes in Brittany, who had been likewise obliged to send hostages to the conqueror, were, in the mean time, making great preparations, by sea and land, to recover their liberty. Cæsar, then in Illyricum, was forced to equip a fleet on the Loire; and, having given the command of it to Brutus, went and defeated them by land, as Brutus did by sea; and, having put their chief men to death, sold the rest for slaves. The Unelli, with Veridoric their chief, together with the Lexovii and Aulerci, were, about the same time, subdued by Sabinus, and the Aquitani by Crassus, with the loss of thirty thousand men. There remained nothing but the countries of the Morini and Menapii to be conquered, of all Gaul. Cæsar marched himself against them: but he found them so well intrenched in their inaccessible fortresses, that he contented himself with burning and ravaging their country; and, having put his troops into winter-quarters, again passed over the Alps, to have a more watchful eye on some of his rivals there. He was, however, soon after obliged to come to defend his Gaulish conquests against some nations of the Germans, who were coming to settle there, to the number of four hundred thousand. These he totally defeated, and then resolved to carry his conquering arms into Germany: but for an account of his exploits there, see the article GERMANY.

Upon his return into Gaul, he found it labouring under a great famine, which had caused a kind of universal revolt. Cotta and Sabinus, who were left in the country of the Eburones, now Liège, were betrayed into an ambush by Ambiorix, one of the Gaulish chiefs, and had most of their men cut off. The Aduatici had fallen upon Q. Cicero, who was left there with one legion, and had reduced him to great straits: at the same time Labienus, with his legion, was attacked by Indutiomarus, at the head of the Rhæni and Senones; but had better luck than the rest, and, by one bold sally upon them, put them to flight, and killed their general. Cæsar acquired no small credit by quelling all these revolts; but each victory lost the lives of so many of his troops, that he was forced to have recourse to Pompey for a fresh supply, who readily granted him two of his own legions to secure his Gaulish conquests.

But it was not long before the Gauls, ever restless under a foreign yoke, raised up a new revolt, and obliged him to return thither. His fear lest Pompey should gain the affections of the Roman people, had obliged him to strip the Gauls of their gold and silver, to bribe them over to his interest; and this gave no small handle to those frequent revolts which happened during his absence. He quickly, however, reduced

the Nervii, Adnatici, Menapii, and Treviri; the last of whom had raised the revolt, under the command of Ambiorix: but he found the flame spread much farther, even to the greatest part of the Gauls, who had chosen Vercingetorix their generalissimo. Cæsar was forced to leave Insurbria, whither he had retired to watch the motions of Pompey, and, in the midst of winter and snow, to repass the Alps, into the province of Narbonne. Here he gathered his scattered troops with all possible speed; and, in spite of the hard weather, besieged and took Noviodunum, now Noyons; and defeated Vercingetorix, who was come to the relief of that place. He next took the city of Avaricum, now Bourges, one of the strongest in Gaul, and which had a garrison of forty thousand men; of whom he made such a dreadful slaughter, that hardly eight hundred escaped. Whilst he was besieging Gergovia, the capital of the Arverni, he was informed that the Nitiobriges, or Agenois, were in arms; and that the Ædui were sending to Vercingetorix ten thousand men, which they were to have sent to reinforce Cæsar. Upon this news, he left Fabius to carry on the siege, and marched against the Ædui. There, upon his approach, submitted, in appearance, and were pardoned; but soon after that whole nation rose up in arms, and murdered all the Italian troops in their capital. Cæsar, at this, was in great straits what measures to take; but resolved at length to raise the siege of Gergovia, and at once attack the enemy's camp, which he did with some success: but when he thought to have gone to Noviodunum, or Noyons, where his baggage, military chest, &c. were left, he heard that the Ædui had carried it off, and burnt the place. Labienus, jolly thinking that Cæsar would want his assistance in the condition he now was, went to join him, and in his way defeated a Gaulish general, named Camlogenus, who came to oppose his march: but this did not hinder the revolt from spreading itself all over Celtic Gaul, whither Vercingetorix had sent for fresh supplies, and, in the mean time, attacked Cæsar; but was defeated, and forced to retire to Alesia, a strong place, now Aisne in Burgundy, as is supposed. Hither Cæsar hastened, and besieged him; and, having drawn a double circumvallation, with a design to starve him in it, as he was likely to have done, upon that account refused all offers of a surrender from him. At length, the long-expected reinforcement came, consisting of one hundred and sixty thousand men, under four generals: these made several fruitless attacks on Cæsar's trenches; but were defeated in three several battles, which at length obliged Vercingetorix to surrender at discretion. Cæsar used all his prisoners with great severity, except the Ædui and Arverni, by whose means he hoped to gain their nations, which were the most potent of Celtic Gaul: nor was he disappointed; for both of them submitted to him, and the former received him into their capital, where he spent the winter, after he had put his army into winter-quarters. This campaign, as it proved one of the hardest he ever had, so he gained more glory by it than any Roman general had done before: yet could not all by this procure from the servile senate, now wholly dedicated to his rival, a prolongation of his proconsulship; upon which he is reported to have laid his hand upon his sword, and said, that that should do it.

Gaul.

He was good as his word; and the Gauls, upon their former ill success, resolving to have as many separate armies as provinces, in order to embarrass him the more, Cæsar, and his generals Labienus and Fabius, were forced to fight them one after another; which they did, however, with such success, that, notwithstanding the hardness of the season, they subdued the Bituriges, Carnuti, Rhemi, and Bellovaci, with their general Corbous, by which he at once quieted all the Belgic provinces bordering on Celtic Gaul. The next who followed were the Treviri, the Eburones, and the Andes, under their general Dunmarus. The last place which held out against him was Uxelodunum; which was defended by the two last acting generals of the Gauls, Drapes the Senonian, and Luterius the Cadurcean. The place being strong, and well garrisoned, Cæsar was obliged to march thither, from the farthest part of Belgic Gaul; and soon after reduced it, for want of water. Here again he caused the right-hands of all that were fit to bear arms to be cut off, to deter the rest from revolting afresh. Thus was the conquest of Gaul finished from the Alps and Pyrenees to the Rhine, all which vast tract was now reduced to a Roman province under the government of a prætor. During his several expeditions into Gaul, Cæsar is said to have taken 800 cities; to have subdued 300 different nations; and to have defeated, in several battles, three millions of men, of whom one million were killed, and another taken prisoner.—The history of the country, from the time of its conquest by the Romans to the present, is given under the articles **ROME** and **FRANCE**.

32
Character,
&c. of the
ancient
Gauls.

The Gauls anciently were divided into a great number of different nations, which were continually at war with one another, and at variance among themselves. Cæsar tells us, that not only all their cities, cantons, and districts, but even almost all families, were divided and torn by factions; and thus undoubtedly facilitated the conquest of the whole. The general character of all these people was an excessive ferocity and love of liberty. This last they carried to such an extreme, that either on the appearance of servitude, or incapacity of action through old age, wounds, or chronic diseases, they put an end to their own lives, or prevailed upon their friends to kill them. In cities, when they found themselves so strictly besieged that they could hold out no longer, instead of thinking how to obtain honourable terms of capitulation, their chief care very often was to put their wives and children to death, and then to kill one another, to avoid being led into slavery. This excessive love of liberty and contempt of death, according to Strabo, very much facilitated their conquest by Cæsar; for putting their numerous forces upon such an experienced enemy as Cæsar, their want of conduct very soon proved the ruin of the whole.

The chief diversion of the Gauls was hunting; and indeed, considering the vast forests with which their country abounded, and the multitude of wild beasts which lodged in them, they were under an absolute necessity to hunt and destroy them, to prevent the country from being rendered totally uninhabitable. Besides this, however, they had also their hippodromes, horse and chariot races, tilts and tournaments; at all of which the bards assisted with their poems, songs,

and musical instruments.—For an account of their religion, see the article **DRUID**.

The Gauls were excessively fond of feasting, in which they were very profuse; as, like all other northern nations, they were great lovers of good eating and drinking. Their chief liquors were beer and wine. Their tables were very low. They eat but little bread, which was baked flat and hard, and easily broken in pieces: but devoured a great deal of flesh, boiled, roasted, or broiled; and this they did in a very slovenly manner, holding the piece in their hands, and tearing it with their teeth. What they could not part by this way, they cut with a little knife which hung at their girdle. When the company was numerous, the *Coryphæe*, or chief of the feast, who was either one of the richest, or noblest, or bravest, sat in the middle, with the master of the house by his side; the rest took their places next according to their rank, having their servants holding their shields behind them. These feasts seldom ended without bloodshed; but if by chance the feast proved a peaceable one, it was generally accompanied not only with music and songs, but likewise with dances, in which the dancers were armed cap-a-pee, and beat time with their swords upon their shields. On certain festivals they were wont to dress themselves in the skins of beasts, and in that attire accompany the processions in honour of their deities or heroes. Others dressed themselves in masquerade habits, some of them very indecent, and played several antic and inmodest tricks. This last custom continued long after their conversion to Christianity.

GAUNT-BELLIED, in the manege, is said of a horse whose belly shrinks up towards his flanks.

GAUNTLOPE, pronounced *gauntlet*, a military punishment for felony, or some other heinous offence.

In vessels of war, it is executed in the following manner. The whole ship's crew is disposed in two rows, standing face to face, on both sides of the deck, so as to form a lane whereby to go *forward* on one side, and return *ast* on the other; each person being furnished with a small twisted cord, called a *knittle*, having two or three knots upon it. The delinquent is then stripped naked above the waist, and ordered to pass forward between the two rows of men, and ast on the other side, a certain number of times, rarely exceeding three; during which every person gives him a stripe as he runs along. In his passage through this painful ordeal, he is sometimes tripped up, and very severely handled while incapable of proceeding. This punishment, which is called *running the gauntlet*, is seldom inflicted, except for such crimes as will naturally excite a general antipathy among the seamen; as, on some occasions, the culprit would pass without receiving a single blow, particularly in cases of mutiny and sedition, to the punishment of which our sailors seem to have a constitutional aversion.

In the land-service, when a soldier is sentenced to run the gauntlet, the regiment is drawn out in two ranks facing each other; each soldier, having a switch in his hand, lashes the criminal as he runs along naked from the waist upwards. While he runs, the drums beat at each end of the ranks. Sometimes he runs three, five, or seven times, according to the nature of the offence. The major is on horseback, and takes care that each soldier does his duty.

Gaul

Gauntlope.

Gavotta
|
Gay.

GAVOTTA, or **GAVOTTE**, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains is twice played over. The first has usually four or eight bars; and the second contains eight, twelve, or more. The first begins with a minim, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant or mediant of the mode, but never upon the final, unless it be a rondeau: and the last begins with the rise of the hand, and ends with the fall upon the final of the mode.

Tempi di GAVOTTA, is when only the time or movement of a gavotte is imitated, without any regard to the measure, or number of bars or strains.—Little airs are often found in sonatas, which have this phrase to regulate their motions.

GAUZE, or **GAUSE**, in commerce, a very slight, thin, open kind of stuff, made of silk, sometimes of thread. There are also figured gauzes, and some with gold or silver on silk ground.

GAY (John), a celebrated English poet, descended from an ancient family in Devonshire, was born at Exeter, and received his education at the free school of Barnstaple in that county, under the care of Mr. William Rayner.—He was bred a mercer in the Strand; but having a small fortune, independent of business, and considering the attendance on a shop as a degradation of those talents which he found himself possessed of, he quitted that occupation, and applied himself to other views, and to the indulgence of his inclination for the muses. In 1712 we find him secretary, or rather domestic steward, to the duchess of Monmouth, in which station he continued till the beginning of the year 1714; at which time he accompanied the earl of Clarendon to Hanover, whither that nobleman was dispatched by queen Anne. In the latter end of the same year, in consequence of the queen's death, he returned to England, where he lived in the highest estimation and intimacy of friendship with many persons of the first distinction both in rank and abilities.—He was even particularly taken notice of by queen Caroline, then princess of Wales, to whom he had the honour of reading in manuscript his tragedy of the *Captives*; and in 1726 dedicated his *Fables*, by permission, to the duke of Cumberland.—From this countenance shewn to him, and numberless promises made him of preferment, it was reasonable to suppose, that he would have been genteelly provided for in some office suitable to his inclination and abilities. Instead of which, in 1727, he was offered the place of gentleman-usher to one of the youngest princesses; an office which, as he looked on it as rather an indignity to a man whose talents might have been so much better employed, he thought proper to refuse; and some pretty warm remonstrances were made on the occasion by his sincere friends and zealous patrons the duke and duchess of Queensberry, which terminated in those two noble personages withdrawing from court in disgust. Mr Gay's dependencies on the promises of the great, and the disappointments he met with, he has figuratively described in his fable of the *Hare with many friends*. However, the very extraordinary success he met with from public encouragement made an ample amends, both with respect to satisfaction and emolument, for those private

disappointments.—For, in the season of 1727-8, appeared his *Beggar's Opera*; the vast success of which was not only unprecedented, but almost incredible.—It had an uninterrupted run in London of sixty-three nights in the first season, and was renewed in the ensuing one with equal approbation. It spread into all the great towns of England; was played in many places to the thirtieth and fortieth time, and at Bath and Bristol fifty; made its progress into Wales, Scotland, and Ireland, in which last place it was acted for twenty-four successive nights; and last of all it was performed at Minorca. Nor was the fame of it confined to the reading and representation alone, for the card-table and drawing-room shared with the theatre and closet in this respect; the ladies carried about the favourite songs of it engraven upon their fan-mounts, and screens and other pieces of furniture were decorated with the same. In short, the fate of this piece was so striking, so apparent, and so perfectly adapted to the taste of all degrees of people, that it overthrew the Italian opera, that Dagon of the nobility and gentry, which had so long seduced them to idolatry, and which Dennis, by the labours and outcries of a whole life, and many other writers by the force of reason and reflection, had in vain endeavoured to drive from the throne of public taste. The profits of this piece was so very great, both to the author and Mr Rich the manager, that it gave rise to a quibble, which became frequent in the mouths of many, viz. *That it had made Rich gay, and Gay rich*; and it has been asserted, that the author's own advantages from it were not less than two thousand pounds. In consequence of this success, Mr Gay was induced to write a second part to it, which he entitled *Polly*. But the disgust subsisting between him and the Court, together with the misrepresentations made of him as having been the author of some disaffected libels and seditious pamphlets, occasioned a prohibition and suppression of it to be sent from the lord chamberlain, at the very time when every thing was in readiness for the rehearsal of it. A very considerable sum, however, accrued to him from the publication of it afterwards in quarto.—Mr Gay wrote several other pieces in the dramatic way, and many very valuable ones in verse. Among the latter, his *Trivia*, or the *Art of walking the streets of London*, though his first poetical attempt, is far from being the least considerable, and is what recommended him to the esteem and friendship of Mr Pope: but, as among his dramatic works his *Beggar's Opera* did at first, and perhaps ever will, stand as an unrivalled master-piece, so, among his poetical works, his *Fables* hold the same rank of estimation, the latter having been almost as universally read as the former was represented, and both equally admired. Mr Gay's disposition was sweet and affable, his temper generous, and his conversation agreeable and entertaining. But he had one foible, too frequently incident to men of great literary abilities, and which subjected him at times to inconveniences which otherwise he needed not to have experienced, viz. an excess of indolence, without any knowledge of economy. So that, though his emoluments were, at some periods of his life, very considerable, he was at others greatly straitened in his circumstances; nor could he prevail on himself to follow the advice of his friend dean Swift, whom we find

in many of his letters endeavouring to persuade him to the purchasing of an annuity, as a reserve for the exigencies that might attend on old age.—Mr Gay chose rather to throw himself on patronage, than secure to himself an independent competency by the means pointed out to him; so that, after having undergone many vicissitudes of fortune, and being for some time chiefly supported by the liberality of the duke and duchess of Queensberry, he died at their house in Burlington-gardens, in December 1732. He was interred in Westminster-abbey, and a monument erected to his memory, at the expense of his aforementioned noble benefactors, with an inscription expressive of their regards and his own deserts, and an epitaph in verse by Mr Pope.

GAZA (Theodore), a famous Greek in the 15th century, was born in 1398. His country being invaded by the Turks, he retired into Italy; where he at first supported himself by transcribing ancient authors, an employment the learned had frequent recourse to before the invention of printing. His uncommon parts and learning soon recommended him to public notice; and particularly to cardinal Bessarion, who procured him a benefice in Calabria. He was one of those to whom the revival of polite literature in Italy was principally owing. He translated from the Greek into Latin, Aristotle's History of Animals, Theophrastus on Plants, and Hippocrates's Aphorisms; and put into Greek, Scipio's Dream, and Cicero's Treatise on Old Age. He wrote several other works in Greek and Latin; and died at Rome, in 1475.

GAZA, (anc. geog.) a principal city, and one of the five tetrapoles of the Philistines. It was situated about 100 stadia from the Mediterranean, on an artificial mound, and strongly walled round. It was destroyed by Alexander the Great, and afterwards by Antiochus. In the time of the Maccabees it was a strong and flourishing city; but was destroyed a third time by Alexander Jannæus. At present it has a miserable appearance. The buildings are mean, both as to the form and matter. Some remains of its ancient grandeur appear in the handsome pillars of Parian marble which support some of the roofs; while others are disposed of here and there, in different parts of almost every beggarly cottage. On the top of the hill, at the north-east corner of the town, are the ruins of large arches sunk low into the earth, and other foundations of a stately building, from whence some of the bashaws have carried off marble pillars of an incredible size. The castle is a contemptible structure, and the port is ruined. E. Long. 34. 55. N. Lat. 31. 28.

GAZE-HOUND, or *Gast-hound*, one that makes more use of his sight than of his nose. Such dogs are much used in the north of England: they are fitter in an open champaign country, than in bushy and woody places. If at any time a well-taught gaze-hound takes a wrong way, he will return upon a signal and begin the chase afresh. He is also excellent at spying out the fastest of a herd; and having separated it from the rest, will never give over the pursuit till he has worried it to death.

GAZELLA, in zoology, a species of CAPRA.

GAZETTE, a newspaper, or printed account of

the transactions of all the countries in the known world, in a loose sheet or half-sheet. This name is with us confined to that paper of news published by authority. The word is derived from *gazetta*, a Venetian coin, which was the usual price of the first news-paper printed there, and which was afterwards given to the paper itself.

The first gazette in England was published at Oxford, the court being there, in a folio half-sheet, Nov. 7, 1665. On the removal of the court to London, the title was changed to the *London Gazette*. The Oxford gazette was published on Tuesdays, the London on Saturdays; and these have continued to be the days of publication ever since.

GAZNA, a city of Asia, once much celebrated, and the capital of a very extensive empire; but which is now either entirely ruined, or become of so little consideration, that it is not taken notice of in our books of geography.—This city was anciently an emporium and fortrefs of Sablestan, not far from the confines of India. During the vast and rapid conquests of the Arabs, all this country had been reduced under their subjection. On the decline of the power of the khalifs, however, the vast empire established by Mahomet and his successors was divided into a number of independent principalities, most of which were but of short duration. In the year of the Hegira 384, answering to the 994th of the Christian æra, the city of Gazna, with some part of the adjacent country, was governed by Mahmud Gazni; who became a great conqueror, and reduced under his subjection a considerable part of India, and most of Persia.

This empire continued in the family of Mahmud Gazni for upwards of 200 years. None of his successors, however, were possessed of his abilities; and therefore the extent of the empire, instead of increasing, was very considerably diminished soon after Mahmud's death. The Seljuks made themselves masters of Khorasan, and could not be driven out; the greatest part of the Persian dominions also fell off; and in the 547th year of the Hegira, the race of Gazni sultans were entirely set aside by one Gauri, who conquered Khofru Shah the reigning prince, and bestowed his dominions on his own nephew Gayathoddin Mohammed. These new sultans proved greater conquerors than the former, and extended their dominions farther than even Mahmud Gazni himself had done. They did not, however, long enjoy the sovereignty of Gazna; for in 1218, Jenghiz Khan, having conquered the greatest part of China and almost all Tartary, began to turn his arms westward; and set out against the sultan of Gazna at the head of 700,000 men.

To oppose this formidable army, Mohammed, the reigning sultan, could muster only 400,000 men; and, in the first battle, 160,000 of his troops are said to have perished. After this victory, Jenghiz Khan advanced; Mohammed not daring to risk a second battle, the loss of which would have been attended with the entire ruin of his kingdom. He therefore distributed his army among the strongest fortified towns he had in his dominions; all of which Jenghiz Khan took one after another. The rapid progress of his conquests, indeed, almost exceeds belief. In 1219 and 1220, he had reduced Zarnuk, Nur, Bokhara, Otrar, Saganak, Uzkant, Alhashi, Jund, Tonkat, Khojend, and.

and Samarcand.—Mohammed, in the mean time, fled first to Bokhara; but on the approach of Jenghiz Khan's army, quitted that place, and fled to Samarcand. When this last city was also in danger of being invested, the sultan did not think proper to trust himself in it more than in the other, though it was garrisoned by 110,000 of his bravest troops; and therefore fled through by-ways into the province of Ghilan in Persia, where he took refuge in a strong fortress called *Esfabad*. But being also found out in this retreat, he fled to an island in the Caspian sea called *Abifkun*; where he ended his days, leaving his empire, such as it was, to his son Jaloloddin.

The new sultan was a man of great bravery and experience in war; but nothing was able to stop the progress of the Moguls. In 1220 and 1221, they made themselves masters of all the kingdoms of Kazarum and Khorasan, committing every where such massacres as were never heard of before or since that time. In the mean time Jaloloddin assembled his forces with the utmost diligence, and defeated two detachments of the Mogul army. This happened while Jenghiz Khan was besieging Bamian; but answered little other purpose, than serving to bring upon that city the terrible destruction, of which an account is given under the article BAMIAN. Immediately after the reduction of that city, Jenghiz Khan marched towards Gazna; which was very strongly fortified, and where he expected to have found Jaloloddin. But he had left the place 15 days before; and, as Jenghiz Khan's army was much reduced, he might perhaps have stood his ground, had it not been for an accident. He had been lately joined by three Turkish commanders, each of whom had a body of 10,000 men under his command. After his victories over the Moguls, these officers demanded the greatest share of the spoils; which being refused, they separated themselves from the sultan. He used his utmost endeavours to make them hearken to reason; and sent several messengers and letters to them, representing the inevitable ruin which must attend their separation, as Jenghiz Khan was advancing against them with his whole army. At last they were persuaded to lay aside their animosities; but it was now too late; for Jenghiz Khan, being informed of what passed, detached 60,000 horse to prevent their joining the sultan's army; who finding himself deprived of this powerful aid, retired towards the river Indus. When he was arrived there, he stopped in a place where the stream was most rapid and the place confined, with a view both to prevent his soldiers from placing any hopes of safety in flight, and to hinder the whole Mogul army from attacking him at once. Ever since his departure from Gazna he had been tormented with a colic; yet, at a time when he suffered most, hearing that the enemy's vanguard was arrived at a place in the neighbourhood called *Herder*, he quitted his litter, and, mounting a horse, marched with some of his chosen soldiers in the night; surprised the Moguls in their camp; and having cut them almost all in pieces, without the loss of a single man on his side, returned with a considerable booty.

Jenghiz Khan, finding by this that he had a vigilant enemy to deal with, proceeded with great circumspection. When he came near the Indus, he drew out

his army in battalia: to Jagatay, one of his sons, he gave the command of the right wing; to Oktay, another son, he gave the command of the left; and put himself in the centre, with 6000 of his guards. On the other side, Jaloloddin prepared for battle like one who had no resource but in victory. He first sent the boats on the Indus farther off; reserving only one to carry over his mother, wife, and children; but unluckily the boat split when they were going to embark, so that they were forced to remain in the camp. The sultan took to himself the command of the main body of the army. His left wing, drawn up under shelter of a mountain which hindered the whole right wing of the Moguls from engaging at once, was commanded by his vizir; and his right by a lord named *Amin Malek*. This lord began the fight; and forced the enemy's left wing, notwithstanding the great disparity of numbers, to give ground. The right wing of the Moguls likewise wanting room to extend itself, the sultan made use of his left as a body of reserve, detaching from thence some squadrons to the assistance of the troops who stood in need of them. He also took one part of them with him when he went at the head of his main body to charge that of Jenghiz Khan; which he did with so much resolution and vigour, that he not only put it in disorder, but penetrated into the place where Jenghiz Khan had originally taken his station; but that prince, having had a horse killed under him, was retired from thence, to give orders for all the troops to engage.

This disadvantage had like to have lost the Moguls the battle; for a report being immediately spread that the enemy had broken through the main body, the troops were so much discouraged, that they would certainly have fled, had not Jenghiz Khan encouraged them by riding from place to place in order to shew himself. At last, however, Jaloloddin's men, who were in all but 30,000, having fought a whole day with ten times their number, were seized with fear, and fled. One part of them retired to the rocks which were on the shore of Indus, where the enemy's horse could not follow them; others threw themselves into the river, where many were drowned, though some had the good fortune to cross over in safety; while the rest, surrounding their prince, continued the fight through despair. The sultan, however, considering that he had scarce 7000 men left, began to think of providing for his own safety: therefore, having bidden a final adieu to his mother, wife and children, he mounted a fresh horse, and spurred him into the river, which he crossed in safety, and even stopped in the middle of it to insult Jenghiz Khan, who was now arrived at the bank. His family fell into the hands of the Moguls; who killed all the males, and carried the women into captivity.

Jaloloddin being now securely landed in India, got up into a tree, in order to preserve himself from wild beasts. Next day, as he walked melancholy among the rocks, he perceived a troop of his soldiers, with some officers, three of whom proved to be his particular friends. These, at the beginning of the defeat, had found a boat in which they had sailed all night, with much danger from the rocks, shelves, and rapid current of the river. Soon after, he saw 300 horse coming towards him; who informed him of 4000 more that

Gazna
||
Gelatina.

that had escaped by swimming over the river; and these also soon after joined the rest. In the mean time an officer of his household, named Jamalarrad, knowing that his master and many of his people were escaped, ventured to load a very large boat with arms, provisions, money, and stuff to clothe the soldiers; with which he crossed the river. For this important service Jaloloddin made him steward of his household, and furnished him the *Chyfen* or the *Glory of the faith*. For some time after, the sultan's affairs seemed to go on prosperously: he gained some battles in India; but the princes of that country, envying his prosperity, conspired against him, and obliged him to repass the Indus. Here he again attempted to make head against the Moguls; but was at last defeated and killed by them, and a final end put to the once mighty empire of Gazna.

The metropolis was reduced by Oktay; who no sooner entered the country in which it was situated, than he committed the most horrid cruelties. The city was well provided with all things necessary for sustaining a siege; had a strong garrison, and a brave and resolute governor. The inhabitants, expecting no mercy from Jenghiz Khan, who they knew had sworn their ruin, were resolved to make a desperate defence. They made frequent sallies on the besiegers, several times overthrew their works, and broke above 100 of their battering rams. But one night, after an oblique fight, part of the city-walls fell down; and a great number of Moguls having filled up the ditch, entered the city sword-in-hand. The governor perceiving all was lost, at the head of his bravest soldiers rushed into the thickest of his enemies, where he and his followers were all slain. However, Gazna was not entirely destroyed, nor were the people all killed; for after the massacre had continued four or five hours, Oktay ordered it to cease, and taxed those who were left alive at a certain rate, in order to redeem themselves and the city. It doth not, however, appear that after this time the city of Gazna ever made any considerable figure.—It was taken by the Moguls in the year 1222.

GECCO, in natural history, a name given by the Indians to their terrible poison, which kills when mixed with the blood in ever such a small quantity. They say that this gecco is a venomous frog or humour vomited out of the mouths of their most poisonous serpents; which they procure in this fatal strength, by hanging up the creatures by the tails, and whipping them to enrage them: they collect this in proper vessels as it falls; and when they would use it, they either poison a weapon with it, or wounding any part of the flesh introduce the smallest quantity imaginable into it; and this is said to be immediate death.

GECKO. See LACERTA.

GEDDES (James), born of a respectable family in Scotland in 1710, was educated for and practised at the bar several years; but died of a consumption before he arrived at the age of 40. He published *An essay on the composition and manner of writing of the ancients*; and left behind him several other tracts.

GELATINA, JELLY, a form of food, or medicine, prepared from the juices of ripe fruits, boiled to proper consistence with sugar, or of the strong decoctions of the horns, bones, or extremities of animals boiled to such a degree as to be stiff and firm when cold,

without the addition of sugar.

The jellies of fruits are cooling, saponaceous, and aecetic; and therefore are good as medicines in all disorders of the primæ viæ arising from alkalescent juices, especially when not given alone, but diluted with water. On the contrary, the jellies made from animal-substances are all alkalescent, and are therefore good in all cases where an acidity of the humours prevails: the alkalescent quality of these, however, is in a great measure taken off by adding lemon-juice and sugar to them. There were formerly a kind of jellies much in use, called *compound jellies*; these had the restorative medicinal drugs added to them, but they are now scarce ever heard off.

GELATINA *Avenæ*, Oat-jelly; a jelly of common oats, recommended by many of the German physicians in all hectic disorders, to be taken with broth of snails and craw-fish.—It is made by boiling a large quantity of oats, freed from the husk, with some hartshorn shavings and currants, together with a leg of veal cut in pieces, and with the bones all broken: these are to be set over the fire with a large quantity of water, till the whole is reduced to a kind of jelly; which when strained and cold will be very firm and hard. A few spoonfuls of this are to be taken every morning, diluted with a basin of either of the above-mentioned broths, or any other warm liquor.

GELD, in the English old customs, a Saxon word signifying *money*, or *tribute*. It also denoted a compensation for some crime committed: Hence *wergeld*, in their ancient laws, was used for the value of a man slain; and *or-geld*, of a beast.

GELDENHAUR (Gerard), in Latin *Geldenbarius*, an historian and Protestant divine in the 16th century. He was a native of Nimeguen, and studied classical learning at Deventer. He went through his course of philosophy at Louvaine, where he contracted a very strict friendship with several learned men, and particularly with Erasmus. He became reader and historian to Charles of Austria, and afterwards to Maximilian of Burgundy. At length he embraced the Protestant religion; taught history at Marburg; and afterwards divinity till his death, in 1542. He wrote, 1. History of Holland. 2. History of the Low Countries; 3. History of the bishops of Utrecht; and other works.

GELDERLAND. See GUELDERLAND.

GELDERS. See GUELDRÉS.

GELDING, the operation of castrating any animal, particularly horses.

The operation consists in cutting out the testicles; in performing which, three things are to be observed: first, regard is to be had to their age; next to the season of the year; and lastly to the state of the moon. For the first, if the operation is to be performed on a colt, he may be gelded at nine or fifteen days old, if the testicles be come down; in regard the sooner he is gelt the better it will be for his growth, shape, and courage; though a horse may be gelt at any age, if proper care is taken in the cure. As for the second, the best time is about April or May, or else about the latter end of September. And for the third, the wane of the moon is the most proper time for performing this operation.

The manner of gelding is as follows. The beast

Gelati
||
Geldin

being cast down on some soft place, the operator takes the stones between his foremost and his great finger, and flitting the cod presses the stones forth; then taking a pair of nippers made very smooth, either of steel, box, or brass-wood, he claps the strings of the stones between them, very near to where the stones are set on, and presses them so hard that there may be no flux of blood; then with a thin, drawing, cauterising iron, sears away the stone. This done, he takes a hard plaster made of rosin, wax, and washed turpentine, well dissolved together, and melts it on the head of the strings: he then sears them, and melts more of the salve, till such time as he has laid a good thickness of it upon the strings.

When this is done to one stone, the nippers are loosened, and the like is done to the other; and the two slits of the cod are then filled with white salt, and the outside of the cod is anointed with hog's grease: and thus they let him rise, and keep him in a warm stable, without tying him up. If he swells much in his cods or sheath, they chase him up and down, and make him trot for an hour in a day, which soon recovers him.

The manner of gelding a hog is as follows: The operator, after having made two cross slits or incisions on the middle of the stones, presses them out, and anoints the fore with tar. But another general method, yet somewhat more dangerous if not well done, is, first to cut the stone on the top, and after having drawn that one forth, the operator puts in his fingers at the same slit, and with a lancet cuts the skin between the two stones, and by that slit presses out the other stone. Then having cleaned out the blood, he anoints the part with fresh grease: and thus there is but one incision made in the cod. Boar-pigs ought to be gelded about six months old; yet they are commonly gelded about three weeks or a month old.

GELENHAUSEN, a small imperial town of Wetteravia in Germany, with a castle built by the emperor Frederic I. E. Long. 8. 13. N. Lat. 50. 20.

GELENIUS (Sigismund), a learned and excellent man, born of a good family at Prague, about the year 1498. Erasmus conceiving an esteem for him at Basil, recommended him to John Frobenius as a corrector for his printing-house; which laborious charge he accepted, and had a great number of Hebrew, Greek, and Latin books to correct: he also translated many works himself from the Greek into Latin; and published a dictionary in four languages, Greek, Latin, German, and Slavonian. Profitable and honourable employments were offered him in other places, but nothing could tempt him to quit his peaceful situation at Basil. He died in 1555. All his translations are highly esteemed.

GELLERT (Christian), one of the finest geniuses Germany has produced, was born at Hænichen, near Freyburg in Saxony in 1715; and studied at Leipzig, at which university he was for many years professor of philosophy and the belles lettres. He early distinguished himself by his talent for poetry; and contracted a strict friendship with the most learned and polite writers in Germany. All his works are filled with sentiment, and bear the impression of the sweetness of his disposition. The most considerable of them are his comedies, his spiritual songs and moral poems,

and particularly his sacred odes, his fables, and his tales. He died in 1769, much lamented.

GELLI (John Baptist), an eminent Italian writer, was born of mean parents at Florence, in the year 1498. He was bred a taylor: but had such an extraordinary genius, that he acquired several languages, and made an uncommon progress in the belles lettres; and though he continued always to work at his trade, became acquainted with all the wits and learned men at Florence, and his merit was universally known. He was chosen a member of the academy there, and the city made him a burges. He acquired the highest reputation by his works, which are, 1. *J. Capricci del Bottai*, quarto; which contains ten dialogues. 2. *La Circe*, octavo: This, which also contains ten dialogues, and treats of human nature, has been translated into Latin, French, and English. 3. *Differenziazioni* in Italian on the poems of Dante and Petrarch. 4. The comedies of *La Sporta* and *La Errore*; and other works. He died in 1563.

GELLIBRAND (Henry), a laborious astronomer of the last century, was born in 1597. Though he was not without good views in the church, yet he became so enamoured with mathematical studies, that on the death of his father he became a student at Oxford, contented himself with his private patrimony, and devoted himself solely to them. On the death of Mr Gunter, he was recommended by Mr Briggs to the trustees of Gresham college, for the astronomical professorship there; to which he was elected in 1627. His friend Mr Briggs dying in 1630, before he had finished his *Trigonometria Britannica*, it was finished by Gellibrand at his request. He wrote several other things, chiefly tending to the improvement of navigation; and died in 1636.

GELLIUS (Aulus), or (as he is sometimes called) *Agellius*; a celebrated grammarian, who lived in the 2d century under Marcus Aurelius and some succeeding emperors. He wrote a collection of observations on authors, for the use of his children; and called it *Noctes Atticae*, because composed in the evenings of a winter he spent at Athens. The chief value of it, is for preserving many facts and monuments of antiquity not to be found elsewhere. Critics and grammarians have bestowed much pains on this writer.

GELLY. See GELATINA.

GEM, in natural history, a common name for all precious stones; in which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, pellucid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance; giving fire with steel, not fermenting with acid menstrua, and very difficultly calcinable in the fire. Of this class there are two genera; the chroastasma, and the chroastaces. See CHROASTASMA and CHROASTACES.

The bodies composing the class of semipellucid gems, are stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter, defaced by earth: however, they are but slightly defaced, and are of great beauty and brightness, of a moderate de-

Gem. degree of transparency, and are usually found in small masses.

Of this class there are two orders: the first of which consists of the femipellucid gems, of but two variegations, and frequently of one plain simple colour; tho' sometimes veined: this order contains four genera, viz. the *larde*, the *chalcedonies*, the *hydropheas*, and the *pramnion*. See the articles *SARDÆ*, *CHALCEDONII*, *HYDROPHANÆ*, and *PRAMNION*.

The second order of femipellucid gems, consisting of those remarkable for their veins, zones, and variegations, contains also four genera, viz. the *achate*, the *onyx*, the *sardonyx*, and the *camea*. See the articles *ACHATÆ*, *ONYCHES*, *SARDONYCHES*, and *CAMÆA*.

The knowledge of gems depends principally on observing their hardness and colour. Their hardness is commonly allowed to stand in the following order: the diamond the hardest of all; then the ruby, sapphire, jacinth, emerald, amethyst, garnet, carnel, chalcedony, onyx, jasper, agate, porphyry, and marble. This difference, however, is not regular and constant, but frequently varies. Good crystals may be allowed to succeed the onyx; but the whole family of metallic glassy fluors seem to be still softer.—In point of colour, the diamond is valued for its transparency, the ruby for its purple, the sapphire for its blue, the emerald for its green, the jacinth for its orange, the amethyst carnel for its carnation, the onyx for its tawny, the jasper, agate, and porphyry for their vermilion, green, and variegated colours, and the garnet for its transparent blood-red.

All these gems are sometimes found coloured and spotted, and sometimes quite limpid and colourless. In this case the diamond-cutter or polisher knows how to distinguish their different species by their different degrees of hardness upon the mill. For the cutting or polishing of gems, the fine powder of the fragments of those that are next in degree of hardness is always required to grind away the softer; but as none of them are harder than the diamond, this can only be polished by its own powder.

Imitation or Counterfeiting of GEMS in Glass.—The art of imitating gems in glass, is too considerable to be passed without notice: some of the leading compositions therein, we shall briefly mention upon the authority of Neri.

These gems are made of pastes; and are noway inferior to the native stones, when carefully made and well polished, in brightness or transparency, but want their hardness.

The general rules to be observed in making the pastes are these: 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work, as will bear the fire well. 3. That the powders be prepared on a porphyry stone; not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantity of the several ingredients be nicely observed. 5. That the materials be all well mixed; and, if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot: for if this be not observed, they will be full of blisters and air-bubbles. 6. That a small vacuity be always left at the top

of the pot, to give room to the swelling of the ingredients.

To make paste of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty.—Take of prepared crystal, ten pounds; salt of polverine, six pounds; sulphur of lead, two pounds; mix all these well together into a fine powder; make the whole with common water into a hard paste; and make this paste into small cakes of about three ounces weight each, with a hole made in their middle; dry them in the sun, and afterwards calcine them in the straitest part of a potter's furnace. After this, powder them, and levigate them to a perfect fineness on a porphyry-stone, and set this powder in pots in a glass-furnace to purify for three days: then cast the whole into water, and afterwards return it into the furnace, where let it stand 15 days, in which time all foulness and blisters will disappear, and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brash thrice calcined; for a sea-green, brash simply calcined to a redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in this, by the same way of working as the making of coloured glasses; and this is so hard, that they very much approach the natural gems.

The colour of all the counterfeit gems made of the several pastes, may be made deeper or lighter, according to the work for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones a paler. Besides the colours made from manganese, verdigrease, and zaffer, which are the ingredients commonly used, there are other very fine ones which care and skill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brash or copper; a sky-colour from silver, and a much finer one from the granates of Bohemia.

GEMARA, in Jewish antiquities, a collection of decisions and determinations on the law, written after the Misna was completed.

It was called *gema*, or *perfection*; because it was considered as so perfect an explication of the law, that after it no further additions could be made, or any thing more desired. It is otherwise called *the tal mud*. See *TALMUD*.

GEMINI, the *TWINS*, in astronomy, one of the 12 signs of the zodiac, the third in order, beginning with Aries. See *ASTRONOMY*, n° 206.

GEMINIANI, a celebrated musician and composer, was born at Lucca in the year 1680. He received his first instructions in music from Alessandro Scarlatti; and after that became a pupil of Carlo Ambrosio Lunati, surnamed *Il Gobbo*, a most celebrated performer on the violin; after which he became a disciple of Corelli, and under him finished his studies on that instrument. In the year 1714, he came to England; where in a short time he so recommended himself by his exquisite performance, that all who professed to love and understand music, were captivated with hearing him. Many of the nobility laid claim to the honour of being his patrons; but he seemed chiefly to attach himself to Baron Kilmansegg, chamberlain to king George I. as elector of Hanover, and a favourite

Geminiani. of that prince. In 1716, he published and dedicated to his patron 12 sonatas a *violino violone e cembalo*: the first six with fugues and double stops as they are vulgarly called; the last with airs of various measures, such as allemandes, courants, and jiggs. This publication was so well relished by his patron, that he mentioned Geminiani to the king as an excellent performer; in consequence of which our musician had the honour to perform before his majesty, in concert with the celebrated Handel who played on the harpsichord.

But though Geminiani was exceedingly admired, yet he had not a talent at associating music with poetry, nor do we find that he ever became a public performer: he was therefore obliged to depend for his subsistence on the friendship of his patrons, and the profits which accrued to him from teaching. He had also the misfortune to be an enthusiast in painting; and the volatility of his temper was such, that, in order to gratify this passion, he not only suspended his studies, and neglected to exercise his talents, but involved himself in debts. In 1727, he was offered the place of master and composer of the state-music in Ireland; but this could not be conferred on a Catholic, and Geminiani refused to change his religion: upon which it was given to Matthew Dubourg, a young man who had been one of his pupils, and was a celebrated performer on the violin. Geminiani then set himself to compose parts to the *opera quinta* of Corelli; or, in other words, to make concertos of the first six of his solos. This work he completed, and, with the help of a subscription, at the head of which were the names of the royal family, published in 1726. In 1732, he published his *opera seconda*, which contains a celebrated minuet that goes by his name. He published many other pieces, the profits of which did not much mend his circumstances; but this perhaps was owing to his rambling disposition and enthusiastic fondness of painting. He was also an utter stranger to the business of an orchestra, and had no idea of the labour and pains necessary in the instruction of fingers for the performance of music to which they were strangers. The consequence of this was, that a *concerto spirituale*, which he had advertised for his own benefit in 1748, failed in the performance. The audience, however, compassionate his distress, and sat very silent till the books were changed; when the performance was continued with compositions of the author's own, and which he executed in such a manner as was never forgot. The profits arising from this performance enabled him to take a journey to Paris; where he staid long enough to get plates engraven for a score of solos, and the parts of two operas of concertos. About the year 1755 he returned to England, and advertised them for sale.

In 1761, Geminiani went over to Ireland; and was kindly entertained there by Mr Matthew Dubourg, who had been his pupil, and was then master of the king's band in Ireland. This person through the course of his life had ever been disposed to render him friendly offices; and it was but a short time after Geminiani's arrival at Dublin, that he was called upon to do him the last. It seems that Geminiani had spent many years in compiling an elaborate treatise on music, which he intended for publication; but soon after his arrival at Dublin, by the treachery of a female fer-

vant, who, it was said, was recommended to him for no other end than that she might steal it, it was conveyed away, and could not be recovered. The greatness of this loss, and his inability to repair it, made a deep impression on his mind; and, as is conjectured, hastened his end; at least he survived it but a short time, ending his days on the 17th of September 1762. The following list comprises the whole of his publications, except two or three articles of small account. Twelve solos for a violin, *opera prima*; six concertos in seven parts, *opera seconda*; six concertos in seven parts, *opera terza*; twelve solos for a violin, *opera quarta*; six solos for a violoncello, *opera quinta*; the same made into solos for a violin; six concertos from his *opera quarta*; six concertos in eight parts, *opera settima*; rules for playing in taste; a treatise on good taste; the art of playing the violin; 12 sonatas from his first solos, *opera undecima*; Ripieno parts to ditto; lessons for the harpsichord; *Guida Armonica*; supplement to ditto; the art of accompaniment, two books; his first two operas of concertos in score; and the enchanted forest.—Of his solos the *opera prima* is esteemed the best. Of his concertos some are excellent, others of them scarce pass the bounds of mediocrity. The sixth of the third opera not only surpasses all the rest, but, in the opinion of the best judges of harmony, is the finest instrumental composition extant.

GEMMA, or BUD, in botany; a compendium or epitome of a plant seated upon the stem and branches, and covered with scales, in order to defend the tender rudiments inclosed from cold and other external injuries, till, their parts being unfolded, they acquire strength, and render any further protection unnecessary.

Buds, together with bulbs, which are a species of buds generally seated upon or near the root, constitute that part of the herb called by Linnæus *hybernacula*; that is, the winter-quarters of the future vegetable: a very proper appellation, as it is during that severe season that the tender rudiments are protected in the manner just mentioned.

Plants, considered in analogy to animals, may properly enough be reckoned both viviparous and oviparous. Seeds are the vegetable eggs; buds, living fetuses, or infant-plants, which renew the species as certainly as the seed.

Buds are placed at the extremity of the young shoots, and along the branches, being fixed by a short foot-stalk upon a kind of brackets, the remainder of the leaves, in the wings or angles of which the buds in question were formed the preceding year. They are sometimes placed single; sometimes two by two, and those either opposite or alternate; sometimes collected in greater numbers in whorls or rings.

With respect to their construction, buds are composed of several parts artificially arranged. Externally, we find a number of scales that are pretty hard, frequently armed with hairs, hollowed like a spoon, and placed over each other like tiles. These scales are fixed into the inner plates of the bark, of which they appear to be a prolongation. Their use is to defend the internal parts of the bud; which, being unfolded, will produce, some, flowers, leaves, and stipule; others, footstalks and scales. All these parts, while they remain in the bud, are tender, delicate, folded

Gemma,
or Bud.Gemma,
or Bud.

over each other, and covered with a thick clammy juice, which is sometimes refinous and odoriferous, as in the tacamahac-tree. This juice serves not only to defend the more tender parts of the embryo-plant from cold, the assaults of insects, and other external injuries; but likewise from excessive perspiration, which, in its young and infant state, would be very destructive. It is conspicuous in the buds of horse-chestnut, poplar and willow trees.

In general, we may distinguish three kinds of buds; that containing the flower, that containing the leaves, and that containing both flower and leaves.

The first, termed *gemma florifera*, and by the French *bouton a fleur* or *a fruit*, contains the rudiments of one or several flowers, folded over each other, and surrounded with scales. In several trees, this kind of bud is commonly found at the extremity of certain small branches, which are shorter, rougher, and less garnished with leaves, than the rest. The external scales of this species of bud are harder than the internal; both are furnished with hairs, and in general more swelled than those of the second sort. The bud containing the flower too is commonly thicker, shorter, almost square, less uniform, and less pointed; being generally terminated obtusely. It is called by Pliny *oculus gemmae*; and is employed in that species of grafting called *inoculation*, or *budding*.

The second species of bud, that, viz. containing the leaves, termed *gemma foliifera*, and by the French *bouton a feuilles* or *a bois*, contains the rudiments of several leaves, which are variously folded over each other, and outwardly surrounded by scales, from which the small stipulae that are seated at the foot of the young branches are chiefly produced. These buds are commonly more pointed than the former sort. In the hazel-nut, however, they are perfectly round; and in horse-chestnut, very thick.

The third sort of bud is smaller than either of the preceding; and produces both flowers and leaves, tho' not always in the same manner. Sometimes the flowers and leaves are unfolded at the same time. This mode of the flower and leaf bud, is termed by Linnaeus *gemma foliifera & florifera*. Sometimes the leaves proceed or emerge out of this kind of bud upon a small branch, which afterwards produces flowers. This mode of the flower and leaf bud is termed by Linnaeus *gemma foliifero-florifera*, and is the most common bud of any.

Such buds as produce branches adorned only with leaves, are called *barren*; such as contain both leaves and flowers, *fertile*. From the bulk of the bud we may often, with ease, foretell whether it contains leaves only, or leaves and flowers together, as in cherry and pear trees.

Neither the buds produced on or near the root, called by some authors *suriones*, nor those produced on the trunk, and from the angles or wings of the leaves, contain, in strict propriety, an entire delineation of the plant; since the roots are wanting; and in various buds, as we have seen, shoots are contained with leaves only, and not with flowers; but as a branch may be considered as a part similar to the whole plant, and, if planted, would, in process of revegetation, exhibit or produce roots and flowers, we may in general allow, that the bud contains the whole plant, or

the principles of the whole plant, which may be unfolded *ad libitum*; and thus resembles the seed, in containing a delineation of the future plant in embryo: for although the bud wants a radicle, or plumula, of which the seed is possessed, yet it would undoubtedly form one, if planted in the earth. But as the medullary part adhering to the bud is too tender, and by the abundance of juice flowing into it from the earth would be disposed to putrefaction, the buds are not planted in the soil, but generally inserted within the bark of another tree; yet placed so that the production of the marrow, or pith, adhering to them, may be inserted into the pith of the branch in which the fissure or cleft is made; by which means there is a large communication of juice. This propagation by gems or buds, called *inoculation*, is commonly practised with the first sort of buds above described.

From the obvious uses of the buds, we may collect the reason why the supreme Author of nature has granted this sort of protection to most of the trees that are natives of cold climates; and, on the other hand, denied it to such as, enjoying a warm benign atmosphere, have not the tender parts of their embryo-shoots exposed to injuries and depredations from the severities of the weather. Of this latter kind are the plants of the following list; some of them very large trees; others, smaller woody vegetables, of the shrub and under-shrub kind: Citron, orange, lemon, cassava, mock orange, blad-apple, shrubby swallow-wort, alaternus, shrubby geraniums, berry-bearing alder, Christ's-thorn, Syrian mallow, baobab or Ethiopian, soursour, Justicia, wild fena, the acacias and sensitive plant, coral-tree, stinking bean-trefoil, medicago, oleander, viburnum, sumach, ivy, tamarisk, heath, Barbadoes cherry, lavatera, rue, shrubby night-shades, Guinea-henweed, cypress, liguam-vitæ, and savine a species of juniper.

On annual plants, whose root as well as stalk perishes after a year, true buds are never produced; in their stead, however, are protruded small branches, like a little feather, from the wings of the leaves, which wither without any farther expansion, if the plants climb, and have no lateral branches; but if, either by their own nature, or from abundance of sap, the plants become branched, the ramuli just mentioned obtain an increase similar to that of the whole plant.

The same appearance obtains in the trees of warm countries, such as those enumerated in the above list, in which a plumula, or small feather, sends forth branches without a scaly covering; as, in such countries, this tender part requires no defence or protection from cold. A scaly covering then is peculiar to buds, as it protects the tender embryo enclosed from all external injuries. When we therefore speak of trees having buds that are naked or without scales, our meaning is the same as if we had said that they have no buds at all.

The buds that are to be unfolded the following year, break forth from the evolved buds of the present year, in such a manner as to put on the appearance of small eminences in the wings or angles of the leaves. These eminences or knots grow but little during the summer; as, in that season, the sap is expended on the increase of the parts of the plant; but in autumn, when the leaves begin to wither and fall off, the buds, placed

Gemmatio
||
Gendarmes

placed on the wings, increase; and the embryo-plant, contained in the bud is so expanded, that the leaves and flowers, the parts to be evolved the following year, are distinctly visible. Thus in horse-chestnut the leaves, and in cornel-tree the flowers, are each to be observed in their respective buds.

As each bud contains the rudiments of a plant, and would, if separated from its parent vegetable, become every way similar to it; Linnaeus, to shew the wonderful fertility of nature, has made a calculation, by which it appears, that in a trunk scarce exceeding a span in breadth, ten thousand buds (that is, herbs) may be produced. What an infinite number, then, of plants might be raised from a very large tree!

GEMMATIO, from *gemma* "a bud;" a term used by Linnaeus, expressive of the form of the buds, their origin, and their contents. It includes both those properly called *buds*, and those which are seated at the roots, styled *bulbs*.

As to the origin of buds, they are formed either of the footstalks of the leaves, of *stipule*, or of scales of the bark. Their contents have been already discovered, in the preceding article, to be either flowers, leaves, or both.

GENDARMES, or GENS D'ARMES, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient Gendarmes, who were thus called from their being completely clothed in armour; (see *Scots GENDARMES, infra*.) These troops are commanded by captain-lieutenants, the king and the princes of the blood being their captains: the king's troop, besides a captain-lieutenant, has two sublieutenants, three ensigns, and three guidons.

Grand GENDARMES, at present are a troop composed of 250 gentlemen; the king himself is their captain, and one of the first peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers.

Small GENDARMERY, are, the Scots Gendarmes, the queen's, the dauphin's, the gendarmes of Anjou, Burgundy, the English and Flemish gendarmes, having each a captain-lieutenant, sub-lieutenant, ensign, guidon, and quarter-master.

Scots GENDARMES were originally instituted by Charles VII. of France, about the middle of the 5th century, and formed a part of his guard; in which station also they acted under other princes. It was their prerogative to take precedence of all the companies of the gendarmery of France; and, on particular occasions, they even preceded the two companies of the king's mousquetaires. The sons of the Scottish monarchs were the usual captains of this company; and, after Mary's accession to the throne, its command belonged to them as a right. It was thence that James VI. made a claim of it for his son prince Henry. This honour, and its emoluments, were also enjoyed by Charles I. and the next in command to this prince was Louis Stuart duke of Lennox. George Gordon, marquis of Huntley, succeeded the duke of Lennox in the year 1624, and took the title of captain or commander in chief when Charles I. mounted the English throne. It is not certain whether Charles II. was ever captain of this company; but it was conferred on his brother the duke of York, who was captain

Genders
||
Genealogy.

of the Scots gendarmes till the year 1667, when he resigned his commission into the hands of the French king. Since that time, no native of Great Britain has enjoyed this command. See *Scots GUARDS*.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

This was the original intention of gender: but, afterwards, other words, which had no proper relation either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor*, in Latin, is feminine; but *arbre*, in French, is masculine: and *dens*, in Latin, is masculine; but *dent*, in French, is feminine.

The oriental languages frequently neglect the use of genders; and the Persian language has none at all; which is no disadvantage, the distinction of genders being in great measure useless.

The Latins, Greeks, &c. generally content themselves to express the different genders by different terminations, as *bonus equus*, "a good horse;" *bona equa*, "a good mare," &c. But in English, we frequently go further, and express the difference of sex by different words: as boar, sow; boy, girl; buck, doe; bull, cow; cock, hen; dog, bitch, &c.—We have only about 24 feminines, distinguished from the males, by the variation of the termination of the male into *ess*; of which number are abbot, abbess; count, countess; actor, actress; heir, heiress; prince, princess, &c. which is all that our language knows of any thing like genders.

The eastern languages, as well as the vulgar languages of the west, have only two genders; the masculine and feminine. The Greek and Latin have likewise the neuter, common, and the doubtful gender; and beside these, they have the epicene, or promiscuous, which under one single gender and termination includes both the kinds:

GENDRE (Lewis le), an esteemed historian, born at Roan. He became canon of Notre-Dame at Paris, subchanor of the same church, and abbot of Notre-Dame at Claire Fontaine in the diocese of Chartres. He wrote a great number of works; the principal of which are, 1. The manners and customs of the French, in the different times of that monarchy. 2. An history of France, in three volumes folio, and in seven volumes duodecimo. 3. The life of Cardinal d'Amboise. He died in 1733, aged 78.

GENDRE (Gilbert Charles le), marquis of St Aubin, counsellor in the parliament of Paris, and afterwards master of requests in the king's household. He wrote several works; but is chiefly distinguished by his *Traite de l'opinion*, 9 vols 12mo. a curious performance, proving, by historic examples, the empire of opinion over the works of art and science. He died at Paris in 1746, aged 59.

GENEALOGY, an enumeration of a series of ancestors; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

The word is Greek, *γενεαλογια* which is formed of *γενεα*, "race, or lineage," and *λογια*, "discourse."

In divers chapters and military orders, it is required that

General.

that the candidates produce their genealogy, to shew that they are noble by so many descents.

GENEALOGICA ARBOR, or *Tree of Consanguinity*, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside each other. This the Greeks called *stemmata*, a word signifying crown, garland, or the like. See the articles **CONSANGUINITY** and **DESCENT**, and the plates there referred to.

GENEP, a strong town of Germany, in the circle of Westphalia, subject to the king of Prussia. E. Long. 4. 20. N. Lat. 51. 42.

GENERAL, an appellation given to whatever belongs to a whole genus.

GENERAL Charge, in law. See **CHARGE to enter Heir**.

GENERAL Terms, among logicians, those which are made the signs of general ideas. See **ABSTRACTION** and **IDEA**.

All things that exist, Mr Locke observes, being particulars, it might be expected that words should be so too in their signification: but we find it quite contrary; for most of the words that make all languages are general terms. This is the effect of reason and necessity. For,

First, it is impossible that every particular thing should have a distinct name; because it is impossible to have distinct ideas of every particular thing; to retain its name, with its peculiar appropriation to that idea.

Secondly, it would be useless, unless all could be supposed to have the same ideas in their minds. For names, applied to particular things, wherof I alone have the ideas in my mind, could not be significant or intelligible to another who is not acquainted with all those particular things which have fallen under my notice.

Thirdly, it would be of no great use for the improvement of knowledge; which, though founded in particular things, enlarges itself by general views; to which things, reduced into sorts under general names, are properly subservient.

In things where we have occasion to consider and discourse of individuals and particulars, we use proper names; as in persons, countries, cities, rivers, mountains, &c. This we see, that jockeys have particular names for their horses, because they often have occasion to maintain this or that particular horse when he is out of sight.

Afterwards observing that a great number of things resemble each other in shape, and other qualities, we frame a general idea that takes in only the qualities in which those many particulars agree; and to this idea we give the name *man*, for example: in which there is nothing new; that which is peculiar to each individual being left out, and only that which is common to all retained. And thus we come to have a general idea and a general name. By the same method the mind proceeds to more general notions and names; as those of animal, substance, being, thing, and such universal terms as stand for any ideas whatsoever.

As to the signification of general words, it is evident they do not barely signify one particular thing; neither do they signify a plurality; but they signify a genus, kind, or sort of things. See the articles **ABSTRACTION** and **GENUS**.

GENERAL Warrant. See **WARRANT**.

GENERAL of an Army, in the art of war, he who commands in chief.

A general ought to be a man of great courage and conduct, to have great experience, and to be of good quality. His conduct appears in establishing his magazines in convenient places; in examining the country, that he may not engage his troops too far while he is ignorant of the means of bringing them off; in substituting them; and in knowing how to take the most advantageous posts, either for fighting or shunning a battle. His experience inspires his army with confidence, and an assurance of victory; and his quality, by creating respect, augments his authority. By his liberality he gets intelligence of the strength and designs of the enemy, and by this means is enabled to take the most successful measures. A general ought likewise to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline.

The office of a general is, to regulate the march and encampment of the army: in the day of battle, to choose out the most advantageous ground; to make the disposition of the army; to post the artillery; and, where there is occasion, to send his orders by his aids-de-camp. At a siege, he is to cause the place to be invested; to order the approaches and attacks; to visit the works; and to send out detachments to secure his convoys.

GENERAL of the Artillery. See **ORDNANCE**.

GENERAL of Horse, and **GENERAL of Foot**, are posts next under the general of the army, and these have upon all occasions an absolute authority over all the horse and foot in the army.

Adjutant-GENERAL, one who attends the general, assists in council, and carries the general's orders to the army. He distributes the daily orders to the majors of brigade. He is likewise charged with the general detail of the duty of the army. The majors of brigade send every morning to the adjutant-general an exact return, by battalion and company, of the men of his brigade. In a day of battle the adjutant-general sees the infantry drawn up; after which, he places himself by the general, to receive any orders which may regard the corps of which he has the detail. In a siege, he orders the number of workmen demanded, and signs the warrant for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and signs all orders for parties. He has an orderly sergeant from each brigade of infantry in the line, to carry such orders as he may have occasion to send from the general.

Lieutenant-GENERAL, is the next in command after the general; and provided he should die or be killed, the order is, that the oldest lieutenant-general shall take the command. This office is the first military dignity after that of a general. One part of their function is, to assist the general with their counsel: they ought therefore, if possible, to possess the same qualities with the general himself; and the more, as they often command armies in chief.

The number of lieutenant-generals have been multiplied of late in Europe, in proportion as the armies have become numerous. They serve either in the field,

General.

General or in sieges, according to the dates of their commissions. In battle, the oldest commands the right wing of the army, the second the left wing, the third the centre; the fourth the right wing of the second line, the fifth the left wing, the sixth the centre; and soon. In sieges, the lieutenant-generals always command the right of the principal attack, and order what they judge proper for the advancement of the siege during the 24 hours they are in the trenches; except the attacks, which they are not to make without an order from the general in chief.

Lieutenant-General of the Ordnance. See ORD-NANCE.

Lieutenant-General of Artillery, is, or ought to be, a very great mathematician, and an able engineer; to know all the powers of artillery; to understand the attack and defence of fortified places, in all its different branches; how to dispose of the artillery in the day of battle to the best advantage; to conduct its march and retreat; as also to be well acquainted with all the numerous apparatus belonging to the train, and to the laboratory, &c.

Major-General, the next officer to the lieutenant-general. His chief business is to receive orders from the general, or in his absence from the lieutenant-general of the day; which he is to distribute to the brigade-majors, with whom he is to regulate the guards, convoys, detachments, &c. On him the whole fatigue and detail of duty of the army roll. It is the major-general of the day who is charged with the encampment of the army, who places himself at the head of it when they march, who marks out the ground of the camp to the quarter-master-general, and who places the new guards for the safety of the camp.

The day the army is to march, he dictates to the field-officers the order of the march, which he has received from the general, and on other days gives them the parole.

In a fixed camp he is charged with the foraging, with reconnoitring the ground for it, and posting the escorts, &c.

In sieges, if there are two separate attacks, the second belongs to him; but if there is but one, he takes, either from the right or left of the attack, that which the lieutenant-general has not chosen.

When the army is under arms, he assists the lieutenant-general, whose orders he executes.

If the army marches to an engagement, his post is at the head of the guards of the army, until they are near enough to the enemy to rejoin their different corps; after which he retires to his own proper post: for the major-generals are disposed on the order of battle as the lieutenant-generals are; to whom, however, they are subordinate, for the command of their divisions. The major-general has one aid-de-camp, paid for executing his orders.

GENERAL is also used for a particular march, or beat of drum; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERAL is also used for the chief of an order of monks; or of all the houses and congregations established under the same rule. Thus we say, the general of the Franciscans, Cistercians, &c.

GENERATE, in music, is used to signify the operation of that mechanical power in nature, which every sound has in producing one or more different sounds. Thus any given sound, however simple, produces along with itself, its octave, and two other sounds extremely sharp, viz. its twelfth above, that is to say, the octave of its fifth; and the other the seventeenth above, or, in other words, the double octave of its third major.

Whether we suppose this procreation of sounds to result from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear those proportions one to another, as being determined at once by the partial and total oscillations of any musical string; or from whatever economy of nature we choose to trace it; the power of one sound thus to produce another, when in action, is said to *generate*. The same word is applied by Signior Tartini and his followers, to any two sounds which, simultaneously heard, produce a third.

GENERATOR, in music, signifies the principal found or sounds by which others are produced. Thus the lowest C for the treble of the harpsichord, besides its octave, will strike an attentive ear with its twelfth above, or G in alt, and with its seventeenth above, or E in alt. The C, therefore, is called their *generator*, the G and E its products or harmonics. But in the approximation of chords, for G, its octave below is substituted, which constitutes a fifth from the generator, or lowest C; and for E, is likewise substituted its fifteenth below, which, with the abovementioned C, forms a third major. To the lowest notes, therefore, exchanged for these in alt by substitution, the denominations of products or harmonics are likewise given, while the C retains the name of their *generator*. But still according to the system of Tartini, two notes in concord, which when sounded produce a third, may be termed the *concurring generators* of that third. (See *Generation Harmonique*, par M. Rameau; see also that delineation of Tartini's system called *The power and principles of harmony*.)

GENERATING LINE or FIGURE, in geometry, is that which by its motion produces any other plane or solid figure. See **GEOMETRY**.

GENERATION, in physiology, the act of procreating and producing a being similar to the parent.

According to Aristotle, the male animals contain the principle, and the female the matter, of generation; for though both are furnished indeed with a seminal liquor, yet the semen of the males alone is prolific. The moderns, on the other hand, as well those who contend for the system of generation from eggs, as they who adopt that of the animalcules in the male-seed, pretend that females have no such seminal liquor at all, and that what has been commonly taken for it is some other animal-fluid.

Harvey is of opinion, that all females are furnished with eggs; and that the embryos, or young animals, are formed in the same manner as a chick in the egg of any bird. Generation, according to this celebrated physician, is effected wholly by means of the uterus, or womb, which conceives the fetus by a kind of contagion communicated to it by the male-seed, much in the same way as the load-stone communicates magnetism

Generate
Generation.

Generation. successively round the, in the same order which they before occupied in the parent. When a great quantity of the seminal liquors of both sexes is received into the womb, there are formed different spheres of attraction, in different parts of these liquors; the consequence of which is, that several fœtuses are formed at the same time.

Nearly akin to Mr Buffon's system, is that of Mr Maupertuis, which he has explained in his *Venus Physique*. He observes, that all the variety observable among mankind, may have been accidental at first; but being once established in the constitution of the parents, they become natural to their posterity. To illustrate this, he gives an instance of a sexdigitary family at Berlin, who had six fingers, or six toes, and frequently both; and that this peculiarity was transmitted equally by the father and mother, but was lost by alliances with those who had only the usual number of fingers or toes.

He farther observes, that most animals, excepting mankind, have stated seasons for procreation; and that the females go with young some a longer, others a shorter time. Mares go from eleven to twelve months; cows and hinds go nine months, as do also women; foxes and wolves, five months; and bitches go only seven weeks; cats nine weeks; and rabbits but thirty-one days. Most birds are hatched in twenty-one days; the canary-birds, and some others, are hatched in thirteen or fourteen days. It appears, therefore, that there is an endless variety in the time and manner of the generation of animals.

Whoever reads this short sketch of the different theories of generation that have hitherto been invented, will probably require no other arguments to convince him, that physicians and philosophers are still as ignorant of the nature of this mysterious operation as they were in the days of Noah.

Concerning the formation and nutrition of the fœtus after the female has conceived, there have also been great disputes; but as this subject is more easily investigated, and in some measure falls under the notice of our senses, there is much less uncertainty concerning these matters than generation, or the manner in which the embryo is originally formed. The following particulars are confirmed by the greatest number of observations.

About the seventh day, the eye may discover the first lineaments of the fœtus; but these lineaments are as yet very imperfect. Two little vesicles appear in an almost transparent jelly, the largest of which is destined to become the head of the fœtus, and the other smaller one is reserved for the trunk. But at this period no extremities are to be seen; the umbilical chord appears only as a very minute thread, and the placenta does not as yet absorb the red particles of the blood. At the end of fifteen days, not only the head but the features of the face begin to be developed.—The nose

appears like a small prominent line; and we are able to distinguish another line under it, which is destined for the separation of the lips. Two black points appear in the place of eyes, and two minute holes mark the ears. At the sides of the trunk both above and below, we see four minute protuberances, which are the rudiments of the arms and legs. At the end of three weeks the body of the fœtus is somewhat augmented, and both the hands and feet are to be distinguished. The upper extremities are found to increase faster than the lower ones, and the separation of the fingers is accomplished sooner than that of the toes.

Towards the end of the first month, the fœtus is about an inch long, and the human form may be decisively ascertained: all the parts of the face may be distinguished; the shape of the body is clearly marked out, the haunches and the abdomen are elevated, the fingers and toes are separated from each other, and the intestines appear like minute threads. After six weeks the fœtus is grown much longer, and the human figure appears to be more perfect, but the head is still larger in proportion than the other parts of the body.

At the end of the second month, the fœtus measures two inches and a quarter; at the end of the third month, three inches and a half; and about the fourth or fifth month, usually about five inches; and from that time to the end of the ninth month, it gradually increases to about the length of twelve inches, sometimes more, and sometimes not quite so much.

The fœtus during all this time assumes an oval figure, which corresponds with the shape of the uterus. Its chin is found reclining on its breast, with its knees drawn up towards its chin, and its arms folded over them. But it seems likely that the posture of some of these parts is varied in the latter months of pregnancy, so as to cause those painful twitches which its mother usually feels from time to time.—In natural cases, its head is probably placed towards the os tincæ from the time of conception to that of its birth; though formerly it was considered as being placed towards the fundus uteri, till about the eighth or ninth month, when the head, by becoming specifically heavier than the other parts of the body, was supposed to be turned downwards.

The capacity of the uterus increases in proportion to the growth of the fœtus, but without becoming thinner in its substance, as might naturally be expected.—The nourishment of the fœtus, during all this time, seems to be derived from the placenta, which appears to be originally formed by that part of the ovum which is next the fundus uteri. The remaining unconnected part of the ovum, and likewise the surface of the placenta, are covered by a membrane called *chorion* (A), within which is another pellucid membrane called *amnios* (B); and these two include a watery fluid, which is the *liquor amnii*, in which the fœtus

(A) Besides these two membranes, Dr Hunter has discovered a third, which is the exterior one, being supposed to be a lamella from the inner surface of the uterus. In the latter months of pregnancy it becomes gradually thinner and more connected with the chorion. He has named it *membrana caduca*.

(B) In some quadrupeds, the urine appears to be conveyed from the bladder through a canal called *urachus*, to the *allantois*; which is a reservoir, resembling a long and blind gut, situated between the chorion and amnios. The human fœtus seems to have no such reservoir, though some writers have supposed that it does exist. From the top of the bladder, a few longitudinal fibres are extended to the umbilical chord; and these fibres have been considered as the urachus, though without having ever been found pervious.

Generation
||
Genesis.

fetus floats till the time of its birth (c).—In the first months of pregnancy, the involucra bear a large proportion to their contents, but this proportion is afterwards reversed as the fetus increases in bulk.

The *placenta*, which is the medium through which the blood is conveyed from the mother to the fetus, and the manner in which this conveyance takes place, deserve to be clearly described, as being a subject not generally understood.—Without such an explanation it might perhaps be readily supposed, that the arteries of the uterus pass into the substance of the placenta; and that the blood, after being conveyed through the umbilical arteries to the fetus, is returned back by the umbilical vein to the placenta, and from thence to the uterus.—Such an idea, however, would be a very erroneous one, and we shall point out the true manner in which this process is conducted.

The *placenta* is a broad, flat, and spongy substance, like a cake, closely adhering to the inner surface of the womb, usually near the fundus, and appearing to be made up by the ramifications of the umbilical arteries and vein. The arteries of the uterus discharge their contents into the spongy cells of this cake; and the veins of the placenta, absorbing the blood from these cells in the same manner as they absorb it in the corpora cavernosa penis, at length form the *umbilical vein*, which passes on to the liver, and from thence to the heart of the fetus, by the *vena cava*. Its circulation, however, through the heart is not conducted in the fetus as it is in the adult: in the latter, the blood is carried from the right auricle of the heart through the pulmonary artery, and is returned to the left auricle by the pulmonary vein; but a dilatation of the lungs is essential to the passage of the blood through the pulmonary artery, and this dilatation cannot take place till after the child is born and has respired. This deficiency, however, is supplied in the fetus, by an immediate communication between the right and left auricle of the heart, through an oval opening in the septum, which divides the two auricles, called *foramen ovale*. The blood is returned again from the fetus, through two arteries called the *umbilical arteries*, which sometimes arise from the iliacs, and sometimes from the aorta descendens. These two vessels taking a winding course with the vein, form with that, and the membranes by which they are surrounded, what is called the *umbilical cord*. These arteries, after ramifying through the substance of the placenta, open and discharge their blood into its cells, from whence it is absorbed by the veins of the uterus; so that a constant deposition and absorption are carried on, and the fetus is found to have a circulation independent of its mother.

GENERATION of Fishes. See FISH.

GENERATION of Plants. See BOTANY, sect. v.

GENERATION of Insects. See INSECTS.

PARTS of GENERATION. See ANATOMY, n° 371, 372.

GENESIS, among mathematicians, signifies the formation or production of some figure or quantity.

GENESIS, among divines, a canonical book of the

Old Testament, and the first of the pentateuch or five books of Moses. The Hebrews call it *Berechith*, or, "In the beginning," these being the first words in the book. The Greeks gave it the name of *Genesis*, from its beginning with the history of the creation of the world. See BIBLE.

GENET, GENNET, or *Jennet*, in the manege, denotes a small-sized well-proportioned Spanish horse.

To ride *a la genet*, is to ride after the Spanish fashion, so short, that the spurs bear upon the horse's flank.

GENETTE, in zoology. See VIVERRA.

GENEVA, a city near the confines of France and Switzerland, in E. Long. 6. o. N. Lat. 46. 20. It has a small territory subject to it, and is a republic *.

The city, called in Latin also *Genæva*, in German *Genf*, and in French *Genève*, is situated where the Rhone makes it exit from the lake, 65 miles from Bern, 75 from Lyons, and 106 from Turin. A part of it stands on an island in the Rhone, and part on the banks on both sides, being a handsome well-fortified city, and pretty large. In some of the streets are arched walks or piazzas. The *Treille* is a most charming place, planted with linden trees; and commanding a fine prospect of the lake, and of several ranges of mountains and rocks rising behind one another, some covered with vineyards and herbage, and others with snow, with openings betwixt them. Immediately below the city, the Rhone is joined by the Arve. Over the former of these rivers are four bridges. The inhabitants of Geneva are mostly Calvinists. Of the six churches, the cathedral of St Peter is the principal, in which is a monument to the memory of Henry duke of Rohan. The service in some of these churches is in French, in others in Italian, and in others in German. The guildhall is a stately free-stone edifice, situated on an eminence, the ascent to which is without any steps, so that a person may not only walk, but ride from the top to the bottom. Here is an arsenal, which is said to contain arms for 12,000 men; and an university, which has 12 professors belonging to it, with a very valuable library. Several learned men have either been natives, or professors and ministers, of this city; particularly Calvin, Theodore Beza, the Diodati, the Turretines, the late Mr Le Clerc, and others. As the quantity of corn produced in the territory of the city is not sufficient for the consumption of the inhabitants, the republic has erected large granaries, which always contain a quantity to supply the inhabitants two years. The bakers, the inn-keepers, the garrison, and the artificers, employed by the city, are obliged to take what corn they want from these granaries, at a small advance of the prime cost. Besides the revenue arising from hence, the city has other incomes, amounting to about 130,000 dollars, with part of which it maintains a garrison consisting of 800 men, well disciplined, and clothed in a blue uniform turned up with red. The environs of the city are extremely pleasant; which, with the goodness of the air and provisions, the mildness of the go-

(c) The *liquor amnii* coagulates like the lymph. It has been supposed to pass into the oesophagus, and to afford nourishment to the fetus; but this does not seem probable. Children have come into the world without an oesophagus, or any communication between the stomach and the mouth; but there has been no well-attested instance of a child's having been born without a placenta; and it does not seem likely that any of the fluid can be absorbed through the pores of the skin, the skin in the fetus being everywhere covered with a great quantity of mucus.

Geneva

vernment, the politeness of the inhabitants, the numbers of foreign gentlemen always residing here, or passing from France, Germany, and other countries, to the north of the Alps, to Italy, and others lying south of them, render it a most agreeable place: hence Mr Addison styled it, very justly, the *court of the Alps*. In all the streets are fountains and canals to supply the inhabitants with water, which is raised by engines from the Rhone. The trade of the city is very considerable, it being a great thoroughfare, and having a variety of manufactures, with a number of industrious and ingenious artificers, particularly in the watchmaking branch. The library belonging to the city is well furnished with excellent books, besides a curious collection of medals and petrifications, and some ancient manuscripts. They are not so rigid in keeping the sabbath here as the Calvinists in England and Scotland: for they tolerate, and even authorize, all manner of manly exercises on Sundays, after divine service; and then it is that the militia also are exercised. The fun rises later here, and sets sooner, than in most other places of the same latitude; which is owing to the Alps. Mr Addison says, that there are merchants in Geneva who are reckoned worth two millions of crowns, tho', perhaps, not one of them spends 500 pounds a-year. At the general hospital, besides the city poor, poor travellers are maintained for one day, and then dismissed, with some money in their pockets, to proceed on their journey. As to the government, it is much like that of Zurich and Bern. The number of burghers is about 1500, and the principal magistrates are the four syndics. There are no less than four councils, viz. the general council of the citizens and burghers, the council of 200, that of 60, and that of 25. Of the last, two persons of the same family cannot be members at the same time. A son here, who refuses to pay his father's debts, is incapable of any office in the state. No marriages are permitted unless both parties are of the Protestant religion. A woman of 40 years of age must not marry a man of less than 30; if she exceed 40, her husband must at least be 35; nor must a man above 60 marry a woman, who is not, at least, 30. A widow must not alter her condition in less than six months after her husband's decease. The kings of France and Britain are constantly mentioned in their public prayers here. It is said that Calvin lied buried in that part of the church-yard called the *Plain-palais*; but the particular spot is either not known, or pretended not to be known. Before the reformation, this city was the see of a bishop, who was possessed of the sovereignty thereof at first, jointly with its counts, and afterwards with the dukes of Savoy; but it got rid of both, about the period abovementioned, and entered into alliance with several of the cantons: at present, however, those only with Bern and Zurich continue in force. The king of France always keeps a resident here. So much are the magistracy afraid of opening a door to luxury and licentiousness, that no theatre is permitted in the city. The lake, to which it gives name, resembles a half-moon, whose convex side lies towards Switzerland. On that side it extends 18 leagues, reckoning along the shore, but on the Savoy side not above 12; and its greatest breadth is upwards of seven. As for its depth, in some places it is said to be unfathomable. Contrary to most other lakes, it decreases

Vol. V.

Geneva
Genista.

in winter, and increases in summer, which is owing to the melting of the snow in the neighbouring mountains. It is hardly ever frozen over; and has the territories of no less than five different states bordering on it, viz. the kingdom of France, the duchy of Savoy, the canton of Bern, the bishopric of Sion, and the republic of Geneva.

GENEVA, or *Gin*, among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper-berries.

Originally, the berries were added to the malt in the grinding; so that the spirit thus obtained was flavoured with the berries from the first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

GENGISKHAN, the renowned sovereign of the Moguls, a barbarous and bloody conqueror. See JENGHIZ KHAN, and (*History of the*) MOGULS.

GENIAL, an epithet given by the Pagans to certain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

GENII, a sort of intermediate beings, by the Mahometans believed to exist, between men and angels. They are of a grosser fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future salvation or damnation like men. The Orientals pretend that these geni inhabited the world many thousand years before the creation of Adam, under the reigns of several princes, who all bore the common name of Solomon: but falling at length into an almost general corruption, Eblis was sent to drive them into a remote part of the earth, there to be confined: that some of that generation still remaining were by Tahmurath, one of the ancient kings of Persia, forced to retreat into the famous mountains of *Kaf*; of which successions and wars they have many fabulous and romantic stories. They also make several ranks and degrees among this kind of beings, (if they are not rather different species); some being absolutely called *Jin*; some *Peri*, or fairies; some *Div*, or giants; and other *Tacwirs*, or fates.

GENIOGLOSSI, in anatomy. See ANATOMY, *Table of the muscles*.

GENIOHYOIDÆUS, in anatomy. *Ibid*.

GENISTA, BROOM or DYERS-WEED; a genus of the decandria order, belonging to the diadelphia class of plants. There are several species of which the most remarkable are, the cytisio-genista, or common broom; and the tinctoria, or dyers-weed.—The first is too well known to need description. Its young flowers are sometimes preserved as pickles; and the plant, when burnt, affords a tolerably pure alkaline salt. Dr Mead relates the case of a dropical patient that was cured by taking half a pint of a decoction of green broom tops, with a spoonful of whole white mustard-seed, every morning and evening. The patient had been tapped three times, and tried the usual remedies before. An infusion of the seeds, drank

18 Q

freely

Geniil
Genius.

Genius.

freely, has been known to produce similar happy effects; but these are by no means to be expected in every instance. Cows, horses, and sheep, refuse the plant.—2. The tinctoria is also a native of Britain. It rises with shrubby stalks three feet high, garnished with spear-shaped leaves placed alternate, and terminated by several spikes of yellow flowers, succeeded by pods. The branches of the plant are used by dyers, for giving a yellow colour; from whence it is called dyers-broom, green-wood, wood-waxen, or dyers-weed. A dram and an half of the powdered seeds operates as a mild purgative. A decoction of the plant is diuretic; and, like the former, has proved serviceable in dropical cases. Horses, cows, goats, and sheep, eat it.

GENITAL, an appellation given to whatever belongs to the parts of generation. See ANAT. n° 371.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the *genitive case*: but, in the vulgar tongues, they make use of a sign to express the relation of this case. In English they prefix the particle *of*; in French *de* or *du*, &c. Though in strictness there are no cases in either of these languages; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit, or demon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and to be his guard. See DEMON.

Among the Romans, Festus observes, the name *genius* was given to the god who had the power of doing all things, *deum qui vim obtineret rerum omnium gerendarum*; which Vossius, *de Idol.* rather chooses to read *genendarum*, who has the power of producing all things; by reason Censorinus frequently uses *gerere* for *gignere*.

Accordingly, St Augustin *de Civitat. Dei*, relates, from Varro, that the genius was a god who had the power of generating all things; and presided over them when produced.

Festus adds, that Aufusilius spake of the *genius* as the Son of God, and the Father of men, who gave them life; others, however, represented the *genius* as the peculiar or tutelary god of each place: and it is certain, the last is the most usual meaning of the word. The ancients had their *genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals, GENIUS POPULI ROM. "the genius of the Roman people;" or GENIO POP. ROM. "to the genius of the Roman people." In this sense, *genius* and *lar* were the same things; as, in effect, Censorinus and Apulius affirm they were. See LARES and PENATES.

The Platonists, and other eastern philosophers, up-

posed the *genii* to inhabit the vast region, or extent of air, between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the wills of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns; this became the lot of the *genii*, whose nature was a mean between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aerial matter. Most of the philosophers, however, held, that the *genii* of particular men were born with them, and died; and Plutarch attributes the ceasing of oracles partly to the death of the *genii*. See ORACLE.

The heathens, who considered the *genii* as the guardians of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befel their wards. They never, or very rarely, appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the *genii* of different men; and that some were much more powerful than others: on which principle it was, that a wizard in *Apian* bids Anthony keep at a distance from Octavius, by reason Anthony's genius was inferior to and stood in awe of that of Octavius. There were also evil *genii*, who took a pleasure in persecuting men, and bringing them evil tidings: such was that in *Paterculus*, &c. which appeared to Brutus the night before the battle of Philippi. These were also called *larvæ*, and *lemures*. See LARVÆ and LEMURES.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which alone they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules; whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art: it can be possessed only by a person who has brought it with him into the world.—What has been said of these two arts may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. Nature has thought fit to make a distribution of her talents among men, in order to render them necessary to

to one another; the wants of men being the very first link of society: she has therefore pitched upon particular persons, to give them aptitude to perform rightly some things which she has rendered impossible to others; and the latter have a greater facility granted them for other things, which facility has been refused to the former. Nature, indeed, has made an unequal distribution of her blessings among her children; yet she has disinherited none; and a man divested of all kinds of abilities, is as great a phenomenon as an universal genius.

From the diversity of genius, the difference of inclination arises in man, whom nature has had the precaution of leading to the employments for which she designs them, with more or less impetuosity in proportion to the greater or lesser number of obstacles they have to surmount, in order to render themselves capable of answering this vocation. Thus the inclinations of men are so very different, because they follow the same mover, that is, the impulse of their genius. This, as with the painter, is what renders one poet pleasing, even when he trespasses against rules; while others are disagreeable, notwithstanding their strict regularity.

The genius of these arts, according to the abbe du Bos, consists in a happy arrangement of the organs of the brain; in a just conformation of each of these organs; as also in the quality of the blood, which disposes it to ferment, during exercise, so as to furnish plenty of spirits to the springs employed in the functions of the imagination. Here he supposes that the composer's blood is heated; for that painters and poets cannot invent in cool blood; nay, that it is evident they must be wrapt into a kind of enthusiasm when they produce their ideas. Aristotle mentions a poet who never wrote so well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures we have in Tasso of Armida and Clorinda, were drawn at the expense of a disposition he had to real madness, into which he fell before he died. "Do you imagine," (says Cicero,) that Pacuvius wrote in cold blood? No, it was impossible. He must have been inspired with a kind of fury, to be able to write such admirable verses."

GENOA, a city of Italy, and capital of a republic of the same name, situated in E. Long. 9. 30. N. Lat. 44. 30.—By the Latin authors it is very frequently, though corruptly, called *Janna*; and its present territories made part of the ancient Liguria. The æra of its foundation is not known. In the time of the second Punic war it was a celebrated emporium; and having declared for the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans; and with the rest of Italy continued under their dominion till the decline of the western empire in 476. Soon after, it fell under the power of Theodoric the Ostrogoth; who having defeated the usurper Odoacer, became king of Italy. This happened in the year 498; and in a short time, the Goths being almost entirely subdued by Belisarius the emperor Justinian's general, Genoa was reannexed to the Roman empire. In 1638, it was plundered and burnt by the Lombards, whose king Protharis erected it into a provincial dukedom.

The Lombards continued masters of Genoa till the

year 774, when they were conquered by Charles the Great, son to Pepin, king of France. He reduced Liguria to the ancient bounds settled by Augustus, and erected it into a marquisate; appointing his relation *Audemarus* the first count or margrave. Genoa at this time being distinguished for its wealth and populousness, began to give its name to the whole coast; and continued under the dominion of these counts for about 100 years, till the race of the Pepins became entirely extinct in Italy, and the empire was transferred to the German princes.—In the year 935 or 936, while the Genoese forces were absent on some expedition, the Saracens surprised the city, which they plundered and burnt, putting to death a great number of the inhabitants, and carrying others into captivity. Having embarked their captives, together with an immense booty, they set sail for Africa: but the Genoese immediately returning, pursued the invaders; and having entirely defeated them, recovered all the captives and booty, and took a great many of the enemy's ships.

About the year 950, the Franks having lost all authority in Italy, the Genoese began to form themselves into a republic, and to be governed by their own magistrates, who were freely elected, and took the name of *Consuls*. In order to support their independence, they applied themselves with great assiduity to commerce and navigation; and being apprehensive that some of the German emperors, who frequently entered Italy as invaders, might renew their pretensions to their state, they consented to acknowledge Berengarius III. duke of Friuli, who had been elected emperor by a party of Italian nobles. Berengarius, who had much ado to maintain himself in his new dignity, endeavoured by his concessions to enlarge the number of his friends and adherents; and accordingly made no difficulty to confirm the new republic in all its rights and privileges. After this the Genoese began to extend their commerce from Spain to Syria, and from Egypt to Constantinople; their vessels, according to the custom of these times, being fitted for fighting as well as merchandise. Having thus acquired great reputation, they were invited, in 1017, by the Pisans, who had likewise formed themselves into a republic, to join with them in an expedition against Sardinia, which had been conquered by the Moors. In this expedition they were successful; the island was reduced; but from this time an enmity commenced between the two republics, which did not end but with the ruin of the Pisans.

The first war with Pisa commenced about 30 years after the Sardinian expedition, and lasted 18 years; when the two contending parties having concluded a treaty of peace, jointly sent their forces against the Moors in Africa, of whom they are said to have killed 100,000. The Genoese were very active in the time of the crusades, and had a principal share in the taking of Jerusalem. They also waged considerable wars with the Moors in Spain, of whom they generally got the better. They also prevailed against the neighbouring states; and, in 1220, had enlarged their territories beyond the skirts of the Apennines, so that the rest of Italy looked upon them with a jealous eye: but in 1314 the factions which had for a long time reigned in the city, notwithstanding

standing all its wealth and power, induced the inhabitants to submit themselves for 20 years to the dominion of Henry VII. emperor of Germany. That emperor, however, died in August 1312; and the vicar he had left, soon after went to Pisa, upon which the dissensions in Genoa revived with greater fury than ever. In 1317, a quarrel happened between the families of Spinola and Doria; which came to such an height, that both parties fought in the streets for 24 days without intermission, raised battering engines against each others houses, and filled the city with blood. At last the Spinola quitted the city, and retired to their territories in the Apennine mountains. The civil war continued till the year 1331; when, by the mediation of the king of Naples, it was concluded, that all exiles should return to the city; that the republic should be governed by the king's vicar; and all the offices of the state be equally divided between the Guelphs and the Gibellines, the two contending parties.

By this ruinous war, the coast of Genoa, formerly adorned with palaces and vineyards, was now reduced to the appearance of a barren waste. So great was the general desolation, that, according to Petrarch, the spectators who failed along were struck with astonishment and horror. Villani, a cotemporary author, relates, that it was supposed by the learned, that greater exploits had not been performed at the siege of Troy; and that the losses each party had sustained would have been sufficient to have purchased a kingdom, the Genoese republic being in his time the richest and most powerful state in Christendom. The annalist Stella informs us, that, before the war, the most extravagant profusion and luxury prevailed among the Genoese: but that, towards the end, many noble families were reduced to indigence and poverty; so that, about 100 years after, it became fashionable for the nobles to live in a plain manner, without any show or magnificence.

In 1336, both parties, suspending their mutual animosities, sent two fleets of 20 galleys each into the German ocean, to the assistance of the king of France, who was engaged in a war with Edward III. king of England. This naval expedition proved the cause of a most remarkable revolution in the Genoese government. The sailors of the fleet, thinking themselves injured by their officers, whom they accused of defrauding them of their pay, proceeded to an open mutiny; and, having expelled the admiral and other commanders, seized the galleys. The king of France being chosen arbitrator, decided in favour of the officers, and imprisoned 16 of the chiefs of the mutineers. Upon this several of the sailors left the fleet, and returned to Genoa; where they went round the coasts, repeating their mutinous complaints, which were greatly hearkened to, upon a false report that the mutineers who had been imprisoned were broke upon the wheel. The factious spirit increased; and at last the Genoese insisted in a tumultuous manner for having an abbot of their own choosing, and 20 of the people with the consent of the captains of the republic assembled for that purpose. While the mob were impatiently expecting their decision, a mechanic, generally accounted a fool, mounted a wooden bench, and called out that one Simon Bucanigree should be chosen abbot. This be-

ing instantly echoed by the populace, he was first declared *abbot*, then *lord*, and at last *duke* of Genoa.

This new expedient did not at all answer the purpose. The dissensions continued as violent as ever, notwithstanding the power of the new magistrates; and by these perpetual divisions the republic was at last so much weakened, that in 1390 the king of France was declared lord of Genoa. Under the French government, however, they soon became exceedingly impatient; and, in 1422, the duke of Milan obtained the sovereignty. With this situation they were equally displeased, and therefore revolted in 1436. Twenty-two years after, finding themselves pressed by a powerful fleet and army sent by Alphonso king of Naples, they again conferred the sovereignty of their state upon the king of France. In 1460, they revolted from the French; and, four years after, put themselves again under the protection of the duke of Milan; from whom they revolted in 1478. He again declared sovereign of the republic in 1488; and, 11 years after, the city and territories of Genoa were conquered by Lewis XII. of France.

The almost unparalleled fickleness of the Genoese disposition was not to be corrected by this misfortune. They revolted in 1506; but next year were again subdued by Lewis. Six years after, they again revolted; and in 1516, the city was taken and plundered by the Spaniards. In 1528, Andrew Doria, a Genoese admiral, in the service of the French, undertook to rescue his country from the dominion of foreign princes, and restore it to its liberty. Knowing well the fickle disposition of his countrymen, he took all occasions of exciting discontents among them against the government. He persuaded them, that the French (who had again obtained the sovereignty) had left them only a shadow of liberty, while they pretended to protect them from their enemies. To the nobility he represented the disgrace of suffering the government to be vested in the hands of foreigners less worthy of authority than themselves. Thus he soon formed a strong faction, and formed his plan; for the execution of which he took the most proper time, namely, when almost three-fourths of the French garrison had been carried off by the plague.—He advanced with 500 men; and his friends having opened the gates of the city to him, he seized the principal posts, and thus became master of it without drawing his sword. The garrison retired to the forts, where they soon after capitulated, and being driven out of the city, Doria re-established the ancient form of government *.

The republic hath since continued to preserve her liberty, though greatly fallen from her ancient splendor, and now become a very inconsiderable state. In 1684, the Genoese had the misfortune to fall under the resentment of Lewis XIV. at which time the city was almost destroyed by a formidable bombardment. In the year 1688, it was bombarded by admiral Byng, and forced to capitulate; but there were at that time no views of making a permanent conquest of the city. In 1730, the island of Corsica revolted from the Genoese, and could never afterwards be reduced by them; for which reason it was sold to the French, who in the year 1770 totally reduced it.

The Genoese territories extend along that part of the Mediterranean sea, commonly called the *gulf of Genoa*,

* See
DORIA.

Genoa, about 152 miles; but their breadth is very unequal, being from eight to about 20 miles. Where they are not bounded by the sea, the following states and countries, taking them from west to east, are their boundaries, *viz.* Piedmont, Monferat, Milan, Placentia, Parma, the dukedom of Tuscany, and the republic of Lucca. This tract, though a great part of it is mountainous, and some of that barren enough, yet produces plenty of excellent fruit, good pasture, wood, garden-stuff, and mulberry-trees, with some wine and oil, but little corn. What they want of the lake, they have either from Lombardy, Sicily, or Naples.

Genoa stands on the coast of the Mediterranean sea, at the bottom of a little gulph, partly on the flat, and partly on the declivity, of a pleasant hill; in consequence of which, it appears to great advantage from the sea. It is defended on the land-side a by double wall, which in circumference is about ten Italian miles. Two of the streets consist entirely of a double straight row of magnificent palaces. The others, though clean and well paved, are crooked and narrow. The palaces of the nobility are almost all of marble, and many of them are painted on the outside. That there should be such a profusion of marble here, is not to be wondered at, as the neighbouring hills abound with it. The city contains a vast number of palaces, churches, and convents, and several hospitals. The palace where the doge resides, and where the great and little council, and the two colleges of the procuratori and governor's assembly, is a large stone building in the centre of the city: but it contains some fine paintings in fresco; two statues of Andrew and John Doria in white marble; and an arsenal, in which are said to be arms for thirty-four thousand men, with a shield, containing one hundred and twenty pistol-barrels, and thirty-three coats of mail, which, it is pretended, were worn by as many Genoese heroines in a crusade. Of the churches, the finest are those of the annunciation, St Mary Carignan, St Dominic, and St Martha. In the cathedral is a dish made of a single emerald. All the inhabitants here, except the principal ladies, who are carried in chairs, walk on foot, on account of the narrowness or steepness of the streets. The fortifications of the city, towards the sea, are remarkably strong. There are two fine stone-bridges over the rivers Bonzevera and Bisagno, the first whereof washes the west, and the other the east side of the city, within which there is also a surprising stone-bridge joining two hills. The harbour, though large, is far from being safe; but no care or expence have been spared, to render it as safe and commodious as possible. The wind to which it is most exposed, is that called *Labecce*, or the south-west. The place where the republic's galleys lie, is called the *Darsena*, where are a great number of Turkish slaves. On a rock, on the west side of the harbour, is the fanal or light-house, a high tower, on the top of which is a lantern, containing thirty-six lamps. The trade of Genoa is chiefly in velvets, damasks, plush, and other silks, brocades, lace, gloves, sweetmeats, fruits, oil, Parmesan cheese, anchovies, and medicinal drugs from the Levant; but the badness of the harbour, and the high price of commodities, greatly check its commerce. In 1751, Genoa was declared a free port for ten years, under certain

restrictions: in that called *Porto Franco*, any merchant may have a ware-house, and import or export goods duty free; but such as are disposed of in the city, or on the continent, are taxed pretty high. The nobility are allowed to trade in the wholesale way; to carry on velvet, silk, and cloth manufactures; and to have shares in merchant-ships: and some of them, as the Palavacini, are actually the greatest merchants in Genoa. Another very profitable article of trade carried on by them is banking, and dealing in bills of exchange. A new academy of painting, sculpture, civil and military architecture, was instituted here in 1751. One may walk the streets of Genoa in the night with the greatest safety, which is more than can be said of many cities in Italy. Excessive splendor and luxury are, in several respects, restrained by salutary laws. No beggars are permitted to ask alms in Genoa, and the inns are better than those at Turin. When a single person is buried, a kind of garland of all sorts of artificial flowers is placed on the coffin. The Genoese in general are esteemed crafty, industrious, and inured to labour above the other Italians.

GENSING. See PANAX.

GENTIANA, GENTIAN, in botany, a genus of the digynia order, belonging to the pentandria class of plants. The most remarkable species are the following:

1. The lutea, or common gentian of the shops. It is a native of the mountainous parts of Germany; from whence the roots, the only part used in medicine, are brought to this country. These have a yellowish-brown colour, and a very bitter taste. The lower leaves are of an oblong oval shape, a little pointed at the end, stiff, of a yellowish green, and have five large veins on the back of each. The stalk rises four or five feet high, garnished with leaves growing by pairs at each joint, almost embracing the stalk at their base. They are of the same form with the lower, but diminish gradually in their size to the top. The flowers come out in whorls at the joints on the upper part of the stalks, standing on short foot-stalks, whose origin is in the wings of the leaves. They are of a pale yellow colour.—The roots of this plant are very frequently used in medicine as stomachic bitters. In taste they are less exceptional than most of the substances of this class. Infusions of gentian-root flavoured with orange-peel, are sufficiently grateful. Some years ago a poisonous root was discovered among the gentian brought to London; the use of which occasioned violent disorders, and in some cases death. This root is easily distinguished from the gentian, by its being internally of a white colour, and void of bitterness.

2. The centaureum, or lesser centaury of the shops, is a native of many parts of Britain. It grows on dry pastures; and its height is commonly proportioned to the goodness of the soil, as in poor soils it will grow to the height of a foot, but in rich ones not above three or four inches. It is an annual plant, with upright branching stalks, garnished with small leaves, placed by pairs. The flowers grow in form of an umbel at the top of the stalk, and are of a bright purple colour. They come out in July, and the seed ripens in autumn. The plant cannot be cultivated in gardens. The tops are an useful aperient bitter, in which.

Gentile,
Gentleman.

which view they are often used in the present practice of medicine.

GENTILE, in matters of religion, a Pagan, or worshippier of false gods.

The origin of this word is deduced from the Jews, who called all those who were not of their name גוֹיִם *gojim*, i. e. *gentes*, which in the Greek translations of the Old Testament is rendered γέντιος; in which sense it frequently occurs in the New Testament; as in Matth. vi. 32. "All these things the nations or Gentiles seek." Where the Latin church also used *gentes* in the same sense as our *Gentiles*, especially in the New Testament. But the word *gentes* soon got another signification, and no longer meant all such as were not Jews; but those only who were neither Jews nor Christians, but followed the superstitions of the Greeks and Romans, &c. In this sense it continued among the christian writers, till their manner of speech, together with their religion, was publicly and by authority received in the empire; when *gentiles*, from *gentes*, came into use: and then both words had two significations, viz. in treaties or laws concerning religion, they signified Pagans, neither Jews nor Christians; and in civil affairs, they were used for all such as were not Romans.

GENTILE, in the Roman law and history, a name which sometimes expresses what the Romans otherwise called *barbarians*, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire.

GENTILIS (Albericus), professor of civil law at Oxford; an Italian by birth. He had quitted Italy with his father, on account of religion. He wrote several works; three books, in particular, *De jure belli*, which have not been unserviceable to Grotius. He died at London in 1608.

GENTILIS (Scipio), brother to the former, and as celebrated a civilian as he, forsook his native country that he might openly profess the Protestant religion. He was counsellor of the city of Nuremberg, and professor of law with uncommon reputation. He was a great humanist; and in his lectures, as well as books, mixed the flowers of polite learning with the thorns of the law. He died in 1616.

GENTLEMAN. Under this denomination are comprehended all above the rank of women*, whereby noblemen are truly called *gentlemen*.

A gentleman is usually defined to be one who, without any title, bears a coat of arms, or whose ancestors have been freemen; and by the coat that a gentleman giveth, he is known to be, or not to be, descended from those of his name that lived many hundred years since.

The word is formed of the French *gentilhomme*; or rather of *gentil*, "fine, fashionable, or becoming;" and the Saxon *man*, q. d. *honestus*, or *honesto loco natus*.—The same signification has the Italian *gentiluomo*, and the Spanish *hidalgo*, or *hijo dalgo*, that is, the son of somebody, or of a person of note.—If we go farther back, we shall find *gentleman* originally derived from the Latin *gentilis homo*; which was used among the Romans for a race of noble persons of the same name, born of free or ingenuous parents, and whose ancestors had never been slaves or put to death by law. Thus Cicero,

in his *Topics*, "*Gentiles sunt, qui inter se eodem sunt nomine, ab ingenuis oriundi, quorum majorum nemo servitutem servavit, qui capite non sunt diminuti*, &c.—Some hold that it was formed from *gentile*, i. e. pagan; and that the ancient Franks, who conquered Gaul, which was then converted to Christianity, were called *gentiles* by the natives, as being yet heathens.—Others relate, that towards the declension of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave soldiers, the one called *gentiliun*, and the other *scutarii* *um*; and that it was hence we derive the names *gentleman* and *esquire*. See *ESQUIRE*.—This sentiment is confirmed by Pasquier, who supposes the appellation *gentiles* and *esquiers* to have been transmitted to us from the Roman soldiery; it being to the *gentiles* and *scutarii*, who were the bravest of the soldiery, that the principal benefices and portions of lands were assigned. See *BENEFICE*.—The Gauls observing, that, during the empire of the Romans, the *scutarii* and *gentiles* had the best tenements or appointments of all the soldiers on the frontiers of the provinces, became insensibly accustomed to apply the same names, *gentilhomme*s and *esquiers*, to such as they found their kings gave the best provisions or appointments to.

GENTLEMAN-UsHER of the Black Rod. See *ROD*.

GENTLEMEN of the Chapel; officers whose duty and attendance is in the royal chapel, being in number thirty-two. Twelve of them are priests; the other twenty, commonly called *clerks of the chapel*, assist in the performance of divine service. One of the first twelve is chosen for confessor of the household; whose office it is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer the sacrament. One of twenty clerks, well versed in music, is chosen first organist, who is master of the children, to instruct them in music, and whatever else is necessary for the service of the chapel; a second is likewise an organist; a third, a lutanist; and a fourth, a violist. There are likewise three vergers, so called from the silver rods they carry in their hands; being a serjeant, a yeoman, and groom of the vestry: the first attends the dean and sub-dean, and finds surplices and other necessaries for the chapel; the second has the whole care of the chapel, keeps the pews, and seats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

GENUS, among metaphysicians and logicians, denotes a number of beings which agree in certain general properties common to them all: so that a genus is nothing else but an abstract idea, expressed by some general name or term. See *LOGIC*, n° 18, &c.

It is plain, therefore, that by a genus we do not barely signify one particular thing, nor yet a plurality of things; but a sort or kind of things, all agreeing in certain general properties.

Thus animal is said to be a genus in respect of man and brute, in regard man and brute agree in the common nature and character of animal: so a right-lined figure of four sides, is a genus in respect of a parallelogram and a trapezium; and so likewise is substance, in respect of subistence extended, which is body, and thinking substance, which is mind.

The method by which the mind advances to form genera

Gentile
Genus

* See
Commonalty

Genus. genera is, according to Mr Locke, as follows.—Observing several things, that differ from the mind's idea of man, for instance, and therefore cannot be comprehended under that name, to agree with man in some certain qualities; by retaining only those qualities, and uniting them into one idea, it gets another more general idea, to which giving a name, it makes a new genus, or a term of a more comprehensive extension. Thus, by leaving out the shape, and other properties signified by the word *man*, and retaining only a body with life, sense, and spontaneous motion, we form the idea signified by the name *animal*. By the same way the mind proceeds to body, substance, and at last to being, thing, and such universal terms as stand for any ideas whatever.

This shews the reason why, in defining things, we make use of the genus, namely, to save the labour of enumerating the several simple ideas which the next term stands for: from whence it appears, that genus is no more than an abstract idea, comprehending a greater or less number of species, or more particular classes. See SPECIES.

GENUS is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences, as rhetoric, anatomy, and natural history.

GENUS, in rhetoric. Authors distinguish the art of rhetoric, as also orations or discourses produced thereby, into three genera or kinds, demonstrative, deliberative, and judiciary. To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, funeral harangues, &c. To the deliberative kind belong persuasions, dissuasions, commendations, &c. To the judiciary kind belong defences and accusations.

GENUS, in natural history, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See BOTANY and ZOOLOGY.

GENUS, in music, by the ancients called *genus melodice*, is a certain manner of dividing and subdividing the principles of melody; that is, the consonant and dissonant intervals, into their concinnous parts.

The moderns considering the octave as the most perfect of intervals, and that whereon all the concords depend, in the present theory of music, the division of that interval is considered as containing the true division of the whole scale.

But the ancients went to work somewhat differently: the diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought first how that might be most conveniently divided; from whence they constituted the diapente and diapacon.

The diatessaron being thus, as it were, the root and foundation of the scale, what they called the genera,

or kinds, arose from its various divisions; and hence they defined the *genus modulandi* to be the manner of dividing the tetrachord and disposing its four sounds as to succession.

The genera of music were three, the enharmonic, chromatic, and diatonic. The two first were variously subdivided: and even the last, tho' that is commonly reckoned to be without any species; yet different authors have proposed different divisions under that name, without giving any particular names to the species, as was done to the other two.

For the characters, &c. of these several genera, see ENHARMONIC, CHROMATIC, and DIATONIC.

GEOCENTRIC, in astronomy, is applied to a planet, or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

GEOFFREY of MONMOUTH, bishop of St Asaph, called by our ancient biographers *Gallofridus Monmouthensis*. Leland conjectures that he was educated in a Benedictine convent at Monmouth, where he was born; and that he became a monk of that order. Bale, and after him Pits, call him archdeacon of Monmouth; and it is generally asserted that he was made bishop of St Asaph in the year 1151 or 1152, in the reign of king Stephen. His history was probably finished after the year 1138. It contains a fabulous account of British kings, from the Trojan Brutus, to the reign of Cadwallader in the year 690. But Geoffrey, whatsoever censure he may deserve for his credulity, was not the inventor of the stories he relates. It is a translation from a manuscript written in the British language, and brought to England from Armorica by his friend Gualter, archdeacon of Oxford. But the achievements of king Arthur, Merlin's prophecies, many speeches and letters, were chiefly his own addition. In excuse for this historian, Mr Wharton judiciously observes, that fabulous histories were then the fashion, and popular traditions a recommendation to his book.

GEOFFROY (STEPHEN FRANCIS), a celebrated physician, botanist, and chemist, born at Paris in 1672. After having finished his studies, he travelled into England, Holland, and Italy. In 1704, he received the degree of doctor of physic at Paris; and at length became professor of chemistry, and physician of the Royal College. He was a member of the Royal Society of London, and of the Academy of Sciences. He wrote, 1. Several very curious Theses in Latin, which were afterwards translated into French. 2. An excellent treatise, intitled *Traictatus de Materia Medica, sive de Medicamentorum simplicium, historia, virtute, defectu, & usu*. He died at Paris, in 1731.

GEOGRAPHICAL MILE, the same with the sea-mile; being one minute, or the 60th part of a degree of a great circle on the earth's surface.

G E O G R A P H Y.

GEOGRAPHY (*γραφικα*, from *γη terra*, and *γραφω scribo*); the doctrine or knowledge of the earth, both as in itself, and as to its affections; or a

description of the terrestrial globe, and particularly of the known and inhabitable parts thereof, with all its different divisions.

SECT.

Geocentric
Geography.

SECT. I. *History of the Science.*

At what time the science of geography began first to be studied among mankind is entirely uncertain. It is generally agreed, that the knowledge of it was derived to the Greeks, who first of the European nations cultivated this science, from the Egyptians or Babylonians; but it is impossible to determine which of these two nations had the honour of the invention. Herodotus tells us, that the Greeks first learned the pole, the gnomon, and the twelve divisions of the day, from the Babylonians. By Pliny, and Diogenes Laertius, however, we are told, that Thales of Miletus first found out the passage of the sun from tropic to tropic; which he could not have done without the assistance of a gnomon. He is said to have been the author of two books, the one on the tropic, and the other on the equinox; both of which he probably determined by the gnomon; and by this he was led to the discovery of the four seasons of the year, which are determined by the solstices and equinoxes.

Thales divided the year into 365 days; which was undoubtedly a method discovered by the Egyptians, and communicated by them to him. It is said to have been invented by the second Mercury, surnamed Trismegistus, who, according to Eusebius, lived about 50 years after the *Exodus*. Pliny tells us expressly, that this discovery was made by observing when the *shadow returned to its marks*; a clear proof that it was done by the gnomon. Thales also knew the method of determining the height of bodies by the length of their shadows, as appears by his proposing this method for measuring the height of the Egyptian pyramids. Hence many learned men have been of opinion, that as the use of the gnomon was known in Egypt long before the dawn of learning in Greece, the pyramids and obelisks, which to common travellers appeared only to be buildings of magnificence, were in reality as many sun-dials on a very large scale, and built with a design to ascertain the season of the year, by the variation of the length of their shadows; and, in confirmation of this opinion, it was found by M. Chazelles in 1694, that the two sides, both of the larger and smaller pyramids, stood exactly north and south; so that, even at this day, they form true meridian lines.

From the days of Thales, who flourished in the fifth century before Christ, very little seems to have been done towards the establishment of geography for 200 years. During this period, there is only one astronomical observation recorded; namely, that of Meton and Euctemon, who observed the summer solstice at Athens, during the archonship of Apseudes, on the 21st of the Egyptian month Phamenoth, in the morning, being the 27th of June, 432. B. C. This observation was made by watching narrowly the shadow of the gnomon, and was done with a design to fix the beginning of their cycle of 19 years.

Timocharis and Ariftillus, who began to observe about 295 B. C. seem to have been the first who attempted to fix the longitudes and latitudes of the fixed stars, by considering their distances from the equator. One of their observations gave rise to the discovery of the precession of the equinoxes, which was

first observed by Hipparchus about 150 years after; and he made use of Timocharis and Ariftillus's method, in order to delineate the parallels of latitude, and the meridians on the surface of the earth; thus laying the foundation of the science of geography as we have it at present.

But though the latitudes and longitudes were thus introduced by Hipparchus, they were not attended to by any of the intermediate astronomers, till the days of Ptolemy. Strabo, Vitruvius, and Pliny, have all of them entered into a minute geographical description of the situation of places, according to the length of the shadows of the gnomon, without taking the least notice of the degrees and minutes of longitude and latitude.

The discovery of the longitudes and latitudes immediately laid a foundation for making maps, or delineations of the surface of the earth *in plano*, on a very different plan from what had been attempted before. Formerly the maps were little more than rude outlines and topographical sketches of different countries. The earliest were those of Scythia, mentioned by Eustathius; who says, that "this Egyptian king, having traversed great part of the earth, recorded his march in maps, and gave copies of his maps not only to the Egyptians, but to the Scythians, to their great astonishment.—Some have imagined, that the Jews made a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh: for Joshua tells us, that they were sent to walk through the land, and that they *described it in seven parts in a book*; and Josephus tells us, that when Joshua sent out people from the different tribes to measure the land, he gave them, as companions, persons well skilled in geometry, who could not be mistaken in the truth.

The first Grecian map on record is that of Anaximander, mentioned by Strabo, lib. i. p. 7. It has been conjectured by some, that this was a general map of the then known world, and is imagined to be the one referred to by Hipparchus under the designation of the *ancient map*. Herodotus minutely describes a map made by Ariftagoras tyrant of Miletus, which will serve to give us some idea of the maps of those ages. He tells us, that Ariftagoras shewed it to Cleomenes king of Sparta, with a view of inducing him to attack the king of Persia, even in his palace at Susa, in order to restore the Ionians to their ancient liberty. It was traced upon brass or copper, and contained the intermediate countries which were to be traversed in that march. Herodotus tells us, that it contained "the whole circumference of the earth, the whole sea, or ocean, and all the rivers;" but these words must not be understood literally. From the state of geography at that time, it may be fairly concluded that by the *sea* was meant no more than the Mediterranean; and therefore, the earth or land signified the coasts of that sea, and more particularly the Lesser Asia, extending towards the middle of Persia. The rivers were the Hays, the Euphrates, and Tigris, which Herodotus mentions as necessary to be crossed in that expedition. It contained one straight line, called the *Royal Highway*, which took in all the stations or places of encampment from Sardis to Susa. Of these there were 111 in the whole journey, containing

Longitudes and latitudes determined.

4
Account of the ancient maps.

HISTORY. taining 13,500 stadia, or 1687 $\frac{1}{2}$ Roman miles of 5000 feet each.

These itinerary maps of the places of encampment were indispensably necessary in all armies. Athenæus quotes Baxton as author of a work intitled, *The encampments of Alexander's march*; and likewise Amyntas to the same purpose. Pliny tells us, that Diogenes and Bæton were the surveyors of Alexander's marches, and then quotes the exact number of miles according to their mensuration; which he afterwards confirms by the letters of Alexander himself. It likewise appears, that Alexander was very careful in examining the measures of his surveyors, and took care to employ the most skilful in every country for this purpose. The same author also acquaints us, that a copy of this great monarch's surveys, was given by Xenocles his treasurer, to Patrocles the geographer, who, as Pliny informs us, was admiral of the fleets of Seleucus and Antiochus. His book on geography is often quoted both by Strabo and Pliny; and it appears, that this author furnished Eratosthenes with the principal materials for constructing his map of the oriental part of the world.

Parallel of latitude how drawn at first.

Eratosthenes was the first who attempted to reduce geography to a regular system, and introduced a regular parallel of latitude. This was traced over certain places where the longest day was of the same length. He began it from the straits of Gibraltar; and it thence passed through the Sicilian sea, and near the southern extremities of Peloponnesus. From thence it was continued through the Island of Rhodes and the Bay of Issus; and there entering Cilicia, and crossing the rivers Euphrates and Tigris, it was extended to the mountains of India. By means of this line, he endeavoured to rectify the errors of the ancient map, supposed to be that of Anaximander. In drawing this parallel, he was regulated by observing where the longest day was fourteen hours and an half, which Hipparchus afterwards determined to be the latitude of 36 degrees.

Attempts to determine the extent of the earth's circumference.

The first parallel through Rhodes was ever afterwards considered with a degree of preference, like the foundation-stone of all ancient maps; and the longitude of the then known world was often attempted to be measured in stadia and miles, according to the extent of that line, by many succeeding geographers. Eratosthenes soon after attempted, not only to draw other parallels of latitude, but also to trace a meridian, at right angles to these, passing through Rhodes and Alexandria, down to Syene and Meroë; and as the progress he thus made tended naturally to enlarge his ideas, he at last undertook a still more arduous task, namely, to determine the circumference of the globe, by an actual measurement of a segment of one of its great circles. Here he made his computation by uniting certain accurate observations made in the heavens, with a corresponding distance carefully surveyed and taken upon a meridian of the earth. The segment of the meridian which he pitched upon for this purpose, was that between Alexandria and Syene, the distance betwixt which places was found to be 5000 stadia. The angle of the shadow on the sun-dial of Alexandria was equal to the 50th part of the circle; but at Syene there was no shadow on the day of the summer solstice; and that this might be the more accurately

observed, they dug a deep well, which being perpendicular, was completely illuminated at the bottom when the sun was vertical. Even this, however, was not sufficient to give the exact line of the tropic; because the sun was found to be vertical, or to cast no shadow at all, for a circular space of 300 stadia. The reason of this is, that the apparent diameter of the sun is 32 minutes, and he must therefore appear perpendicular to an extent of ground equivalent to that space.

The investigation of this problem of the circumference of the earth was essentially necessary for determining the radical principles of all maps; and therefore the most eminent of the ancient geographers made repeated attempts to discover this exactly. Eratosthenes made the circumference 250,000 or 252,000 stadia; thus allowing 700 stadia, or 87 $\frac{1}{2}$ Roman miles, to each degree. Hipparchus added 25,000 stadia to this measurement of Eratosthenes, which increased the degree to 96 Roman miles. Ptolemy, however, having obtained a more accurate measurement than that of Eratosthenes, reduced the circumference of the earth to 180,000 stadia, and the degree to 62 $\frac{1}{2}$ Roman miles.

The map of Eratosthenes, though the best of which antiquity can boast, was nevertheless exceedingly imperfect and inaccurate. It contained little more than the states of Greece, and the dominions of the successors of Alexander, digested according to the surveys above-mentioned. He had seen, indeed, and has quoted, the voyages of Pytheas into the great Atlantic ocean, which gave him some faint idea of the western parts of Europe; but so imperfect, that they could not be realised into the outlines of a chart. Strabo tells us, that he was extremely ignorant of Gaul, Spain, Germany, and Britain. He was equally ignorant of Italy, the coasts of the Adriatic, Pontus, and all the countries towards the north. We are also told by the same author, that Eratosthenes made the distance between Epidamnus or Dyrrhachium on the Adriatic, and the bay of Thermæ on the Ægean sea, to be only 900 stadia, when in reality it was above 2000; and in another instance, he had enlarged the distance from Carthage to Alexandria to 15,000 stadia, when in reality it was no more than 9000.

Such was the state of geography and the nature of the maps prior to the time of Hipparchus; who, as already observed, made a closer connection between geography and astronomy, by determining the longitudes and latitudes from celestial observations. It must be owned, however, that the previous steps to this new projection of the sphere had been in a great measure made easy by Archimedes, upwards of 50 years before the time of Hipparchus, when he invented his noble theorems for measuring the surface of a sphere and its different segments.

It appears that war has been generally the occasion of making the most accurate maps of different countries; and therefore geography made great advances from the progress of the Roman arms. In all the provinces occupied by that people, we find that camps were every where constructed at proper intervals, and roads were raised with substantial materials, for making an easier communication between them; and thus civilisation and surveying were carried on according to system throughout the extent of that large empire.

Inaccuracy of the ancient maps.

HISTORY. Every new war produced a new survey and itinerary of the countries where the scenes of action passed; so that the materials of geography were accumulated by every additional conquest. Polybius tells us, that at the beginning of the second Punic war, when Hannibal was preparing his expedition against Rome, the countries through which he was to pass, were carefully measured by the Romans. Julius Cæsar caused a general survey of the Roman empire to be made, by a decree of the senate. Three surveyors, Zenodorus, Theodotus, and Polyclitus, had this task assigned them, and are said to have completed it in 25 years. The Roman itineraries that are still extant, also shew what care and pains they had been at in making surveys in all the different provinces of their empire; and Pliny has filled the third, fourth, and fifth books of his Natural History with the geographical distances that were thus measured. We have likewise another set of maps still preserved to us, known by the name of the *Peutingerian Tables*, published by Welfer and Bertius, which give a sufficient specimen of what Vegetius calls the *Itinera Picta*, for the clearer direction of their armies in their march.

The Roman empire had been enlarged to its greatest extent, and all its provinces well known and surveyed, when Ptolemy, in the reign of Antoninus Pius, about 150 years after Christ, composed his system of geography. The principal materials he made use of for composing this work, were the *proportions of the gnomon to its shadow*, taken by different astronomers at the times of the equinoxes and solstices; calculations founded upon the length of the longest days; the measures or computed distances of the principal roads contained in their surveys and itineraries; and the various reports of travellers and navigators, who often determined the distances of places by hearsay and conjecture. All these were compared together, and digested into one uniform body or system; and afterwards were translated by him into a new mathematical language, expressing the different degrees of longitude and latitude, according to the invention of Hipparchus, but which Ptolemy had the merit of carrying into full practice and execution, after it had been neglected for upwards of 250 years. With such imperfect and inaccurate materials, it is no wonder to find many errors in Ptolemy's system. Neither were these errors such as had been introduced in the more distant extremities of his maps, but even in the very centre of that part of the world which was the best known to the ancient Greeks and Romans, and where all the famed ancient astronomers had made their observations.—Yet this system, with all its imperfections, continued in vogue till the beginning of the present century. The improvements in geography which at that time, and since have taken place, were owing to the great progress made in astronomy by several eminent men who lived during that period. More correct methods and instruments for observing the latitude were found out, and the discovery of Jupiter's satellites afforded a much easier method of finding the longitudes than was formerly known. The voyages made by different nations also, which were now become much more frequent than formerly, brought to the knowledge of the Europeans a vast number of countries utterly unknown to them before. The late voyages of Captain

Cooke, made by order of his Britannic Majesty, have contributed more to the improvement of geography than any thing that has been done during the present century; so that now the geography of the utmost extremities of the earth is in a fair way of being much better known to the moderns, than that of the most adjacent countries was to the ancients. This, however, must be understood only of the sea-coasts of these countries; for, as to their internal geography, it is less known now than before, except in a very few places.

On the whole, it may be observed, that geography is a science even yet far from perfection. The maps of America and the eastern parts of Asia are, perhaps, more unfinished than any of the rest. Even the maps of Great Britain and Ireland are very imperfect and unsatisfactory; and the numbers we have of them, varied, and republished, without any real improvement, justly confirm an observation made by Lord Bacon, namely, that an opinion of plenty is one of the causes of want. The late Dr Bradley was of opinion, that there were but two places in England whose longitude might be depended upon as accurately taken; and that these were the observatory at Greenwich, and Serburn-castle the seat of the Earl of Macclesfield in Oxfordshire; and that their distance was one degree in space, or four minutes in time. Even this was found to be inaccurate, the distance in time being observed by the late transit of Venus to be only three minutes and forty-seven seconds. It were well, however, if there were no greater errors with regard to other places: but if we examine the longitude of the Lizard, we shall find scarce any two geographers that agree concerning it; some making it $4^{\circ} 40'$ from London; others 5° , and $5^{\circ} 14'$; while some enlarge it to 6° . Our best maps are therefore still to be considered as unfinished works, where there will always be many things to be added and corrected, as different people have an opportunity.

SECT. II. Principles and Practice of Geography.

THE practical part of geography consists in measuring the distances between different places on the surface of the earth, and laying them down upon paper according to their different longitudes and latitudes. For this purpose, an exact observation of the longitudes and latitudes of the different places is sufficient; for when once these are known, the distance between the places themselves is easily found, that is to say, provided the extent of the circumference of the earth is known; for without this, it is impossible to ascertain the distance between any two places except by actual mensuration. For the solution of this problem, it is only necessary to measure one degree of the earth's surface; which may be done in the following manner. Having found exactly the latitude of the place from whence your mensuration is to commence, by the directions given under ASTRONOMY, n^o 209. proceed exactly northward or southward, carefully measuring the distance as you go along, till you find by another celestial observation that you are got to one degree of latitude either farther north or farther south than the place from whence you set out. The distance between the two places is the length of a degree on the earth's surface; and consequently, if multiplied by 360, will give the measure of the whole circumference of the earth.

Geography still imperfect.

How to measure a degree of the earth's surface.

This.

This method, however, though in theory it seems to be so easy and simple, is nevertheless attended with very great, nay, almost insurmountable, difficulties in practice. It is impossible to find a perfect plane on the surface of the earth, which extends for so great a length. In the mensuration of a degree, therefore, the inequalities with which the earth every where abounds are found to be exceeding great obstacles. For this reason, we are obliged to have recourse to trigonometrical calculations of the distances between different places, till we arrive at one distant from that whence we set out by a degree of latitude. But it is impossible to make any calculation in the trigonometrical way without some small error; nay, often not without a very great one; for the different states of the atmosphere are found greatly to affect trigonometrical mensurations. Hence there hath arisen a prodigious disagreement among those who have attempted to measure the circumference of the terraqueous globe; for as a degree of the earth's surface cannot be measured but by many calculations, the error in one being repeated in all the rest must necessarily become very considerable at last. Those who first attempted this mensuration, computed the circumference of the earth to be 50,000 Italian miles; by Ptolemy it was reckoned only 21,600 of the same miles; and the more modern geometers have computed the circumference of the earth at about 25,000 miles.

A method more easily practicable would seem to be by attempting to measure the degrees of longitude. We know, that at the equator a degree of longitude is equal to a degree of latitude; but as we advance towards either of the poles, the degrees of longitude continually decrease by reason of the approximation of the meridians to each other, till at the pole itself they totally vanish. If we know the length of a degree of longitude at the equator, therefore, we can easily, by a geometrical calculation liable to no unavoidable error, find the length of a degree of longitude at any distance either north or south from the equator. Again, if we know the measure of a degree of longitude at any distance from the equator, we may easily, by a like calculation, find the length of a degree of longitude at the equator itself. If, therefore, attempts are made to measure the degrees of longitude at the equator itself, and in many different places north and south from it, making at the same time proper geometrical calculations, it is plain that all these different operations will tend to confirm or correct one another, and by their mutual agreement or disagreement among themselves we will know which of them comes nearest the truth.

As a difference in longitude makes also a difference in the hour of the day, we have from thence a much easier method of measuring a degree of longitude than of measuring one of latitude. We know, that if two places are distant from each other by 15 degrees of longitude, it will be one o'clock in the afternoon in the one, when it is only twelve o'clock in the other. If they are distant from each other by a single degree of longitude, it will be four minutes after twelve at the one, when it is exactly twelve at the other. If they are distant half a degree, the difference will be two minutes; or if a quarter of a degree, the difference in time will be one minute. Instruments for

computing time, are now brought to such a degree of perfection, that if two of them are exactly set with each other, they may be safely trusted for a much longer time than what is necessary for the operation we now speak of. Having therefore chosen our first station, and drawn there a meridian line as directed at ASTRONOMY, n^o 174, 175. we must observe exactly when the sun is in the meridian, and then set our time-piece to twelve o'clock. We must then proceed directly eastward or westward a considerable way, till we arrive at some other convenient station; and having there also drawn a meridian line, we are to observe exactly by it when the sun comes to the meridian, and looking upon our time-piece at the same time, we will know how much the one place differs from the other in longitude by the distance of time shewn by the time-piece either before or after twelve, when the sun is exactly in the meridian of the second station.

The advantages which this method hath over the other, arise from the exactness with which the instrument is supposed to measure time, and from there being a less space on the surface of the earth to be measured than in the other. A minute, or even half a minute of time, may be observed by a proper instrument very exactly; and one of Mr Harrison's time-pieces may undoubtedly be trusted as perfectly exact for two or three days. If we attempt the mensuration of a degree of longitude at the equator, we must choose out second station at a considerable distance before we can expect a variation in time great enough to be observed with any tolerable accuracy: thus before a difference of one minute at the equator could be perceived, we must travel more than 17 English miles eastward or westward; but in the latitude of 60 degrees we would only have half that space to travel, and therefore could measure it with more exactness; at the latitude of 70 degrees, little more than a third of that space would require to be measured; and at 80 degrees, scarce an eighth part. The extreme cold in these high latitudes, however, renders it almost impossible to penetrate so far; though the voyage of the Hon. Constantine Phipps afforded a very favourable opportunity for a mensuration of this kind, and several as favourable opportunities as could be wished occurred in the voyages of captain Cook, had such a thing been thought of. Yet it is not to be expected that the extent of the earth's circumference will ever be known with great accuracy, though we are certainly not yet arrived at the nearest approximation to truth which is attainable on this subject.

Hitherto we have supposed the circumference of the earth to be exactly circular, or the globe itself to be a perfect sphere; but, from some observations, this appears not to be the case. Some time ago, the French made an observation, shewing that a pendulum vibrates slower in proportion as it is brought nearer to the equator: that is, the gravity or celerity of descent of the pendulum, and of all other bodies, is less in countries approaching to the equator than in places near either pole. This excited the curiosity of the celebrated philosophers Huygens and Newton, who thence conjectured that the earth must have some other figure than what was commonly supposed. Sir Isaac Newton afterwards demonstrated that this diminution of weight naturally arises from the earth's rotation

round its axis; which, according to the laws of circular motion, repels all heavy bodies from the axis of motion: so that this motion, being swifter at the equator than in parts more remote, the weight of bodies must also be much less there than nearer the poles *. —To determine this matter, several mathematicians were by the French king employed to measure a degree on the earth's surface in different parts of the world; and, according to their mensurations, the diameter of the earth from north to south is shorter than that from east to west, by 36 miles.

With regard to the method of finding the longitudes and latitudes of particular places, rules have been already laid down under *ASTRONOMY*, nº 209. and 282, 283. The same thing, however, may be done by other methods. Thus, the latitude may be found by observing exactly the meridian altitude of the sun, and knowing his declination for that day, the declination subtracted from the meridian altitude gives the complement of the latitude, and this last subtracted from 90° leaves the latitude required. As to the longitude, Mr Harrison, by his invention of time-pieces which go much more exactly than either clocks or watches could be made to do formerly, hath in a great measure facilitated that. For, supposing any person, possessed of one of these time-pieces, to set out on a journey, *ex g.* from London. If he adjusts his time-piece properly before he goes away, he will know the hour at London exactly, let him go where he pleases; and when he hath proceeded so far either eastward or westward, that a difference is perceived betwixt the hours shown by his time-piece, and those on the clocks or watches at the place to which he goes, the distance of that place from London in degrees and minutes of longitude will be known; and if the length of a degree of longitude is known, the real distance between the two places may also be easily found. It is not to be expected, however, that any instrument, with whatever care it may be constructed, can always be depended upon as an exact measurer of time; and therefore frequent corrections of longitudes taken in this manner will be necessary. The method of finding the longitude from the eclipses of Jupiter's satellites appears to be the best of any. Eclipses of the sun, and occultations of the stars by the moon, are also very proper, though they happen but seldom. Eclipses of the moon have also been made use of for this purpose; but it is found impossible to observe either the beginning or end of a lunar eclipse with the accuracy necessary for determining the longitude of any place. —All these different methods agree in this, that they determine the longitude by the difference of time between the observation of the phenomenon in two different places; and of this time, four minutes are to be allowed for every degree of longitude either east or west.

After the geographer is thus become acquainted with the longitudes and latitudes of a great number of different places, he may delineate them upon paper, or make a *map*, either of the whole world, or of any particular country with which he is best acquainted. General maps of the world, or of very large tracts, answer the purpose of shewing in what manner the different countries of the world lie with respect to each other. They cannot be made of such a size as to admit

the delineation of many particular towns or cities, neither indeed is it at all required. Where the whole world is delineated at once, the mind can hardly take in more than the idea of the situations of different kingdoms from one another; the situations of the different cities of each particular kingdom being almost wholly overlooked, and not attended to: and this happens likewise where a very large portion of the globe, as one of the four quarters, is represented on a single map. Besides these, therefore, it is necessary to have particular maps of all the different countries done upon a larger scale, that thus the mind may not be fatigued by endeavouring to comprehend too much at once. The qualifications which maps ought to have, in order to render them complete, are, 1. That they represent the countries exactly of the same shape, and in the same proportions to the eye, that they really have on the earth itself. 2. That the divisions of one country from another be distinctly marked, and readily perceptible, without a disagreeable and tedious search. 3. That the longitudes and latitudes of different places be found exactly on the map, and with little or no trouble.

The foundation of all maps is what is called the *projection of the sphere*, i. e. the delineation of those circles apparently traced out by the sun in the heavens, upon some substance, either plane or spherical, designed to represent the surface of the earth; upon which also are delineated the parallels of latitude, and the meridians, in as great numbers as the size of the map will admit of without confusion.

These delineations upon a spherical surface are very easy: and under the article *GLOBE*, full directions are given for the construction of the spherical substances upon which maps of the earth and the heavens are usually delineated; and which, when furnished with the rest of their apparatus, are called *terrestrial* and *celestial globes*. The method of drawing the maps for these globes, is never followed in any other case; for which reason it is also referred to the article *GLOBE*. The ordinary kinds of maps are constructed by delineating the circles of the sphere upon a plane surface, according to the rules of perspective. This is properly the projection of the sphere; and is designed to give a view of the terraqueous globe, as it would appear, at some distance, to an eye that could take in the whole extent of it at once.

§. 1. Of Projections of the Sphere, and Maps.

Of projections there are two kinds, the *orthographic* and *stereographic*; both of which represent the surface of the earth projected upon the plane of one of its great circles.

1. The *orthographic* supposes the eye to be placed at an infinite distance in the axis of the circle of projection, while the second supposes it to be only in the pole of that circle. The circles on which the projections are usually made, are, the equator, some of the meridians, or the rational horizon of some particular place. For maps of the world, a meridian is generally chosen; and most commonly that one which passes through Ferro, one of the Canary Islands, because thus the continents of Europe, Asia, and Africa, are conveniently delineated in one circle, and America in the other.

14
On the
plane of
a meridian.
2d Plate
CXV.

1. To project the sphere orthographically on the plane of any meridian, we have only to consider, that as the eye is supposed to be at an infinite distance, all the rays which come from the disk of the earth are parallel; and consequently all lines drawn from the eye to the disk must be perpendicular to the latter. Let, therefore, $ABCD$, (fig. 1.) represent the plane of one of the meridians. The equator, which cuts all the meridians in the middle, must be represented by an infinite number of points let fall upon the plane of projection, and dividing it exactly in the middle; that is, by the right line BD . The parallels of latitude, being also perpendicular to the plane of the meridian, will be marked out by an infinite number of right lines let fall from their peripheries upon that plane, thus forming the right lines ab , cd , &c. The meridians will likewise be represented on the disk by an infinite number of right lines let fall perpendicularly from their peripheries upon the plane of projection, and thus will form the elliptic curves $AtoC$ $AzoC$, &c. From an inspection of the figure, therefore, it appears, that in this projection both longitudes and latitudes are measured by a line of sines, and both of them decrease prodigiously as we approach the edges of the disk; and hence the countries which lie at a distance from the equator are exceedingly distorted, and it is even impossible to draw them with any degree of accuracy. The orthographic projection on the plane of a meridian, therefore, is never used for a map of the world.

15
On the
equator,
fig. 2.

2. On the plane of the equator, the orthographic projection represents the meridians as straight lines diverging from a centre, and the parallels of latitude as concentric circles. The latter, however, are by no means to be placed at equal distances from each other; for the meridians are to be divided by the line of sines, as in the last; and thus the equatorial parts of the globe are as much distorted and confused as the polar ones were in the foregoing. This projection, therefore, is seldom used for a map of the whole world, though it answers very well for a representation of the polar regions.

16
On any
particular
horizon,
fig. 3.

3. On the horizon of any particular place, except either of the poles, or any point lying directly under the equator, the orthographic projection represents both parallels and meridians by segments of ellipses. The figure shews a map done on the horizon of Ur of the Chaldees: it is obvious, however, that a considerable degree of distortion takes place here also; though less than in the former cases. Projections of this kind, therefore, are used only for the construction of solar eclipses. See *ASTRONOMY*, n° 269.

17
Stereographic
projection.

II. The *stereographic* projection of the sphere supposes the eye to be in the pole of the circle of projection. The laws of this projection are,

1. A right circle is projected into a line of half tangents.

2. The representation of a right circle, perpendicularly opposed to the eye, will be a circle in the plane of the projection.

3. The representation of a circle placed oblique to the eye, will be a circle in the plane of the projection.

4. If a great circle is to be projected upon the plane of another great circle, its centre will lie in the

line of measures, distant from the centre of the primitive by the tangent of its elevation above the plane of the primitive.

5. If a lesser circle, whose poles lie in the plane of the projection, were to be projected; the centre of its representation would be in the line of measures, distant from the centre of the primitive, by the secant of the lesser circles distance from its pole, and its semi-diameter or radius be equal to the tangent of that distance.

6. If a lesser circle were to be projected, whose poles lie not in the plane of the projection, its diameter in the projection, if it falls on each side of the pole of the primitive, will be equal to the sum of the half tangents of its greatest and nearest distance from the pole of the primitive, set each way from the centre of the primitive in the line of measures.

7. If the lesser circle to be projected fall entirely on one side of the pole of the projection, and do not encompass it: then will its diameter be equal to the difference of the half tangents of its greatest and nearest distance from the pole of the primitive; set off from the centre of the primitive one; and the same way in the line of measures.

8. In the stereographic projection, the angles made by the circles of the surface of the sphere, are equal to the angles made by their representatives in the plane of their projection.

For a demonstration of these laws, see the articles *PERSPECTIVE* and *PROJECTION*. The method of delineating general maps of the world will, however, be easily understood by the following directions.

19
On the
plane of a
meridian,
fig. 6.

1. To delineate a map of the earth upon the plane of a meridian. Draw a circle of any convenient magnitude, as $ABCD$, to represent one half of the earth's disc; draw two diameters AB , CD , intersecting each other at right angles; AB will then represent the equator, and CD that meridian which is directly perpendicular to the plane of projection, C will be the north pole, and D the south pole. Divide the circle into 360 equal parts, representing the degrees of latitude; or into smaller parts, if it can admit of such a division, to represent minutes. Then, by means of a sector, divide the equator AB into two lines of semitangents EA and EB , which will represent the degrees of longitude. Then with the secant of 80° , as a radius describe the arch of the circle Ced , which represents a meridian cutting the plane of projection at an angle of 80° ; with the secant of 70° , describe the arch CaD , which represents a meridian cutting the plane of projection at 70° ; and thus proceed with the rest of the meridians, which are usually drawn at every ten degrees longitude, as the parallels are at every ten degrees latitude. These last are to be drawn with the tangents for radii as the meridians are with the secants; GH , representing the parallel of ten degrees, with the tangent of 80° , that of 20 with the tangent of 70° , &c. The elliptic AQB is drawn with the tangent of 66.31 for a radius, its greatest distance from the equator being 23. 29. This is the most common projection for maps of the world, and is that on which the map Plate CXVI. is delineated. It hath this disadvantage, however, that neither the degrees of longitude nor latitude continue of the same length, even under the same parallel; and consequently the shape of the countries

tries is somewhat distorted: it is also exceedingly difficult to find the precise degree of longitude or latitude belonging to any place, upon maps of this kind, as must be evident from an inspection of the figures.

2. On the plane of the horizon. Suppose, for instance, it is desired to have London the centre of the map: its latitude we will suppose to be 51 degrees 32 minutes. Take then the point E (fig. 5.) for London; and from this, as a centre, describe the circle ABCD to represent the horizon; which you are then to divide into four quadrants, and each of these into 90 degrees. Let the diameter BD be the meridian, B the northern quarter, D the southern; the line of equinoctial east and west shews the first vertical, A the west, C the east, or a place of 90 degrees from the zenith in the first vertical. All the verticals are represented by right lines drawn from the centre E to the several degrees of the horizon. Divide BD into 180 degrees, as in the former method; the point in EB, representing 51 deg. 32 min. of the arch B C, will be the projection of the north pole, which note with the letter P. The point in ED representing 51 deg. 32 min. of the arch DC, (reckoning from C towards D), will be the projection of the intersection of the equator and meridian of London; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As also towards D, and from B towards P, viz. 51, 52, 53, &c.

Then taking the corresponding points of equal degrees, 88, 89, &c. about those, as diameters, describe circles, which will represent parallels, or circles of latitude, with the equator, tropics, and polar circles. For the meridians, first describe a circle through the three points A, P, C. This will represent the meridian 90 degrees from London. Let its centre be M in BD, (continued to the point N, which represents the south pole), PN being the diameter, through M draw a parallel to A C, viz. FH, continued each way to K and L. Divide the circle PHNF into 360 degrees; and from the point P draw right lines to the several degrees, cutting KFHL; through the several points of intersection, and the two poles P, N, as through three given points, describe circles representing all the meridians. The centres for describing the arches will be in the same KL, as being the same that are found by the former intersection; but are to be taken with this caution, that for the meridian next BDN towards A, the most remote centre towards L be taken for the second, the second from this, &c.—The circles of longitude and latitude thus drawn, insert the places from a table.

Maps of this kind may be useful for particular purposes: but the irregular length of the degrees, both of longitude and latitude, render them very unfit for representing the countries in their proper shape; and the difficulties in finding the particular degrees of longitude and latitude are even greater in this than any other projection, as is evident from the inspection of fig. 4.

III. Besides these, there may be a variety of other projections, though few of them are applicable to any particular purpose. The three following are those most generally useful, as having each some peculiar

property which cannot be found in any other but themselves.

1. If, instead of its globular figure, we suppose the earth to have a conical one, it is plain, that the meridians would be represented by straight lines diverging from the apex of the cone, while the parallels are shewn by concentric circles, placed at equal distances. This kind of projection is shewn in the map of the world, Plate CXVII. It hath this great advantage, that the longitudes and latitudes may be found with the greatest ease, by means of a moveable index placed on the centre. The whole earth may also be thus represented on a single circle: but thus the countries towards the south pole are prodigiously augmented in breadth in proportion to their length; for the degrees of longitude constantly increase the farther we are removed from the pole, while those of latitude still remain the same. This apparent error, however, doth not in the least affect the real proportion of the map, or render it more difficult to find the longitudes or latitudes upon it.

2. Mercator's projection supposes the earth, instead of a globular, to have a cylindrical figure; in consequence of which, the degrees of longitude become of an equal length throughout the whole surface, and are marked out on the map by parallel lines. The circles of latitude also are represented by lines crossing the former at right angles, but at unequal distances. The farther we remove from the equator, the longer the degrees of latitude become in proportion to those of longitude, and that in no less a degree than as the secant of an arch to the radius of the circle: that is, if we make one degree of longitude at the equator the radius of a circle; at one degree distant from the equator, a degree of latitude will be expressed by the secant of one degree; at ten degrees distance, by the secant of ten degrees; and so on*. A map of the world, therefore, cannot be delineated upon this projection, without distorting the shape of the countries in an extraordinary manner. The projection itself is, however, very useful in navigation, as it shews the different bearings with perfect accuracy, which cannot be done upon any other map. See the map of the New Discoveries, Plate CXVII.

3. The globular projection, is an invention of M. de la Hire, and is more useful than any of the former for exhibiting the true shape of the countries. It may be made in the following manner: Having drawn a circle, representing one half of the earth's disc, draw two diameters as before, which represent the equator and vertical meridian. Divide each of these into 180 equal parts, for the measures of the degrees of longitude and latitude. Then, through the two poles, and every tenth division on the equator, draw arches of circles for the meridians; and in like manner, through every tenth degree on each semicircle, draw an arch, which shall likewise pass through every tenth division on the meridian, for the parallels of latitude.

IV. The construction of maps of particular parts of the earth requires a different operation. Large portions of its surface may indeed be drawn on the plane of the meridian, as before directed; but when maps, as a small part, as the island of Britain for instance, is to be represented on a large scale, it would be found

PRINCIPLES and PRACTICE

PRINCIPLES and PRACTICE

difficult to draw the arches of such large circles as are necessary, and therefore the following method may be adopted. In this case, the degrees of longitude and latitude may be both represented by straight lines. It is to be remembered, however, that though the degrees of latitude always continue of an equal length, it is not so with those of longitude. They must necessarily decrease as we approach the pole. The proportion in which they decrease, may be found by the line of longitudes on the plain scale; or by the following

TABLE, shewing the Number of Miles contained in a Degree of Longitude, in each Parallel of Latitude from the Equator.

29	52	48	59	30	90	89	01	05
30	51	96	60	30	00	90	00	00

Suppose, then, it is required to draw the meridians and parallels for a map of Britain. This island is known to lie between 50 and 60 degrees of latitude, and two and seven of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table you find, that in the latitude of 50° the length of a degree of longitude is to one of latitude as 38.57 is to 60; that is, a degree of longitude in lat. 50, is somewhat more than half the length of a degree of latitude. The exact proportion may easily be taken by a diagonal scale; after which you are to

mark out seven or eight of those degrees upon a right line, for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out ten degrees of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in Lat. 60°, which is found to be very nearly one half a degree of latitude. It will always be proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees of longitude on each side. Then, having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by their means set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be followed where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass, on which the towns lie with respect to one another, or their bearings, cannot be exactly known, except by a globe, or Mercator's projection. Their distances, however, may by this means be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

§. 2. Description and Use of the Globes and Armillary Sphere.

WHEN we have thus discovered, by means of maps, or any other way, the true situation of the different places of the earth with regard to one another, we may easily know every other particular relative to them; as, how far distant they are from us, what hour of the day it is, what season of the year, &c. at any particular place. As each of these problems, however, would require a particular and sometimes troublesome calculation, machines have been invented, by which all the calculations may be saved, and every problem in geography may be solved mechanically, and in the most easy and expeditious manner. These machines are the celestial and terrestrial globes, and the armillary sphere; of which, and the method of using them, we proceed to give a description.

If a map of the world be accurately delineated on a spherical ball, the surface thereof will represent the surface of the earth: for the highest hills are so inconsiderable with respect to the bulk of the earth, that they take off no more from its roundness than grains of sand do from the roundness of a common globe; for the diameter of the earth is 8000 miles in round numbers, and no known hill upon it is much above three miles in perpendicular height.

For the proof of the earth's being spherical, see ASTRONOMY, n° 123.

With regard to what we call *up* and *down*, see the article GRAVITY.

To an observer placed any where in the indefinite space, where there is nothing to limit his view, all remote objects appear equally distant from him; and seem to be placed in a vast concave sphere, of which his eye is the centre. The moon is much nearer to us than the sun; some of the planets are sometimes nearer, and sometimes farther from us, than the sun; others of them never come so near to us as the sun always is; the

24
The terrestrial globe.

25
The face of
the heavens
and of the
earth repre-
sented in a
machine.

the remotest planet in our system is beyond comparison nearer to us than any of the fixed stars are: and yet all these celestial objects appear equally distant from us. Therefore, if we imagine a large hollow sphere of glass to have as many bright studs fixed to its inside, as there are stars visible in the heaven, and these studs to be of different magnitudes, and placed at the same angular distances from each other as the stars are; the sphere will be a true representation of the starry heaven, to an eye supposed to be in its centre, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the centre of this starry sphere, and the sphere be made to turn round on this axis, it will represent the apparent motion of the heavens round the earth.

If a great circle be so drawn upon this sphere, as to divide it into two equal parts or hemispheres, and the plane of the circle be perpendicular to the axis of the sphere, this circle will represent the *equinoctial*, which divides the heaven into two equal parts, called the *northern* and *southern hemispheres*; and every point of that circle will be equally distant from the *poles*, or ends of the axis in the sphere. That pole which is in the middle of the northern hemisphere, will be called the *north pole of the sphere*; and that which is in the middle of the southern hemisphere, the *south pole*.

If another grand circle be drawn upon the sphere, in such a manner as to cut the equinoctial at an angle of 23½ degrees in two opposite points, it will represent the *ecliptic*, or circle of the sun's apparent annual motion; one half of which is on the north side of the equinoctial, and the other half on the south.

If a large stud be made to move eastward in this ecliptic, in such a manner as to go quite round it in the time that the sphere is turned round westward 366 times upon its axis; this stud will represent the *sun*, changing his place every day a 366th part of the ecliptic; and going round westward, the same way as the stars do; but with a motion so much slower than the motion of the stars, that they will make 366 revolutions about the axis of the sphere, in the time that the sun makes only 365. During one half of these revolutions, the sun will be on the north side of the equinoctial; during the other half, on the south; and at the end of each half, in the equinoctial.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the starry sphere to be about five or six feet, a small insect on the globe would see only a very little portion of its surface; but it would see one half of the starry sphere, the convexity of the globe hiding the other half from its view. If the sphere be turned westward round the globe, and the insect could judge of the appearances which arise from that motion, it would see some stars rising to its view in the eastern side of the sphere, whilst others were setting on the western: but as all the stars are fixed to the sphere, the same stars would always rise in the same points of view on the east side, and set in the same points of view on the west side. With the sun it would be otherwise; because the sun is not fixed to any point of the sphere, but moves slowly along an oblique circle in it. And if the insect should look towards the south, and call that point of the globe, where the equinoctial in the sphere seems to cut it on the left side, the *east point*; and where it cuts the

globe on the right side, the *west point*; the little animal would see the sun rise north of the east, and set north of the west, for 182½ revolutions; after which, for as many more, the sun would rise south of the east, and set south of the west. And in the whole 365 revolutions, the sun would rise only twice in the east point, and set twice in the west. All these appearances would be the same, if the starry sphere stood still (the sun only moving in the ecliptic) and the earthly globe were turned round the axis of the sphere eastward. For, as the insect would be carried round with the globe, he would be quite insensible of its motion, and the sun and stars would appear to move westward.

We may imagine as many circles described upon the earth as we please; and we may imagine the plane of any circle described upon the earth to be continued, until it marks a circle in the concave sphere of the heavens.

The horizon is either *sensible* or *rational*. The *sensible* horizon is that circle which a man standing upon a large plane observes to terminate his view all around, where the heaven and earth seem to meet. The plane of our sensible horizon continued to the heaven, divides it into two hemispheres; one visible to us, the other hid by the convexity of the earth.

The plane of the *rational horizon*, is supposed parallel to the plane of the sensible; to pass through the centre of the earth, and to be continued to the heavens. And although the plane of the sensible horizon touches the earth in the place of the observer, yet this plane, and that of the rational horizon, will seem to coincide in the heaven, because the whole earth is but a point compared to the sphere of the heaven.

The earth being a spherical body, the horizon, or limit of our view, must change as we change our place.

The *poles of the earth*, are those two points on its surface in which its axis terminates. The one is called the *north pole*, and the other the *south pole*.

The *poles of the heavens*, are those two points in which the earth's axis produced terminates in the heaven; so that the *north pole* of the heaven is directly over the north pole of the earth, and the *south pole* of the heaven is directly over the south pole of the earth.

The *equator* is a great circle upon the earth, every part of which is equally distant from either of the poles. It divides the earth into two equal parts, called the *northern* and *southern hemispheres*. If we suppose the plane of this circle to be extended to the heaven, it will mark the *equinoctial* therein; and will divide the heaven into two equal parts, called the *northern* and *southern hemispheres* of the heaven.

The *meridian* of any place is a great circle passing through that place and the poles of the earth. We may imagine as many such meridians as we please; because any place that is ever so little to the east or west of any other place, has a different meridian from that place; for no one circle can pass through any two such places and the poles of the earth.

The *meridian* of any place is divided by the poles into two semicircles: that which passes thro' the place is called the *geographical*, or *upper*, *meridian*; and that which passes through the opposite place, is called the *lower meridian*.

When the rotation of the earth brings the plane of the

In *Isalemmet*, Shewing the time of Sun rising & sun setting, the length of the Days & Nights, and the point of the Compass on which the Sun rises & sets, for every Degree of Latitude, and for every Degree of the Suns North & South declination.

Method of enlarging this Diagram in Mercators Chart

A. Bell Sculp.

the geographical meridian to the sun, it is *noon* or *mid-day* to that place; and when the lower meridian comes to the sun, it is *mid-night*.

All places lying under the same geographical meridian, have their noon at the same time, and consequently all the other hours. All those places are said to have the same *longitude*, because no one of them lies either eastward or westward from any of the rest.

30
Hour-circles.

If we imagine 24 semicircles, one of which is the geographical meridian of a given place, to meet at the poles, and to divide the equator into 24 equal parts; each of those meridians will come round to the sun in 24 hours, by the earth's equable motion round its axis in that time. And, as the equator contains 360 degrees, there will be 15 degrees contained between any two of these meridians which are nearest to one another: for 24 times 15 is 360. And as the earth's motion is eastward, the sun's apparent motion will be westward, at the rate of 15 degrees each hour. Therefore,

They whose geographical meridian is 15 degrees westward from us, have noon, and every other hour, an hour sooner than we have. They whose meridian is fifteen degrees westward from us, have noon, and every other hour, an hour later than we have: and so on in proportion, reckoning one hour for every fifteen degrees.

31
Tropics.

For the ecliptic circle, signs, and degrees, see ASTRONOMY, n° 122,—137.

The *tropics* are lesser circles in the heaven, parallel to the equinoctial; one on each side of it, touching the ecliptic in the points of its greatest declination; so that each tropic is $23\frac{1}{2}$ degrees from the equinoctial, one on the north side of it, and the other on the south. The northern tropic touches the ecliptic at the beginning of Cancer, the southern at the beginning of Capricorn; for which reason the former is called the *tropic of Cancer*, and the latter the *tropic of Capricorn*.

32
Polar circles.

The *polar circles* in the heaven, are each $23\frac{1}{2}$ degrees from the poles, all around. That which goes round the north pole, is called the *arctic circle*. The south polar circle, is called the *antarctic circle*, from its being opposite to the arctic.

The ecliptic, tropics, and polar circles, are drawn upon the terrestrial globe, as well as upon the celestial. But the ecliptic, being a great fixed circle in the heavens, cannot properly be said to belong to the terrestrial globe; and is laid down upon it only for the convenience of solving some problems. So that, if this circle on the terrestrial globe was properly divided into the months and days of the year, it would not only suit the globe better, but would also make the problems thereon much easier.

1. Description of the Terrestrial Globe.

33
The terrestrial globe described.

THE equator, ecliptic, and tropics, polar circles, and meridians, are laid down upon the globe in the manner already described. The ecliptic is divided into 12 signs, and each sign into 30 degrees. Each tropic is $23\frac{1}{2}$ degrees from the equator, and each polar circle $23\frac{1}{2}$ degrees from its respective pole. Circles are drawn parallel to the equator, at every ten degrees distance from it on each side to the poles: these circles are called *parallels of latitude*. On large globes there

VOL. V.

are circles drawn perpendicularly through every tenth degree of the equator, intersecting each other at the poles: but on globes of or under a foot diameter, they are only drawn through every fifteenth degree of the equator; these circles are generally called *meridians*, sometimes *circles of longitude*, and at other times *hour-circles*.

The globe is hung in a brass-ring called the *brazen meridian*; and turns upon a wire in each pole hung half its thickness into one side of the meridian ring; by which means that side of the ring divides the globe into two equal parts, called the *eastern* and *western hemispheres*; as the equator divides it into two equal parts, called the *northern* and *southern hemispheres*. The ring is divided into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to shew the latitudes of places. The degrees on the other half of the meridian are numbered from the poles to the equator, where they end at 90: their use is to shew how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is north or south of the equator.

The brazen meridian is let into two notches made in a broad flat ring called the *wooden horizon*; the upper surface of which divides the globe into two equal parts, called the *upper* and *lower hemisphere*. One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, and the 32 points of the compass.—The graduated side of the brass meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globes.

There is a small *horary circle*, so fixed to the north part of the brazen meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an *index*, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brazen meridian.

There is a thin slip of brass, called the *quadrant of altitude*, which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brazen meridian by a nut and screw. The divisions end at the nut, and the quadrant is turned round upon it.

2. Description and Use of the Armillary Sphere.

34
Armillary sphere described.

THE exterior parts of this machine are, a compasses of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial *AA*, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries) for shewing the sun's right ascension in degrees; and also into 24 hours, for shewing his right ascension in time. 2. The ecliptic *BB*, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year; in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The

Plate CXVI
fig. 1.

tropic of Cancer *CC*, touching the ecliptic at the beginning of Cancer in *e*, and the tropic of Capricorn *DD*, touching the ecliptic at the beginning of Capricorn in *f*; each $23\frac{1}{2}$ degrees from the equinoctial circle. 4. The arctic circle *E*, and the antarctic circle *F*, each $23\frac{1}{2}$ degrees from its respective pole at *N* and *S*. 5. The equinoctial circle *GG*, passing through the north and south poles of the heaven at *N* and *S*, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial circle *HH*, passing through the poles of the heaven, and through the solstitial points Cancer and Capricorn in the ecliptic. Each quarter of the former of these circles is divided into 90 degrees, from the equinoctial to the poles of the world, for shewing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for shewing the latitude of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun *T*, which is carried round the ecliptic *BB*, by turning the nut; and in the south pole of the ecliptic is a pin *d*, on which is another quadrantal wire, with a small moon *Z* upon it, which may be moved round by the hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of $5\frac{1}{2}$ degrees, in two opposite points called the *moon's nodes*; and also for shifting these points backward in the ecliptic, as the *moon's nodes* shift in the heaven.

Within these circular rings is a small terrestrial globe *I*, fixt on an axis *KK*, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at *N* and *S*. On this axis is fixed the flat celestial meridian *LL*, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon *MM*, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at the opposite points of its equator, which is a moveable brass ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian *LL*. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass for shewing the amplitude of the sun and moon both in degrees and points. The celestial meridian *LL*, passes thro' two notches in the north and south points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixed to the rings; and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal *N*, and may be elevated or depressed upon the joint *O*, to any number of degrees from 0 to 90, by means of the arc *P*, which is fixed in the strong brass arm *Q*, and slides in the upright piece *R*, in which is a screw at *r*, to fix it at any proper elevation.

In the box *T* are two wheels (as in Dr Long's PRINCIPLES and PRACTICE sphere), and two pinions, whose axes come out at *V* and *U*; either of which may be turned by the small winch *W*. When the winch is put upon the axis *V*, and turned backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun *T*, and moon *Z*, round the same way, and causing them to rise above and set below the horizon. But when the winch is put upon the axis *U*, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest and they were carried round it; shewing that they rise and set in the same points of the horizon, and at the same times in the hour-circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to shew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem *R*, and taking hold of the arm *Q*, move it up or down until the given degree of latitude for any place be at the side of the stem *R*; and then the axis of the sphere will be properly elevated so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian *LL*, down towards the north notch of the horizon, and set the horizon to that latitude; then, turn the nut *b* until the sun *T* comes to the given day of the year in the ecliptic, and the sun will be at its proper place for that day: find the place of the moon's ascending node, and also the place of the moon, by an Ephemeris, and set them right accordingly: lastly, turn the winch *W*, until either the sun comes to the meridian *LL*, or until the meridian comes to the sun (according as you want the sphere or earth to move) and set the hour-index to the XII, marked noon, and the whole machine will be rectified.

—Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour-index will shew the times thereof for the given day.

As those who understand the use of the globes will be at no loss to work many other problems by this sphere, it is needless to enlarge any farther upon it.

3. Directions for using Globes.

In using globes, keep the east side of the horizon towards you (unless the problem requires the turning of it), which side you may know by the word East upon the horizon; for then you have the graduated side of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated side of the meridian.

In working some problems, it will be necessary to turn the whole globe and horizon about, that you may for using the terrestrial globe, look on the west side thereof; which turning will be apt to jog the ball so, as to shift away that degree of the

the globe which was before set to the horizon or meridian: to avoid which inconvenience, you may thrust in the feather-end of a quill between the ball of the globe and the brazen meridian; which, without hurting the ball, will keep it from turning in the meridian, whilst you turn the west side of the horizon towards you.

PROB. I. *To find the latitude and longitude of any given place upon the globe.*—Turn the globe on its axis, until the given place comes exactly under that graduated side of the brazen meridian on which the degrees are numbered from the equator; and observe what degree of the meridian the place then lies under; which is its latitude, north or south, as the place is north or south of the equator.

The globe remaining in this position, the degree of the equator, which is under the brazen meridian, is the longitude of the place, which is east or west, as the place lies on the east or west side of the first meridian of the globe.—All the Atlantic ocean, and America, is on the west side of the meridian of London; and the greatest part of Europe, and of Africa, together with all Asia, is on the east side of the meridian of London, which is reckoned the *first meridian* of the globe by the British geographers and astronomers.

PROB. II. *The longitude and latitude of a place being given, to find that place on the globe.*—Look for the given longitude in the equator (counting it eastward or westward from the first meridian, as it is mentioned to be east or west;) and bringing the point of longitude in the equator to the brazen meridian, on that side which is above the fourth point of the horizon: then count from the equator, on the brazen meridian, to the degree of the given latitude, towards the north or south pole, according as the latitude is north or south; and under that degree of latitude on the meridian, you will have the place required.

PROB. III. *To find the difference of longitude, or difference of latitudes, between any two given places.*—Bring each of these places to the brazen meridian, and see what its latitude is: the lesser latitude subtracted from the greater, if both places are on the same side of the equator, or both latitudes added together if they are on different sides of it, is the difference of latitude required. And the number of degrees contained between these places, reckoned on the equator, when they are brought separately under the brazen meridian, is their difference of longitude, if it be less than 180; but if more, let it be subtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the brazen meridian, and set the hour-index to XII, turn the globe until the other place comes to the brazen meridian; and the number of hours and parts of an hour, passed over by the index, will give the longitude in time; which may be easily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N. B. When we speak of bringing any place to the brazen meridian, it is the graduated side of the meridian that is meant.

PROB. IV. *Any place being given, to find all those places that have the same longitude or latitude with it.*—Bring the given place to the brazen meridian; then all those places which lie under that side of the meri-

dian, from pole to pole, have the same longitude with the given place. Turn the globe round its axis; and all those places which pass under the same degree of the meridian that the given place does, have the same latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the first meridian, it is evident, that the point of the equator which is cut by the first meridian, has neither latitude nor longitude.—The greatest latitude is 90 degrees, because no place is more than 90 degrees from the equator: And the greatest longitude is 180 degrees, because no place is more than 180 degrees from the first meridian.

PROB. V. *To find the antæci, periæci, and antipodes, of any given place.*—Bring the given place to the brazen meridian; and having found its latitude, keep the globe in that situation, and count the same number of degrees of latitude from the equator towards the contrary pole; and where the reckoning ends, you have the *antæci* of the given place upon the globe. Those who live at the equator have no *antæci*.

The globe remaining in the same position, set the hour-index to the upper XII on the horary circle, and turn the globe until the index comes to the lower XII; then, the place which lies under the meridian, in the same latitude with the given place, is the *periæci* required. Those who live at the poles have no *periæci*.

As the globe now stands (with the index at the lower XII), the *antipodes* of the given place will be under the same point of the brazen meridian where its *antæci* stood before. Every place upon the globe has its *antipodes*.

PROB. VI. *To find the distance between any two places on the globe.*—Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply these degrees by 60, and the product will give the distance in geographical miles: but to find the distance in miles, multiply the degrees by 69½, and the product will be the number of miles required. Or, take the distance betwixt any two places with a pair of compasses, and apply that extent to the equator; the number of degrees, intercepted between the points of the compasses, is the distance in degrees of a great circle; which may be reduced either to geographical miles, or to English miles, as above.

PROB. VII. *A place on the globe being given, and its distance from any other place; to find all the other places upon the globe which are at the same distance from the given place.*—Bring the given place to the brazen meridian, and screw the quadrant of altitude to the meridian directly over that place; then keeping the globe in that position, turn the quadrant quite round upon it, and the degree of the quadrant that touches the second place will pass over all the other places which are equally distant with it from the given place.

This is the same as if one foot of a pair of compasses was set in the given place, and the other foot extended to the second place, whose distance is known; for if the compasses be then turned round the first place as a centre, the moving foot will go over all those places which are at the same distance with the

PRINCIPLES and PRACTICE second from it.

PROB. VIII. *The hour of the day at any place being given, to find all those places where it is noon at that time.*—Bring the given place to the brazen meridian, and set the index to the given hour; this done, turn the globe until the index points to the upper XII, and then all the places that lie under the brazen meridian have noon at that time.

N. B. The upper XII always stands for noon; and when the bringing of any place to the brazen meridian is mentioned, the side of that meridian on which the degrees are reckoned from the equator is meant, unless the contrary side be mentioned.

PROB. IX. *The hour of the day at any place being given, to find what o'clock it then is at any other place.*—Bring the given place to the brazen meridian, and set the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

PROB. X. *To find the sun's place in the ecliptic, and his declination, for any given day of the year.*—Look on the horizon for the given day, and right against it you have the degree of the sign in which the sun is (or his place) on that day at noon. Find the same degree of that sign in the ecliptic line upon the globe, and having brought it to the brazen meridian, observe what degree of the meridian stands over it; for that is the sun's declination, reckoned from the equator.

PROB. XI. *The day of the month being given, to find all those places of the earth over which the sun will pass vertically on that day.*—Find the sun's place in the ecliptic for the given day, and having brought it to the brazen meridian, observe what point of the meridian is over it; then, turning the globe round its axis, all those places which pass under that point of the meridian are the places required; for as their latitude is equal, in degrees and parts of a degree, to the sun's declination, the sun must be directly over-head to each of them at its respective noon.

PROB. XII. *A place being given in the torrid zone, to find those two days of the year on which the sun shall be vertical to that place.*—Bring the given place to the brazen meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and observe the two degrees of the ecliptic which pass exactly under that degree of latitude: lastly, find on the wooden horizon, the two days of the year in which the sun is in those degrees of the ecliptic, and they are the days required: for on them, and none else, the sun's declination is equal to the latitude of the given place; and consequently, he will then be vertical to it at noon.

PROB. XIII. *To find all those places of the north frigid zone, where the sun begins to shine constantly without setting, on any given day, from the 21st of March to the 23d of September.*—On these two days, the sun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and so make the day and night equal to all places of the earth. But as the sun declines from the equator, towards either pole, he will shine just as many degrees round that pole, as are equal to his declination from

the equator: so that no place within that distance of the pole will then go through any part of the dark, and consequently the sun will not set to it. Now, as the sun's declination is northward, from the 21st of March to the 23d of September, he must constantly shine round the north pole all that time; and on the day that he is in the northern tropic, he shines upon the whole north frigid zone; so that no place within the north polar circle goes through any part of the dark on that day. Therefore,

Having brought the sun's place for the given day to the brazen meridian, and found his declination (by Prob. IX.) count as many degrees on the meridian, from the north pole, as are equal to the sun's declination from the equator, and mark that degree from the pole where the reckoning ends: then turning the globe round its axis, observe what places in the north frigid zone pass directly under that mark; for they are the places required.

The like may be done for the south frigid zone, from the 23d of September to the 21st of March, during which time the sun shines constantly on the south pole.

PROB. XIV. *To find the place over which the sun is vertical at any hour of a given day.*—Having found the sun's declination for the given day (by Prob. X.) mark it with a chalk on the brazen meridian: then bring the place where you are (suppose Edinburgh) to the brazen meridian, and set the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point of the sun's declination marked upon the meridian, has the sun that moment in the zenith, or directly over head.

PROB. XV. *The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.*—The moon is never eclipsed but when she is full, and so directly opposite to the sun, that the earth's shadow falls upon her. Therefore, whatever place of the earth the sun is vertical to at that time, the moon must be vertical to the antipodes of that place: so that the sun will be then visible to one half of the earth, and the moon to the other.

Find the place to which the sun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the brazen meridian, as in the former problem: then, as the sun will be visible to all those parts of the globe which are above the horizon, the moon will be visible to all those parts which are below it, at the time of her greatest obscuration.

PROB. XVI. *To rectify the globe for the latitude, the zenith, and the sun's place.*—Find the latitude of the place, (by Prob. I.) and if the place be in the northern hemisphere, raise the north pole above the north point of the horizon, as many degrees (counted from the pole upon the brazen meridian) as are equal to the latitude of the place. If the place be in the southern hemisphere, raise the south pole above the south point of the horizon as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the brazen meridian, and fasten the quadrant of altitude so, that the chattered edge of its nut (which is even with the graduated

ated edge) may be joined to the zenith, or point of latitude. This done, bring the sun's place in the ecliptic for the given day (found by Prob. X.) to the graduated side of the brazen meridian, and set the hour-index to XII at noon, which is the uppermost XII on the hour-circle; and the globe will be rectified.

PROB. XVII. *The latitude of any place, not exceeding $66\frac{1}{2}$ degrees, and the day of the month, being given; to find the time of sun rising and setting; and consequently the length of the day and night.*—Having rectified the globe for the latitude, and for the sun's place on the given day (as directed in the preceding problem), bring the sun's place in the ecliptic to the eastern side of the horizon, and the hour-index will shew the time of sun-rising; then turn the globe on its axis, until the sun's place comes to the western side of the horizon, and the index will shew the time of sun-setting.

The hour of sun-setting doubled, gives the length of the day; and the hour of sun-rising doubled, gives the length of the night.

PROB. XVIII. *The latitude of any place, and the day of the month, being given; to find when the morning twilight begins, and the evening twilight ends, at that place.*—This problem is often limited: for, when the sun does not go 18 degrees below the horizon, the twilight continues the whole night; and for several nights together in summer, between 49 and $66\frac{1}{2}$ degrees of latitude; and the nearer to 66 $\frac{1}{2}$, the greater is the number of these nights. But when it does begin and end, the following method will shew the time for any given day.

Rectify the globe, and bring the sun's place in the ecliptic to the eastern side of the horizon; then mark with a chalk that point of the ecliptic which is in the western side of the horizon, it being the point opposite to the sun's place: this done, lay the quadrant of altitude over the said point, and turn the globe eastward, keeping the quadrant at the chalk mark, until it is just 18 degrees high on the quadrant; and the index will point out the time when the morning twilight begins: for the sun's place will then be 18 degrees below the eastern side of the horizon. To find the time when the evening twilight ends, bring the sun's place to the western side of the horizon; and the point opposite to it, which was marked with the chalk, will be rising in the east: then, bring the quadrant over that point, and keeping it thereon, turn the globe westward, until the said point be 18 degrees above the horizon on the quadrant, and the index will shew the time when the evening twilight ends; the sun's place being then 18 degrees below the western side of the horizon.

PROB. XIX. *To find on what day of the year the sun begins to shine constantly without setting, on any given place in the north frigid zone; and how long he continues to do so.*—Rectify the globe to the latitude of the place, and turn it about until some point of the ecliptic, between Aries and Cancer, coincides with the north point of the horizon where the brazen meridian cuts it; then find, on the wooden horizon, what day of the year the sun is in that point of the ecliptic; for that is the day on which the sun begins to shine constantly on the given place, without setting. This done, turn the globe, until some point of the ecliptic, between

Cancer and Libra, coincides with the north point of the horizon, where the brazen meridian cuts it; and find, on the wooden horizon, on what day the sun is in that point of the ecliptic; which is the day that the sun leaves off constantly shining on the said place, and rises and sets to it as to other places on the globe. The number of natural days, or complete revolutions of the sun about the earth, between the two days above found, is the time that the sun keeps constantly above the horizon without setting; for all that portion of the ecliptic, which lies between the two points which intersect the horizon in the very north, never sets below it; and there is just as much of the opposite part of the ecliptic that never rises: therefore, the sun will keep as long constantly below the horizon in winter, as above it in summer.

PROB. XX. *To find in what latitude the sun shines constantly without setting, for any length of time less than 182 $\frac{1}{2}$ of our days and nights.*—Find a point in the ecliptic half as many degrees from the beginning of Cancer (either toward Aries or Libra) as there are natural days in the time given; and bring that point to the north side of the brazen meridian, on which the degrees are numbered from the pole towards the equator: then, keep the globe from turning on its axis, and slide the meridian up or down until the forefaid point of the ecliptic comes to the north point of the horizon, and then the elevation of the pole will be equal to the latitude required.

PROB. XXI. *The latitude of a place, not exceeding $66\frac{1}{2}$ degrees, and the day of the month, being given; to find the sun's amplitude or point of the compass on which he rises or sets.*—Rectify the globe, and bring the sun's place to the eastern side of the horizon; then observe what point of the compass on the horizon stands right against the sun's place, for that is his amplitude at rising. This done, turn the globe westward, until the sun's place comes to the western side of the horizon, and it will out the point of his amplitude at setting. Or, you may count the rising amplitude in degrees, from the east point of the horizon, to that point where the sun's place cuts it; and the setting amplitude, from the west point of the horizon, to the sun's place at setting.

PROB. XXII. *The latitude, the sun's place, and his altitude, being given; to find the hour of the day, and the sun's azimuth, or number of degrees that he is distant from the meridian.*—Rectify the globe, and bring the sun's place to the given height upon the quadrant of altitude; on the eastern side of the horizon, if the time be in the forenoon; or the western side, if it be in the afternoon: then the index will shew the hour; and the number of degrees in the horizon, intercepted between the quadrant of altitude and the south point, will be the sun's true azimuth at that time.

PROB. XXIII. *The latitude, hour of the day, and the sun's place, being given; to find the sun's altitude and azimuth.*—Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the sun's place in the ecliptic, and the degree of the quadrant cut by the sun's place is his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the sun's azimuth, reckoned from the south.

PROB. XXIV. *The latitude, the sun's altitude, and his*

his azimuth being given; to find his place in the ecliptic, the day of the month, and hour of the day, though they had all been left.—Rectify the globe for the latitude and zenith, and set the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the sun's place; and the day of the month answering thereto, will be found over the like place of the sun on the wooden horizon. Keep the quadrant of altitude in that position; and, having brought the sun's place to the brazen meridian, and the hour-index to XII at noon, turn back the globe, until the sun's place cuts the quadrant of altitude again, and the index will shew the hour.

Any two points of the ecliptic, which are equidistant from the beginning of Cancer or of Capricorn, will have the same altitude and azimuth at the same hour, though the months be different; and therefore it requires some care in this problem, not to mistake both the month and the day of the month: to avoid which, observe, that from the 20th of March to the 21st of June, that part of the ecliptic which is between the beginning of Aries and beginning of Cancer is to be used; from the 21st of June to the 23d of September, between the beginning of Cancer and beginning of Libra; from the 23d of September to the 21st of December, between the beginning of Libra and the beginning of Capricorn; and from the 21st of December to the 20th of March, between the beginning of Capricorn and beginning of Aries. And as one can never be at a loss to know in what quarter of the year he takes the sun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

PROB. XXV. *To find the length of the longest day at any given place.*—If the place be on the north side of the equator (find its latitude by Prob. I.) and elevate the north pole to that latitude; then, bring the beginning of Cancer to the brazen meridian, and set the hour-index to XII at noon. But if the given place be on the south side of the equator, elevate the south pole to its latitude, and bring the beginning of Capricorn to the brazen meridian, and the hour-index to XII. This done, turn the globe westward, until the beginning of Cancer or Capricorn (as the latitude is north or south) comes to the horizon; and the index will then point out the time of sun-setting, for it will have gone over all the afternoon hours, between mid-day and sun-set; which length of time being doubled, will give the whole length of the day from sun-rising to sun-setting. For, in all latitudes, the sun rises as long before mid-day, as he sets after it.

PROB. XXVI. *To find in what latitude the longest day is, of any given length, less than 24 hours.*—If the latitude be north, bring the beginning of Cancer to the brazen meridian, and elevate the north pole to about $66\frac{1}{2}$ degrees; but if the latitude be south, bring the beginning of Capricorn to the meridian, and elevate the south pole to about $66\frac{1}{2}$ degrees; because the longest day in north latitude is, when the sun is in the first point of Cancer; and in south latitude, when he is in the first point of Capricorn. Then set the hour-index to XII at noon, and turn the globe west-

ward, until the index points at half the number of hours given; which done, keep the globe from turning on its axis, and slide the meridian down in the notches, until the aforesaid point of the ecliptic (*viz.* Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

PROB. XXVII. *The latitude of any place, not exceeding $66\frac{1}{2}$ degrees, being given; to find in what climate the place is.*—Find the length of the longest day at the given place, by Prob. XXV. and whatever be the number of hours whereby it exceedeth twelve, double that number, and the sum will give the climate in which the place is.

PROB. XXVIII. *The latitude, and the day of the month, being given; to find the hour of the day when the sun shines.*—Set the wooden horizon truly level, and the brazen meridian due north and south by a mariner's compass; then, having rectified the globe, stick a small sewing-needle into the sun's place in the ecliptic, perpendicular to that part of the surface of the globe: this done, turn the globe on its axis, until the needle comes to the brazen meridian, and set the hour-index to XII at noon; then, turn the globe on its axis, until the needle points exactly towards the sun (which it will do when it casts no shadow on the globe), and the index will shew the hour of the day.

4. The Use of the Celestial Globe.

HAVING done for the present with the terrestrial globe, we shall proceed to the use of the celestial; first premising, that as the equator, ecliptic, tropics, polar-circles, horizon, and brazen meridian, are exactly alike on both globes, all the former problems concerning the sun are solved the same way by both globes. The method also of rectifying the celestial globe is the same as rectifying the terrestrial. *N. B.* The sun's place for any day of the year stands directly over that day on the horizon of the celestial globe, as it does on that day of the terrestrial.

The latitude and longitude of the stars, or of all other celestial phenomena, are reckoned in a very different manner from the latitude and longitude of places on the earth: for all terrestrial latitudes are reckoned from the equator; and longitudes from the meridian of some remarkable place, as of London by the British, and of Paris by the French. But the astronomers of all nations agree in reckoning the latitudes of the moon, stars, planets, and comets, from the ecliptic; and their longitudes from the equinoctial colure, in that semi-circle of it which cuts the ecliptic at the beginning of Aries; and thence eastward, quite round, to the same semi-circle again. Consequently those stars which lie between the equinoctial and the northern half of the ecliptic, have north declination and south latitude; those which lie between the equinoctial and the southern half of the ecliptic, have south declination and north latitude; and all those which lie between the tropics and poles, have their declinations and latitudes of the same denomination.

There are six great circles on the celestial globe, which cut the ecliptic perpendicularly, and meet in two opposite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called

36

How to use the celestial globe.

37

Latitude and longitude of the stars.

led its poles. These polar points divide those circles into 12 femicircles; which cut the ecliptic at the beginnings of the twelve signs. They resemble so many meridians on the terrestrial globe : and as all places which lie under any particular meridian-femicircle on that globe, have the same longitude; so all those points of the heaven, through which any of the above femicircles are drawn, have the same longitude.—And as the greatest latitudes on the earth are at the north and south poles of the earth, so the greatest latitudes in the heaven are at the north and south poles of the ecliptic.

For the division of the stars into constellations, &c. see ASTRONOMY, n° 203. 206.

PROB. I. *To find the right ascension and declination of the sun, or any fixed star.*—Bring the sun's place in the ecliptic to the brass meridian : then that degree in the equinoctial which is cut by the meridian, is the sun's *right ascension* ; and that degree of the meridian which is over the sun's place, is his *declination*. Bring any fixed star to the meridian, and its right ascension will be cut by the meridian in the equinoctial ; and the degree of the meridian that stands over it, is its declination.

So that right ascension and declination, on the celestial globe, are found in the same manner as longitude and latitude on the terrestrial.

PROB. II. *To find the latitude and longitude of any star.*—If the given star be on the north side of the ecliptic, place the 90th degree of the quadrant of altitude on the north pole of the ecliptic, where the twelve femicircles meet, which divide the ecliptic into the 12 signs ; but if the star be on the south side of the ecliptic, place the 90th degree of the quadrant on the south pole of the ecliptic : keeping the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the star : then, the number of degrees in the quadrant, between the ecliptic and the star, is its latitude ; and the degree of the ecliptic, cut by the quadrant, is the star's longitude, reckoned according to the sign in which the quadrant then is.

PROB. III. *To represent the face of the starry firmament, as seen from any given place of the earth, at any hour of the night.*—Rectify the celestial globe for the given latitude, the zenith, and sun's place, in every respect, as taught by the XVIIth problem for the terrestrial ; and turn it about, until the index points to the given hour : then, the upper hemisphere of the globe will represent the visible half of the heaven for that time ; all the stars upon the globe being then in such situations, as exactly correspond to those in the heaven. And if the globe be placed duly north and south, by means of a small sea-compass, every star in the globe will point toward the like star in the heaven : by which means, the constellations and remarkable stars may be easily known. All those stars which are in the eastern side of the horizon, are then rising in the eastern side of the heaven ; all in the western, are setting in the western side ; and all those under the upper part of the brass meridian, between the fourth point of the horizon and the north pole, are at their greatest altitude, if the latitude of the place be north ; but if the latitude be south, those stars which lie under the upper part of the meridian, between the

north point of the horizon and the south pole, are at their greatest altitude.

PROB. IV. *The latitude of the place, and day of the month, being given ; to find the time when any known star will rise, or be upon the meridian, or set.*—Having rectified the globe, turn it about until the given star comes to the eastern side of the horizon, and the index will shew the time of the star's rising ; then turn the globe westward, and when the star comes to the brass meridian, the index will shew the time of the star's coming to the meridian of your place ; lastly, turn on, until the star comes to the western side of the horizon, and the index will shew the time of the star's setting. *N. B.* In northern latitudes, those stars which are less distant from the north pole than the quantity of its elevation above the north point of the horizon, never set ; and those which are less distant from the south pole than the number of degrees by which it is depressed below the horizon, never rise : and *vice versa* in southern latitudes.

PROB. V. *To find at what time of the year a given star will be upon the meridian, at a given hour of the night.*—Bring the given star to the upper femicircle of the brass meridian, and set the index to the given hour ; then turn the globe, until the index points to XII at noon, and the upper femicircle of the meridian will then cut the star's place, answering to the day of the year sought ; which day may be easily found against the like place of the sun among the signs on the wooden horizon.

PROB. VI. *The latitude, day of the month, and azimuth of any known star, being given ; to find the hour of the night.*—Having rectified the globe for the latitude, zenith, and sun's place, lay the quadrant of altitude to the given degree of azimuth in the horizon : then turn the globe on its axis, until the star comes to the graduated edge of the quadrant ; and when it does, the index will point out the hour of the night.

PROB. VII. *The latitude of the place, the day of the month, and altitude of any known star, being given ; to find the hour of the night.*—Rectify the globe as in the former problem, guess at the hour of the night, and turn the globe until the index points at the supposed hour : then lay the graduated edge of the quadrant of altitude over the known star ; and if the degree of the star's height in the quadrant upon the globe answers exactly to the degree of the star's observed altitude in the heaven, you have guessed exactly : but if the star on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the star, until its centre comes to the observed altitude in the quadrant ; and then the index will shew the true time of the night.

PROB. VIII. *An easy method for finding the hour of the night by any two known stars, without knowing either their altitude or azimuth ; and then, of finding both their altitude and azimuth, and thereby the true meridian.*—Tie one end of a thread to a common musket-bullet ; and, having rectified the globe as above, hold the other end of the thread in your hand, and carry it slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour-circle ;

which

PRINCIPLES
and
PRACTICE

which done, lay the graduated edge of the quadrant over any one of these two stars on the globe, which the thread cut in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then, the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitudes in the quadrant. At which moment, if a common azimuth-compass be so set upon a floor or level pavement, that these stars in the heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compass will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the fourth-most end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

PROB. IX. *To find the place of the moon, or of any planet; and thereby to shew the time of its rising, setting, and passing South in Danks's or Weaver's ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and, according to its longitude and latitude, as shewn by the ephemeris, mark the same with a chalk upon the globe. Then, having rectified the globe, turn it round its axis westward; and as the said mark comes to the eastern side of the horizon, to the brazen meridian, and to the western side of the horizon, the index will shew at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.*

For an explanation of the harvest-moons by a globe, see ASTRONOMY, n° 168.

For the description and use of a planetary globe, see ASTRONOMY, n° 320.

For the equation of time, see ASTRONOMY, n° 181.

43
Solution of
several problems by an
analemma.

Most of the above problems may also be performed by means of accurate maps; but this requires a great deal of calculation, which is often very troublesome. The Analemma, or Orthographic Projection, delineated on 2^d Plate CXVI. will solve many of the most curious; and with the assistance of the maps will be almost equivalent to a terrestrial globe. The parallel lines drawn on this figure represent the degrees of the sun's declination from the equator, whether north or south, amounting to 23½ nearly. On these lines are marked the months and days which correspond to such and such declinations. The size of the figure does not admit of having every day of the year inserted; but by making allowance for the intermediate days, in proportion to the rest, the declination may be guessed at with tolerable exactness. The elliptical lines are designed to shew the hours of sun-rising or sun-setting before or after six o'clock. As 60 minutes make an hour of time, a fourth part of the space between each of the hour-lines will represent 15 minutes; which the eye can readily guess at, and which is as great exactness as can be expected from any mechanical invention,

or as is necessary to answer any common purpose. The circles drawn round the centre at the distance of 11½ each, shew the point of the compass on which the sun rises and sets, and on what point the twilight begins and ends.

In order to make use of this analemma, it is only necessary to consider, that, when the latitude of the place and the sun's declination are both north or both south, the sun rises before six o'clock, between the east and the elevated pole; that is, towards the north, if the latitude and declination are north; or towards the south, if the latitude and declination are south. Let us now suppose it is required to find the time of the sun's rising and setting, the length of the days and nights, the time when the twilight begins and ends, and what point of the horizon the sun rises and sets on, for the Lizard point in England, Frankfort in Germany, or Abbeville in France, on the 30th of April. The latitude of these places by the maps will be found nearly 50° north. Place the moveable index so that its point may touch 50° on the quadrant of north latitude in the figure; then observe where its edge cuts the parallel line on which April 30th is wrote. From this reckon the hour-lines towards the centre, and you will find that the parallel-line is cut by the index nearly at the distance of one hour and 15 minutes. So the sun rises at one hour fifteen minutes before six, or 45 minutes after four in the morning, and sets 15 minutes after seven in the evening. The length of the day is 14 hours 30 minutes. Observe how far the intersection of the edge of the index with the parallel of April 30th is distant from any of the concentric circles; which you will find to be a little beyond that marked *two points of the compass*; and this shews, that on the 30th of April the sun rises two points and somewhat more from the east towards the north, or a little to the northward of E. N. E. and sets a little to the northward of W. N. W. To find the beginning and ending of twilight, take from the graduated arch of the circle 17½ degrees with a pair of compasses; move one foot of the compasses extended to this distance along the parallel for the 30th of April, till the other joint touches the edge of the index, which must fill point at 50. The place where the other foot rests on the parallel of April 30th, then denotes the number of hours before six at which the twilight begins. This is somewhat more than three hours and an half; which shews, that the twilight then begins soon after two in the morning, and likewise that it begins to appear near five points from the east towards the north. The uses of this analemma may be varied in a great number of ways; but the example just now given will be sufficient for the ingenious reader.—The small circles on the same plate, marked *Island, Promontory, &c.* are added in order to render the maps more intelligible, by shewing how the different subjects are commonly delineated on them.

HAVING thus explained the use of the globes, and general principles of geography, we must refer to the maps for the situation of each particular country, with regard to longitude, latitude, &c. and to the names of the countries as they occur in the order of the alphabet, for the most remarkable particulars concerning them.

Lat. E. from London

G E O M E T R Y

ORIGINALLY signified no more than the art of measuring the earth, or any distances or dimensions within it: but at present it denotes the science of magnitude in general; comprehending the doctrine and relations of whatever is susceptible of augmentation or diminution, considered in that light.

Hence to geometry may be referred the consideration not only of lines, surfaces, and solids; but also of time, velocity, number, weight, &c.

This science had its rise among the Egyptians, who were in a manner compelled to invent it, to remedy confusion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their possessions. Thus this invention, which at first consisted only in measuring the lands, that every person might have what belonged to him, was called *geometry*, or the art of measuring land; and it is probable that the draughts and schemes, which they were annually compelled to make, helped them to discover many excellent properties of these figures; which speculations continued to be gradually improved, and are so to this day.

From Egypt geometry passed into Greece; where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The Elements of Geometry, written by this last in 15 books, are a most convincing proof to what perfection this science was carried among the ancients. However, it must be acknowledged, that it fell short of modern geometry; the bounds of which, what by the invention of fluxions, and the discovery of the almost infinite orders of curves, are greatly enlarged.

We may distinguish the progress of geometry into three ages; the first of which was in its meridian glory at the time when Euclid's Elements appeared; the second, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this science, which has been carried to its utmost perfection by Sir Isaac Newton and Mr Leibnitz.

In treating this useful subject, we shall divide it into two parts; the first containing the general principles; and the second, the application of these principles to the mensuration of surfaces, solids, &c.

P A R T I.

GENERAL PRINCIPLES OF GEOMETRY.

Art. 1. A Point is that which is not made up of parts, or which is of itself indivisible.

2. A line is a length without breadth, as B—

3. The extremities of a line are points; as the extremities of the line AB, are the points A and B, fig. 1.

4. If the line AB be the nearest distance between its extremes A and B, then it is called a *strait line*, as AB; but if it be not the nearest distance, then it is called a *curve line*, as a b, fig. 1.

5. A surface is that which is considered as having only length and breadth, but no thickness, as fig. 2.

6. The terms or boundaries of a surface are lines.

7. A plain surface is that which lies equally between its extremes.

8. The inclination between two lines meeting one another, (provided they do not make one continued line), or the opening between them, is called an *angle*; thus the inclination of the line AB to the line CB (fig. 3.) meeting one another at B, or the opening between the two lines AB and CB, is called an *angle*.

9. When the lines forming the angle are right lines, then it is called a *right-lined angle*, as fig. 4.; if one of them be right and the other curved, it is called a *mixed angle*, as fig. 5.; if both of them be curved it is called a *curve-lined angle*, as fig. 6.

10. If a right line AB fall upon another DC, (fig. 7.) so as to incline neither to one side nor to the other; but make the angles ABD, ABC, on each side equal to one another; then the line AB is said to be *perpendicular* to the line DC, and the two angles are called *right-angles*.

11. An obtuse angle is that which is greater than a right one, as fig. 8.; and an acute angle, that which is less than a right one, as fig. 9.

12. If a right line DC be fastened at one of its ends C, and the other end D be carried quite round, then the space comprehended is called a *circle*; the curve-line described by the point D, is called the *periphery* or *circumference* of the circle; the fixed point C is called the *centre* of it; fig. 10.

13. The describing line CD is called the *radius*, viz. any line drawn from the centre to the circumference; whence all radii of the same or equal circles are equal.

14. Any line drawn through the centre, and terminated both ways by the circumference, is called a *diameter*, as BD is a diameter of the circle BADE. And the diameter divides the circle and circumference into two equal parts, and is double the radius.

15. The circumference of every circle is supposed to be divided into 360 equal parts, called *degrees*; and each degree is divided into 60 equal parts, called *minutes*; and each minute into 60 equal parts, called *seconds*; and these into *thirds*, *fourths*, &c. these parts being greater or less according as the radius is.

16. Any part of the circumference is called an *arc*, or *arc*; and is called an arc of as many degrees as it contains parts of the 360, into which the circumference was divided: thus if AD be the $\frac{1}{4}$ of the circumference, then the arc AD is an arc of 45 degrees.

17. A line drawn from one end of an arc to the other, is called a *chord*, and is the measure of the arc: (a) thus

thus the right line AB is the chord of the arc ADB, fig. 11.

18. Any part of a circle cut off by a chord, is called a *segment*; thus the space comprehended between the chord AB and circumference ADB (which is cut off by the chord AB) is called a *segment*. Whence it is plain,

1st, That all chords divide the circle into two segments.

2^{dly}, The less the chord is, the more unequal are the segments, and *e contra*.

3^{dly}, When the chord is greatest, *viz.* when it is a diameter, then the segments are equal, *viz.* each a semicircle.

19. Any part of a circle (less than a semicircle) contained between two radii and an arc, is called a *sector*; thus the space contained between the two radii, AC, BC, and the arc AB, is called the sector, fig. 12.

20. The right line of any arc, is a line drawn perpendicular from one end of the arc, to a diameter drawn through the other end of the same arc; thus (fig. 13.) AD is the right line of the arc AB, it being a line drawn from A, the one end of the arc AB, perpendicular to CB, a diameter passing through B, the other end of the arc AB.

Now the lines standing on the same diameter, still increase till they come to the centre, and then becoming the radius, it is plain that the radius EC is the greatest possible sine, and for that reason it is called the *whole sine*.

Since the whole line EC must be perpendicular to the diameter FB (by def. 20.), therefore producing the diameter EG, the two diameters FB, EG, must cross one another at right angles, and so the circumference of the circle must be divided by them into four parts, EB, BG, GF, and FE, and these four parts are equal to one another (by def. 10.), and so EB a quadrant, or fourth part of the circumference; therefore the radius EC is always the sine of the quadrant, or fourth part of the circle EB.

Sines are said to be of so many degrees, as the arc contains parts of the 360, into which the circumference is supposed to be divided; so the radius being the sine of a quadrant, or fourth part of the circumference, which contains 90 degrees (the fourth part of 360), therefore the radius must be the sine of 90 degrees.

21. The part of the radius comprehended between the extremity of the right sine and the lower end of the arc, *viz.* DB, is called the *versed sine* of the arc AB.

22. If to any point in the circumference, *viz.* B, there be drawn a diameter FCB, and from the point B, perpendicular to that diameter, there be drawn the line BH; that line is called a *tangent* to the circle in the point B; which tangent can touch the circle only in one point B, else if it touched it in more, it would go within it, and so not be a tangent but a chord, (by art. 17.)

23. The tangent of any arc AB, is a right line drawn perpendicular to a diameter through the one end of the arc B, and terminated by a line CAH, drawn from the centre through the other end A; thus BH is the tangent of the arc AB.

24. And the line which terminates the tangent, *viz.* CH, is called the *secant* of the arc AB.

25. What an arc wants of a quadrant is called the *complement* of that arc; thus AE, being what the arc AB wants of the quadrant EB, is called the complement of the arc AB.

26. And what an arc wants of a semicircle is called the *supplement* of that arc; thus since AF is what the arc AB wants of the semicircle BAF, it is the supplement of the arc AB.

27. The sine, tangent, &c. of the complement of any arc, is called the *co-sine*, *co-tangent*, &c. of that arc; thus the sine, tangent, &c. of the arc AE is called the *co-sine*, *co-tangent*, &c. of the arc AB.

28. The sine of the supplement of an arc is the same with the sine of the arc itself; for, drawing them according to the definitions, there results the self-same line.

29. A right-lined angle is measured by an arc of a circle described upon the angular point as a centre, comprehended between the two legs that form the angle; thus (fig. 14.) the angle ABD is measured by the arc AD of the circle CADE that is described upon the point B as a centre; and the angle is said to be of as many degrees as the arc is; so if the arc AD be 45 degrees, then the angle ABD is said to be an angle of 45 degrees.

Hence the angles are greater or less, according as the arc described about the angular point and terminated by the two legs contain a greater or a less number of degrees.

30. When one line falls perpendicularly on another, as AB on CD, fig. 15, then the angles are right (by the 10th def.); and describing a circle on the centre B, since the angles ABC ABD are equal, their measures must be so too, *i. e.* the arcs AC AD must be equal; but the whole CAD is a semicircle, since CD, a line passing through the centre B, is a diameter; therefore each of the parts AC AD is a quadrant, *i. e.* 90 degrees; so the measure of a right angle is always 90 degrees.

31. If one line AB fall any way upon another, CD, then the sum of the two angles ABC ABD is always equal to the sum of two right angles; fig. 16. For on the point B, describing the circle CAD, it is plain, that CAD is a semicircle (by the 14th); but CAD is equal to CA and AD the measure of the two angles; therefore the sum of the two angles is equal to a semicircle, that is, to two right angles, (by the last).

Cor. 1. From whence it is plain, that all the angles which can be made from a point in any line, towards one side of the line, are equal to two right angles.

2. And that all the angles which can be made about a point, are equal to four right ones.

32. If one line AC cross another BD in the point E, then the opposite angles are equal, *viz.* BEA to CED, and BEC equal to AED; fig. 17. For upon the point E, as a centre, describing the circle ABCD, it is plain ABC is a semicircle, as also BCD (by the 14th); therefore the arc ABC is equal to the arc BCE; and from both taking the common arc BC, there will remain AB equal to CD, *i. e.* the angle BEA equal to the angle CED (by art. 29.) After the same manner

manner we may prove, that the angle BEC is equal to the angle AED.

33. Lines which are equally distant from one another, are called *parallel lines*; as AB, CD, fig. 18.

34. If a line GH cross two parallels AB, CD, (fig. 19.) then the external opposite angles are equal, *viz.* GEB equal to CFH, and AEG equal to HFD. For since AB and CD are parallel to one another, they may be considered as one broad line, and GH crossing it; then the vertical or opposite angles GEB CFH are equal (by art. 32.), as also AEG and HFD by the same.

35. If a line GH cross two parallels AB CD, then the alternate angles, *viz.* AEF and EFD, or CFE and FEB, are equal; that is, the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the same); but GEB is equal to CFH (by the last); therefore AEF is equal to EFD. The same way we may prove FEB equal to EFC.

36. If a line GH cross two parallel lines AB, CD, then the external angle GEB is equal to the internal opposite one EFD, or GEA equal to CFE. For the angle AEF is equal to the angle EFD (by the last); but AEF is equal to GEB (by art. 32.), therefore GEB is equal to EFD. The same way we may prove AEG equal to CFE.

37. If a line GH cross two parallel lines AB, CD, then the sum of the two internal angles, *viz.* BEF and DFE, or AEF and CFE, are equal to two right angles; for since the angle GEB is equal to the angle EFD (by art. 36.), to both add the angle FEB, then GEB and BEF are equal to BEF and DFE; but GEB and BEF are equal to two right angles (by art. 31.), therefore BEF and DFE are also equal to two right angles. The same way we may prove that AEF and CFE are equal to two right angles.

38. A figure is any part of space bounded by lines or a line. If the bounding lines be straight, it is called a *rectilinear figure*, as fig. 20. if they be curved, it is called a *curvilinear figure*, as fig. 21. and fig. 22.; if they be partly curve lines and partly straight, it is called a *mixt figure*, as fig. 23.

39. The most simple rectilinear figure is that which is bounded by three right lines, and is called a *triangle*, as fig. 24.

40. Triangles are divided into different kinds, both with respect to their sides and angles: with respect to their sides they are commonly divided into three kinds, *viz.*

41. A triangle having all its three sides equal to one another, is called an *equilateral triangle*, as fig. 25.

42. A triangle having two of its sides equal one another, and the third side not equal to either of them, is called an *Isosceles triangle*, as fig. 26.

43. A triangle having none of its sides equal to one another, is called a *scalene triangle*, as fig. 27.

44. Triangles, with respect to their angles, are divided in three different kinds, *viz.*

45. A triangle having one of its angles right, is called a *right-angled triangle*, as fig. 28.

46. A triangle having one of its angles obtuse, or greater than a right angle, is called an *obtuse-angled triangle*, as fig. 29.

47. Lastly, a triangle having all its angles acute, is called an *acute-angled triangle*, as fig. 30.

48. In all right-angled triangles, the sides comprehending the right angle are called the *legs*, and the side opposite to the right angle is called the *hypotenuse*. Thus in the right-angled triangle ABC, fig. 31. (the right angle being at B) the two sides AB and BC, which comprehend the right angle ABC, are the legs of the triangle; and the side AC, which is opposite to the right angle ABC, is the hypotenuse of the right-angled triangle ABC.

49. Both obtuse and acute angled triangles are in general called *oblique-angled triangles*; in all which any side is called the *base*, and the other two the *sides*.

50. The perpendicular height of any triangle is a line drawn from the vertex to the base perpendicularly; thus if the triangle ABC (fig. 32.) be proposed, and BC be made its base, then A will be the vertex, *viz.* the angle opposite to the base; and if from A you draw the line AD perpendicular to BC, then the line AD is the height of the triangle ABC standing on BC as its base.

Hence all triangles standing between the same parallels have the same height, since all the perpendiculars are equal by the nature of parallels.

51. A figure bounded by four sides is called a *quadrilateral* or *quadrangular figure*, as ABDC, fig. 33.

52. Quadrilateral figures whose opposite sides are parallel, are called *parallelograms*. Thus in the quadrilateral figure ABDC, if the side AC be parallel to the side BD which is opposite to it, and AB be parallel to CD, then the figure ABDC is called a parallelogram.

53. A parallelogram having all its sides equal and angles right, is called a *square*, as fig. 34.

54. That which hath only the opposite sides equal and its angles right, is called a *rectangle*, as fig. 35.

55. That which hath equal sides but oblique angles, is called a *rhombus*, as fig. 36. and is just an inclined square.

56. That which hath only the opposite sides equal and the angles oblique, is called a *rhomboides*, as fig. 37. and may be conceived as an inclined rectangle.

57. When none of the sides are parallel to another, then the quadrilateral figure is called a *trapezium*.

58. Every other right lined figure, that has more sides than four, is in general called a *polygon*. And figures are called by particular names according to the number of their sides, *viz.* one of five sides is called a *pentagon*, of six a *hexagon*, of seven a *heptagon*, and so on. When the sides forming the polygon are equal to one another, the figure is called a regular figure or polygon.

59. In any triangle ABC (fig. 38.) one of its legs, as BC, being produced towards D, the external angle ACD is equal to both the internal opposite ones taken together, *viz.* to ABC and BAC. In order to prove this, through C, draw CE parallel to AB; then since CE is parallel to AB, and the lines AC and BD crosseth them, the angle ECD is equal to ABC (by art. 36.) and the angle ACE equal to CAB (by art. 35.); therefore the angles ECD and ECA are equal to the angles ABC and CAB; but the angles ECD and ECA are together

gether equal to the angle ACD ; therefore the angle ACD is equal to both the angles ABC and CAB taken together.

Cor. Hence it may be proved, that if two lines AB and CD (fig. 39.) be crossed by a third line EF , and the alternate angles AEF and EFD be equal, the lines AB and CD will be parallel; for if they are not parallel, they must meet one another on one side of the line EF (suppose at G) and fo form the triangle EFG , one of whose sides GE being produced to A , the exterior angle AEF must (by this article) be equal to the sum of the two angles EFG and EGF ; but, by supposition, it is equal to the angles EFG alone; therefore the angle AEF must be equal to the sum of the two angles EFG and EGF , and at the same time equal to the angle EFG alone, which is absurd; fo the lines AB and CD cannot meet, and therefore must be parallel.

60. *In any triangle ABC, all the three angles taken together are equal to two right angles.* To prove this, you must produce BC , one of its legs, to any distance, suppose to D ; then by the last proposition, the external angle, ACD , is equal to the sum of the two internal opposite ones CAB and ABC ; to both add the angle ACB , then the sum of the angles ACD and ACB will be equal to the sum of the angles CAB and CBA and ACB . But the sum of the angles ACD and ACB , is equal to two right ones (by art. 32.), therefore the sum of the three angles CAB and CBA and ACB , is equal to two right angles; that is, the sum of the three angles of any triangle ACB is equal to two right angles.

Cor. 1. Hence in any triangle given, if one of its angles be known, the sum of the other two is also known: for since (by the last) the sum of all the three is equal to two right angles, or a semicircle, it is plain, that taking any one of them from a semicircle or 180 degrees, the remainder will be the sum of the other two. Thus (in the former triangle ABC) if the angle ABC be 40 degrees, by taking 40 from 180 we have 140 degrees; which is the sum of the two angles BAC , ACB : the converse of this is also plain, viz. the sum of any two angles of a triangle being given, the other angle is also known by taking that sum from 180 degrees.

2. In any right-angled triangle, the two acute angles must just make up a right one between them; consequently, any one of the oblique angles being given, we may find the other by subtracting the given one from 90 degrees, which is the sum of both.

61. If in any two triangles, ABC (fig. 40.) DEF (fig. 41.) two legs of the one, viz. AB and AC , be equal to two legs of the other, viz. to DE and DF , each to each respectively, i. e. AB to DE and AC to DF ; and if the angles included between the equal legs be equal, viz. the angle BAC equal to the angle EDF ; then the remaining leg of the one shall be equal to the remaining leg of the other, viz. BC to EF ; and the angles opposite to equal legs shall be equal, viz. ABC equal to DEF (being opposite to the equal legs AC and DF), also ACB equal to DFE (which are opposite to the equal legs AB and DE). For if the triangle ABC be supposed to be lifted up and put upon the triangle DEF , and the point A on the point D ; it is plain, since BA and DE are of equal

length, the point E will fall upon the point B ; and since the angles BAC EDF are equal, the line AC will fall upon the line DF ; and they being of equal length, the point C will fall upon the point F ; and so the line BC will exactly agree with the line EF , and the triangle ABC will in all respects be exactly equal to the triangle DEF ; and the angle ABC will be equal to the angle DEF , also the angle ACB will be equal to the angle DFE .

Cor. 1. After the same manner it may be proved, that if in any two triangles ABC , DEF , (see the preceding figure) two angles ABC and ACB of the one, be equal to two angles DEF and DFE of the other, each to each respectively, viz. the angle ABC to the angle DEF , and the angle ACB equal to the angle DFE , and the sides included between these angles be also equal, viz. BC equal to EF , then the remaining angles and the sides opposite to the equal angles, will also be equal each to each respectively; viz. the angle BAC equal to the angle EDF , the side AB equal to DE , and AC equal to DF : for if the triangle ABC be supposed to be lifted up and laid upon the triangle DEF , the point B being put upon the point E , and the line BC upon the line EF , since BC and EF are of equal lengths, the point C will fall upon the point F , and since the angle ACB is equal to the angle DFE , the line CA will fall upon the line FD , and by the same way of reasoning the line BA will fall upon the line ED ; and therefore the point of intersection of the two lines BA and CA , viz. A , will fall upon the point of intersection of the two lines ED and FD , viz. D , and consequently BA will be equal to ED , and AC equal to DF , and the angle BAC equal to the angle EDF .

Cor. 2. It follows likewise from this article, that if any triangle ABC (fig. 42.) has two of its sides AB and AC equal to one another, the angles opposite to these sides will also be equal, viz. the angles ABC equal to the angle ACB . For suppose the line AD , bisecting the angle BAC , or dividing it into two equal angles BAD and CAD , and meeting BC in D , then the line AD will divide the whole triangle BAC into two triangles ABD and DAC ; in which BA and AD two sides of the one, are equal to CA and AD two sides of the other. each to each respectively, and the included angles BAD and DAC are by supposition equal; therefore (by this article) the angle ABC must be equal to the angle ACB .

62. *Any angle, as BAD (fig. 43.) at the circumference of a circle $BAD E$, is but half the angle BCD at the centre standing on the same arch $B E D$.* To demonstrate this, draw through A and the centre C , the right line ACE , then the angle ECD is equal to both the angles DAC and ADC (by art. 59.); but since AC and CD are equal (being two radii of the same circle) the angles subtended by them must be equal also, (by art. 62. cor. 2.) i. e. the angle CAD equal to the angle CDA ; therefore the sum of them is double any one of them, i. e. DAC and ADC is double of CAD , and therefore ECD is also double of DAC : the same way it may be proved, that ECB is double of CAB ; and therefore the angle BCD is double of the angle BAD , or BAD the half of BCD , which was to be proved.

Cor. 1. Hence an angle at the circumference is measured by half the arc it subtends; for the angle at the centre (standing on the same arc) is measured by the whole arc (by art. 29.); but since the angle at the centre is double that at the circumference, it is plain the angle at the circumference must be measured by only half the arc it stands upon.

Cor. 2. Hence all angles, $\angle ACB$, $\angle ADB$, $\angle AEB$, &c. (fig. 44.) at the circumference of a circle, standing on the same chord AB , are equal to one another; for by the last corollary they are all measured by the same arc, viz. half the AB which each of them subtends.

Cor. 3. Hence an angle in a segment greater than a semicircle is less than a right angle; thus, if $\angle ADB$ be a segment greater than a semicircle, (see the last figure) than the arc AB , on which it stands, must be less than a semicircle, and the half of it less than a quadrant or a right angle; but the angle $\angle ADB$ in the segment is measured by the half of AB , therefore it is less than a right angle.

Cor. 4. An angle in a semicircle is a right angle. For since $\angle ABD$ (fig. 46.) is a semicircle, the arc AED must also be a semicircle: but the angle $\angle ABD$ is measured by half the arc AED , that is, by half a semicircle or quadrant; therefore the angle $\angle ABD$ is a right one.

Cor. 5. Hence an angle in a segment less than a semicircle, as $\angle ABD$, (fig. 45.) is greater than a right angle: for since the arc ABD is less than a semicircle, the arc AED must be greater than a semicircle, and so it is half greater than a quadrant, i. e. than the measure of a right angle; therefore the angle $\angle ABD$, which is measured by half the arc AED , is greater than a right angle.

62. If from the centre C of the circle ABE , (fig. 47.) there be let fall the perpendicular CD on the chord AB , then that perpendicular will bisect the chord AB in the point D . To demonstrate this, draw from the centre to the extremities of the chord the two lines CA , CB ; then since the lines CA and CB are equal, the angles $\angle CAB$, $\angle CBA$, which they subtend must be equal also, (by art. 62. cor. 2.) but the perpendicular CD divides the triangle ACB into two right-angled triangles ACD and CDB , in which the sum of the angles $\angle ACD$ and $\angle CAD$ in the one, is equal to the sum of the angles $\angle DCB$ and $\angle CBD$ in the other, each being equal to a right angle, (by cor. 2. of art. 61.) but $\angle CAD$ is equal to $\angle CBD$, therefore $\angle ACD$ is equal to $\angle DCB$. So in the two triangles ACD and CBD , the two legs AC and CD in the one, are equal to the two legs BC and CD in the other, each to each respectively, and the included angles $\angle ACD$ and $\angle DCB$ are equal; therefore the remaining legs AD and BD are equal (by art. 61.) and consequently AB bisected in D .

64. If from the centre C of a circle ABE , there be drawn a perpendicular CD on the chord AB , and produced till it meet the circle in F , then the line CF bisects the arch AB in the point F ; for (see the foregoing figure) joining the points A and F , F and B by the straight lines AF , FB , then in the triangles ADF , BDF , AD is equal to BD (by art. 62.) and DF common to both; therefore AD and DF , two legs of the triangle ADF , are equal to BD and DF , two legs of the triangle BDF , and the included angles $\angle ADF$ $\angle BDF$

are equal, being both right; therefore (by art. 61.) the remaining legs AF and FB are equal; but in the same circle equal lines are chords of equal arches, therefore the arches AF and FB are equal. So the whole arch ABF is bisected in the point F by the line CF .

Cor. 1. From art. 63. it follows, that any line bisecting a chord at right angles is a diameter; for since (by art. 63.) a line drawn from the centre perpendicular to a chord, bisects that chord at right angles; therefore, conversely, a line bisecting a chord at right angles, must pass through the centre, and consequently be a diameter.

Cor. 2. From the two last articles it follows, that the sine of any arc is the half of the chord of twice the arc; for (see the foregoing scheme) AD is the sine of the arc AF , by the definition of a sine, and AF is half the arc ABF , and AD half the chord AB (by art. 63.); therefore the corollary is plain.

65. In any triangle, the half of each side is the sine of the opposite angle; for if a circle be supposed to be drawn through the three angular points A , B , and D of the triangle ABD , fig. 48. then the angle $\angle DAB$ is measured by half the arch BKD (by cor. 1. of art. 62.) but the half of BD , viz. BE , is the sine of half the arch BKD , viz. the sine of BK (by cor. 2. of the last) which is the measure of the angle $\angle BAD$; therefore the half of BD is the sine of the angle $\angle BAD$; the same way it may be proved, that the half of AD is the sine of the angle $\angle ABD$, and the half of AB is the sine of the angle $\angle ADB$.

66. The sine, tangent, &c. of any arch is called also the *sine*, *tangent*, &c. of the angle whose measure the arc is: thus because the arc GD (fig. 49.) is the measures of the angle $\angle GCD$; and since GH is the sine, DE the tangent, HD the versed sine, CE the secant, also GK the co-sine, BF the co-tangent, and CF the co-secant, &c. of the arch GD ; then GH is called the *sine*, DE the *tangent*, &c. of the angle $\angle GCD$, whose measure is the arch GD .

67. If two equal and parallel lines, AB and CD (fig. 50.) be joined by two others, AC and BD ; then these shall also be equal and parallel. To demonstrate this, join the two opposite angles A and D with the line AD ; then it is plain this line AD divides the quadrilateral, $ACDB$, into two triangles, viz. ABD , ACD , in which AB a leg of the one, is equal to DC a leg of the other, by supposition, and AD is common to both triangles; and since AB is parallel to CD , the angle $\angle BAD$ will be equal to the angle $\angle ADC$, (by art. 36.) therefore in the two triangles BA and AD , and the angle $\angle BAD$, is equal to $\angle ADC$ and DA , and the angle $\angle ADC$; that is, two legs and the included angle in the one, is equal to two legs and the included angle in the other; therefore (by art. 61.) BD is equal to AC , and since the angle $\angle DAC$ is equal to the angle $\angle ADB$, therefore the lines BD , AC are parallel (by cor. art. 59.)

Cor. 1. Hence it is plain, that the quadrilateral $ABDC$ is a parallelogram, since the opposite sides are parallel.

Cor. 2. In any parallelogram the line joining the opposite angles (called the *diagonal*) as AD , divides the figure into two equal parts, since it has been proved

ved that the triangles ABD ACD are equal to one another.

Cor. 3. It follows also, that a triangle ACD on the same base CD, and between the same parallels with a parallelogram ABDC, is the half of that parallelogram.

Cor. 4. Hence it is plain, that the opposite sides of a parallelogram are equal; for it has been proved, that ABDC being a parallelogram, AB will be equal to CD, and AC equal to BD.

68. All parallelograms on the same or equal bases, and between the same parallels, are equal to one another; that is, if BD and GH (fig. 51.) be equal, and the lines BH and AF be parallel, then the parallelograms ABDC, BDFE, and EFHG, are equal to one another. For AC is equal to EF, each being equal to BD, (by *cor. 4. of 67.*) To both add CE, then AE will be equal to CF. So in the two triangles ABE CDF, AB a leg of the one, is equal to CD a leg in the other; and AE is equal to CF, and the angle BAE is equal to the angle DCF (by art. 36.); therefore the two triangles ABE CDF are equal (by art. 61.); and taking the triangle CDE from both, the figure ABKC will be equal to the figure KDEF; to both which add the little triangle KBD, then the parallelogram ABDC will be equal to the parallelogram BDFE. The same way it may be proved, that the parallelogram EFHG is equal to the parallelogram EFDB; so the three parallelograms ABDC, BDFE, and EFHG will be equal to one another.

Cor. Hence it is plain, that triangles on the same base, and between the same parallels, are equal; since they are the half of the parallelograms on the same base and between the same parallels, (by *cor. 3. of last art.*)

69. In any right-angled triangle, ABC, (fig. 52.) the square of the hypotenuse BC, viz. BCMH, is equal to the sum of the squares made on the two sides AB and AC, viz. to ABDE and ACGF. To demonstrate this, through the point A draw AKL perpendicular to the hypotenuse BC, join AH, AM, CD, and BG; then it is plain that DB is equal to BA (by art. 53.); also BH is equal to BC (by the same); so in the two triangles DBC ABH, the two legs DB and BC in the one are equal to the two legs AB and BH in the other; and the included angles DBC and ABH are also equal; (for DBA is equal to CBH, being both right; to each add ABC, then it is plain that DBC is equal to ABH) therefore the triangles DBC ABH are equal (by art. 61.) but the triangle DBC is half of the square ABDE (by *cor. 3. of 67.*) and the triangle ABH is half the parallelogram BKLH (by the same), therefore half the square ABDE is equal to half the parallelogram BKLH. Consequently the square ABDE is equal to the parallelogram BKLH. The same way it may be proved, that the square ACGF is equal to the parallelogram CKML. So the sum of the squares ABDE and ACGF is equal to the sum of the parallelograms BKLH and CKML, but the sum of these parallelograms is equal to the square BCMH; therefore the sum of the squares on AB and AC is equal to the square on BC.

Cor. 1. Hence in a right-angled triangle, the hypotenuse and one of the legs being given, we may ea-

ily find the other, by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder will be the leg required.

Cor. 2. Hence, the legs in a right-angled triangle being given, we may find the hypotenuse, by taking the sum of the squares of the given legs, and extracting the square root of that sum.

70. If upon the line AB (fig. 53.) there be drawn a semicircle ADB, whose centre is C, and on the point C there be raised a perpendicular to the line AB, viz. CD; then it is plain the arc DB is a quadrant, or contains 90 degrees; suppose the arc DB to be divided into 9 equal arcs, each of which will contain 10 degrees, then on the point B raising BE perpendicular to the line AB, it will be a tangent to the circle in the point B, and if to every one of the divisions of the quadrant, viz. B 10, B 20, B 30, B 40, &c. you draw the sine, tangent, &c. (as in the scheme) we shall have the sine, tangent, &c. to every 10 degrees in the quadrant; and the same way we may have the sine, tangent, &c. to every single degree in the quadrant, by dividing it into 90 equal parts beginning from B, and drawing the sine, tangent, &c. to all the arcs beginning at the same point B. By this method they draw the lines of sines, tangents, &c. of a certain circle on the scale; for after drawing them on the circle, they take the length of them, and set them off in the lines drawn for that purpose. The same way, by supposing the radius of any number of equal parts, (suppose 1000, or 10,000, &c.) it is plain the sine, tangent, &c. of every arc must consist of some number of these equal parts, and by computing them in parts of the radius, we have tables of sines, tangents, &c. to every arc in the quadrant, called *natural sines, tangents, &c.* and the logarithms of these give us tables of logarithmic sines, tangents, &c. See LOGARITHMS.

71. In any triangle, ABC, (fig. 1.) if one of its sides, as AC, be bisected in E, (and consequently AC double of AE) and through E be drawn ED, parallel to BC, and meeting AB in D, then BC will be double of ED, and AB double of AD. Through D draw DF, parallel to AC, meeting BC in F: for since, by construction, DF is parallel to AC, and DE parallel to BC; therefore, (by art. 36.) the angle BFD will be equal to the angle BCA, (and by the same article) the angle BCA will be equal to the angle DEA, consequently the angle BFD will be equal to the angle DEA; also, (by art. 36.) the angle BDF will be equal to the angle DAE; and since DF is parallel to EC, and DE parallel to FC, the quadrilateral DFCE will be a parallelogram; and therefore, (by art. 59. *cor. 4.*) DF will be equal to EC, which, by construction, is equal to AE; so in the two triangles BDF DAE, the two angles BFD and BDF in the one, are equal to the two angles DEA and DAE in the other, each to each respectively; and the included side DF, is equal to the included side AE; therefore, (by art. 61. *cor. 1.*) AD will be equal to DB, and consequently AB double of AD; also (by the same) DE will be equal to BF; but DE is also (by art. 67. *cor. 4.*) equal to FC; therefore BF and ED together, or BC, will be double of DE.

After the same manner it may be proved, that if in the triangle AKG, (fig. 2.) AE be taken equal to a third

Geometry
Plates,
n^o II.

third part of AK, and through E be drawn ED, parallel to KG, and meeting AG in D; then ED will be equal to a third part of GK, and AD equal to a third part of AG.

Likewise if in any triangle ABC, (fig. 3.) upon the side AB, be taken AE, equal to one-fourth, one-fifth, one-sixth, &c. of AB, and through E be drawn ED parallel to BC and meeting AC in D; then DE will be one-fourth, one-fifth, one-sixth, &c. of BC, and AD the like part of AC; and, in general, if in any triangle ABC, there be assumed a point E on one of its sides AB, and through that point be drawn a line ED, parallel to one of its sides BC, and meeting the other side AC in D; then whatever part AE is of AB, the same part will ED be of BC, and AD of AC.

Cor. Hence it follows, that if in any triangle ABC, there be drawn ED, parallel to one of its sides BC, and meeting the other two in the points E and D, then $AE : AB :: ED : BC :: AD : AC$; that is, AE is to AB, as ED is to BC, and that as AD to AC.

72. If any two triangles ABC, fig. 4. a b c, fig. 5. are similar, or have all the angles of the one equal to all the angles of the other, each to each respectively; that is, the angle CAB equal to the angle c a b, and the angle ABC equal to the angle a b c, and the angle ACB equal to the angle a c b; then the legs opposite to the equal angles are proportioned, *viz.* $AB : ab :: AC : ac :: BC : bc$; and $AB : ab :: BC : bc :: AC : ac :: BC : bc$. On AB of the largest triangle set off AE equal to a b, and through E draw ED parallel to BC, meeting AC in D; then since DE and BC are parallel, and AB crossing them, the angle AED will (by art. 36.) be equal to the angle ABC, which (by supposition) is equal to the angle a b c, also the angle DAE is (by supposition) equal to the angle c a b; so in the two triangles AED, a b c, the two angles DAE AED of the one, are equal to two angles c a b a b c of the other, each to each respectively, and the included side AE is (by construction) equal to the included side ab; therefore, (by art. 61. cor. 1.) AD is equal to a c, and DE equal to c b; but since, in the triangle ABC, there is drawn DE parallel to BC one of its sides, and meeting the two other sides in the points D and E, therefore (by cor. art. 71.) $AB : AE :: AC : AD$, and $AB : AE :: BC : DE$, and $AC : AD :: BC : DE$; and in the three last proportions, instead of the lines AE, DE, and AD, putting in their equals a b, b c, and a c, we shall have $AB : ab :: AC : ac$, and $AB : ab :: BC : bc$, and lastly, $AC : ac :: BC : bc$.

73. The chord, sine, tangent, &c. of any arc in one circle, is to the chord, sine, tangent, &c. of the same arc in another, as the radius of the one is to the radius of the other, fig. 6, 6. Let ABD a b d be two circles, BD b d two arcs of these circles, equal to one another, or consisting of the same number of degrees; FD f d the tangents, BD b d the chords, BE b e the sines, &c. of these two arcs BD b d, and CD c d the radii of the circles; then say, $CD : c d :: FD : f d$, and $CD : c d :: BD : b d$, and $CD : c d :: BE : b e$, &c. For since the arcs BD b d are equal, the angles BCD b c d will be equal; and FD f d, being tangents to the points D and d, the angles CDF c d f will be equal, being each a right angle (art. 22.) so in the two triangles CDF c d f, the two angles FCD CDF of

the one, being equal to the two angles f c d c d f of the other, each to each, the remaining angle CFD, will be equal to the remaining angle c f d (by art. 60.); therefore the triangles CFD c f d are similar, and consequently (by art. 73.) $CD : c d :: FD : f d$. In the same manner it may be demonstrated, that $CD : c d :: BD : b d$, and $CD : c d :: BE : b e$, &c.

74. Let ABD (fig. 7.) be a quadrant of a circle described by the radius CD; BD any arc of it, and BA its complement; BG or CF the sine, CG or BF the co-sine; DE the tangent, and CE the secant of that arc BD. Then since the triangles CDE CGB are similar or equiangular, it will be (by art. 72.) $DE : EC :: GB : BC$, *i. e.* the tangent of any arc, is to the secant of the same, as the sine of it is to the radius. Also since $DE : EC :: GB : BC$; therefore, by inverting that proportion, we have $EC : DE :: BC : GB$, *i. e.* the secant is to the tangent, as the radius is to the sine of any arc.

Again, since the triangles CDE CGB are similar, therefore (by art. 72.) it will be $CD : CE :: CG : CB$, *i. e.* as the radius is to the secant of any arc, so is the co-sine of that arc to the radius. And by inverting the proportion we have this, *viz.* as the secant of any arc is to the radius, so is the radius to the co-sine of that arc.

75. In all circles the chord of 60 is always equal in length to the radius. Thus in the circle AEBD, (fig. 8.) if the arc AEB be an arc of 60 degrees, then drawing the chord AB, I say AB shall be equal to the radius CB or AC; for in the triangle ACB, the angle ACB is 60 degrees, being measured by the arc AEB; therefore the sum of the other two angles is 120 degrees, (by cor. 1. of 60.) but since AC and CB are equal, the two angles CAB, CBA will also be equal; consequently each of them half their sum 120, *viz.* 60 degrees; therefore all the three angles are equal to one another, consequently all the legs, therefore AB is equal to CB.

Cor. Hence the radius from which the lines on any scale are formed, is the chord of 60 on the line of chords.

Geometrical Problems.

PROB. I. From a point C (fig. 9.) in a given line AB to raise a perpendicular to that line.

Rule. From the point C take the equal distances CB, CA on each side of it. Then stretch the compasses to any distance greater than CB or CA, and with one foot of them in B, sweep the arc EF with the other; again, with the same opening, and one foot in A, sweep the arc GH with the other, and these two arcs will intersect one another in the point D; then join the given points C and D with the line CD, and that shall be the perpendicular required.

2. To divide a given right line AB (fig. 10.) into two equal parts; that is, to bisect it.

Rule. Take any distance with your compasses that you are sure is greater than half the given line; then setting one foot of them in B, with the other sweep the arc DFC; and with the same distance, and one foot in A, with the other sweep the arc CED; these two arcs will intersect one another in the points D, which joined by the right line DC will bisect AB in G.

3. From

3. From a given point D, (fig. 11.) to let fall a perpendicular on a given line AB.

Rule. Set one foot of the compasses in the point D, and extend the other to any distance greater than the least distance between the given point and the line, and with that extent sweep the arc AEB, cutting the line in the two points A and B, then (by the last prob.) bisect the line AB in the point C; lastly join C and D, and that line CD is the perpendicular required.

4. (Fig. 12.) Upon the end B of a given right line BA, to raise a perpendicular.

Rule. Take any extent in your compasses, and with one foot in B fix the other in any point C without the given line; then with one point of the compasses in C, describe with the other the circle EBD, and thro' E and C draw the diameter ECD meeting the circle in D; join D and B, and the right line DB is that required; for EBD is a right angle (by cor. 4. of 63.)

5. (Fig. 13.) To draw one line parallel to another given line AB, that shall be distant from one another by any given distance D.

Rule. Extend your compasses to the given distance D; then setting one foot of them in any point of the given line (suppose A,) with the other sweep the arc FCG; again, at the same extent, and one foot in any other point of the given line B, sweep the arc HDK, and draw the line CD touching them, and that will be parallel to the given line AB, and distant from it by the line D as was required.

6. (Fig. 14.) To divide a given line AB into any number of equal parts, suppose 7.

Rule. From the point A draw any line AD, making an angle with the line AB, then through the point B, draw a line BC parallel to AD; and from A, with any small opening of the compasses, set off a number of equal parts (on the line AD,) less by one than the proposed number (here 6.); then from B set off the same number of the same parts (on the line BC); lastly, join 6 and 1, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1, and these lines will cut the given line as required.

7. (Fig. 15.) To quarter a given circle, or to divide it into four equal parts.

Rule. Through the centre C of the given circle, draw a diameter AB, then upon the point C raise a perpendicular DCE to the line AB; and these two diameters AB and DE shall quarter the circle.

8. (Fig. 16.) Through three given points A, B, and D, to draw a circle. *Note.* The three points must not lie in the same straight line.)

Rule. Join A and B, also B and D, with the freight lines AB BD; then (by prob. 2.) bisect AB with the line EC, also BD with the line FC, which two lines will cut one another in some point C; that is the centre of the circle required: then fixing one point of your compasses in D, and stretching the other to A, describe the circle ABDC, which will pass through the three points given. The reason of this is plain from cor. 1. of art. 64.

9. (Fig. 17.) From the point A of the given line AB, to draw another line (suppose AC) that shall make with AB an angle of any number of degrees, suppose 45.

Rule. Let the given line AB be produced, then take off your scale the length of the chord of 60 degrees, which is equal to the radius of the circle the scale was made for (by art. 75.); and setting one foot in A, with the other sweep off the arc BC; then with your compasses take from your scale the chord of 45 degrees, and set off that distance from B to C. Lastly, join A and C, and the line AC is that required. For the angle CAB, which is measured by the arc BC, is an angle of 45 degrees, as was required.

10. An angle BAC (fig. 18.) being given, to find how many degrees it contains.

Rule. With your compasses take the length of your chord of 60 from your scale. Then, setting one foot of them in A, with the other sweep the arc BC, which is the arc comprehended between the two legs AB, AC produced if needful. Lastly, take with your compasses the distance BC, and applying it to your line of chords on the scale, you will find how many degrees the arc BC contains, and consequently the degrees of the angle BAC which was required.

11. Three lines x , y , and z being given, (fig. 19.) to form a triangle of them; but any two of these lines taken together must always be greater than the third.

Rule. Make any one of them, as x , the base; then with your compasses take another of them, as z , and setting one foot in one end of the line x , as B, with the other sweep the arc DE; and taking with your compasses the length of the other y , set one foot of them in A, the other end of the line x , and with the other sweep the arc FG, which will cut the other in C; lastly, join CA and CB, and the triangle CAB is that required.

12. To make a triangle, having one of its legs of any number of equal parts (suppose 160,) and one of the angles at that leg 50 degrees, and the other 44 degrees.

Rule. Draw an indefinite line ED, (fig. 20.) then take off the line of equal parts with your compasses, 160 of them, and set them on the indefinite line, as BC; then (by prob. 9.) draw BA, making the angle ABC of 50 degrees, and (by the same) draw from C the line AC, making the angle ACB of 44 degrees; which two lines will meet one another in A, and the triangle ABC is that required. See TRIGONOMETRY.

13. Upon a given line AB (fig. 21.) to make a square.

Rule. Upon the extremity A of the given line AB, raise a perpendicular AC (by prob. 4.); then take AC equal to AB, and with that extent, setting one foot of the compasses in C, sweep with the other foot the arc GH; then with the same extent, and one foot in B, with the other sweep the arc EF, which will meet the former in some point D; lastly, join C and D, D and B, and the figure ABDC will be the square required.

14. On a given line AB (fig. 22.) to draw a rhomb that shall have one of its angles equal to any number of degrees, suppose 60 degrees.

Rule. From the point A of the given line AB, draw the line AC, making the angle CAB of 60 degrees, (by prob. 9.) then take AC equal to AB, and with that extent, fixing one foot of the compasses in B,

B, with the other describe the arc GH; and at the same extent, fixing one foot of the compasses in C, with the other describe the arc EF cutting the former in D; lastly, join CD and DB, and the figure ACDB is that required.

15. Given two lines x and z , of these two to make a rectangle.

Rule. Draw a line, as AB, (fig. 23. 23.) equal in length to one of the given lines x ; and on the extremity A of that line, raise a perpendicular AC, on which take AC equal to the other line z ; then take with your compasses the length of the line AB, and at that extent, fixing one foot of them in C, with the other sweep the arc EF; and also taking with your compasses the extent of the line AC, fix one foot of them in B, and with the other sweep the arc GH,

which will meet the former in D; lastly, join CD and BD, and the figure ABDC will be that required.

16. Two lines x and z being given, of these to form a rhomboides that shall have one of its angles any number of degrees, suppose 50.

Rule. Draw a line AB (fig. 24. 24.) equal in length to one of the lines, as x ; then draw the line AC, making with the former the angle BAC equal to the proposed, suppose 50 degrees, and on that line take AC equal to the given line z ; then with your compasses take the length of AB, and fixing one foot in C, sweep the arc EF; also, taking the length of AC, and setting one foot in B, with the other sweep the arc GH, which will cut the former in D; then join CD and DB, so the figure ACDB will be that required.

P A R T II.

THE APPLICATION OF THE FOREGOING PRINCIPLES TO THE MENSURATION OF SURFACES, SOLIDS, &c.

CHAP. I. Of the Mensuration of Lines and Angles.

A Line, or length, to be measured, whether it be distance, height, or depth, is measured by a line less than it. With us the least measure of length is an inch: not that we measure no line less than it, but because we do not use the name of any measure below that of an inch; expressing lesser measures by the fractions of an inch: and in this treatise we use decimal fractions as the easiest. Twelve inches make a foot; three feet and an inch make the Scots ell; six ells make a fall; forty falls make a furlong; eight furlongs make a mile: so that the Scots miles is 1184 paces, accounting every pace to be five feet. These things are according to the statutes of Scotland; notwithstanding which, the glaziers use a foot of only eight inches; and other artists for the most part use an English foot, on account of the several scales marked on the English foot-measure for their use. But the English foot is somewhat less than the Scots; so that 185 of these make 186 of those.

Lines, to the extremities and any intermediate point of which you have easy access, are measured by applying to them the common measure a number of times. But lines, to which you cannot have such access, are measured by methods taken from geometry; the chief whereof we shall here endeavour to explain. The first is by the help of the geometrical square.

“As for the English measures, the yard is 3 feet, or 36 inches. A pole is sixteen feet and a half, or five yards and a half. The chain, commonly called *Gunter's chain*, is four poles, or 22 yards, that is, 66 feet. An English statute-mile is fourscore chains, or 1760 yards, that is, 5280 feet.

“The chain (which is now much in use, because it is very convenient for surveying) is divided into 100 links, each of which is $7\frac{1}{2}$ of an inch: whence it is easy to reduce any number of those links to feet, or any number of feet to links.

“A chain that may have the same advantages in

“surveying in Scotland, as Gunter's chain has in England, ought to be in length 74 feet, or 24 Scots ells, “if no regard is had to the difference of the Scots “and English foot above-mentioned. But, if regard “is had to that difference, the Scots chain ought to “consist of $74\frac{1}{2}$ English feet, or 74 feet 4 inches and “ $\frac{1}{2}$ of an inch. This chain being divided into 100 “links, each of those links is 8 inches and $\frac{2}{3}$ of “an inch. In the following table, the most noted “measures are expressed in English inches and decimals of an inch.”

English Inch. Dec.

The English foot, is	-	-	12	000

Another pike of Constantinople, according to Mess. Mallet and De la Porte,	27	920

PROPOSITION I.

PROB. To describe the structure of the geometrical square.—The geometrical square is made of any solid matter, as brals or wood, or of any four plain rulers joined together at right angles, (as in fig. 1.) where A is the centre, from which hangs a thread with a small weight at the end, so as to be directed always to the centre. Each of the sides BE and DE is divided into an hundred equal parts, or (if the sides be long enough to admit of it) into a thousand parts; C and F at two sights, fixed on the side AD. There is moreover an index GH, which, when there is occasion, is joined to the centre A, in such manner as that it can move round, and remain in any given situation. On this index are two sights perpendicular to the right line going from the centre of the instrument: these are K and L. The side DE of the instrument is called the upright side; E the reclining side.

PROPOSITION II.

FIG. 2. To measure an accessible height, AB, by the help of a geometrical square, its distance being known.—Let BR be an horizontal plane, on which there stands perpendicularly any line AB: let BD, the given distance of the observer from the height, be 96 feet; let the height of the observer's eye be supposed 6 feet: and let the instrument, held by a steady hand, or rather leaning on a support, be directed towards the summit A, so that one eye (the other being shut) may see it clearly through the sights; the perpendicular or plumb-line meanwhile hanging free, and touching the surface of the instrument: let now the perpendicular be supposed to cut off on the right side KN 80 equal parts. It is clear that LKN, ACK, are similar triangles; for the angles LKN, ACK are right angles, and therefore equal; moreover LN and AC are parallel, as being both perpendicular to the horizon; consequently, (by art. 60. cor. 1. Part I.) the angles KLN, KAC, are equal; wherefore, (by art. 60. cor. 2. of Part I.) the angles LNK, and AKC, are likewise equal: so that in the triangles NKL, KAC, (by art. 72. of Part I.) as NK : KL :: KC (i. e. BD)

: CA; that is, as 80 to 100, so is 96 feet to CA. Therefore, by the rule of three, CA will be found to be 120 feet; and CB, which is 6 feet, being added, the whole height is 126 feet.

But if the distance of the observer from the height, as BE, be such, that when the instrument is directed as formerly toward the summit A, the perpendicular falls on the angle P, opposite to H, the centre of the instrument, and BE or CG be given of 120 feet: CA will also be 120 feet. For in the triangles HGP, ACG, equiangular, as in the preceding case, as PG : GH :: GC : CA. But PG is equal to GH; therefore GC is likewise equal to CA: that is, CA will be 120 feet, and the whole height 126 feet as before.

Let the distance BF be 300 feet, and the perpendicular or plumb-line cut off 40 equal parts from the reclining side: Now, in this case, the angle, QAC, QZI, are equal, and the angles QZI, ZIS, are equal; therefore the angle ZIS is equal to the angle QAC. But the angles ZSI, QCA are equal, being right angles; therefore, in the equiangular triangles ACQ, SZI, it will be, as ZS : SI :: CQ : CA; that is, as 100 to 40, so is 300 to CA. Wherefore, by the rule of three, CA will be found to be of 102 feet. And, by adding the height of the observer, the whole BA will be 126 feet. Note, that the height is greater than the distance, when the perpendicular cuts the right side, and less if it cut the reclined side: and that the height and distance are equal, if the perpendicular fall on the opposite angle.

SCHOLIUM.

If the height of a tower, to be measured as above, end in a point, (as in fig. 3.) the distance of the observer opposite to it, is not CD, but is to be accounted from the perpendicular to the point A; that is, to CD must be added the half of the thickness of the tower, viz. BD: which must likewise be understood in the following propositions, when the case is similar.

PROPOSITION III.

FIG. 4. From the height of a tower AB given, to find a distance on the horizontal plane BC, by the geometrical square.—Let the instrument be so placed, as that the mark C in the opposite plane may be seen through the sights; and let it be observed how many parts are cut off by the perpendicular. Now, by what hath been already demonstrated, the triangles AEF, ABC, are similar; therefore, it will be as EF, to AE, so AB (composed of the height of the tower BG, and of the height of the centre of the instrument A, above the tower BG) to the distance BC. Wherefore, if, by the rule of three, you say, as EF to AE, so is AB to BC, it will be the distance sought.

PROPOSITION IV.

FIG. 5. To measure any distance at land or sea, by the geometrical square.—In this operation, the index is to be applied to the instrument, as was shown in the description; and, by the help of a support, the instrument is to be placed horizontally at the point A; then let it be turned till the remote point F, whose distance is to be measured, be seen through the fixed sights; and bring the index to be parallel with the other side of the instrument, observe by the sights upon it any accessible mark B, at a sensible distance: then carrying the instrument to the point B, let the immovable

moveable sights be directed to the first station A, and the sights of the index to the point F. If the index cut the right side of the square, as in K, in the two triangles BRK, and BAF, which are æquiangular, it will be as BR to RK, so BA (the distance of the stations to be measured with a chain) to AF; and the distance AF sought will be found by the rule of three. But if the index cut the reclined side of the square in any point L, where the distance of a more remote point is sought; in the triangles BLS, BAG, the side LS shall be to SB, as BA to AG, the distance sought; which accordingly will be found by the rule of three.

PROPOSITION V.

FIG. 6. *To measure an accessible height by means of a plain mirror.*—Let AB be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC; let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observer's eye. The triangles ABC and EDC are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of incidence and reflexion of the ray AC, as is demonstrated in optics; wherefore the remaining angles at A and E are also equal: therefore it will be, as CD to DE, so CB to BA; that is, as the distance of the observer from the point of the mirror in the right line betwixt the observer and the height, is to the height of the observer's eye, so is the distance of the tower from that point of the mirror, to the height of the tower sought; which therefore will be found by the rule of three.

Note 1. The observation will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observer may see a point of the glass exactly in a line betwixt him and the tower.

Note 2. In place of a mirror may be used the surface of water contained in a vessel, which naturally becomes parallel to the horizon.

PROPOSITION VI.

FIG. 7. *To measure an accessible height AB by means of two staffs.*—Let there be placed perpendicularly in the ground a longer staff DE, likewise a shorter one FG, so as the observer may see A, the top of the height to be measured, over the ends D F of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, shall be equiangular; for the angles at C and H are right ones; likewise the angle A is equal to the angle FDH; wherefore the remaining angles DFH, and ADC, are also equal: wherefore, as FH, the distance of the staffs, to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff. And thence CA will be found by the rule of three.

To which if the length DE be added, you will have the whole height of the tower BA.

S C H O L I U M.

FIG. 8. Many other methods may be occasionally contrived for measuring an accessible height. For example, from the given length of the shadow BD, to

find out the height AB, thus: Let there be erected a staff CE perpendicularly, producing the shadow EF: The triangles ABD, CEF, are equiangular; for the angles at B and E are right; and the angles ADB and CFE are equal, each being equal to the angle of the sun's elevation above the horizon: Therefore, as EF, the shadow of the staff, to EC, the staff itself; so BD, the shadow of the tower, to BA, the height of the tower. Though the plane on which the shadow of the tower falls be not parallel to the horizon, if the staff be erected in the same plane, the rule will be the same.

PROPOSITION VII.

To measure an inaccessible height by means of two staffs.—Hitherto we have supposed the height to be accessible, or that we can come at the lower end of it; now if, because of some impediment, we cannot get to a tower, or if the point whose height is to be found out be the summit of a hill, so that the perpendicular be hid within the hill; if, for want of better instruments, such an inaccessible height is to be measured by means of two staffs, let the first observation be made with the staffs DE and FG, (as in prop. 6.); then the observer is to go off in a direct line from the height and first station, till he come to the second station; where (fig. 11.) he is to place the longer staff perpendicularly at RN, and the shorter staff at KO, so that the summit A may be seen along their tops; that is, so that the points KNA may be in the same right line. Through the point N, let there be drawn the right line NP parallel to FA: Wherefore in the triangles KNP, KAF, the angles KNP, KAF are equal, also the angle AKF is common to both; consequently the remaining angle KPN is equal to the remaining angle KFA. And therefore, PN : FA :: KP : KF. But the triangles PNL, FAS are similar; therefore, PN : FA :: NL : SA. Therefore, (by the 11. 5. Eucl.) KP : KF :: N L : SA. Thence, alternately, it will be, as KP (the excess of the greater distance of the short staff from the long one above its lesser distance from it) to NL, the excess of the longer staff above the shorter; so KF, the distance of the two stations of the shorter staff to SA, the excess of the height sought above the height of the shorter staff. Wherefore SA will be found by the rule of three. To which let the height of the shorter staff be added, and the sum will give the whole inaccessible height BA.

Note 1. In the same manner may an inaccessible height be found by a geometrical square, or by a plain speculum. But we shall leave the rules to be found out by the student, for his own exercise.

Note 2. That by the height of the staff we understand its height above the ground in which it is fixed.

Note 3. Hence depends the method of using other instruments invented by geometricians; for example, of the geometrical cross; and if all things be justly weighed, a like rule will serve for it as here. But we incline to touch only upon what is most material.

PROPOSITION VIII.

FIG. 9. *To measure the distance AB, to one of whose extremities we have access, by the help of four staffs.*—Let there be a staff fixed at the point A; then going back at some sensible distance in the same right line, let another be fixed in C, so as that both the points A

and B be covered and hid by the staff C: likewise going off in a perpendicular from the right line CB, at the point A, (the method of doing which shall be shewn in the following *scholium*), let there be placed another staff at H; and in the right line CKG (perpendicular to the same CB, at the point B), and at the point of it K, such that the points K, H, and B may be in the same right line, let there be fixed a fourth staff. Let there be drawn, or let there be supposed to be drawn, a right line GH parallel to CA. The triangles KGH, HAB, will be equiangular; for the angles HAB KGH are right angles. Also the angles ABH, KHG are equal; wherefore, as KG (the excess of CK above AH) to GH, or to CA, the distance betwixt the first and second staff; so is AH, the distance betwixt the first and third staff, to AB the distance sought.

SCHOLIUM.

Fig. 10. To draw on a plane a right line AE perpendicular to CH, from a given point A; take the right lines AB, AD, on each side equal; and in the points B and D, let there be fixed stakes, to which let there be tied two equal ropes BE, DE, or one having a mark in the middle, and holding in your hand their extremities joined, (or the mark in the middle, if it be but one), draw out the ropes on the ground; and then, where the two ropes meet, or at the mark, when by it the rope is fully stretched, let there be placed a third stake at E; the right line AE will be perpendicular to CH in the point A (prob. i. of Part I.). In a manner not unlike to this, may any problems that are resolved by the square and compasses, be done by ropes and a cord turned round as a radius.

PROPOSITION IX.

FIG. 12. To measure the distance AB, one of whose extremities is accessible.—From the point A, let the right line AC of a known length be made perpendicular to AB, (by the preceding *scholium*): likewise draw the right line CD perpendicular to CB, meeting the right line AB in D: then as DA : AC :: AC : AB. Wherefore, when DA and AC are given, AB will be found by the rule of three.

SCHOLIUM.

All the preceding operations depend on the equality of some angles of triangles, and on the similarity of the triangles arising from that equality. And on the same principles depend innumerable other operations which a geometrician will find out of himself, as is very obvious. However, some of these operations require such exactness in the work, and without it are so liable to errors, that, *cæteris paribus*, the following operations, which are performed by a trigonometrical calculation, are to be preferred; yet could we not omit those above, being most easy in practice, and most clear and evident to those who have only the first elements of geometry. But if you are provided with instruments, the following operations are more to be relied upon. We do not insist on the easiest cases to those who are skilled in plain trigonometry, which is indeed necessary to any one who would apply himself to practice. See TRIGONOMETRY.

PROPOSITION X.

FIG. 13. To describe the construction and use of the geometrical quadrant.—The geometrical quadrant is

the fourth part of a circle divided into 90 degrees, to which two sights are adapted, with a perpendicular or plumb-line hanging from the centre. The general use of it is for investigating angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. This instrument is made of any solid matter, as wood, copper, &c.

PROPOSITION XI.

FIG. 14. To describe and make use of the graphometer.—The graphometer is a semicircle made of any hard matter, of wood, for example, or brass, divided into 180 degrees; so fixed on a *fulcrum*, by means of a brass ball and socket, that it easily turns about, and retains any situation; two sights are fixed on its diameter. At the centre there is commonly a magnetical needle in a box. There is likewise a moveable ruler, which turns round the centre, and retains any situation given it. The use of it is to observe any angle, whose vertex is at the centre of the instrument in any plane, (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

PROPOSITION XII.

FIG. 15, and 16. To describe the manner in which angles are measured by a quadrant or graphometer.—Let there be an angle in a vertical plane, comprehended between a line parallel to the horizon HK, and the right line RA, coming from any remarkable point of a tower or hill, or from the sun, moon, or a star. Suppose that this angle RAH is to be measured by the quadrant: let the instrument be placed in the vertical plane, so as that the centre A may be in the angular point: and let the sights be directed towards the object at R, (by the help of the ray coming from it, if it be the sun or moon, or by the help of the visual ray, if it is any thing else), the degrees and minutes in the arc BC cut off by the perpendicular, will measure the angle RAH required. For, from the make of the quadrant, BAD is a right angle; therefore BAR is likewise right, being equal to it. But, because HK is horizontal, and AC perpendicular, HAC will be a right angle; and therefore equal also to BAR. From those angles subtract the part HAB that is common to both; and there will remain the angle BAC equal to the angle RAH. But the arc BC is the measure of the angle BAC; consequently, it is likewise the measure of the angle RAH.

Note, That the remaining arc on the quadrant DC is the measure of the angle RAZ, comprehended between the forefaid right line RA and AZ which points to the zenith.

Let it now be required to measure the angle ACB (fig. 16.) in any plane, comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its *fulcrum* (as was shown above); and let the immovable sights on the side of the instrument DE be directed towards the point A; and likewise (while the instrument remains immovable) let the sights of the ruler FG (which is moveable about the centre C) be directed to the point B. It is evident that the moveable ruler cuts off an arc DH, which is the measure of the angle ACB sought.

Moreover,

Moreover, by the same method, the inclination of CE, or of FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and is moveable about the centre of the instrument, and the measure of this inclination or angle found in degrees.

PROPOSITION XIII.

FIG. 17. *To measure an accessible height by the geometrical quadrant.*—By the 12th prop. of this Part, let the angle C be found by means of the quadrant. Then in the triangle ABC, right-angled at B, (BC being supposed the horizontal distance of the observer from the tower), having the angle at C, and the side BC, the required height BA will be found by the 3^d case of plain trigonometry. See TRIGONOMETRY.

PROPOSITION XIV.

FIG. 18. *To measure an inaccessible height by the geometrical quadrant.*—Let the angle ACB be observed with the quadrant (by the 12th prop. of this Part); then let the observer go from C to the second station D, in the right line BCD (provided BCD be a horizontal plane); and after measuring this distance CD, take the angle ADC likewise with the quadrant. Then, in the triangle ADC, there is given the angle ADC, with the angle ACD; because ACB was given before: therefore (by art. 59. of Part I.) the remaining angle CAD is given likewise. But the side CD is likewise given, being the distance of the station C and D; therefore (by the first case of oblique-angled triangles in trigonometry) the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypotenuse AC are given; consequently, by the fourth case of trigonometry, the height sought AB will be found; as also (if you please) the distance of the station C, from AB the perpendicular within the hill or inaccessible height.

PROPOSITION XV.

FIG. 19. *From the top of a given height, to measure the distance BC.*—Let the angle BAC be observed by the 12th prop. of this; wherefore in the triangle ABC, right-angled at B, there is given by observation the angle at A; whence (by the 59th art. of Part I.) there will also be given the angle BCA: moreover the side AB (being the height of the tower) is supposed to be given. Wherefore, by the 3^d case of trigonometry, BC, the distance sought, will be found.

PROPOSITION XVI.

FIG. 20. *To measure the distance of two places A and B, of which one is accessible, by the graphometer.*—Let there be erected at two points A and C, sufficiently distant, two visible signs; then (by the 12th prop. of this Part) let the two angles BAC, BCA, be taken by the graphometer. Let the distance of the stations A and C be measured with a chain. Then the third angle B being known, and the side AC being likewise known; therefore, by the first case of trigonometry, the distance required, AB will be found.

PROPOSITION XVII.

FIG. 21. *To measure by the graphometer, the distance of two places, neither of which is accessible.*—Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought; let the angles ACD, ACB, BCD, and likewise the angles BDC, BDA, CDA, be measured by the graphometer;

let the distance of the stations C and D be measured by a chain, or (if it be necessary) by the preceding practice. Now, in the triangle ACD, there are given two angles ACD and ADC; therefore, the third CAD is likewise given; moreover the side CD is given; therefore, by the first case of trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found by the 4th case of trigonometry of oblique-angled triangles.

PROPOSITION XVIII.

FIG. 22. *It is required by the graphometer and quadrant, to measure an accessible height AB, placed so on a steep, that one can neither go near it in an horizontal plane, nor recede from it, as we supposed in the solution of the 14th prop.*—Let there be chosen any situation as C, and another D; where let some mark be erected: let the angles ACD and ADC be found by the graphometer; then the third angle DAC will be known. Let the side CD, the distance of the stations, be measured with a chain, and thence (by trigonometry) the side AC will be found. Again, in the triangle ACB, right-angled at B, having found by the quadrant the angle ACB, the other angle CAB is known likewise: but the side AC in the triangle ADC is already known; therefore the height required AB will be found by the 4th case of right-angled triangles. If the height of the tower is wanted, the angle BCF will be found by the quadrant; which being taken from the angle ACB already known, the angle ACF will remain: but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was also known before; therefore, in the triangle AFC, all the angles and one of the sides AC being known, AF, the height of the tower above the hill, will be found by trigonometry.

SCHOLIUM.

It were easy to add many other methods of measuring heights and distances; but, if what is above be understood, it will be easy (especially for one that is versed in the elements) to contrive methods for this purpose, according to the occasion: so that there is no need of adding any more of this sort. We shall furnish here a method by which the diameter of the earth may be found out.

PROPOSITION XIX.

FIG. 1. *To find the diameter of the earth from one observation.*—Let there be chosen a high hill AB, near the sea-shore, and let the observer on the top of it, with an exact quadrant divided into minutes and seconds by transverse divisions, and fitted with a telescope in place of the common sights, measure the angle ABE contained under the right line AB, which goes to the centre, and the right line BE drawn to the sea, a tangent to the globe at E; let there be drawn from A perpendicular to BD, the line AF meeting BE in F. Now in the right-angled triangle BAF all the angles are given, also the side AB, the height of the hill; which is to be found by some of the foregoing methods, as exactly as possible; and (by trigonometry) the sides BF and AF are found. But, by cor. 36th 3. Eucl.

Geometry
Plate,
n^o IV.

3. Eucl. AF is equal to FE; therefore BE will be known. Moreover, by 36th 3. Eucl. the rectangle under BA and BD is equal to the square of BE. And thence by 17th 6. Eucl. as AB : BE :: BE : BD. Therefore, since AB and BE are already given, BD will be found by 11th 6. Eucl. or by the rule of three; and subtracting BA, there will remain AD the diameter of the earth sought.

SCHOLIUM.

Many other methods might be proposed for measuring the diameter of the earth. The most exact is that proposed by Mr Picart of the academy of sciences at Paris.

“According to Mr Picart, a degree of the meridian at the latitude of 49° 21', was 57,060 French toises, each of which contains six feet of the same measure: from which it follows, that, if the earth be an exact sphere, the circumference of a great circle of it will be 123,249,600 Paris feet, and the semidiameter of the earth 19,615,800 feet: but the French mathematicians, who of late have examined Mr Picart's operations, assure us, that the degree in that latitude is 57,183 toises. They measured a degree in Lapland, in the latitude of 66° 20', and found it of 57,438 toises. By comparing these degrees, as well as by the observations on pendulums, and the theory of gravity, it appears that the earth is an oblate spheroid; and (supposing those degrees to be accurately measured) the axis or diameter that passes through the poles will be to the diameter of the equator, as 177 to 178, or the earth will be 22 miles higher at the equator than at the poles. A degree has likewise been measured at the equator, and found to be considerably less than at the latitude of Paris; which confirms the oblate figure of the earth. But an account of this last mensuration has not been published as yet. If the earth was of an uniform density from the surface to the centre, then, according to the theory of gravity, the meridian would be an exact ellipsis, and the axis would be to the diameter of the equator as 230 to 231; and the difference of the semidiameter of the equator and semiaxis about 17 miles.”

In what follows, a figure is often to be laid down on paper, like to another figure given; and because this likeness consists in the equality of their angles, and in the sides having the same proportion to each other (by the definitions of the 6th of Eucl.) we are now to shew what methods practical geometers use for making on paper an angle equal to a given angle, and how they constitute the sides in the same proportion. For this purpose they make use of a protractor, (or, when it is wanting, a line of chords), and of a line of equal parts.

PROPOSITION XX.

FIG. 2. 3. 4. 5. and 6. To describe the construction and use of the protractor, of the line of chords, and of the line of equal parts. The protractor is a small semicircle of brass, or such solid matter. The semicircumference is divided into 180 degrees. The use of it is, to draw angles on any plane, as on paper, or to examine the extent of angles already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let

the side AB coincide with one of the sides that contain the angle proposed; the number of degrees cut off by the other side, computing on the protractor from B, will shew the quantity of the angle that is to be measured.

But if an angle is to be made of a given quantity on a given line, and at a given point of that line, let AB coincide with the given line, and let the centre A of the instrument be applied to that point. Then let there be a mark made at the given number of degrees; and a right line drawn from that mark to the given point, will constitute an angle with the given right line of the quantity required; as is manifest.

This is the most natural and easy method, either for examining the extent of an angle on paper, or for describing on paper an angle of a given quantity.

But when there is scarcity of instruments, or because a line of chords is more easily carried about, (being described on a ruler on which there are many other lines besides), practical geometers frequently make use of it. It is made thus: let the quadrant of a circle be divided into 90 degrees; (as in fig. 4.) The line AB is the chord of 90 degrees; the chord of every arc of the quadrant is transferred to this line AB, which is always marked with the number of degrees in the corresponding arc.

Note, that the chord of 60 degrees is equal to the radius, by corol. 15. 4th Eucl. If now a given angle EDF is to be measured by the line of chords from the centre D, with the distance DG, (the chord of 60 degrees), describe the arch GF; and let the points G and F be marked where this arch intersects the sides of the angle. Then if the distance GF, applied on the line of chords from A to B, gives (for example) 25 degrees, this shall be the measure of the angle proposed.

When an obtuse angle is to be measured with this line, let its complement to a semicircle be measured, and thence it will be known. It were easy to transfer to the diameter of a circle the chords of all arches to the extent of a semicircle; but such are rarely found marked upon rules.

But now, if an angle of a given quantity, suppose of 50 degrees, is to be made at a given point M of the right line KL (fig. 6.) From the centre M, and the distance MN, equal to the chord of 60 degrees, describe the arc QN. Take off an arc NR, whose chord is equal to that of 50 degrees on the line of chords; join the points M and R; and it is plain that MR shall contain an angle of 50 degrees with the line KL proposed.

But sometimes we cannot produce the sides, till they be of the length of a chord of 60 degrees on our scale; in which case it is fit to work by a circle of proportions (that is a sector), by which an arc may be made of a given number of degrees to any radius.

The quantities of angles are likewise determined by other lines usually marked upon rules, as the lines of sines, tangents, and secants; but, as these methods are not so easy or so proper in this place, we omit them.

To delineate figures similar or like to others given, besides the equality of the angles, the same proportion is to be preserved among the sides of the figure that is to be delineated, as is among the sides of the figures given. For which purpose, on the rules used by artists, there

there is a line divided into equal parts, more or less in number, and greater or less in quantity, according to the pleasure of the maker.

A foot is divided into inches; and an inch, by means of transverse lines, into 100 equal parts; so that with this scale, any number of inches, below 12, with any part of an inch, can be taken by the compasses, providing such part be greater than the one 100th part of an inch. And this exactness is very necessary in delineating the plans of houses, and in other cases.

PROPOSITION XXI.

FIG. 7. To lay down on paper, by the protractor or line of chords, and line of equal parts, a right-lined figure like to one given, providing the angles and sides of the figure given be known by observation or mensuration. For example, suppose that it is known that in a quadrangular figure, one side is of 235 feet, that the angle contained by it and the second side is of 84°, the second side of 288 feet, the angle contained by it and the third side of 72°, and that the third side is 294 feet. These things being given, a figure is to be drawn on paper like to this quadrangular figure. On your paper at a proper point A, let a right line be drawn, upon which take 235 equal parts, as AB. The part representing a foot is taken greater or lesser, according as you would have your figure greater or less. In the adjoining figure, the 100th part of an inch is taken for a foot. And accordingly an inch divided into 100 parts, and annexed to the figure, is called a scale of 100 feet. Let there be made at the point B (by the preceding proposition) an angle ABC of 85°, and let BC be taken of 288 parts like to the former. Then let the angle BCD be made of 72°, and the side CD of 294 equal parts. Then let the side AD be drawn; and it will complete the figure like to the given. The measures of the angle A and D can be known by the protractor or line of chords, and the side AD by the line of equal parts; which will exactly answer to the corresponding angles and to the side of the primary figure.

After the very same manner, from the sides and angles given, which bound any right-lined figure, a figure like to it may be drawn, and the rest of its sides and angles be known.

COROLLARY.

Hence any trigonometrical problem in right-lined triangles, may be resolved by delineating the triangle from what is given concerning it, as in this proposition. The unknown sides are examined by a line of equal parts, and the angles by a protractor or line of chords.

PROPOSITION XXII.

The diameter of a circle being given, to find its circumference nearly.—The periphery of any polygon inscribed in the circle is less than the circumference, and the periphery of any polygon described about a circle is greater than the circumference. Whence Archimedes first discovered that the diameter was in proportion to the circumference, as 7 to 22 nearly; which serves for common use. But the moderns have computed the proportion of the diameter to the circumference to greater exactness. Supposing the diameter 100, the periphery will be more than 314, but less than 315. The diameter is more near-

ly to the circumference, as 113 to 355. But Ludolph van Cuelen exceeded the labours of all; for by immense study he found, that, supposing the diameter 100,000,000,000,000,000,000,000,000,000,000, the periphery will be less than

314,159,265,358,979,323,846,264,338,327,951,

but greater than

314,159,265,358,979,323,846,264,338,327,950;

whence it will be easy, any part of the circumference being given in degrees and minutes, to assign it in parts of the diameter.

Of Surveying and Measuring of LAND.

HITHERTO we have treated of the measuring of angles and sides, whence it is abundantly easy to lay down a field, a plane, or an entire country: for to this nothing is requisite but the protraction of triangles, and of other plain figures, after having measured their sides and angles. But as this is esteemed an important part of practical geometry, we shall subjoin here an account of it with all possible brevity; suggesting withal, that a surveyor will improve himself more by one day's practice, than by a great deal of reading.

PROPOSITION XXIII.

To explain what surveying is, and what instruments Surveyors use.—First, it is necessary that the surveyor view the field that is to be measured, and investigate its sides and angles, by means of an iron chain (having a particular mark at each foot of length, or at any number of feet, as may be most convenient for reducing lines or surfaces to the received measures), and the graphometer described above. Secondly, it is necessary to delineate the field in *piano*, or to form a map of it; that is, to lay down on paper a figure similar to the field; which is done by the protractor (or line of chords) and of the line of equal parts. Thirdly, It is necessary to find out the area of the field so surveyed and represented by a map. Of this last we are to treat below.

The sides and angles of small fields are surveyed by the help of a plain table: which is generally of an oblong rectangular figure, and supported by a *fulcrum*, so as to turn every way by means of a ball and socket. It has a moveable frame, which surrounds the board, and serves to keep a clean paper put on the board close and tight to it. The sides of the frame facing the paper are divided into equal parts every way. The board hath besides a box with a magnetic needle, and moreover a large index with two sights. On the edge of the frame of the board are marked degrees and minutes, so as to supply the room of a graphometer.

PROPOSITION XXIV.

FIG. 8. To delineate a field by the help of a plain-table, from one station whence all its angles may be seen and their distances measured by a chain.—Let the field that is to be laid down be ABCDE. At any convenient place F, let the plain-table be erected; cover it with clean paper, in which let some point near the middle represent the station. Then applying at this place the index with the sights, direct it so as that through the sights some mark may be seen at one of the angles, suppose A; and from the point F, representing the station, draw a faint right line along the side of the index: then, by the help of the chain, let FA the distance

tance of the station from the forefaid angle be measured. Then taking what part you think convenient for a foot or pace from the line of equal parts, set off on the faint line the parts corresponding to the line FA that was measured; and let there be a mark made representing the angle of the field A. Keeping the table immovable, the fame is to be done with the rest of the angles; then right lines joining those marks shall include a figure like to the field, as is evident from 5, 6. Eucl.

C O R O L L A R Y.

The same thing is done in like manner by the graphometer: for having observed in each of the triangles, AFB, BFC, CFD, &c. the angle at the station F, and having measured the lines from the station to the angles of the field, let similar triangles be protracted on paper (by the 21. prop. of this) having their common vertex in the point of station. All the lines, excepting those which represent the sides of the field, are to be drawn faint or obscure.

Note 1. When a surveyor wants to lay down a field let him place distinctly in a register all the observations of the angles, and the measures of the sides, until, at time and place convenient, he draw out the figure on paper.

Note 2. The observations made by the help of the graphometer are to be examined: for all the angles about the point F ought to be equal to four right ones. (by cor. 2. art. 30. of Part I.)

P R O P O S I T I O N XXV.

FIG. 9. *To lay down a field by means of two stations, from each of which all the angles can be seen, by measuring only the distance of the stations.*—Let the instrument be placed at the station F: and having chosen a point representing it upon the paper which is laid upon the plain table, let the index be applied at this point, so as to be moveable about it. Then let it be directed successively to the several angles of the field: and when any angle is seen through the sights, draw an obscure line along the side of the index. Let the index, with the sights, be directed after the same manner to the station G: on the obscure line drawn along its side, pointing to A, set off from the scale of equal parts a line corresponding to the measured distance of the stations, and this will determine the point G. Then remove the instrument to the station G, and applying the index to the line representing the distance of the stations, place the instrument so that the first station may be seen through the sights. Then the instrument remaining immovable, let the index be applied at the point representing the second station G, and be successively directed by means of its sights, to all the angles of the field, drawing (as before) obscure lines: and the intersection of the two obscure lines that were drawn to the same angle from the two stations will always represent that angle on the plan. Care must be taken that those lines be not mistaken for one another. Lines joining those intersections will form a figure on the paper like to the field.

S C H O L I U M.

It will not be difficult to do the same by the graphometer, if you keep a distinct account of your observations of the angles made by the line joining the stations, and the lines drawn from the stations to the

respective angles of the field. And this is the most common manner of laying down whole countries. The tops of two mountains are taken for two stations, and their distance is either measured by some of the methods mentioned above, or is taken according to common report. The sights are successively directed towards cities, churches, villages, forts, lakes, turnings of rivers, woods, &c.

Note, The distance of the stations ought to be great enough, with respect to the field that is to be measured; such ought to be chosen as are not in a line with any angle of the field. And care ought to be taken likewise that the angles, for example, FAG, FDG, &c. be neither very acute, nor very obtuse. Such angles are to be avoided as much as possible; and this admonition is found very useful in practice.

P R O P O S I T I O N XXVI.

FIG. 10. *To lay down any field, however irregular its figure may be, by the help of the graphometer.*—Let ABCEDHG be such a field. Let its angles (in going round it) be observed with a graphometer (by the 12. of this) and noted down; let its sides be measured with a chain; and (by what was said on the 21. of this) let a figure like to the given field be protracted on paper. If any mountain is in the circumference, the horizontal line hid under it is to be taken for a side, which may be found by two or three observations according to some of the methods described above; and its place on the map is to be distinguished by a shade, that it may be known a mountain is there.

If not only the circumference of the field is to be laid down on the plan, but also its contents, as villages, gardens, churches, public roads, we must proceed in this manner.

Let there be (for example) a church F, to be laid down in the plan. Let the angles ABF BAF be observed and protracted on paper in their proper places, the intersection of the two sides BF and AF will give the place of the church on the paper: or, more exactly, the lines BF AF being measured, let circles be described from the centres B and A, with parts from the scale corresponding to the distances BF and AF, and the place of the church will be at their intersection.

Note 1. While the angles observed by the graphometer are taken down, you must be careful to distinguish the external angles, as E and G, that they may be rightly protracted afterwards on paper.

Note 2. Our observations of the angles may be examined by computing if all the internal angles make twice as many right angles, four excepted, as there are sides of the figure: (for this is demonstrated by 32. 1. Eucl.) But in place of any external angle DEC, its complement to a circle is to be taken.

P R O P O S I T I O N XXVII.

FIG. 11. *To lay down a plain field without instruments.*—If a small field is to be measured, and a map of it to be made, and you are not provided with instruments; let it be supposed to be divided into triangles, by right lines, as in the figure; and after measuring the three sides of any of the triangles, for example of ABC, let its sides be laid down from a convenient scale on paper, (by the 22. of this.) Again, let the other two sides BD CD of the triangle CBD be measured and protracted on the paper by the same

scale

scale as before. In the same manner proceed with the rest of the triangles of which the field is composed, and the map of the field will be perfected; for the three sides of a triangle determine the triangle; whence each triangle on the paper is similar to its correspondent triangle in the field, and is similarly situated; consequently the whole figure is like to the whole field.

S C H O L I U M.

If the field be small, and all its angles may be seen from one station, it may be very well laid down by the plain-table, (by the 24. of this.) If the field be larger, and have the requisite conditions, and great exactness is not expected, it likewise may be plotted by means of the plain-table, or by the graphometer, (according to the 25. of this;) but in fields that are irregular and mountainous, when an exact map is required, we are to make use of the graphometer, (as in the 26. of this,) but rarely of the plain-table.

Having protracted the bounding lines, the particular parts contained within them may be laid down by the proper operations for this purpose, (delivered in the 26th proposition; and the method described in the 27th proposition may be sometimes of service;) for we may trust more to the measuring of sides, than to the observing of angles. We are not to compute four-sided and many sided figures till they are resolved into triangles: for the sides do not determine those figures.

In the laying down of cities, or the like, we may make use of any of the methods described above that may be most convenient.

The map being finished, it is transferred on clean paper, by putting the first sketch above it, and marking the angles by the point of a small needle. These points being joined by right lines, and the whole illuminated by colours proper to each part, and the figure of the mariner's compass being added to distinguish the north and south, with a scale on the margin, the map or plan will be finished and neat.

We have thus briefly and plainly treated of surveying, and shown by what instruments it is performed; having avoided those methods which depend on the magnetic needle, not only because its direction may vary in different places of a field (the contrary of this at least doth not appear,) but because the quantity of an angle observed by it cannot be exactly known; for an error of two or three degrees can scarcely be avoided in taking angles by it.

As for the remaining part of surveying, whereby the area of a field already laid down on paper is found in acres, roods, or any other superficial measures; this we leave to the following section, which treats of the mensuration of surfaces.

" Besides the instruments described above, a surveyor ought to be provided with an off-set staff equal in length to 10 links of the chain, and divided into 10 equal parts. He ought likewise to have 10 arrows or small straight sticks near two feet long, shod with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have the 10 arrows at first setting out. When the

" chain is stretched in the line, and the near end touches the place from which you measure, the leader sticks one of the 10 arrows in the ground, at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being stretched in the line, so that the near end touches the first arrow, the leader sticks down another arrow at his end of the chain. The line is preserved straight, if the arrows be always set so as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain, the arrows are to be carried to him again, and he is to stick one of them into the ground, at the end of the chain. And the same is to be done at the 21. 31. 41. &c. chains, if there are so many in a right line to be measured. In this manner you can hardly commit an error in numbering the chains, unless of 10 chains at once.

" The off-set staff serves for measuring readily the distances of any things proper to be represented in your plan, from the station-line while you go along. These distances ought to be entered into your field-book, with the corresponding distances from the last station, and proper remarks, that you may be enabled to plot them justly, and be in no danger of mistaking one for another when you extend your plan. The field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with the distances from the stations. The distances taken by the off-set staff, on either side of the station-line, are to be entered into columns on either side of the middle column, according to their position with respect to that line. The names and characters of the objects, with proper remarks, may be entered in columns on either side of these last.

" Because, in the place of the graphometer described by our author, surveyors now make use of the theodolite, we shall subjoin a description of Mr Sisson's latest improved theodolite from Mr Gardner's practical surveying improved. See a figure of it in the IVth Plate.

" In this instrument, the three staffs, by brass ferrils at top, screw into bell-metal joints, that are moveable between brass pillars, fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press, that set the limb horizontal: Next above is another such plate, through which the said screws pass, and on which, round the centre, is fixed a frustum of a cone of bell-metal, whose axis is being connected with the centre of the bell) is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass-box; and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes; in whose plate are fixed four brass pillars, that, joining at top, hold the centre pin of the bell-metal double sextant, whose double index is fixed on the centre of the same plate: Within the double sextant is fixed the spirit-level, (c) and

“and over it the telescope.

“The compass-box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

“The limb has two *heurs de luce* against the diamonds in the box, instead of 180 each, and is curiously divided into whole degrees, and numbered to the left hand at every 10 to twice 180, having three indexes distant 120, (with Nonius's divisions on each for the decimals of a degree,) that are moved by a pinion fixed below one of them, without moving the limb; and in another is a screw and spring under, to fix it to any part of the limb. It has also divisions numbered, for taking the quarter girt in inches of round timber at the middle height, when standing 10 feet horizontally distant from its centre; to which at 20 must be doubled, and at 30 tripled; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

“The double sextant is divided on one side from under its centre (when the spirit-tube and telescope are level) to above 60 degrees each way, and numbered at 10, 20, &c. and the double index (through which it is moveable) shews on the same side the degree and decimal of any altitude or depression to that extent by Nonius's divisions: On the other side are divisions numbered, for taking the upright height of timber, &c. in feet, when distant 10 feet; which at 20 must be doubled, and at 30 tripled; and also the quantities for reducing hypotenusal lines to horizontal. It is moveable by a pinion fixed in the double index.

“The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distant object as perfect, as most of triple its length. In its focus are very fine cross wires, whose intersection is in the plane of the double sextant; and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that, whenever the limb is set horizontal, (which is readily done by making the spirit-tube level over two screws, and the like over the other two,) the double sextant and telescope are moveable in a vertical plane; and then every angle taken on the limb (though the telescope be never so much elevated or depressed) will be an angle in the plane of the horizon. And this is absolutely necessary in plotting a horizontal plane.

“If the lands to be plotted are hilly, and not in any one plane, the lines measured cannot be truly laid down on paper, without being reduced to one plane, which must be the horizontal, because angles are taken in that plane.—

“In viewing your objects, if they have much altitude or depression, either write down the degree and decimal shewn on the double sextant, or the links shewn on the back side; which last subtracted from every chain in the station-line, leaves the length in the horizontal plane. But if the degree is taken, the following table will shew the quantity.

A Table of the links to be subtracted out of every chain in hypotenusal lines of several degrees altitude, or depression, for reducing them to horizontal.

<i>Degrees. Links.</i>	<i>Degrees. Links.</i>	<i>Degrees. Links.</i>
4,95 — $\frac{1}{2}$	14,07 — 3	23,074 — 8
5,73 — $\frac{1}{2}$	16,26 — 4	24,495 — 9
7,02 — $\frac{1}{2}$	18,195 — 5	25,84 — 10
8,11 — 1	19,95 — 6	27,13 — 11
11,48 — 2	21,565 — 7	28,36 — 12

“Let the first station line really measure 1107 links, and the angle of altitude or depression be 19°, 95; looking in the table you will find against 19°, 95, is 6 links. Now 6 times 11 is 66, which subtracted from 1107, leaves 1041, the true length to be laid down in the plan.

“It is useful in surveying, to take the angles, which the bounding lines form, with the magnetic needle, in order to check the angles of the figure, and to plot them conveniently afterwards.”

Of the Surfaces of Bodies.

THE smallest superficial measure with us is a square inch; 144 of which make a square foot. Wrights make use of these in the measuring of deals and planks; but the square foot which the glazier's use in measuring of glass, consists only of 64 square inches. The other measures are, first, the ell square; secondly, the fall, containing 36 square ells; thirdly, the rood, containing 40 falls; fourthly, the acre, containing 4 roods. Slaters, masons, and pavers, use the ell square and the fall; surveyors of land use the square ell, the fall, the rood, and the acre.

The superficial measures of the English are, first, the square foot; secondly, the square yard, containing 9 square feet, for their yard contains only 3 feet; thirdly, the pole, containing 30½ square yards; fourthly, the rood, containing 40 poles; fifthly, the acre, containing 4 roods. And hence it is easy to reduce our superficial measures to the English, or theirs to ours.

“In order to find the content of a field, it is most convenient to measure the lines by the chains described above, p. 9, that of 22 yards for computing the English acres, and that of 24 Scots ells for the acres of Scotland. The chain is divided into 100 links, and the square of the chain is 10,000 square links; 10 squares of the chain, or 100,000 square links, give an acre. Therefore, if the area be expressed by square links, divide by 100,000, or cut off five decimal places, and the quotient shall give the area in acres and decimals of an acre. Write the entire acres apart; but multiply the decimals of an acre by 4, and the product shall give the remainder of the area in roods and decimals of a rood. Let the entire roods be noted apart after the acres; then multiply the decimals of a rood by 40, and the product shall give the remainder of the area in falls or poles. Let the entire falls or poles be then writ after the roods, and multiply the decimals of a fall by 36, if the area is required in the measures of Scotland; but multiply the decimals of a pole by 30½, if the area is required in the measures of England, and the product shall give the remainder of the area in square ells in the former case, but

"in square yards in the latter. If, in the former case, you would reduce the decimals of the square ell to square feet, multiply them by 9.50994; but, in the latter case, the decimals of the English square yard are reduced to square feet, by multiplying them by 9.

"Suppose, for example, that the area appears to contain 12.65842 square links of the chain of 24 ells; and that this area is to be expressed in acres, roods, falls, &c. of the measures of Scotland. Divide the square links by 100,000, and the quotient 12.65842 shows the area to contain 12 acres $\frac{65842}{100000}$ of an acre. Multiply the decimal part by 4, and the product 2.63368 gives the remainder in roods and decimals of a rood. Those decimals of the rood being multiplied by 40, the product gives 25.3472 falls. Multiply the decimals of the fall by 36, and the product gives 12.4092 square ells. The decimals of the square ell multiplied by 9.50994 give 4.7458 square feet. Therefore the area proposed amounts to 12 acres, 2 roods, 25 falls, 12 square ells, and $4\frac{7458}{100000}$ square feet.

"But if the area contains the same number of square links of Gunter's chain, and is to be expressed by English measures, the acres and roods are computed in the same manner as in the former case. The poles are computed as the falls. But the decimals of the pole, viz. $\frac{3457}{10000}$, are to be multiplied by 30 $\frac{1}{2}$ (or 30.25), and the product gives 10.5028 square yards. The decimals of the square yard, multiplied by 9, give 4.5252 square feet; therefore, in this case, the area is in English measure 12 acres, 2 roods, 25 poles, 10 square yards, and $4\frac{5252}{10000}$ square feet.

"The Scots acre is to the English acre, by statute, as 100,000 to 78,694, if we have regard to the difference betwixt the Scots and English foot above mentioned. But it is customary in some parts of England to have 18,21, &c. feet to a pole, and 160 such poles to an acre; whereas, by the statute, 16 $\frac{1}{2}$ feet make a pole. In such cases the acre is greater in the duplicate ratio of the number of feet to a pole.

"They who measure land in Scotland by an ell of 37 English inches, make the acre less than the true Scots acre by $593\frac{1}{2}$ square English feet, or by about $\frac{1}{10}$ of the acre.

"An husband-land contains 6 acres of sock and sythe-land, that is, of land that may be tilled with a plough, and mown with a sythe; 13 acres of arable land make an oxgang or oxengate; four oxengate make a pound-land of old extent (by a decree of the Exchequer, March 11. 1585), and is called *librata terra*. A forty-shilling land of old extent contains eight oxgang, or 104 acres.

"The arpent, about Paris, contains 32400 square Paris feet, and is equal to 2 $\frac{1}{2}$ Scots roods, or 3 $\frac{1}{2}$ English roods.

"The *altus quadratus*, according to Varro, Columella, &c. was a square of 120 Roman feet. The *jugerum* was the double of this. It is to the Scots acre as 10,000 to 20,456, and to the English acre as 10,000 to 16,097. It was divided (like the *as*) into 12 *uncia*, and the *uncia* into 24 *scrupula*."—This, with the three preceding paragraphs, are taken

from an ingenious manuscript, written by Sir Robert Stewart professor of natural philosophy. The greatest part of the table in p. 9, 10. was taken from it likewise.

PROPOSITION XXVIII.

FIG. 12. To find out the area of a rectangular parallelogram ABCD.—Let the side AB, for example, be 5 feet long, and BC (which conflutes with BA at right angle at B) be 17 feet. Let 17 be multiplied by 5, and the product 85 will be the number of square feet in the area of the figure ABCD. But if the parallelogram proposed is not rectangular as BEFC, its base BC multiplied into its perpendicular height AB (not into its side BE) will give its area. This is evident from art. 68. of Part I.

PROPOSITION XXIX.

FIG. 13. To find the area of a given triangle.—Let the triangle BAC be given, whose base BC is supposed 9 feet long: let the perpendicular AD be drawn from the angle A opposite to the base, and let us suppose AD to be 4 feet. Let the half of the perpendicular be multiplied into the base, or the half of the base into the perpendicular, or take the half of the product of the whole base into the perpendicular, the product gives 18 square feet for the area of the given triangle.

But if only the sides are given, the perpendicular is found either by protracting the triangle, or by 12th and 13th 2. Eucl. or by trigonometry. But how the area of a triangle may be found from the given sides only, shall be shewn in the 31st proposition.

PROPOSITION XXX.

FIG. 14. To find the area of any rectilineal figure.—If the figure be irregular, let it be resolved into triangles; and drawing perpendiculars to the bases in each of them, let the area of each triangle be found by the preceding proposition, and the sum of these areas will give the area of the figure.

SCHOLIUM I.

In measuring boards, planks, and glass, their sides are to be measured by a foot-rule divided into 100 equal parts; and after multiplying the sides, the decimal fractions are easily reduced to lesser denominations. The mensuration of these is easy, when they are rectangular parallelograms.

SCHOLIUM 2.

If a field is to be measured, let it first be plotted on paper, by some of the methods above described, and let the figure so laid down be divided into triangles, as was shewn in the preceding proposition.

The base of any triangle, or the perpendicular upon the base, or the distance of any two points of the field, is measured by applying it to the scale according to which the map is drawn.

SCHOLIUM 3.

But if the field given be not in a horizontal plane, but uneven and mountainous, the scale gives the horizontal line between any two points, but not their distance measured on the uneven surface of the field. And indeed it would appear, that the horizontal plane is to be accounted the area of an uneven and hilly country. For if such ground is laid out for building on, or for planting with trees, or bearing corn, since these stand perpendicular to the horizon, it is plain, that a mountainous country cannot be considered as of greater extent for those uses than the horizontal

plane: nay, perhaps, for nourishing of plants, the horizontal plane may be preferable.

If, however, the area of a figure, as it lies regularly on the surface of the earth, is to be measured, this may be easily done by resolving it into triangles as it lies. The sum of their areas will be the area sought; which exceeds the area of the horizontal figure more or less, according as the field is more or less uneven.

PROPOSITION XXXI.

FIG. 13. *The sides of a triangle being given, to find the area, without finding the perpendicular.*—Let all the sides of the triangle be collected into one sum; from the half of which let the sides be separately subtracted, that three differences may be found betwixt the foresaid half sum and each side; then let these three differences and the half sum be multiplied into one another, and the square root of the product will give the area of the triangle. For example, let the sides be 10, 17, 21; the half of their sum is 24; the three differences betwixt this half sum and the three sides, are 14, 7, and 3. The first being multiplied by the second, and their product by the third, we have 294 for the product of the differences; which multiplied by the foresaid half sum 24, gives 7056; the square root of which 84 is the area of the triangle. The demonstration of this, for the sake of brevity, we omit. It is to be found in several treatises, particularly in Clavius's Practical Geometry.

PROPOSITION XXXII.

FIG. 15. *The area of the ordinate figure ABEFGH in equal to the product of the half circumference of the polygon, multiplied into the perpendicular drawn from the centre of the circumscribed circle to the side of the polygon.*—For the ordinate figure can be resolved into as many equal triangles, as there are sides of the figure; and since each triangle is equal to the product of half the base into the perpendicular, it is evident that the sum of all the triangles together, that is the polygon, is equal to the product of half the sum of the bases (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the sides; for example, to AB.

PROPOSITION XXXIII.

FIG. 16. *The area of a circle is found by multiplying the half of the periphery into the radius, or the half of the radius into the periphery.*—For a circle is not different from an ordinate or regular polygon of an infinite number of sides, and the common height of the triangles into which the polygon or circle may be supposed to be divided is the radius of the circle.

Were it worth while, it were easy to demonstrate accurately this proposition, by means of the inscribed and circumscribed figures, as is done in the 5th prop. of the treatise of Archimedes concerning the dimensions of the circle.

COROLLARY.

Hence also it appears, that the area of the sector ABCD is produced by multiplying the half of the arc into the radius, and likewise that the area of the segment of the circle AIDC is found by subtracting from the area of the sector the area of the triangle ABC.

PROPOSITION XXXIV.

FIG. 17. *The circle is to the square of the diameter, as 11 to 14 nearly.*—For if the diameter AB be supposed to be 7, the circumference AHBK will be almost 22 (by the 22^d prop. of this Part), and the area of the square DC will be 49; and, by the preceding prop. the area of the circle will be $38\frac{1}{2}$; therefore the square DC will be to the inscribed circle as 49 to $38\frac{1}{2}$, or as 98 to 77, that is, as 14 to 11. Q. E. D.

If greater exactness is required, you may proceed to any degree of accuracy: for the square DC is to the inscribed circle, as 11 to $11 - \frac{1}{14} + \frac{1}{14} - \frac{1}{14} + \frac{1}{14} - \frac{1}{14} + \frac{1}{14}$, &c. in infinitum.

“This series will be of no service for computing the area of the circle accurately, without some further artifice, because it converges at too slow a rate.”
“The area of the circle will be found exactly enough for most purposes, by multiplying the square of the diameter by 7854, and dividing by 10,000, or cutting off four decimal places from the product; for the area of the circle is to the circumscribed square nearly as 7854 to 10,000.”

PROPOSITION XXXV.

FIG. 18. *To find the area of a given ellipse.*—Let ABCD be an ellipse, whose greater diameter is BD, and the lesser AC, bisecting the greater perpendicularly in E. Let a mean proportional HF be found (by 13th 6. Eucl.) between AC and BD, and (by the 33^d of this) find the area of the circle described on the diameter HF. This area is equal to the area of the ellipse ABCD. For because, as BD to AC, so the square of BD to the square of HF, (by 2. cor. 20th 6. Eucl.): but (by the 2^d 12. Eucl.) as the square of BD to the square of HF, so is the circle of the diameter BD to the circle of the diameter HF: therefore as BD to AC, so is the circle of the diameter BD to the circle of the diameter HF. And (by the 5th prop. of Archimedes of spheroids) as the greater diameter BD to the lesser AC, so is the circle of the diameter BD to the ellipse ABCD. Consequently (by the 11th 5. Eucl.) the circle of the diameter BD will have the same proportion to the circle of the diameter HF, and to the ellipse ABCD. Therefore, (by 9th 5. Eucl.) the area of the circle of the diameter HF will be equal to the area of the ellipse ABCD. Q. E. D.

SCHOLIUM.

From this and the two preceding propositions, a method is derived of finding the area of an ellipse. There are two ways: 1st, Say, as one is to the lesser diameter, so is the greater diameter to a fourth number, (which is found by the rule of three.) Then again say, as 14 to 11, so is the fourth number found to the area sought. But the second way is shorter. Multiply the lesser diameter into the greater, and the product by 11; then divide the whole product by 14, and the quotient will be the area sought of the ellipse. For example, Let the greater diameter be 10, and the lesser 7; by multiplying 10 by 7, the product is 70; and multiplying that by 11, it is 770; and dividing 770 by 14, the quotient will be 55, which is the area of the ellipse sought.

“The area of the ellipse will be found more accurately, by multiplying the product of the two diameters by 7854.”

We shall add no more about other plain surfaces, whether rectilinear or curvilinear, which seldom occur in practice; but shall subjoin some propositions about measuring the surfaces of solids.

PROPOSITION XXXVI.

To measure the surface of any prism.—By the 14th definition of the 11th Eucl. a prism is contained by planes, of which two opposite sides (commonly called the bases) are plain rectilinear figures; which are either regular and ordinate, and measured by prop. 32. of this; or however irregular, and then they are measured by the 28th prop. The other sides are parallelograms, which are measured by prop. 28th; and the whole superficies of the prism consists of the sum of those taken altogether.

PROPOSITION XXXVII.

To measure the superficies of any pyramid.—Since its basis is a rectilinear figure, and the rest of the planes terminating in the top of the pyramid are triangles; these measured separately, and added together, give the surface of the pyramid required.

PROPOSITION XXXVIII.

To measure the superficies of any regular body.—These bodies are called regular, which are bounded by equilateral and equiangular figures. The superficies of the tetraedon consists of four equal and equiangular triangles; the superficies of the hexaedron, or cube, of six equal squares; an octedron, of eight equal equilateral triangles; a dodecaedron, of twelve equal and ordinate pentagons; and the superficies of an icosaedron of twenty equal and equilateral triangles. Therefore it will be easy to measure these surfaces from what has been already shown.

In the same manner we may measure the superficies of a solid contained by any planes.

PROPOSITION XXXIX.

FIG. 19. To measure the superficies of a cylinder.—Because a cylinder differs very little from a prism, whose opposite planes (or bases) are ordinate figures of an infinite number of sides, it appears that the superficies of a cylinder, without the bases, is equal to an infinite number of parallelograms; the common altitude of all which is the same with the height of the cylinder, and the bases of them all differ very little from the periphery of the circle which is the base of the cylinder. Therefore this periphery multiplied into the common height, gives the superficies of the cylinder, excluding the bases; which are to be measured separately by the 33^d proposition.

This proposition concerning the measure of the surface of the cylinder (excluding its basis) is evident from this, that when it is conceived to be spread out, it becomes a parallelogram, whose base is the periphery of the circle of the base of the cylinder stretched into a right line, and whose height is the same with the height of the cylinder.

PROPOSITION XL.

FIG. 20. To measure the surface of a right cone.—The surface of a right cone is very little different from the surface of a right pyramid, having an ordinate polygon for its base of an infinite number of sides; the surface of which (excluding the base) is equal to the sum of the triangles. The sum of the bases of these triangles is equal to the periphery of the circle of the

base, and the common height of the triangles is the side of the cone AB; wherefore the sum of these triangles is equal to the product of the sum of the bases (*i. e.* the periphery of the base of the cone) multiplied into the half of the common height, or it is equal to the product of the periphery of the base.

If the area of the base is likewise wanted, it is to be found separately by the 33^d prop. If the surface of a cone is supposed to be spread out on a plane, it will become a sector of a circle, whose radius is the side of the cone; and the arc terminating, the sector is made from the periphery of the base. Whence, by corol. 33^d prop. of this, its dimension may be found.

COROLLARY.

Hence it will be easy to measure the surface of a frustrum of a cone cut by a plane parallel to the base.

PROPOSITION XLI.

FIG. 21. To measure the surface of a given sphere.—Let there be a sphere, whose centre is A, and let the area of its convex surface be required. Archimedes demonstrates (37th prop. 1. book of the sphere and cylinder) that its surface is equal to the area of four great circles of the sphere; that is, let the area of the great circle be multiplied by 4, and the product will give the area of the sphere; or, (by the 20th 6. and 2^d 12. of Eucl.) the area of the sphere given is equal to the area of a circle whose radius is the right line BC, the diameter of the sphere. Therefore having measured (by 33^d prop.) the circle described with the radius BC, this will give the surface of the sphere.

PROPOSITION XLII.

FIG. 22. To measure the surface of a segment of a sphere.—Let there be a segment cut off by the plane ED. Archimedes demonstrates (49. and 50. 1. De sphaera) that the surface of this segment, excluding the circular base, is equal to the area of a circle whose radius is the right line BE drawn from the vertex B of the segment to the periphery of the circle DE. Therefore, (by the 33^d prop.) it is easily measured.

COROLLARY.

Hence that part of the surface of a sphere that lieth between two parallel planes is easily measured, by subtracting the surface of the lesser segment from the surface of the greater segment.

COROLLARY 2.

Hence likewise it follows, that the surface of a cylinder, described about a sphere (excluding the basis) is equal to the surface of the sphere, and the parts of the one to the parts of the other, intercepted between planes parallel to the basis of the cylinder.

Of solid Figures and their Mensuration, comprehending likewise the Principles of Gauging Vessels of all Figures.

As in the former part of this treatise we took an inch for the smallest measure in length, and an inch square for the smallest superficial measure; so now, in treating of the mensuration of solids, we take a cubical inch for the smallest solid measure. Of these 109 make a Scots pint; other liquid measures depend on this, as is generally known.

In dry measures, the firlo, by statute, contains 19 $\frac{1}{2}$ pints; and on this depend the other dry measures: therefore, if the content of any solid be given in cubical

bical inches, it will be easy to reduce the same to the common liquid or dry measures, and conversely to reduce these to solid inches. The liquid and dry measures, in use among other nations, are known from their writers.

"As to the English liquid measures, by act of parliament 1706, any round vessel commonly called a cylinder, having an even bottom, being seven inches in diameter throughout, and six inches deep from the top of the inside to the bottom, (which vessel will be found by computation to contain $230\frac{2}{3}\frac{1}{2}$ cubical inches,) or any vessel containing 231 cubical inches, and no more, is deemed to be a lawful wine-gallon. An English pint therefore contains $28\frac{1}{2}$ cubical inches; 2 pints make a quart; 4 quarts a gallon; 18 gallons a roundlet; 3 roundlets and an half, or 63 gallons, make a hoghead; the half of a hoghead is a barrel; 1 hoghead and a third, or 84 gallons, make a puncheon; 1 puncheon and a half, or 2 hogheads, or 126 gallons, make a pipe or butt; the third part of a pipe, or 42 gallons, make a tierce; 2 pipes, or 3 puncheons, or 4 hogheads, make a ton of wine. Though the English wine gallon is now fixed at 231 cubical inches, the standard kept in Guildhall being measured, before many persons of distinction, May 23. 1688, it was found to contain only 224 such inches.

"In the English beer-measure, a gallon contains 282 cubical inches; consequently $35\frac{1}{2}$ cubical inches make a pint, 2 pints make a quart, 4 quarts make a gallon, 9 gallons a firkin, 4 firkins a barrel. In ale, 8 gallons make a firkin, and 32 gallons make a barrel. By an act of the first of William and Mary, 34 gallons is the barrel, both for beer and ale, in all places, except within the weekly bills of mortality.

"In Scotland it is known that 4 gills make a mutchkin, 2 mutchkins make a chopin; a pint is two chopins; a quart is two pints; and a gallon is four quarts, or eight pints. The accounts of the cubical inches contained in the Scots pint vary considerably from each other. According to our author, it contains 109 cubical inches. But the standard-jugs kept by the dean of guild of Edinburgh (one of which has the year 1555, with the arms of Scotland, and the town of Edinburgh, marked upon it) having been carefully measured several times, and by different persons, the Scots pint, according to those standards, was found to contain about $103\frac{1}{2}$ cubic inches. The pewterers jugs (by which the vessels in common use are made) are said to contain sometimes betwixt 105 and 106 cubic inches. A cask that was measured by the brewers of Edinburgh, before the commissioners of excise in 1707, was found to contain $46\frac{1}{2}$ Scots pints; the same vessel contained $18\frac{1}{2}$ English ale-gallons. Supposing this mensuration to be just, the Scots pint will be to the English ale-gallon as 289 to 750; and if the English ale-gallon be supposed to contain 282 cubical inches, the Scots pint will contain 108.664 cubical inches. But it is suspected, on several grounds, that the experiment was not made with sufficient care and exactness.

"The commissioners appointed by authority of parliament to settle the measures and weights, in their

act of Feb. 19. 1618, relate, That having caused fill the Linlithgow firloft with water, they found that it contained $21\frac{1}{2}$ pints of the just Stirling jug and measure. They likewise ordain that this shall be the just and only firloft; and add, *That the wideness and breadth of the which firloft, under and above even over within the buirds, shall contain nineteen inches and the sixth part of an inch, and the deepness seven inches and a third part of an inch.* According to this act (supposing their experiment and computation to have been accurate) the pint contained only 99.56 cubical inches; for the content of such a vessel as is described in the act, is 2115.85, and this divided by $21\frac{1}{2}$ gives 99.56. But, by the weight of water said to fill this firloft in the same act, the measure of the pint agrees nearly with the Edinburgh standard above mentioned.

"As for the English measures of corn, the Winchester gallon contains $272\frac{1}{2}$ cubical inches; 2 gallons make a peck; 4 pecks, or 8 gallons (that is, 2178 cubical inches) make a bushel; and a quarter is 8 bushels.

"Our author says, that $19\frac{1}{2}$ Scots pints make a firloft. But this does not appear to be agreeable to the statute above-mentioned, nor to the standard-jugs. It may be conjectured that the proportion assigned by him has been deduced from some experiment of how many pints, according to common use, were contained in the firloft. For if we suppose those pints to have been each of 108.664 cubical inches, according to the experiment made in the 1707 before the commissioners of excise, described above; then $19\frac{1}{2}$ such pints will amount to 2118.94, cubical inches; which agrees nearly with 2115.85, the measure of the firloft by statute above-mentioned. But it is probable, that in this he followed the act 1587, where it is ordained, That the wheat-firloft shall contain 19 pints and two joucates. A wheat-firloft marked with the Linlithgow stamps being measured, was found to contain about 2211 cubical inches. By the statute of 1618 the barley-firloft was to contain 31 pints of the just Stirling-jug.

"A Paris pint is 48 cubical Paris inches, and is nearly equal to an English wine-quart. The *Boisseau* contains 644.68099 Paris cubical inches, or 780.36 English cubical inches.

"The Roman *amphora* was a cubical Roman foot, the *congius* was the eighth part of the *amphora*, the *sextarius* was one sixth of the *congius*. They divided the *sextarius* like the *as* or *libra*. Of dry measures, the *medimnus* was equal to two *amphoras*, that is, about $1\frac{1}{2}$ English legal bushels; and the *modius* was the third part of the *amphora*."

PROPOSITION XLIII.

To find the solid content of a given prism.—By the 29th prop. let the area of the base of the prism be measured, and be multiplied by the height of the prism, the product will give the solid content of the prism.

PROPOSITION XLIV.

To find the solid content of a given pyramid.—The area of the base being found, (by the 30th prop.) let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, the product will give the solid content, by 17th 12. Eucl.

C O R.

COROLLARY.

If the solid content of a *frustum* of a pyramid is required, first let the solid content of the entire pyramid be found; from which subtract the solid content of the part that is wanting, and the solid content of the broken pyramid will remain.

PROPOSITION XLV.

To find the content of a given cylinder.—The area of the base being found by prop. 33. if it be a circle, and by prop. 35. if it be an ellipse, (for in both cases it is a cylinder), multiply it by the height of the cylinder, and the solid content of the cylinder will be produced.

COROLLARY.

FIG. 23. And in this manner may be measured the solid content of vessels and calks not much different from a cylinder, as ABCD. If towards the middle EF it be somewhat grosser, the area of the circle of the base being found (by 33^d prop.) and added to the area of the middle circle EF, and the half of their sum (that is, an arithmetical mean between the area of the base and the area of the middle circle) taken for the base of the vessel, and multiplied into its height, the solid content of the given vessel will be produced.

Note, That the length of the vessel, as well as the diameters of the base, and of the circle EF, ought to be taken within the flaves; for it is the solid content within the flaves that is sought.

PROPOSITION XLVI.

To find the solid content of a given cone.—Let the area of the base (found by prop. 33.) be multiplied into $\frac{1}{3}$ of the height, the product will give the solid content of the cone; for by the 10th 12. Eucl. a cone is the third part of a cylinder that has the same base and height.

PROPOSITION XLVII.

FIG. 24. 25. To find the solid content of a frustum of a cone cut by a plane parallel to the plane of the base.—First, let the height of the entire cone be found, and thence (by the preceding prop.) its solid content; from which subtract the solid content of the cone cut off at the top, there will remain the solid content of the *frustum* of the cone.

How the content of the entire cone may be found, appears thus: Let ABCD be the *frustum* of the cone (either right or scalenous, as in the figures 2. and 3.) let the cone ECD be supposed to be completed; let AG be drawn parallel to DE, and let AH and EF be perpendicular on CD; it will be (by 2^d 6. Eucl.) as CG : CA :: CD : CE; but (by art. 72. of Part. I.) as CA : AH :: CE : EF; consequently (by 22^d 5. Eucl.) as CG : AH :: CD : EF; that is, as the excess of the diameter of the lesser base is to the height of the *frustum*, so is the diameter of the greater base to the height of the entire cone.

COROLLARY.

FIG. 26. Some calks whose flaves are remarkably bended about the middle, and strain towards the ends, may be taken for two portions of cones, without any considerable error. Thus AB EF is a *frustum* of a right cone, to whose base EF, on the other side, there is another similar *frustum* of a cone joined, EDC F. The vertices of these cones, if they be supposed to be completed, will be found at G and H. Whence, (by the

preceding proposition) the solid content of such vessels may be found.

PROPOSITION XLVIII.

FIG. 27. A cylinder circumscribed about a sphere, that is, having its base equal to a great circle of the sphere, and its height equal to the diameter of the sphere, is to the sphere as 3 to 2.

Let ABEC be the quadrant of a circle, and ABDC the circumscribed square; and likewise the triangle ADC; by the revolution of the figure about the right line AC, as axis, a hemisphere will be generated by the quadrant, a cylinder of the same base and height by the square, and a cone by the triangle. Let these three be cut any how by the plane HF, parallel to the base AB; the section in the cylinder will be a circle whose radius is FH, in the hemisphere a circle of the radius EF, and in the cone a circle of the radius GF.

By (art. 69. of Part I.) EAq , or $HFG = EFq$ and FAq taken together, (but $AFq = FGq$, because $AC = CD$); therefore the circle of the radius FH is equal to a circle of the radius EF, together with a circle of the radius GF; and since this is true every where, all the circles together described by the respective radii HF (that is, the cylinder) are equal to all the circles described by the respective radii EF and FG (that is, to the hemisphere and the cone taken together; but, (by the 10th 12. Eucl.) the cone generated by the triangle DAC is one third part of the cylinder generated by the square BC. Whence it follows, that the hemisphere generated by the rotation of the quadrant ABEC is equal to the remaining two third parts of the cylinder, and that the whole sphere is $\frac{2}{3}$ of the double cylinder circumscribed about it.

This is that celebrated 39th prop. 1. book of Archimedes of the sphere and cylinder; in which he determines the proportion of the cylinder to the sphere inscribed to be that of 3 to 2.

COROLLARY.

Hence it follows, that the sphere is equal to a cone whose height is equal to the semidiameter of the sphere, having for its base a circle equal to the superficies of the sphere, or to four great circles of the sphere, or to a circle whose radius is equal to the diameter of the sphere, (by prop. 41. of this.) And indeed a sphere differs very little from the sum of an infinite number of cones that have their bases in the surface of the sphere, and their common vertex in the centre of the sphere; so that the superficies of the sphere, (of whose dimension see prop. 41. of this) multiplied into the third part of the semidiameter, gives the solid content of the sphere.

PROPOSITION XLIX.

FIG. 28. To find the solid content of a sector of the sphere.—A spherical sector ABC (as appears by the corollary of the preceding prop.) is very little different from an infinite number of cones, having their bases in the superficies of the sphere BEC, and their common vertex in the centre. Wherefore the spherical superficies BEC being found, (by prop. 42. of this,) and multiplied into the third part of AB the radius of the sphere, the product will give the solid content of the sector ABC.

COROLLARY.

It is evident how to find the solidity of a spherical segment

segment less than a hemisphere, by subtracting the cone ABC from the sector already found. But if the spherical segment be greater than a hemisphere, the cone corresponding must be added to the sector, to make the segment.

PROPOSITION L.

FIG. 29. *To find the solidity of the spheroid, and of its segments cut by planes perpendicular to the axis.*—

In prop. 44. of this, it is shewn, that every where $EH : EG :: CF : CD$; but circles are as the squares described upon their rays, that is, the circle of the radius EH is to the circle of the radius EG, as CFg to CDg . And since it is so every where, all the circles described with the respective rays EH, (that is, the spheroid made by the rotation of the semi-elliptis AFB around the axis AB,) will be to all the circles described by the respective radii EG, (that is, the sphere described by the rotation of the semicircle ADB on the axis AB,) as ECg to CDg ; that is, as the spheroid to the sphere on the same axis, so is the square of the other axis of the generating ellipse to the square of the axis of the sphere.

And this holds, whether the spheroid be found by a revolution around the greater or lesser axis.

COROLLARY 1.

Hence it appears, that the half of the spheroid, formed by the rotation of the space AHFC around the axis AC, is double of the cone generated by the triangle AFC about the same axis; which is the 32^d prop. of Archimedes of conoids and spheroids.

COROLLARY 2.

Hence, likewise, is evident the measure of segments of the spheroid cut by planes perpendicular to the axis. For the segment of the spheroid made by the rotation of the space ANHE, round the axis AE, is to the segment of the sphere having the same axis AC, and made by the rotation of the segment of the circle AMGE, as CFg to CDg .

But if the measure of this solid be wanted with less labour, by the 34th prop. of Archimedes of conoids and spheroids, it will be as BE to AC+EB; so is the cone generated by the rotation of the triangle AHE round the axis AE, to the segment of the sphere made by the rotation of the space ANHE round the same axis AE; which could easily be demonstrated by the method of indivisibles.

COROLLARY 3.

Hence it is easy to find the solid content of the segment of a sphere or spheroid intercepted between two parallel planes, perpendicular to the axis. This agrees as well to the oblate as to the oblong spheroid; as is obvious.

COROLLARY 4.

FIG. 30. If a cask is to be valued as the middle piece of an oblong spheroid, cut by the two planes DC and FG, at right angles to the axis: first, let the solid content of the half spheroid ABCD be measured by the preceding prop. from which let the solidity of the segment DEC be subtracted, and there will remain the segment ABCD; and this doubled will give the capacity of the cask required.

The following method is generally made use of for finding the solid content of such vessels. The double area of the greatest circle, that is, of that which is de-

scribed by the diameter AB at the middle of the cask, is added to the area of the circle at the end, that is, of the circle DC or FG (for they are usually equal), and the third part of this sum is taken for a mean base of the cask; which therefore multiplied into the length of the cask OP, gives the content of the vessel required.

Sometimes vessels have other figures, different from those we have mentioned; the easy methods of measuring which may be learned from those who practise this art. What hath already been delivered, is sufficient for our purpose.

PROPOSITION LI.

FIG. 31. and 32. *To find how much is contained in a vessel that is in part empty, whose axis is parallel to the horizon.*—Let AGBH be the great circle in the middle of the cask, whose segment GBH is filled with liquor, the segment GAH being empty; the segment GBH is known, if the depth EB be known, and EH a mean proportional between the segments of the diameter AB and EB; which are found by a rod or ruler put into the vessel at the orifice. Let the basis of the cask, at a medium, be found, which suppose to be the circle CKDL; and let the segment KCL be similar to the segment GAH (which is either found by the rule of three, because as the circle AGBH is to the circle CKDL, so is the segment GAH to the segment KCL; or is found from the tables of segments made by authors); and the product of this segment multiplied by the length of the cask will give the liquid content remaining in the cask.

PROPOSITION LII.

To find the solid content of a regular and ordinate body.—A tetraedon being a pyramid, the solid content is found by the 44th prop. The hexaedron, or cube, being a kind of prism, it is measured by the 43^d prop. An octaedron consists of two pyramids of the same square base and of equal heights; consequently its measure is found by the 44th prop. A dodecaedron consists of 12 pyramids having equal equilateral and equiangular pentagonal bases; and so one of these being measured (by the 44th prop. of this) and multiplied by 12, the product will be equal to the solid content of the dodecaedron. The icosaedron consists of 20 equal pyramids having triangular bases; the solid content of one of which being found (by the 44th prop.) and multiplied by 20, gives the whole solid. The bases and heights of these pyramids, if you want to proceed more exactly, may be found by trigonometry. See TRIGONOMETRY.

PROPOSITION LIII.

To find the solid content of a body, however irregular.—Let the given body be immersed into a vessel of water, having the figure of a parallelepipedon or prism, and let it be noted how much the water is raised upon the immersion of the body. For it is plain, that the space which the water fills, after the immersion of the body, exceeds the space filled before its immersion, by a space equal to the solid content of the body, however irregular. But when this excess is of the figure of a parallelepipedon or prism, it is easily measured by the 43^d prop. of this, viz. by multiplying the area of the base, or mouth of the vessel, into the difference of the elevations of the water before and after

after immersion: Whence is found the solid content of the body given.

In the same way the solid content of a part of a body may be found, by immersing that part only in water.

There is no necessity to insist here on diminishing or enlarging solid bodies in a given proportion. It will be easy to deduce these things from the 11th and 12th books of Euclid.

"The following rules are subjoined for the ready computation of the contents of vessels, and of any solids in the measures in use in Great Britain.

"I. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and altitude of the vessel being given in inches and decimals of an inch.

"Square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height: then multiply the product by the decimal fraction .0034; and this last product shall give the content in wine-gallons and decimals of such a gallon. To express the rule arithmetically; let D represent the number of inches and decimals of an inch in the diameter of the vessel, and H the inches and decimals of an inch in the height of the vessel; then the content in wine-gallons shall be $DDH \times \frac{1}{10000}$, or $DDH \times .0034$. Ex. Let the diameter $D = 51.2$ inches, the height $H = 62.3$ inches, then the content shall be $51.2 \times 51.2 \times 62.3 \times .0034 = 555.27.332$ wine-gallons. This rule follows from prop. 33. and 45. For, by the former, the area of the base of the vessel is in square inches $DD \times .7854$; and by the latter, the content of the vessel in solid inches is $DDH \times .7854$; which divided by 231 (the number of cubical inches in a wine-gallon) gives $DDH \times .0034$, the content in wine-gallons. But though the charges in the excise are made (by statute) on the supposition that the wine-gallon contains 231 cubical inches; yet it is said, that in sale, 224 cubical inches, the content of the standard measured at Guildhall (as was mentioned above), are allowed to be a wine-gallon.

"II. Supposing the English ale-gallon to contain 282 cubical inches, the content of a cylindric vessel is computed in such gallons, by multiplying the square of the diameter of a vessel by its height as formerly, and their product by the decimal fraction .0027,851: that is, the solid content in ale-gallons is $DDH \times .0027,851$.

"III. Supposing the Scots pint to contain about 103.4 cubical inches, (which is the measure given by the standards at Edinburgh, according to experiments mentioned above), the content of a cylindric vessel is computed in Scots pints, by multiplying the square of the diameter of the vessel by its height, and the product of these by the decimal fraction .0076. Or the content of such a vessel in Scots pints is $DDH \times .0076$.

"Supposing the Winchester bushel to contain 2187 cubical inches, the content of a cylindric vessel is computed in those bushels by multiplying the square of the diameter of the vessel by the height, and the product by the decimal fraction .0003,606. But the standard bushel having been measured by Mr Everard and others in 1696, it was found to contain

"only 2145.6 solid inches; and therefore it was enacted in the act for laying a duty upon malt, That every round bushel, with a plain and even bottom, being 18½ inches diameter throughout, and 8 inches deep, should be esteemed a legal Winchester bushel. According to this act (ratified in the first year of queen Anne) the legal Winchester bushel contains only 2150.42 solid inches. And the content of a cylindric vessel is computed in such bushels, by multiplying the square of the diameter by the height, and their product by the decimal fraction .0003,625. Or the content of the vessel in those bushels is $DDH \times .0003,625$.

"V. Supposing the Scots wheat-firlet to contain 21½ Scots pints, (as is appointed by the statute 1618), and the pint to be conform to the Edinburgh standards above mentioned, the content of a cylindric vessel in such firlets is computed by multiplying the square of the diameter by the height, and their product by the decimal fraction .00358. This firlet, in 1426, is appointed to contain 17 pints; in 1457, it was appointed to contain 18 pints; in 1587, it is 19½ pints; in 1628, it is 21½ pints: and though this last statute appears to have been founded on wrong computations in several respects, yet this part of the act that relates to the number of pints in the firlet seems to be the least exceptionable; and therefore we suppose the firlet to contain 21½ pints of the Edinburgh standard, or about 2197 cubical inches; which a little exceeds the Winchester bushel, from which it may have been originally copied.

"VI. Supposing the bear-firlet to contain 31 Scots pints, (according to the statute 1618), and the pint conform to the Edinburgh standards, the content of a cylindric vessel in such firlets is found by multiplying the square of the diameter by the height, and this product by .00245.

"When the section of the vessel is not a circle, but an ellipsis, the product of the greatest diameter by the least, is to be substituted in those rules for the square of the diameter.

"VII. To compute the content of a vessel that may be considered as a *frustum* of a cone in any of those measures.

"Let A represent the number of inches in the diameter of the greater base, B the number of inches in the diameter of the lesser base. Compute the square of A, the product of A multiplied by B, and the square of B, and collect these into a sum. Then find the third part of this sum, and substitute it in the preceding rules in the place of the square of the diameter; and proceed in all other respects as before. Thus, for example, the content in wine-gallons in $AA \times AB \times BB \times \frac{1}{3} \times H \times .0034$.

"Or, to the square of half the sum of the diameters A and B, add one third part of the square of half their difference, and substitute this sum in the preceding rules for the square of the diameter of the vessel; for the square of $\frac{1}{2} A \times \frac{1}{2} B$ added to $\frac{1}{3}$ of the square of $A - B$, gives $\frac{1}{3} AA \times \frac{1}{3} AB \times \frac{1}{3} BB$.

"VIII. When a vessel is a *frustum* of a parabolic conoid, measure the diameter of the section at the

" middle of the height of the *frustum*; and the content will be precisely the same as of a cylinder of this diameter, of the same height with the vessel.

" IX. When a vessel is a *frustum* of a sphere, if you measure the diameter of the section at the middle of the height of the *frustum*, then compute the content of a cylinder of this diameter of the same height with the vessel, and from this subtract $\frac{1}{4}$ of the content of a cylinder of the same height, on a base whose diameter is equal to its height; the remainder will give the content of the vessel. That is, if D represent the diameter of the middle section, and H the height of the *frustum*, you are to substitute $DD - \frac{1}{4} HH$ for the square of the diameter of the cylindric vessel in the first six rules.

" X. When the vessel is a *frustum* of a spheroid, if the bases are equal, the content is readily found by the rule in p. (24.) In other cases, let the axis of the solid be to the conjugate axis as n to 1; let D be the diameter of the middle section of the *frustum*, H the height or length of the *frustum*; and substitute in the first six rules $DD - \frac{HH}{3nn}$ for the square of the diameter of the vessel.

" XI. When the vessel is an hyperbolic conoid, let the axis of the solid be to the conjugate axis as n to 1, D the diameter of the section at the middle of the *frustum*, H the height or length: compute $DD \times \frac{1}{3n} \times HH$, and substitute this sum for the square of the diameter of the cylindric vessel in the first six rules.

" XII. In general, it is usual to measure any round vessel, by distinguishing it into several *frustums*, and taking the diameter of the section at the middle of each *frustum*; thence to compute the content of each, as if it was a cylinder of that mean diameter; and to give their sum as the content of the vessel. From the total content, computed in this manner, they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the *frustum* to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry or wet inches; having regard to the inclination or drip of the vessel, when it has any.

" This method of computing the content of a *frustum* from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use, the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same, in the different parts of the same or of similar vessels, when the altitude of the *frustum* is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactness be required, the error in measuring the *frustum* of a conical vessel, in this manner, is $\frac{1}{4}$ of the content of a cone

" similar to the vessel, of an altitude equal to the height of the *frustum*. In a sphere, it is $\frac{1}{4}$ of a cylinder of a diameter and height equal to the *frustum*. In the spheroid and hyperbolic conoid, it is the same as in a cone generated by the right-angled triangle, contained by the two semiaxes of the figure, revolving about that side which is the semiaxis of the *frustum*.

" In the usual method of computing a table for a vessel, by subtracting from the whole content the number that expresses the uppermost area, as often as there are inches in the uppermost *frustum*, and afterwards the numbers for the other areas successively; it is obvious, that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high, if the vessel stands on its lesser base, but too low when it stands on its greater base; because, when one inch is dry, for example, it is not the area at the middle of the uppermost *frustum*, but rather the area at the middle of the uppermost inch, that ought to be subtracted from the total content, in order to find the content in this case.

" XIII. To measure round timber: Let the mean circumference be found in feet and decimals of a foot; square it; multiply this square by the decimal .079,577, and the product by the length. Ex. Let the mean circumference of a tree be 10 3 feet, and the length 24 feet. Then $10 3 \times 10 3 \times .079,577 \times 24 = 202.615$, is the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is .0795,774,715, and that the areas of circles are as the squares of their circumferences.

" But the common way used by artificers for measuring round timber, differs much from this rule. They call one fourth part of the circumference the *girt*, which is by them reckoned the side of a square, whose area is equal to the area of the section of the tree; therefore they square the *girt*, and then multiply by the length of the tree. According to their method, the tree of the last example would be computed at 159.13 cubical feet only.

" How square timber is measured, will be easily understood from the preceding propositions. Fifty solid feet of hewn timber, and forty of rough timber, make a load.

" XIV. To find the burden of a ship, or the number of tons it will carry, the following rule is commonly given. Multiply the length of the keel taken within board, by the breadth of the ship within board, taken from the midship beam from plank to plank, and the product by the depth of the hold, taken from the plank below the keelson to the under part of the upper deck plank, and divide the product by 94, the quotient is the content of the tonnage required. This rule however cannot be accurate; nor can one rule be supposed to serve for the measuring exactly the burden of ships of all sorts. Of this the reader will find more in the Memoirs of the Royal Academy of Sciences at Paris, for the year 1721.

" Our author having said nothing of weights, it may be of use to add briefly, that the English Troy-

" Troy-pound contains 12 ounces, the ounce 20 penny-weight, and the penny-weight 24 grains; that the Averdupois pound contains 16 ounces, the ounce 16 drams, and that 112 pounds is usually called the hundred weight. It is commonly supposed, that 14 pounds Averdupois are equal to 17 pounds Troy. According to Mr Everard's experiments, 1 pound Averdupois is equal to 14 ounces 12 penny-weight and 16 grains Troy, that is, to 7000 grains; and an Averdupois ounce is 437½ grains. The Scots Troy-pound (which, by the statute 1718, was to be the same with the French) is commonly supposed equal to 15½ ounces English Troy, or 7560 grains. By a mean of standards kept by the dean of guild at Edinburgh, it is 7599½ or 7600 grains. They who have measured the weights

" which were sent from London, after the union of the kingdoms, to be the standards by which the weights in Scotland should be made, have found the English Averdupois pound (from a medium of the several weights) to weigh 7000 grains, the same as Mr Everard; according to which, the Scots, Paris, or Amsterdam pound, will be to the pound Averdupois as 38 to 35. The Scots Troy-lbne contains 16 pounds, the pound 2 marks or 16 ounces, an ounce 16 drops, a drop 36 grains. Twenty Scots ounces make a Tron-pound; but because it is usual to allow one to the score, the Tron-pound is commonly 21 ounces. Sir John Skene, however, makes the Tron-lbne to contain only 19½ pounds."

George.

G E O

G E O

George.

GEORGE I. II. and III. kings of Great Britain. —George I. the son of Ernest Augustus, duke of Brunfwick Lunenburgh, and elector of Hanover; succeeded to the throne of Great Britain in 1714, in virtue of an act of parliament, passed in the latter part of the reign of king William III. limiting the succession of the crown, after the demise of that monarch, and queen Anne (without issue), to the princess Sophia of Hanover, and the heirs of her body, being Protestants. —George II. the only son of the former, succeeded him in 1727, and enjoyed a long rein of glory; dying amidst the most rapid and extensive conquests in the 77th year of his age. He was succeeded by his grandson George III. our present sovereign. For particulars, see BRITAIN, n° 369, —458.

GEORGE, or *Knights of St GEORGE*, has been the denomination of several military orders, whereof that of the garter is one of the most illustrious. See GARTER.

King GEORGE's Islands, are two islands in the South Sea, lying in W. Long. 144. 56. S. Lat. 14. 28. They were first discovered by commodore Byron in 1765, and have since been visited by Captain Cook in 1774. Commodore Byron's people had an encounter with the inhabitants, which proved fatal to some of the natives; but Captain Cook was more fortunate. A lieutenant and two boats well armed were sent on shore by Captain Cook; and landed without opposition. As soon as the gentlemen landed, the islanders embraced them by touching noses, a mode of civility used in New Zealand, which is 900 leagues distant, and the only place besides this where the custom has been observed to prevail. Notwithstanding this ceremony, however, very little real friendship seemed to take place on the part of the islanders. They crowded about the boats as the people were stepping into them, and seemed in doubt whether they should detain them or let them go; at last, however, not thinking themselves sufficiently strong, they seemed contented with their departure, and assisted them in pushing off their boats; but some of the most turbulent threw stones into the water which fell very near them, and all seemed to glory that they had as it were driven them off. The British, however, brought off five dogs of a white colour with fine long hair, with which the island seemed to be plentifully supplied. These they purchased with small nails, and some ripe bananas which had been brought from the Marquesas.

On this island Mr Forester found a kind of scurvy-grass, which the natives informed him they were wont to bruise and mix with shell-fish; after which, they threw it into the sea whenever they perceived a shoal of fish. This preparation intoxicates them for some time; and thus they are caught on the surface of the water without any other trouble than that of taking them out. The name of this plant among the natives is *e novu*. The largest island, which they call *Tiookea*, is something of an oval shape, and about ten leagues in circuit; the other island, which lies two leagues to the westward of Tiookea, is four leagues long from north-east to south-west, and from five to three miles long. The soil of both is extremely scanty; the foundation consists of coral, very little elevated above the surface of the water.

St GEORGE del Mina, the capital of the Dutch settlements, on the gold-coasts of Guinea, situated seven or eight miles west of Cape-coast castle, the capital of the British settlements there. W. Long. 5° and N. Lat. 5°.

St GEORGE, a fort and town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel, belonging to the English; it is otherwise called *Madrasi*, and by the natives *Chili-palam*. It fronts the sea, and has a salt-water river on its back side, which hinders the fresh-water springs from coming near the town, so that they have no good water within a mile of them. In the rainy seasons it is incommoded by inundations; and from April to September it is so scorching hot, that if the sea-breezes did not cool the air, there would be no living there. There are two towns, one of which is called the *White Town*, which is walled round, and has several bulwarks and bastions to defend it: it is 400 paces long and 150 broad, and is divided into regular streets. Here are two churches, one for the Protestants, and the other for the Papists; as also a good hospital, a town-hall, and a prison for debtors. They are a corporation, and have a mayor and aldermen, with other proper officers. The *Black Town* is inhabited by Gentoos, Mahometans, and Portuguese and Armenian Christians, and each religion have their temples and churches. This, as well as the White Town, is ruled by the English governor and his council. The diamond-mines are but a week's journey from this place, which renders them pretty plentiful,

but there are no large ones since that great diamond was procured by governor Pitt. This colony produces very little of its own growth or manufacture for foreign markets, and the trade is in the hands of the Armenians and Gentoos. The chief things the British deal in, besides diamonds, are calicoes, chintz, muslins, and the like. This colony may consist of 80,000 inhabitants in the towns and villages, and there are generally 400 or 500 Europeans. Their rice is brought by sea to Gangam and Oriza, their wheat from Surat and Bengal, and their fire-wood from the islands of Diu: so that an enemy, with a superior force at sea, may easily distress them. The houses of the White Town are built with brick, and have lofty rooms and flat roofs; but the Black Town consists chiefly of thatched cottages. The military power is lodged in the governor and council, who are also the last resort in civil causes. The company have two chaplains, who officiate by turns, and have each 100*l.* a-year, besides the advantages of trade. They never attempt to make proselytes, but leave that to the Popish missionaries. The salaries of the company's writers are very small: but, if they have any fortune of their own, they may make it up by trade; which must generally be the case, for they commonly grow rich. It was taken by the French in 1746, who restored it to the peace of Aix la Chapelle.

St GEORGE'S, the largest of the Bermuda or Summer islands. W. Long. 65. 10. N. Lat. 32. 30.

Cross of St GEORGE, a red one in a field argent, which makes part of the British standard.

GEORGIA, a country of Asia, subject to the Turks. It is bounded on the north by Circassia, on the east by Daghestan and Shirvan, on the south by Armenia, and on the west by the Euxine or Black Sea; comprehending the greatest part of the ancient Colchis, Iberia, and Albania. About the etymon of the name of this country, authors are not agreed. The most probable opinion is, that it is a corruption softening of *Kurgia*, from the river Kur; whence also it is supposed that the inhabitants are called by the Persians indifferently *Georgi*, *Gurgi*, and *Kurgi*; and the country *Kurgistan* and *Gurgistan*: It is divided by a ridge of mountains into eastern and western; the former of which is again subdivided into the kingdoms of Caket, Carduel or Carthuel, and Goguetia; and the latter into the provinces of Abcassia, Mireta, or Imaretta, and Guriel. Another division is into Georgia Proper, Abcassia, and Mingrelia.

"Georgia (says Sir John Chardin) is as fertile a country as can be seen; the bread is as good here as in any part of the world; the fruit of an exquisite flavour, and of different sorts; no place in Europe yields better pears and apples, and no place in Asia better pomegranates. The country abounds with cattle, venison, and wild-fowl, of all sorts; the river Kuris is well stocked with fish; and the wine is so rich, that the king of Persia has always some of it for his own table. The inhabitants are robust, valiant, and of a jovial temper; great lovers of wine, and esteemed very trusty and faithful; endowed with good natural parts, but, for want of education, very vicious. The women are generally so fair and comely, that the wives and concubines of the king of Persia and his court are for the most part Georgian women. Nature has adorned them

with graces no where else to be met with; it is impossible to see them without loving them; they are of a good size, clean-limbed, and well-shaped." Another traveller, however, of no mean character, thus expresses himself with respect to the women: "As to the Georgian women, they did not at all surprize us; for we expected to find them perfect beauties. They are, indeed, no way disagreeable; and may be counted beauties, if compared with the Curdes. They have an air of health that is pleasing enough; but, after all, they are neither so handsome nor so well shaped as is reported. Those who live in the towns have nothing extraordinary, more than the others; so that I may, I think, venture to contradict the accounts that have been given of them by most travellers."

Georgia abounds with woods and mountains, intermixed with a great number of beautiful plains.

The only rivers of note in this country are the Cyrus, Cyrrus, Corus, or Kur, and the Aragus. The first springs from the Moschian mountains, which separate Colchis from Armenia, waters the country now called *Mokan*, and, after receiving into its channel the Aragus and Araxes, falls by one mouth into the Caspian sea. This river is navigable the greatest part of its course. The Aragus springs from the mountains that separate Iberia from Colchis, and falls into the Cyrus.

Iberia, or Georgia, is tributary or subject either to the Porte or the king of Persia, and known to the Persians by the name of Gurgistan, that is, "the land of the Georgians;" for *tanis* is an ancient Celtic word, signifying a country, and still in use among the eastern nations, as appears from the modern names of Curdestan, Indostan, &c. that is, the country of the Curdes, of the Indians, &c.

The whole country of Georgia is but thinly inhabited, and has but very few cities in proportion to its extent and fertility; which is doubtless in a great measure owing to the barbarous and unnatural traffic carried on here in boys and girls, parents selling their children, masters their servants, and lords their vassals and tenants. Every one, in short, trades in the males and females he is master of, and disposes of them to the Turks and Persians, who employ them in their armies and seragios, as slaves, mutes, eunuchs, soldiers, statesmen, and concubines, according to their capacities, and the favour they have obtained with their masters.

This country formerly abounded with great cities, as appears not only from its history, but from the ruins of many of them still visible, which shew that they must have been very large, opulent, and magnificently built. These were all destroyed by the inundations of northern barbarians from mount Caucasus, as the A-lans, Huns, Suevi, and some others, so much noted in history for their strength, courage, and conquests.

The air of Georgia is serene, dry, and healthful; but very cold in winter, and hot in summer.

The fine weather commonly begins about May, and lasts till November. But the lands want a good deal of watering to make them produce a plentiful crop; when they yield all sorts of grain, fruit, and pulse, in abundance, which sell at so cheap a rate that the people want for nothing. The cattle, both small and great, are fat and good, and in great numbers; but the common

Georgia. mon people live mostly on swine's flesh, which is every where excellent, and, by their own account, wholesome and of easy digestion. The river Kur, as well as the Caspian sea, which lies east of Georgia, supplies it with plenty and variety of fish.

The mountains of Caucasus, that lie partly in this country, are known at present to the inhabitants by the names of *Cochas* and *Cochias*, which are, without doubt, a corruption of the ancient. The Arabs call them the *Mountains of Raf*.

The inhabitants are civil enough to strangers, allowing them to live and trade as they please, and to profess what religion they have a mind: hence people of various nations are seen here, as Turks, Armenians, Persians, Jews, Greeks, Indians, Tartars, Russians, and other Europeans. But the Armenians are the most numerous; and, by carrying on the greatest part of the trade, are also the richest; for which reason the Georgians hate and despise them, regarding them in much the same light as the Europeans do the Jews. The Georgians wear four caps on their heads, and a kind of long vest, open before, but which may be buttoned at pleasure; their breeches and under-garments are like those of the Persians, as is the entire dress of the women.

Their houses, especially those of the better sort, are also after the model of those of Persia, as well as all their public buildings: and they may afford to have them built after the best manner, having not only stone, wood, plaster, lime, and all other materials, in the greatest plenty and cheapness; but also can have the most laborious work done by their own vassals, over whom they have such an absolute power, that they can keep them employed whole months together, without allowing them either wages or food.

Iberia, or Georgia, according to Josephus, was first peopled by Tubal, the brother of Gomer and Magog. His opinion is confirmed by the Septuagint; for Meshech and Tubal are by these interpreters rendered *Moschi* and *Iberians*. We know little of the history of the country till the reign of Mithridates, when their king, named *Artocius*, siding with that prince against Lucullus, and afterwards against Pompey, was defeated by the latter, with great slaughter; but afterwards obtained a peace, upon delivering up his sons as hostages. Little notice is taken of the succeeding kings by the ancient historians. They were probably tributary to the Romans till that empire was overturned, when this, with the other countries in Asia bordering on it, fell successively under the power of the Saracens and Turks. A certain prince of Georgia, named *Heraclius*, has lately made a great noise, and a considerable progress in his endeavours to shake off the Turkish yoke, having, according to advices from the east, several times defeated the Ottoman troops: but it seems either his former good fortune forsook him, or an accommodation took place; for all the intelligence from that part of the world, for some time past, hath been entirely silent with regard to him.

The capital of the country is *TEFLIS*; for an account of which, see that article.

GEORGIA, one of the provinces of the British empire in America, lying between South Carolina and Florida. It extends 120 miles upon the sea-coast, and 300 miles from thence to the Apalachian moun-

tains, and its boundaries to the north and south are the rivers Savannah and Altamaha. The British ministry had been long desirous of erecting a colony on this tract of country, that was considered as dependent upon Carolina. One of those influences of benevolence, which liberty, the source of every patriotic virtue, renders more frequent in Britain than in any other country, served to determine the views of government with regard to this place. A rich and humane citizen, at his death, left the whole of his estate to set at liberty such insolvent debtors as were detained in prison by their creditors. Prudential reasons of policy concurred in the performance of this will dictated by humanity; and the government gave orders, that such unhappy prisoners as were released, should be transplanted into that desert country, which was now intended to be peopled. It was named *Georgia*, in honour of the reigning sovereign.

The parliament added 9,843 l. 15 s. to the estate left by the will of a citizen; and a voluntary subscription produced a much more considerable sum. General Oglethorpe was fixed upon to direct these public finances, and to carry into execution so excellent a project. He chose to conduct, himself, the first colonists that were sent to Georgia; where he arrived in January 1733, and fixed his people on a spot ten miles distant from the sea, in an agreeable and fertile plain on the banks of the Savannah. This rising settlement was called *Savannah*, from the name of the river; and inconsiderable as it was in its infant state, was, however, to become the capital of a flourishing colony. It consisted at first of no more than 100 persons; but before the end of the year the number was increased to 618, of whom 127 had emigrated at their own expence. Three hundred men, and 113 women, 102 lads, and 83 girls, formed the beginning of this new population, and the hopes of a numerous posterity.

This settlement was increased in 1735 by the arrival of some Scotch Highlanders. Their national courage induced them to accept an establishment offered them upon the borders of the Altamaha, to defend the colony, if necessary, against the attacks of the neighbouring Spaniards. Here they built the towns of *Darien* and *Frederica*, and several of their countrymen came over to settle among them.

In the same year, a great number of Protestants driven out of Saltzburg by a fanatical priest, embarked for Georgia to enjoy peace and liberty of conscience. At first they settled on a spot just above that of the infant colony; but they afterwards chose to be at a greater distance, and to go as far down as the mouth of the Savannah, where they built a town called *Ebenezer*.

Some Switzers followed the example of these wise Saltzburgers, though they had not, like them, been persecuted. They also settled on the banks of the Savannah; but at the distance of 34 miles from the Germans. Their colony consisting of 100 habitations, was named *Purifburgh*, from Pury their founder; who having been at the expence of their settlement, was deservedly chosen their chief, in testimony of their gratitude to him.

In these four or five colonies, some men were found more inclined to trade than agriculture. These, there-

Royal's
Hist.

fore, separated from the rest in order to build the city Augusta, 236 miles distant from the ocean. The goodness of the soil, though excellent in itself, was not the motive of their fixing upon this situation; but they were induced to it by the facility it afforded them of carrying on the peltry trade with the savages. Their project was so successful, that, as early as the year 1739, 600 people were employed in this commerce. The sale of these skins was carried on with the greater facility from the circumstance of the Savannah admitting the largest ships to sail upon it as far as the walls of Augusta.

The mother-country ought, one would imagine, to have formed great expectations from a colony, where she had sent near 5000 men, and laid out 64,968 l. exclusive of the voluntary contributions that had been raised by zealous patriots. But to her great surprise she received information in 1741, that there remained scarce a sixth part of that numerous colony sent to Georgia; who being now totally discouraged, seemed only desirous to fix in a more favourable situation. The reasons of these calamities were inquired into and discovered.

This colony, even in its infancy, brought with it the seeds of its decay. The government, together with the property of Georgia had been ceded to individuals. The first use that the proprietors of Georgia made of the unlimited power they were invested with was to establish a system of legislation, that made them entirely masters not only of the police, justice, and finances, of the country, but even of the lives and estates of its inhabitants. Every species of right was withdrawn from the people, who are the original possessors of them all. Obedience was required of the people, though contrary to their interest and knowledge; and it was considered here, as in other countries, as their duty and their fate.

As great inconveniences had been found to arise in other colonies from large possessions, it was thought proper in Georgia to allow each family only 50 acres of land; which they were not permitted to mortgage, or even to dispose of by will to their female issue. This last regulation of making only the male issue capable of inheritance, was soon abolished; but there still remained too many obstacles to excite a spirit of emulation. It seldom happens, that a man resolves to leave his country but upon the prospect of some great advantage that works strongly upon his imagination. All limits, therefore, prescribed to his industry, are so many checks which prevent him from engaging in any project. The boundaries assigned to every plantation must necessarily have produced this bad effect. Several other errors still affected the original plan of this country, and prevented its increase.

The taxes imposed upon the most fertile of the British colonies, are very inconsiderable; and even these are not levied till the settlements have acquired some degree of vigour and prosperity. From its infant state, Georgia had been subjected to the fines of a feudal government, with which it had been as it were fettered. The revenues raised by this kind of service increased prodigiously, in proportion as the colony extended itself. The founders of it, blinded by a spirit of avidity, did not perceive that the smallest duty imposed upon the trade of a populous and flourishing

province, would much sooner enrich them than the largest fines laid upon a barren and uncultivated country.

To this species of oppression was added another, which, however incredible it may appear, might arise from a spirit of benevolence. The planters in Georgia were not allowed the use of slaves. Carolina and some other colonies having been established without their assistance, it was thought that a country destined to be the bulwark of those African possessions ought not to be peopled by a set of slaves, who could not be in the least interested in the defence of their oppressors. But it was not at the same time foreseen, that colonists, who were less favoured than their neighbours by the mother-country, who were situated in a country less susceptible of tillage, and in a hotter climate, would want strength and spirit to undertake a cultivation that required greater encouragement.

The indolence which so many obstacles gave rise to, found a further excuse in another prohibition that had been imposed. The disturbances produced by the use of spirituous liquors over all the continent of North America, induced the founders of Georgia to forbid the importation of rum. This prohibition, though well intended, deprived the colonists of the only liquor that could correct the bad qualities of the waters of the country, which were generally unwholesome; and of the only means they had to restore the waste of strength and spirits that must be the consequence of incessant labour. Besides this, it prevented their commerce with the Antilles; as they could not go thither to barter their wood, corn, and cattle, that ought to have been their most valuable commodities, in return for the rum of those islands.

The mother-country at length perceived how much these defects in the political regulations and institutions had prevented the increase of the colony, and freed them from the restraints they had before been clogged with. The government in Georgia was settled upon the same plan as that which had rendered Carolina so flourishing; and, instead of being dependent on a few individuals, became one of the national possessions.

GEORGIA *Southern*. See AMERICA, n° 20.

GEORGIC, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry. The word is borrowed from the Latin *georgicus*, and that of the Greek *γεωργικός*, of *γῆ, terra*, "earth," and *εργον, opus*, "I work, or labour," of *εργον, opus*, "work."

Hesiod and Virgil are the two greatest masters in this kind of poetry.

The moderns have produced nothing in this kind, except Rapin's book of Gardening; and the celebrated poem entitled Cyder, by Mr Phillips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

GERANITES, in natural history, an appellation given to such of the semipellucid gems as are marked with a spot resembling a crane's eye.

GERANIUM, crane's bill; a genus of the decandria order, belonging to the monodelphia class of plants. There are 57 species; the most remarkable of which are, 1. The Pratenese, with a crowfoot leaf, and

Gerard
Gerbier.

and large blue flowers, a native of many parts of Britain, growing in moist meadows, but is often planted in gardens on account of the beauty of its flowers. Of this there are two varieties, with white, and variegated flowers. 2. The fanguineum, a native of Germany and Switzerland, with deep-red or purple flowers from the side of the branches, one upon each foot-stalk. Of this there are several varieties, differing from one another chiefly in the figure of the stalks and leaves. 3. The phœum, a native of the Alps and Helvetian mountains, with blackish purple flowers, two upon each footstalk. 4. The nodofum, a native of France, with pale purple flowers, two upon each footstalk. 5. The macrorrhizum, or sweet-smelling geranium, a native of Germany and Switzerland, with beautiful purple flowers. 6. The striatum, with white flowers, beautifully variegated with purple. 7. The zonale, a native of the Cape of Good Hope, with an hairy lady's-mantle leaf, red flowers, and a shrubby stalk branching six or eight feet high.

The first six species are hardy plants, with fibrous perennial roots, and annual stalks which rise from the root in spring. The flowers come out in May, June, and July; and are extremely numerous, each consisting of five small spreading petals. These are succeeded by plenty of seed in August and September; which, if permitted to scatter, will raise an abundant crop of young plants. They may also be propagated by parting the roots. The last sort is that most commonly cultivated in gardens; but being a native of a warm climate, will not bear the open air here in the winter-time. There is a variety of this species, which is particularly valued on account of its finely variegated leaves.

GERARD (John), a learned Lutheran divine, was professor of divinity, and rector of the academy of Jena, the place of his birth. He wrote, 1. The harmony of the Eastern languages; 2. A treatise on the Coptic church; and other works which are esteemed. He died in 1668.

GERARDE (John), a surgeon in London, and the greatest botanist of his time, was many years chief gardener to Lord Burleigh; who was himself a great lover of plants, and had the best collection of any nobleman in the kingdom, among which were a great number of exotics introduced by Gerarde. In 1597 he published his *Herbal*, which was printed at the expense of J. Norton, who procured the figures from Franckfort. In 1663, Thomas Johnson, an apothecary, published an improved edition of Gerarde's book; which met with such approbation by the University of Oxford, that they conferred on him the degree of doctor of physic; and it is still much esteemed. The descriptions in the herbal are plain and familiar; and both these authors have laboured more to make their readers understand the characters of the plants, than to inform them that they themselves understood Greek and Latin.

GERBIER, (Sir Balthazar), a painter of Antwerp, born in the year 1592, distinguished himself by painting small figures in distemper. King Charles I. was so pleased with his performances, that he invited him to his court, where he obtained the esteem of the Duke of Buckingham, and grew into great favour. He was not only knighted, but sent to Brussels, where he long resided as agent for the king of Great Britain.

GERM, among gardeners. See GEMMA.

GERMAN, in genealogy, denotes *entire* or *whole*; thus, a brother-german is one both by the father's and mother's side; and cousins-german are the children of brothers or sisters.

GERMAN, or *Germanic*, also denotes any thing belonging to Germany; as the German empire, German flute, &c.

GERMANDER, in botany. See the article TEUCRIUM.

GERMANICUS CÆSAR, the son of Drusus, and paternal nephew to the emperor Tiberius, who adopted him; a renowned general, but still more illustrious for his virtues. He took the title of *Germanicus* from his conquests in that country; and though he had the moderation to refuse the empire offered to him by his army, Tiberius, jealous of his success, and of the universal esteem he acquired, caused him to be poisoned, A. D. 29, aged 34. He was a protector of learning; and composed some Greek comedies and Latin poems, some of which are still extant.

GERMANY, a very extensive empire of Europe, but which, in different ages of the world, hath had very different limits. Its name, according to the most probable conjecture, is derived from the Celtic words *Ghar man*, signifying a warlike man, to which their other name, *Allman*, or *Aleman*, likewise alludes.

The ancient history of the Germans is altogether wrapped up in obscurity; nor do we, for many ages, know any thing more of them, than what may be learned from the history of their wars with the Romans. The first time we find them mentioned by the Roman historians, is about the year 211 B. C. at which time Marcellus subdued Insurbia and Liguria, and defeated the Gælatæ, a German nation, situated on the banks of the Rhine. From this time history is silent with regard to any of these northern nations, till the eruption of the Cimbri and Teutones, who inhabited the most northerly parts of Germany. The event of their enterprise is related under the articles AMBRONES, CIMBRI, and TEUTONES. We must not, however, imagine, because these people happened to invade Italy at the same time, that therefore their countries were contiguous to one another. The Cimbri and Teutones only, dwelt beyond the Rhine; while the Ambrones inhabited the country between Switzerland and Provence. It is indeed very difficult to fix the limits of the country called *Germany* by the Romans. The southern Germans were intermixed with the Gauls, and the northern ones with the Scythians; and thus the ancient history of the Germans includes that of the Dacians, Huns, Goths, &c. till the destruction of the western Roman empire by them. Ancient Germany, therefore, we may reckon to have included the northern part of France, the Netherlands, Holland, *Germany* so called at present, Denmark, Prussia, Poland, Hungary, part of Turkey in Europe, and Muscovy.

The Romans divided Germany into two regions; Belgic or Lower Germany, which lay to the southward of the Rhine; and Germany Proper, or High Germany. The first lay between the rivers Seine and the Rhine; and in this we find a number of different nations, the most remarkable of which were the following.

many.

Germany.

1. The Ubii, whose territory lay between the Rhine and the Mosæ, and whose capital was the city of Cologne. 2. Next to them were the Tungri, supposed to be the same whom Cæsar calls *Eburones* and *Condrusi*; and whose metropolis, then called *Attuatica*, has since been named *Tongres*. 3. Higher up from them, and on the other side of the Moselle, were the Treviri, whose capital was Augusta Trevirorum, now *Triers*. 4. Next to them were the Tribocci, Nemetes, and Vangiones. The former dwelt in Alsace, and had Argentoratum, now *Strasbourg*, for their capital; the others inhabited the cities of Worms, Spire, and Mentz. 5. The Mediomatrici were situated along the Moselle, about the city of Metz in Lorraine; and above them were situated another German nation, named *Raurici*, *Rauraci*, or *Rauriaci*, and who inhabited that part of Helvetia, or Switzerland, about Basil. To the westward and southward of these were the Nervii, Sueffones, Silvanectes, Leuci, Rhemi, Lingones, &c. who inhabited Belgic Gaul.

Between the heads of the Rhine and Danube were seated the ancient kingdom of Vindelicia, whose capital was called *Augusta Vindelicorum*, now *Augsburg*. Below it on the banks of the Danube were the kingdoms of Noricum and Pannonia. The first of these was divided into Noricum *Ripense* and *Mediterraneum*. It contained a great part of the provinces of Austria, Styria, Carinthia, Tyrol, Bavaria, and some others of less note. The latter contained the kingdom of Hungary, divided into Upper and Lower; and extending from Illyricum to the Danube, and the mountains Cætii in the neighbourhood of *Vindebana*, now *Vienna*.

³
Nations in-
habiting
High Ger-
many.

Upper or High Germany lay beyond the Rhine and the Danube. Between the Rhine and the Elbe were the following nations. 1. The Chauci, Upper and Lower; who were divided from each other by the river *Weser*, now the *Wefer*. Their country contained what is now called *Bremen*, *Lunenburg*, *Friesland*, and *Groningen*. The upper Chauci had the *Che-rusei*, and the lower the *Chamavi* on the south-east, and the German Ocean on the north-west. 2. The Frisii, upper and lower, were divided from the lower Chauci by the river *Amisæ*, now the *Ems*; and from one another by an arm of the Rhine. Their country still retains the name of *Friesland*, and is divided into east and west; but the latter is now dismembered from Germany, and become one of the Seven United Provinces. 3. Beyond the *Ise*la, now the *Ise*, which bounded the country of the Frisii, were situated the *Bructeri*, who inhabited that tract now called *Broek-morland*; and the *Marfi*, about the river *Luppe*. On the other side of that river were the *Uspii* or *Uspites*; but these were famed for often changing their territories, and therefore found in other places. 4. Next to these were the *Juones*, or inhabitants of *Juliers*, between the *Maese* and the *Rhine*. 5. The *Catti*, another ancient and warlike nation, inhabited *Hesse* and *Thuringia*, from the *Hartzian* mountains to the *Rhine* and *Weser*; among whom were comprehended the *Mattiaci*, whose capital is by some thought to be *Mar-purg*, by others *Baden*. 6. Next to these were the *Seducii*, bordering upon *Susbia*; *Narisci*, or the ancient inhabitants of *Northgow*, whose capital was *Nu-remberg*; and the *Marcomanni*, whose country an-

ciently reached from the Rhine to the head of the Danube, and to the Neckar. The *Marcomanni* afterwards went and settled in *Bohemia* and *Moravia*, under their general or king *Maroboduus*; and some of them in *Gaul*, whence they drove the *Boii*, who had feated themselves there. 7. On the other side of the *Danu-be*, and between the *Rhine* and it, were the *Hermunduri*, who possessed the country now called *Mis-sia* in *Upper Saxony*; though some make their territories to have extended much farther, and to have reached quite to, or even beyond, the kingdom of *Bohemia*, once the feat of the *Boii*, whence its name. 8. Beyond them, on the north of the *Danube*, was another feat of the *Marcomanni* along the river *Albis*, or *Elbe*. 9. Next to *Bohemia* were situated the *Quadi*, whose territories extended from the *Danube* to *Moravia*, and the northern part of *Austria*. These are comprehended under the ancient name of *Sævi*; part of whom at length forced their way into *Spain*, and settled a kingdom there. 10. Eastward of the *Quadi* were situated the *Bastarnæ*, and parted from them by the *Granna*, now *Gran*; a river that falls into the *Danube*, and by the *Carpathian* mountains, from them called *Alpes Bas-tarnicæ*. The country of the *Bastarnæ* indeed made part of the *European Sarmatia*, and so was without the limits of *Germany* properly so called; but we find these people so often in league with the *German* nations, and joining them for the destruction of the *Romans*, that we cannot but account them as one people.

Between those nations already taken notice of, seated along the other side of the *Danube* and the *Hercynian* forest, were several others whose exact situation is uncertain, viz. the *Martingi*, *Burii*, *Borades*, *Lygii*, or *Logiones*, and some others, who are placed by our geographers along the feated above-mentioned, between the *Danube* and the *Vistula*.

On this side the *Hercynian* forest, were the famed *Rhætii*, now *Grisons*, seated among the *Alps*. Their country, which was also called *Western Illyricum*, was divided into *Rhætia Prima* or *Propria*, and *Secunda*; and was then of much larger extent, spreading itself towards *Susbia*, *Bavaria*, and *Austria*.

On the other side of the *Hercynian* forest, were, 1. The *Sævi*, who spread themselves from the *Vistula* to the river *Elbe*. 2. The *Longobardi*, so called, according to some, on account of their wearing long beards; but, according to others, on account of their consisting of two nations, viz. the *Bardi* and *Lingones*. These dwelt along the river *Elbe*, and bordered southward on the *Chauci* above-mentioned. 3. The *Burgundi*, of whose original feat we are uncertain. 4. The *Semnones*; who, about the time of *Tiberius*, were seated on the river *Elbe*. 5. The *Angles*, *Saxons*, and *Goths*; were probably the descendants of the *Cimbri*; and inhabited the countries of *Denmark*, along the *Baltic* sea, and the peninsula of *Scandinavia*, containing *Norway*, *Sweden*, *Lapland*, and *Finmark*. 6. The *Vandals* were a *Gothic* nation, who, proceeding from *Scandinavia*, settled in the countries now called *Mecklenburgh* and *Brandenburgh*. 7. Of the same race were the *Dacians*, who settled themselves in the neighbourhood of *Palus Mæotis*, and extended their territories along the banks of the *Danu-be*.

4
Wars of the
Scordisci
with the
Romans.

These were the names of the German nations who performed the most remarkable exploits in their wars with the Romans. Besides these, however, we find mention made of the Scordisci, a Thracian nation, who afterwards settled on the banks of the Danube. About the year 113 B. C. they ravaged Macedonia, and cut off a whole Roman army sent against them; the general, M. Porcius Cato, grandson to Cato the censor, being the only person who had the good fortune to make his escape. After this, they ravaged all Thessaly; and advanced to the coasts of the Adriatic, into which, because it stopped their farther progress, they discharged a shower of darts. By another Roman general, however, they were driven back into their own country with great slaughter; and, soon after, Metellus weakened them by repeated defeats, that they were incapable, for some time, of making any more attempts on the Roman provinces. At last, in the consulship of M. Livius Drusus and L. Calpurnius Piso, the former prevailed on them to pass the Danube, which thenceforth became the boundary between the Romans and them. Notwithstanding this, in the time of the Jugurthine war, the Scordisci repassed the Danube on the ice, every winter, and being joined by the Triballi a people of Lower Mæsia, and the Daci of Upper Mæsia, penetrated as far as Macedonia, committing every where dreadful ravages. So early did these northern nations begin to be formidable to the Romans, even when they were most renowned for warlike exploits.

5
Expedition
of Julius
Cæsar into
Germany.

Till the time of Julius Cæsar, however, we hear nothing more concerning the Germans. About 58 years B. C. he undertook his expedition into Gaul; during which, his assistance was implored by the Ædui, against Ariovistus, a German prince who oppressed them. Cæsar, pleased with this opportunity of increasing his power, invited Ariovistus to an interview; but this being declined, he next sent deputies desiring him to restore the hostages he had taken from the Ædui, and to bring no more troops over the Rhine into Gaul. To this a haughty answer was returned; and a battle soon after ensued, in which Ariovistus was entirely defeated, and with great difficulty made his escape.

In 55 B. C. Cæsar having subdued the Suevones, Bellovaci, Ambiani, Nervii, and other nations of Belgic Gaul, hastened to oppose the Usipetes and Tencteri. These nations having been driven out of their own country by the Suevi, had crossed the Rhine with a design to settle in Gaul. As soon as he appeared, the Germans sent him a deputation, offering to join him provided he would assign them lands. Cæsar replied, that there was no room in Gaul for them; but he would desire the Ubii to give them leave to settle among them. Upon this, they desired time to treat with the Ubii; but in the mean time fell upon some Roman squadrons: which so provoked Cæsar, that he immediately marched against them, and, coming unexpectedly upon them, defeated them with great slaughter. They fled in the utmost confusion; but the Romans pursued them to the conflux of the Rhine and the Mæse, where the slaughter was renewed with such fury, that almost 400,000 of the Germans perished. After this, Cæsar being resolved to spread the terror of the Roman name through Germany,

VOL. V.

built a bridge over the Rhine, and entered that country. In this expedition, however, which was his last in Germany, he performed no remarkable exploit. A little before his death, indeed, he had projected the conquest of that as well as of a great many other countries; but his assassination prevented the execution of his designs. Nor is there any thing recorded of the Germans till about 17 B. C. when the Tencteri made an irruption into Gaul, and defeated M. Lollius, proconsul of that province. At last, however, they were repulsed, and forced to retire with great loss beyond the Rhine.

Soon after this the Rheti invaded Italy, where they committed the greatest devastations, putting all the males they met to the sword, without distinction of sex or age: nay, we are told, that when they happened to take women with child, they consulted their augurs to know whether the child was a male or female; and if they pronounced it a male, the mother was immediately massacred. Against these barbarians was sent Drusus, the second son of Livia, a youth of extraordinary valour and great accomplishments. He found means to bring them to a battle; in which the Romans proved victorious, and cut in pieces great numbers of their enemies, with very little loss on their own side. Those who escaped the general slaughter, being joined by the Vindelici, took their route towards Gaul, with a design to invade that province. But Augustus, upon the first notice of their march, dispatched against them Tiberius with several chosen legions. He was no less successful than Drusus had been; for, having transported his troops over the lake Brigantium, now Constance, he fell unexpectedly on the enemy, gave them a total overthrow, took most of their strong-holds, and obliged the whole nation to submit to such terms as he chose to impose upon them. Thus were the Vindelici, the Rheti, and Norici, three of the most barbarous nations in Germany, subdued. Tiberius, to keep the conquered countries in awe, planted two colonies in Vindelicia, and opened from thence a road into Rætia and Noricum. One of the cities which he built for the defence of his colonies, he called, from his father Drusus, *Drusomagus*; the other by the name of Augustus, *Augusta Vindelicorum*; which cities are now known by the names of *Münzingen* and *Augsburg*. He next encountered the Pannonians, who had been subdued by Agrippa, but revolted on hearing the news of that great commander's death, which happened 11 years B. C. Tiberius, however, with the assistance of their neighbours the Scordisci, soon forced them to submit. They delivered up their arms, gave hostages, and put the Romans in possession of all their towns and strong-holds. Tiberius spared their lives; but laid waste their fields, plundered their cities, and sent the best part of their youth into other countries.

In the mean time, Drusus having prevented the Gauls from revolting, which they were ready to do, prepared to oppose the Germans who dwelt beyond the Rhine. They had collected the most numerous and formidable army that had ever been seen in those parts; with which they were advancing towards the Rhine, in order to invade Gaul. Drusus defeated them as they attempted to cross that river; and, pursuing the advantage he had gained, entered the country of the

Usipetes,

Germany.

2
Exploits of
Drusus in
Germany.

Ulpetes, now *Relinchusen*, and from thence advanced against the Sicambri, in the neighbourhood of the Lyppe and Ifel. Them he overthrew in a great battle, laid waste their country, burnt most of their cities, and, following the course of the Rhine, approached the German ocean, reducing the Frisii and the Chauci between the Ems and the Elbe. In these marches the troops suffered extremely for want of provisions; and Drusus himself was often in great danger of being drowned, as the Romans who attended him were at that time quite unacquainted with the flux and reflux of the ocean.

The Roman forces went into east Friesland for their winter-quarters; and next year (10 B. C.) Drusus marched against the Tencteri, whom he easily subdued. Afterwards, passing the Lypus, now the Lyppe, he reduced the Catti and Cherusci, extending his conquests to the banks of the Visurgis or Wefer: which he would have passed, had he not been in want of provisions, the enemy having laid waste the country to a considerable distance. As he was retiring, the Germans unexpectedly fell upon him in a narrow passage; and having surrounded the Roman army, cut a great many of them in pieces. But Drusus having animated his men by his example, after a bloody conflict, which lasted the whole day, the Germans were defeated with such slaughter, that the ground was strewed for several miles with dead bodies. Drusus found in their camp a great quantity of iron-chains which they had brought for the Romans; and so great was their confidence, that they had agreed before-hand about the division of the booty. The Tencteri were to have the horse, the Cherusci and Sicambri the baggage, and the Ulpetes and Catti the captives. After this victory, Drusus built two forts to keep the conquered countries in awe; the one at the confluence of the Lyppe and the Alme, the other in the country of the Catti on the Rhine. On this occasion also he made a famous canal, long after called in honour of him *Fossa Drusiana*, to convey the waters of the Rhine into the Sala or Sale. It extended eight miles; and was very convenient for conveying the Roman troops by water to the countries of the Frisii and Chauci, which was the design of the undertaking.

The following year, (9 B. C.), Augustus, bent on subduing the whole of Germany, advanced to the banks of the Rhine, attended by his two sons-in-law Tiberius and Drusus. The former he sent against the Daci, who lived on the south side of the Danube; and the latter to complete the conquests he had so successfully begun in the western parts of Germany. The former easily overcame the Daci, and transplanted 40,000 of them into Gaul. The latter, having passed the Rhine, subdued all the nations from that river to the Elbe; but having attempted in vain to cross this last, he set out for Rome: an end, however, was put to his conquests and his life by a violent fever, with which he was seized on his return.

After the death of Drusus, Tiberius again over-ran all those countries in which Drusus had spent the preceding summer; and struck some of the northern nations with such terror, that they sent deputies to sue for peace. This, however, they could not obtain upon any terms; the emperor declaring that he would not conclude a peace with one, unless they all desired

it. But the Catti, or according to some the Sicambri, could not by any means be prevailed upon to submit; so that the war was still carried on, though in a languid manner, for about 18 years. During this period, some of the German nations had quitted their forests, and begun to live in a civilized manner under the protection of the Romans; but one Quintilius Varus being sent to command the Roman forces in that country, so provoked the inhabitants by his extortions, that not only those who still held out refused to submit, but even the nations that had submitted were seized with an eager desire of throwing off the yoke. Among them was a young nobleman of extraordinary parts and valour, named *Arminius*. He was the son of Sigimer, one of the most powerful lords among the Catti, had served with great reputation in the Roman armies, and been honoured by Augustus with the privileges of a Roman citizen and the title of knight. But the love of his country prevailing over his gratitude, he resolved to improve the general discontent which reigned among his countrymen, to deliver them from the bondage of a foreign dominion. With this view he engaged, underhand, the leading men of all the nations between the Rhine and the Elbe, in a conspiracy against the Romans. In order to put Varus off his guard, he at the same time advised him to shew himself to the inhabitants of the more distant provinces, administer justice among them, and accustom them, by his example, to live after the Roman manner, which he said would more effectually subdue them than the Roman sword. As Varus was a man of a peaceable temper, and averse from military toils, he readily consented to this insidious proposal; and, leaving the neighbourhood of the Rhine, marched into the country of the Cherusci. Having there spent some time in hearing causes and deciding civil controversies, Arminius persuaded him to weaken his army, by sending out detachments to clear the country of robbers. When this was done, some distant nations of Germany rose up in arms by Arminius's directions; while those through which Varus was to pass in marching against them, pretended to be in a state of profound tranquillity, and ready to join the Romans against their enemies.

On the first news of the revolt, Varus marched against the enemy with three legions and six cohorts; but being attacked by the Germans as he passed through a wood, his army was almost totally cut off, while he himself and most of his officers fell by their own hands. Such a terrible overthrow, though it raised a general consternation in Rome, did not, however, dishearten Augustus, or cause him to abandon his enterprise. About two years after, (A. D. 12), Tiberius and Germanicus were appointed to command in Germany. The death of Augustus, however, which happened soon after, prevented Tiberius from going on his expedition; and Germanicus was for some time hindered from proceeding in his, by a revolt of the legions, first in Pannonia, and then in Germany. About the year 15, Germanicus having brought over the soldiers to their duty, laid a bridge across the Rhine, over which he marched 12,000 legionaries, 26 cohorts of the allies, and eight *ale* (squadrons of 300 each) of horse. With these he first traversed the Cæsan forest, (part of the Hercynian, and thought to lie part-

Germany. ly in the duchy of Cleves, and partly in Westphalia), and some other woods. On his march he was informed that the Marſi were celebrating a feſtival with great mirth and jollity. Upon this he advanced with ſuch expedition, that he ſurprized them in the midſt of their debauch; and giving his army full liberty to make what havock they pleaſed, a terrible maſſacre enſued, and the country was deſtroyed with fire and ſword for 50 miles round, without the loſs of a ſingle man on the part of the Romans.—This general maſſacre roused the Bruſteri, the Tubantes, and the Uſipetes; who, beſetting the paſſes through which the Roman army was to return, fell upon their rear, and put them into ſome diſorder; but the Romans ſoon recovered themſelves, and defeated the Germans with conſiderable loſs.

12
Exploits of
Germanicus.

The following year, (A. D. 16), Germanicus taking advantage of ſome intestine broils which happened among the Catti, entered their country, where he put great numbers to the ſword. Moſt of their youth, however, eſcaped by ſwimming over the Adrana, now the *Eder*, and attempted to prevent the Romans from laying a bridge over that river: but being diſappointed in this, ſome of them ſubmitted to Germanicus, while the greater part, abandoning their villages, took refuge in the woods; ſo that the Romans, without oppoſition, ſet fire to all their villages, towns, &c. and having laid their capital in aſhes, began their march back to the Rhine.

Germanicus had ſcarce reached his camp, when he received a meſſage from Segeltes, a German prince, in the intereſt of the Romans, acquainting him that he was beſieged in his camp by Arminius. On this advice, he inſtantly marched againſt the beſiegers; entirely defeated them; and took a great number of priſoners, among whom was Thuneldis, the wife of Arminius, and daughter of Segeltes, whom the former had carried off, and married againſt her father's will. Arminius then, more enraged than ever, for the loſs of his wife, whom he tenderly loved, ſtirred up all the neighbouring nations againſt the Romans. Germanicus, however, without being diſmayed by ſuch a formidable confederacy, prepared himſelf to oppoſe the enemy with vigour: but, that he might not be obliged to engage ſuch numerous forces at once, he detached his Lieutenant Cæcina, at the head of 40 cohorts, into the territories of the Bruſteri; while his cavalry, under the command of Pedo, entered the country of the Friſi. As for Germanicus himſelf, he embarked the remainder of his army, conſiſting of four legions, on a neighbouring lake; and tranſported them by rivers and canals to the place appointed on the river Ems, where the three bodies met. In their march they found the ſaid remains of the legions conducted by Varus, which they buried with all the ceremony their circumſtances could admit. After this they advanced againſt Arminius, who retired and poſted himſelf advantageouſly cloſe to a wood. The Roman general followed him; and coming up with him, ordered his cavalry to advance and attack the enemy. Arminius, at their firſt approach, pretended to fly; but ſuddenly wheeled about, and giving the ſignal to a body of troops, whom he had concealed in the wood, to riſh out, obliged the cavalry to give ground. The cohorts then advanced to their relief; but they too were

put into diſorder, and would have been puſhed into a moras, had not Germanicus himſelf advanced with the reſt of the cavalry to their relief. Arminius did not think it prudent to engage theſe freſh troops, but retired in good order; upon which Germanicus alſo retired towards the Ems. Here he embarked with four legions, ordered Cæcina to reconduct the other four by land, and ſent the cavalry to the ſea-ſide, with orders to march along the ſhore to the Rhine. Though Cæcina was to return by roads well known, yet Germanicus adviſed him to paſs, with all poſſible ſpeed, a cauſeway, called the *long bridge*, which led acroſs waſt marſhes, ſurrounded on all ſides with woods and hills that gently roſe from the plain.

Arminius, however, having got notice of Cæcina's march, arrived at the long bridges before Cæcina, and filled the woods with his men, who, on the approach of the Romans, ruſhed out, and attacked them with great fury. The legions, not able to manage their arms in the deep waters and ſlippery ground, were obliged to yield; and would in all probability have been entirely defeated, had not night put an end to the combat. The Germans, encouraged by their ſucceſs, inſtead of reſreſhing themſelves with ſleep, ſpent the whole night in diverting the courſes of the ſprings which roſe in the neighbouring mountains; ſo that, before day, the camp which the Romans had begun was laid under water, and their works were overturned. Cæcina was for ſome time at a loſs what to do; but at laſt reſolved to attack the enemy by day-break, and, having driven them to their woods, to keep them there in a manner beſieged, till the baggage and wounded men ſhould paſs the cauſeway, and get out of the enemy's reach. But when his army was drawn up, the legions poſted on the wings, ſeized with a ſudden panic, deſerted their ſtations, and occupied a field beyond the marſhes. Cæcina thought it adviſable to follow them; but the baggage ſtuck in the mire, as he attempted to croſs the marſhes, which greatly embarraſſed the ſoldiers. Arminius perceiving this, laid hold of the opportunity to begin the attack; and crying out, "This is a ſecond Varus, the ſame fate attends him and his legions," fell on the Romans with inexpreſſible fury. As he had ordered his men to aim chiefly at the horſes, great numbers of them were killed; and the ground becoming ſlippery with their blood and the ſlime of the marſh, the reſt either fell or threw their riders, and, galloping through the ranks, put them in diſorder. Cæcina diſtinguiſhed himſelf in a very eminent manner; but his horſe being killed, he would have been taken priſoner, had not the firſt legion reſcued him. The greedineſs of the enemy, however, ſaved the Romans from utter deſtruction; for juſt as the legions were quite ſpent, and on the point of yielding, the barbarians on a ſudden abandoned them in order to ſeize their baggage. During this reſpite, the Romans ſtruggled out of the marſh, and having gained the dry fields, formed a camp with all poſſible ſpeed, and fortified it in the beſt manner they could.

The Germans having loſt the opportunity of deſtroying the Romans, contrary to the advice of Arminius, attacked their camp next morning, but were repulſed with great ſlaughter; after which they gave Cæcina no more moleſtation till he reached the banks of the Rhine. Germanicus, in the mean time, having

Germany.

Germany. conveyed the legions he had with him down the river Ems into the ocean, in order to return by sea to the river Rhine, and finding that his vessels were overloaded, delivered the second and fourteenth legions to Publius Vitellius, desiring him to conduct them by land. But this march proved fatal to great numbers of them; who were either buried in the quicksands, or swallowed up by the overflowing of the tide, to which they were as yet utter strangers. Those who escaped, lost their arms, utensils, and provisions; and passed a melancholy night upon an eminence, which they had gained by wading up to the chin. The next morning the land returned with the tide of ebb; when Vitellius, by a hasty march, reached the river Ufingis, by some thought to be the Hoerensfer, on which the city of Groningen stands. There Germanicus, who had reached that river with his fleet, took the legions again on board, and conveyed them to the mouth of the Rhine, whence they all returned to Cologne, at a time when it was reported they were totally lost.

This expedition, however, cost the Romans very dear, and procured very few advantages. Great numbers of men had perished; and by far the greatest part of those who had escaped so many dangers returned without arms, utensils, horses, &c. half naked, lamed, and unfit for service. The next year, however, Germanicus, bent on the entire reduction of Germany, made vast preparations for another expedition. Having considered the various accidents that had befallen him during the war, he found that the Germans were chiefly indebted for their safety to their woods and marshes, their short summers and long winters; and that his troops suffered more from their long and tedious marches than from the enemy. For this reason he resolved to enter the country by sea, hoping by that means to begin the campaign earlier, and surprise the enemy. Having, therefore, built with great dispatch, during the winter, 1000 vessels of different sorts, he ordered them early in the spring (A. D. 16) to fall down the Rhine, and appointed the island of the Batavians for the general rendezvous of his forces. When the fleet was sailing, he detached Silius one of his lieutenants, with orders to make a sudden irruption into the country of the Catti; and, in the meantime, he himself, upon receiving intelligence that a Roman fort on the Luppias was besieged, hastened with six legions to its relief. Silius was prevented, by sudden rains, from doing more than taking some small booty, with the wife and daughter of Arpen king of the Catti; neither did those who besieged the fort wait the arrival of Germanicus. In the mean time, the fleet, arriving at the island of the Batavians, the provisions and warlike engines were put on board and sent forward; ships were assigned to the legions and allies; and the whole army being embarked, the fleet entered the canal formerly cut by Drusus, and from his name called *Fossa Drusiana*. Hence he sailed prosperously to the mouth of the Ems; where, having landed his troops, he marched directly to the Weser, where he found Arminius encamped on the opposite bank, and determined to dispute his passage. The next day Arminius drew out his troops in order of battle: but Germanicus, not thinking it advisable to attack them, ordered the horse to ford over under the command of his lieutenants Stertinius and Emilus;

who, to divide the enemy's forces, crossed the river in two different places. At the same time Cariovalda, the leader of the Batavian auxiliaries, crossed the river where it was most rapid: but, being drawn into an ambuscade, he was killed, together with most of the Batavian nobility; and the rest would have been totally cut off, had not Stertinius and Emilus hastened to their assistance. Germanicus in the mean time passed the river without molestation. A battle soon after ensued; in which the Germans were defeated with so great a slaughter that the ground was covered with arms and dead bodies for more than ten miles round; and among the spoils taken on this occasion, were found, as formerly, the chains with which the Germans had hoped to bind their captives.

In memory of this signal victory Germanicus raised a mount, upon which he placed as trophies the arms of the enemy, and inscribed underneath the names of the conquered nations. This so provoked the Germans, though already vanquished and determined to abandon their country, that they attacked the Roman army unexpectedly on its march, and put them into some disorder. Being repulsed, they encamped between a river and a large forest surrounded by a marsh except on one side, where it was inclosed by a broad rampart formerly raised by the Angrivarii as a barrier between them and the Cherusci. Here another battle ensued; in which the Germans behaved with great bravery, but in the end were defeated with great slaughter.

After this second defeat, the Angrivarii submitted, and were taken under the protection of the Romans, and Germanicus put an end to the campaign. Some of the legions he sent to their winter-quarters by land, while he himself embarked with the rest on the river Ems, in order to return by sea. The ocean proved at first very calm, and the wind favourable: but all of a sudden a storm arising, the fleet, consisting of 1000 vessels, was dispersed: some of them were swallowed up by the waves; others were dashed in pieces against the rocks, or driven upon remote and inhospitable islands, where the men either perished by famine, or lived upon the flesh of the dead horses with which the shores soon appeared strewed; for, in order to lighten their vessels, and disengage them from the shoals, they had been obliged to throw overboard their horses and beasts of burden, nay, even their arms and baggage. Most of the men, however, were saved, and even great part of the fleet recovered. Some of them were driven upon the coast of Britain; but the petty kings who reigned there, generously sent them back.

On the news of this misfortune, the Catti, taking new courage, ran to arms; but Caius Silius being detached against them with 30,000 foot and 3000 horse, kept them in awe. Germanicus himself, at the head of a numerous body, made a sudden irruption into the territories of the Marfi, where he recovered one of Varus's eagles, and having laid waste the country, he returned to the frontiers of Germany, and put his troops into winter-quarters; whence he was soon recalled by Tiberius, and never suffered to return into Germany again.

After the departure of Germanicus, the more northern nations of Germany were no more molested by the Romans. Arminius carried on a long and successful war with Maroboduus king of the Marcomanni,

manni, whom he at last expelled, and forced to apply to the Romans for assistance; but, excepting Germanicus, it seems they had at this time no other general capable of opposing Arminius, so that Maroboduus was never restored. After the final departure of the Romans, however, Arminius having attempted to enslave his country, by the treachery of his own kindred. The Germans held his memory in great veneration; and Tacitus informs us, that in his time they still celebrated him in their songs.

Nothing remarkable occurs in the history of Germany from this time till the reign of the emperor Claudius. A war indeed is said to have been carried on by Lucius Domitius, father to the emperor Nero. But of his exploits we know nothing more than that he penetrated beyond the river Elbe, and led his army farther into the country than any of the Romans had ever done. In the reign of Claudius, however, the German territories were invaded by Cn. Domitius Corbulo, one of the greatest generals of his age. But when he was on the point of forcing them to submit to the Roman yoke, he was recalled by Claudius, who was jealous of the reputation he had acquired.

In the reign of Vespasian, a terrible revolt happened among the Batavians and those German nations who had submitted to the Romans, a particular account of which is given under the article Rome. The revolters were with difficulty subdued; but, in the reign of Domitian, the Dacians invaded the empire, and proved a more terrible enemy than any of the other German nations had been. After several defeats, the emperor was at last obliged to consent to pay an annual tribute to Decebalus king of the Dacians; which continued to the time of Trajan. But this warlike prince refused to pay tribute; alleging, when it was demanded of him, that "he had never been conquered by Decebalus." Upon this the Dacians passed the Danube, and began to commit hostilities in the Roman territories. Trajan, glad of this opportunity to humble an enemy whom he began to fear, drew together a mighty army, and marched with the utmost expedition to the banks of the Danube. As Decebalus was not apprised of his arrival, the emperor passed the river without opposition, and entering Dacia, laid waste the country with fire and sword. At last he was met by Decebalus with a numerous army. A bloody engagement ensued, in which the Dacians were defeated; tho' the victory cost the Romans dear: the wounded were so numerous, that they wanted linen to bind up their wounds; and to supply the defect, the emperor generously devoted his own wardrobe. After the victory, he pursued Decebalus from place to place, and at last obliged him to consent to a peace on the following terms. 1. That he should surrender the territories which he had unjustly taken from the neighbouring nations. 2. That he should deliver up his arms, his warlike engines, with the artificers who made them, and all the Roman deserters. 3. That, for the future, he should entertain no deserters, nor take into his service the natives of any country subject to Rome. 4. That he should dismantle all his fortresses, castles, and strong-holds; and lastly, that he should have the same friends and foes with the people of Rome.

With these hard terms Decebalus was obliged to

comply, though fore against his will; and being introduced to Trajan, threw himself on the ground before him, acknowledging himself his vassal: after which the latter, having commanded him to send deputies to the senate for the ratification of the peace, returned to Rome.

This peace was of no long duration. Four years after, (A.D. 105), Decebalus, unable to live in servitude as he called it, began, contrary to the late treaty, to raise men, provide arms, entertain deserters, fortify his castles, and invite the neighbouring nations to join him against the Romans as a common enemy. The Scythians hearkened to his solicitations; but the Jazyges, a neighbouring nation, refusing to bear arms against Rome, Decebalus invaded their country. Hereupon Trajan marched against him; but the Dacian, finding himself unable to withstand him by open force, had recourse to treachery, and attempted to get the emperor murdered. His design, however, proved abortive, and Trajan pursued his march into Dacia. That his troops might the more readily pass and repass the Danube, he built a bridge over that river; which by the ancients is styled the most magnificent and wonderful of all his works*. To guard the bridge, he ordered two castles to be built; one on this side the Danube, and the other on the opposite side; and all this was accomplished in the space of one summer. Trajan, however, as the season was now far advanced, did not think it advisable to enter Dacia this year, but contented himself with making the necessary preparations.

In the year 106, early in the spring, Trajan set out for Dacia; and having passed the Danube on the bridge he had built, reduced the whole country, and would have taken Decebalus himself had he not put an end to his own life, in order to avoid falling into the hands of his enemies. After his death the kingdom of Dacia was reduced to a Roman province; and several castles were built in it, and garrisons placed in them, to keep the country in awe.

After the death of Trajan, the Roman empire began to decline, and the northern nations to be daily more and more formidable. The province of Dacia indeed was held by the Romans till the reign of Gallienus; but Adrian, who succeeded Trajan, caused the arches of the bridge over the Danube to be broken down, lest the barbarians should make themselves masters of it, and invade the Roman territories. In the time of Marcus Aurelius, the Marcomanni and Quadi invaded the empire, and gave the emperor a terrible overthrow. He continued the war, however, with better success afterwards, and invaded their country in his turn. It was during the course of this war that the Roman army is said to have been saved from destruction by that miraculous event related under the article CHRISTIANS, in Vol. III. p. 1935. par. ult.

In the end, the Marcomanni and Quadi were, by repeated defeats, brought to the verge of destruction; insomuch that their country would probably have been reduced to a Roman province, had not Marcus Aurelius been diverted from pursuing his conquests by the revolt of one of his generals. After the death of Marcus Aurelius, the Germanic nations became every day more and more formidable to the Romans. Far from being able to invade and attempt the conquest of

Germany.

Germany. these northern countries, the Romans had the greatest difficulty to repress the incursions of their inhabitants. But for a particular account of their various invasions of the Roman empire, and its total destruction by them at last, see the article *ROME*.

19 Roman em-
pire de-
stroyed by
the Heruli.
The immediate destroyers of the Roman empire were the Heruli; who, under their leader Odoacer, de-throned Augustulus the last Roman emperor, and proclaimed Odoacer king of Italy. The Heruli were soon expelled by the Ostrogoths; and these in their turn were subdued by Justinian, who re-annexed Italy to the eastern empire. But the Popes found means to obtain the temporal as well as spiritual jurisdiction over a considerable part of the country, while the Lombards subdued the rest. These last proved very troublesome to the Popes, and at length besieged Adrian I. in his capital. In this distress he applied to Charles the Great, king of France; who conquered both Italy and Germany, and was crowned emperor of the west in 800. See *FRANCE*, n° 24, &c.

20
History of
Germany
since the
time of
Charle-
magne.

The posterity of Charlemagne inherited the empire of Germany until the year 880; at which time the different princes assumed their original independence, rejected the Carolinian line, and placed Arnulph king of Bohemia on the throne. Since this time, Germany has ever been considered as an elective monarchy. Princes of different families, according to the prevalence of their interest and arms, have mounted the throne. Of these the most considerable, until the Austrian line acquired the imperial power, were the houses of Saxony, Franconia, and Swabia. The reigns of these emperors contain nothing more remarkable than the contests between them and the popes; for an account of which, see the article *ITALY*. From hence, in the beginning of the 13th century, arose the factions of the Guelphs and Gibelines, of which the former was attached to the popes, and the latter to the emperor; and both, by their virulence and inveteracy, tended to disquiet the empire for several ages. The emperors too were often at war with the Infidels; and sometimes, as happens in all elective kingdoms, with one another, about the succession.

But what more deserves our attention is the progress of government in Germany, which was in some measure opposite to that of the other kingdoms of Europe. When the empire, raised by Charlemagne, fell asunder, all the different independent princes assumed the right of election; and those now distinguished by the name of *electors* had no peculiar or legal influence in appointing a successor to the imperial throne; they were only the officers of the king's household, his secretary, his steward, chaplain, marshal, or master of his horse, &c. By degrees, however, as they lived near the king's person, and had, like all other princes, independent territories belonging to them, they increased their influence and authority; and in the reign of Otto III. 984, acquired the sole right of electing the emperor. Thus, while in the other kingdoms of Europe, the dignity of the great lords, who were all originally allodial or independent barons, was diminished by the power of the king, as in France, and by the influence of the people, as in Great Britain; in Germany, on the other hand, the power of the electors was raised upon the ruins of the emperor's supremacy, and of the people's jurisdiction. In 1440, Fre-

deric III. duke of Austria, was elected emperor, and the imperial dignity continued in the male line of that family for 300 years. His successor Maximilian married the heiress of Charles duke of Burgundy; where-by Burgundy, and the 17 provinces of the Netherlands, were annexed to the house of Austria. Charles V. grandson of Maximilian, and heir to the kingdom of Spain, was elected emperor in the year 1519. Under him Mexico and Peru were conquered by the Spaniards; and in his reign happened the REFORMATION in several parts of Germany, which, however, was not confirmed by public authority till the year 1648, by the treaty of Westphalia, and in the reign of Ferdinand III. The reign of Charles V. was continually disturbed by his wars with the German princes and the French king Francis I. Though successful in the beginning of his reign, his good fortune, towards the conclusion of it, began to forsake him; which, with other reasons, occasioned his abdication of the crown.

* See
Charles V.

His brother Ferdinand I. who in 1558 succeeded to the throne, proved a moderate prince with regard to religion. He had the address to get his son Maximilian declared king of the Romans in his own lifetime, and died in 1564. By his last will he ordered, that if either his own male issue, or that of his brother Charles, should fail, his Austrian estates should revert to his second daughter Anne, wife to the elector of Bavaria, and her issue. We mention this destination, as it gave rise to the late opposition made by the house of Bavaria to the pragmatic sanction, in favour of the empress queen of Hungary, on the death of her father Charles VI. The reign of Maximilian II. was disturbed with internal commotions, and an invasion from the Turks; but he died in peace, in 1576. He was succeeded by his son Rodolph; who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom he ceded Hungary and Austria in his lifetime. He was succeeded in the empire by Matthias; under whom the reformers, who went under the names of *Lutherans* and *Calvinists*, were so much divided among themselves, as to threaten the empire with a civil war. The ambition of Matthias at last tended to reconcile them; but the Bohemians revolted, and threw the imperial commissaries out of a window at Prague. This gave rise to a ruinous war, which lasted 30 years. Matthias thought to have exterminated both parties; but they formed a confederacy, called the *Evangelic League*, which was counterbalanced by a Catholic league.

Matthias dying in 1618, was succeeded by his cousin Ferdinand II.; but the Bohemians offered their crown to Frederic the elector Palatine, the most powerful Protestant prince in Germany, and son-in-law to his Britannic majesty James I. That prince was incautious enough to accept of the crown; but he lost it, by being entirely defeated by the duke of Bavaria and the imperial generals at the battle of Prague; and he was even deprived of his electorate, the best part of which was given to the duke of Bavaria. The Protestant princes of Germany, however, had among them at this time many able commanders, who were at the head of armies, and continued the war with wonderful obstinacy: among them were the margrave of Baden Durlach, Christian duke of Brunswick, and count Mansfield; the last was one of the best generals of the age.

Germany. age. Christiern IV. king of Denmark declared for them; and Richlieu, the French minister, was not fond of seeing the house of Austria aggrandized. The emperor, on the other hand, had excellent generals; and Christiern, having put himself at the head of the evangelic league, was defeated by Tilly, an imperialist of great reputation in war. Ferdinand made so moderate a use of his advantages obtained over the Protestants, that they formed a fresh confederacy at Leipzig, of which the celebrated Gustavus Adolphus king of Sweden was the head. An account of his glorious victories is given under the article SWEDEN. At last he was killed at the battle of Lutzen, in 1632. But the Protestant cause did not die with him. He had brought up a set of heroes, such as the duke of Saxe Weimar, Torstenson, Banier, and others, who shook the Austrian power; till, under the mediation of Sweden, a general peace was concluded among all the belligerent powers, at Munster, in the year 1648; which forms the basis of the present political system of Europe.

Ferdinand II. was succeeded by his son Ferdinand III. This prince died in 1657; and was succeeded the emperor Leopold, a severe, unamiable, and not very fortunate prince. He had two great powers to contend with, France on the one side, and the Turks on the other; and was a loser in his war with both. France took from him Alsace, and many other frontier places of the empire; and the Turks would have taken Vienna, had not the siege been raised by John Sobieski king of Poland. Prince Eugene of Savoy was a young adventurer in arms about the year 1697; and being one of the imperial generals, gave the Turks the first checks they received in Hungary. The empire, however, could not have withstood the power of France; who pursued her conquests with such rapidity, that the other parts of Europe were alarmed, and a great confederacy, consisting of the Empire, Great Britain, the Dutch under William Prince of Orange, and the northern powers, was formed to check the progress of the French, and render abortive the ambitious plan contrived by Lewis XIV. for founding an universal monarchy. At last, however, a peace was concluded at Ryfwick, in 1697; and two years after, the Turks consented to a peace, which was signed at Carlowitz in 1699. The Hungarians, secretly encouraged by the French, and exasperated by the unfeeling tyranny of Leopold, were still in arms, under the protection of the Porte, when that prince died in 1705.

He was succeeded by his son Joseph, who put the electors of Cologne and Bavaria to the ban of the empire; but being ill served by prince Lewis of Baden, general of the empire, the French partly recovered their affairs, notwithstanding their repeated defeats. The duke of Marlborough had not all the success he expected or deserved. Joseph himself was suspected of a design to subvert the Germanic liberties; and it was plain by his conduct, that he expected England should take the labouring oar in the war, which was to be entirely carried on for his benefit. The English were disgusted at his slowness and selfishness; but he died in 1711, before he had reduced the Hungarians; and leaving no male issue, he was succeeded in the empire by his brother Charles VI. whom the allies

Germany. were endeavouring to place on the throne of Spain, in opposition to Philip, duke of Anjou, grandson to Lewis XIV.

When the peace of Utrecht took place in 1713, Charles at first made a shew as if he would continue the war; but found himself unable, now that he was forsaken by the English. He therefore was obliged to conclude a peace with France at Baden in 1714, that he might attend the progress of the Turks in Hungary; where they received a total defeat from prince Eugene, at the battle of Peterwaradin. They received another of equal importance from the same general in 1717, before Belgrade, which fell into the hands of the imperialists; and next year the peace of Passarowitz, between them and the Turks, was concluded. Charles employed every minute of his leisure in making arrangements for increasing and preserving his hereditary dominions in Italy and the Mediterranean. Happily for him, the crown of Britain devolved to the house of Hanover; an event which gave him a very decisive weight in Europe, by the connections between George I. and II. and the empire. Charles was sensible of this; and carried matters with so high a hand, that, about the years 1724 and 1725, a breach ensued between him and George I. and so uneasy was the system of affairs all over Europe at that time, that the capital powers often changed their old alliances, and concluded new ones contradictory to their interest. Without entering into particulars, it is sufficient to observe, that the safety of Hanover, and its aggrandizement, was the main object of the British court; as that of the emperor was the establishment of the pragmatic sanction, in favour of his daughter, the present empress-queen, he having no male issue. Mutual concessions upon those great points restored a good understanding between George II. and the emperor Charles; and the elector of Saxony, flattered with the view of gaining the throne of Poland, relinquished the great claims he had upon the Austrian succession.

The emperor, after this, had very bad success in a war he entered into with the Turks, which he had undertaken chiefly to indemnify himself for the great sacrifices he had made in Italy to the princes of the house of Bourbon. Prince Eugene was then dead, and he had no general to supply his place. The system of France, however, under cardinal Fleury, happened at that time to be pacific; and she obtained for him, from the Turks, a better peace than he had reason to expect. Charles, to keep the German and other powers easy, had, before his death, given his eldest daughter, the present empress queen, in marriage to the duke of Lorraine, a prince who could bring no accession of power to the Austrian family.

Charles died in 1740; and was no sooner in the grave, than all he had so long laboured for must have been overthrown, had it not been for the firmness of George II. The young king of Prussia entered and conquered Silesia, which he said had been wrongfully dimembered from his family. The king of Spain and the elector of Bavaria set up claims directly incompatible with the pragmatic sanction, and in this they were joined by France; though all those powers had solemnly guaranteed it. The imperial throne, after a considerable vacancy, was filled up by the elector of Bavaria, who took the title of Charles VII. in January

Germany. 1742. The French poured their armies into Bohemia, where they took Prague; and the queen of Hungary, to take off the weight of Prussia, was forced to cede to that prince the most valuable part of the duchy of Silesia by a formal treaty.

Her youth, her beauty, and sufferings, and the noble fortitude with which she bore them, touched the hearts of the Hungarians, into whose arms she threw herself and her little son; and though they had been always remarkable for their disaffection to the house of Austria, they declared unanimously in her favour. Her generals drove the French out of Bohemia; and George II. at the head of an English and Hanoverian army, gained the battle of Dettingen, in 1743. Charles VII. was at this time miserable on the imperial throne, and would have given the queen of Hungary almost her own terms; but she haughtily and impolitically rejected all accommodation, though advised to it by his Britannic majesty, her best and indeed only friend. This obstinacy gave a colour for the king of Prussia to invade Bohemia, under pretence of supporting the imperial dignity: but though he took Prague, and subdued the greatest part of the kingdom, he was not supported by the French; upon which he abandoned all his conquests, and retired into Silesia. This event confirmed the obstinacy of the queen of Hungary; who came to an accommodation with the emperor, that he might recover Silesia. Soon after, his imperial majesty, in the beginning of the year 1745, died; and the duke of Lorraine, then grand duke of Tuscany, consort to the queen of Hungary, after surmounting some difficulties, was chosen emperor.

The bad success of the allies against the French and Bavarians in the Low Countries, and the loss of the battle of Fontenoy, retarded the operations of the empress-queen against his Prussian majesty. The latter beat the emperor's brother, prince Charles of Lorraine, who had before driven the Prussians out of Bohemia: and the conduct of the empress-queen was such, that his Britannic majesty thought proper to guarantee to him the possession of Silesia, as ceded by treaty. Soon after, his Prussian majesty pretended that he had discovered a secret convention which had been entered into between the empress-queen, the empress of Russia, and the king of Poland as elector of Saxony, to strip him of his dominions, and to divide them among themselves. Upon this his Prussian majesty, very suddenly, drove the king of Poland out of Saxony, defeated his troops, and took possession of Dresden; which he held till a treaty was made under the mediation of his Britannic majesty, by which the king of Prussia acknowledged the duke of Lorraine, great duke of Tuscany, for emperor. The war, however, continued in the Low Countries, not only to the disadvantage, but to the discredit, of the Austrians and Dutch, till it was finished by the treaty of Aix-la-Chapelle, in April 1748. By that treaty Silesia was once more guaranteed to the king of Prussia. It was not long before that monarch's jealousies were renewed and verified; and the empress of Russia's views falling in with those of the empress-queen and the king of Poland, who were unnaturally supported by France in their new schemes, a fresh war was kindled in the empire. The king of Prussia declared

against the admission of the Russians into Germany, and his Britannic majesty against that of the French. Upon those two principles all former differences between these monarchs were forgotten, and the British parliament agreed to pay an annual subsidy of 670,000*l.* to his Prussian majesty during the continuance of the war.

The flames of war now broke out in Germany with greater fury and more destructive violence than ever. The armies of his Prussian majesty, like an irresistible torrent, burst in Saxony; totally defeated the imperial general Brown at the battle of Lowositz; forced the Saxons to lay down their arms, though almost impregnable fortified at Pirna; and the elector of Saxony fled to his regal dominions in Poland. After this, his Prussian majesty was put to the ban of the empire; and the French poured, by one quarter, their armies, as the Russians did by another, into the empire. The conduct of his Prussian majesty on this occasion is the most amazing that is to be met with in history; for a particular account of which, see the article PRUSSIA.

At last, however, the taking of Colberg by the Russians, and of Schweidnitz by the Austrians, was on the point of completing his ruin, when his most formidable enemy, the empress of Russia, died, January 5. 1762; George II. his only ally, had died on the 25th of October, 1760.

The deaths of those illustrious personages were followed by great consequences. The British ministry of George III. sought to finish the war with honour, and the new emperor of Russia recalled his armies. His Prussian majesty was, notwithstanding, so very much reduced by his losses, that the empress-queen, probably, would have completed his destruction, had it not been for the wise backwardness of other German princes, not to annihilate the house of Brandenburg. At first the empress-queen rejected all terms proposed to her, and ordered 30,000 men to be added to her armies. The visible backwardness of her generals to execute her orders, and new successes obtained by his Prussian majesty, at last prevailed on her to agree to an armistice, which was soon followed by the treaty of Hubertsburg, which secured to his Prussian majesty the possession of Silesia. Upon the death of the emperor, her husband, in 1765, her son Joseph, who had been crowned king of the Romans in 1764, succeeded him in the empire.

At present, Germany is bounded on the north by the Baltic Sea, Denmark, and the German Ocean; on the east by Prussia, Hungary, and Poland; and on the west by the Low Countries, Lorraine, and Franche Comté: so that it now comprehends the Palatinates of Cologne, Triers, and Liege, which formerly belonged to the Gauls; and is dismembered of Friesland, Groningen, and Overysel, which are now incorporated with the Low Countries.

Since the time of Charles the Great, this country Situation, has been divided into High and Low Germany. The extent, &c. first comprehends the Palatinate of the Rhine, Fran- of Germa- conia, Suabia, Bavaria, Bohemia, Moravia, Austria, ny. Carinthia, Carniola, Stiria, the Swiss, and the Grisons. The provinces of Low Germany are, the Low Country of the Rhine, Triers, Cologne, Mentz, Westphalia, Hesse, Brunswick, Misnia, Lusatia, High Saxony upon the Elbe, Low Saxony upon the Elbe, Mecklenburg, Lu-

Germany.

Lunenbourg, Brandenburg, and Pomerania. For a particular description of all these, see the articles as they occur in the order of the alphabet.

22
Constitu-
tion of the
empire.

The empire, as we have already observed, is elective; and the laws require no other qualifications in a candidate, but that he be *justus, bonus, et utilis*, without any limitation in regard to religion, nation, state, or age. But as the Popish electors are more in number than the Protestant, a Roman-catholic prince is always chosen. The election is at Frankfort on the Maine, within three months after the former emperor's death. The electors appear either in person or by their envoys; and if an elector absent himself, the election, notwithstanding, is valid. Before the day of election, all foreigners are ordered to depart the town. Whoever has more than half the voices of the college for him, is elected; and an elector may even give his vote for himself. When the election is over, the person elected, or his plenipotentiary, must immediately subscribe and swear to the capitulation of election: but if the person elected is not present in person, he must swear to it himself before he is crowned, and before he can take upon him the government; which, till then, belongs to the vicars of the empire. His coronation, for which he appoints a day himself, is always performed in the place where he was elected; though both election and coronation ought to be in the city of Aix-la-Chapelle. He then takes a general oath of a ruler, and, among other things, promises all due veneration to the Pope and church. The emperors used formerly to be crowned by the Popes, till the reign of Charles V. but from that time the papal coronation has been dispensed with. However, immediately upon his entering upon the government, he testifies his veneration for the Pope by an embassy. The title of the emperor runs thus: "N. by the grace of God, elected Roman emperor (*imperator*), at all times augmentor of the empire (*semper Augustus*), in or of Germany king." Then follow the titles of the hereditary imperial dominions. The states of the empire give the emperor the title of "Most illustrious, most powerful, and most invincible Roman emperor;" the last of which is omitted by the electors. The emperor is looked upon by all other crowned heads and states in Europe as the first European potentate, and as such precedence is given him and his ambassadors. He is the supreme head of the German empire; but his power in the administration thereof is very limited. With respect to ecclesiastical matters, his prerogative consists principally in the right of the first petition (*jus primarii arum precum*); by virtue of which, in all foundations and cloisters of the empire, he may, once during his administration, confer a benefice on any person qualified for it by the statutes; and in that of a panis brief to each foundation or cloister in the empire, by virtue of which, such foundation is obliged to admit into it the person who has obtained the emperor's brief, and there provide him, during life, with meat, drink, cloaths, and other necessities. With respect to temporal matters, he can create princes, dukes, marquises, counts, barons, knights, &c. raise countries and territories to a higher rank; bestow arms, and grant letters of respite and protection, securing a debtor against his creditor; establish universities, fairs, and markets; empower any

Germany.

person to adopt another, and to assume a title from his estate; erect any place into a sanctuary; confer majority on minors; legitimate children born out of wedlock; confirm the contracts and stipulations of the empire; remit oaths extorted from them; invest such as possess fiefs of the empire, and decide in feudal matters relative thereto, &c. but he cannot grant to any person privileges detrimental to the rights of the immediate sovereign of that person. He can also grant exclusive privileges for printing particular books, and for new-invented machines, &c. He appoints most of the officers, civil and military, of the empire, except such as are hereditary; as the great chancellor, treasurer, &c. but these are only honorary. In ancient times the emperor had considerable domains and incomes in the empire; but almost all these have been successively mortgaged and alienated, so that at present the certain revenues of the emperor are very inconsiderable: but then, as he has the disposal of most offices, the creation of princes and noblemen, is entitled to all confiscations and forfeitures, and invests the several princes in their estates, besides those that hold fiefs of the empire in Italy, the profit of these articles may amount to a large sum. He has also some offerings from the Jews, and the free gifts of the order of knights of the empire. A successor in the empire is frequently chosen by the electors during the life of the emperor, who is styled *king of the Romans*. He is elected and crowned in the same manner as the emperor; has the title of *majesty*; takes precedence of all other kings in Christendom; and succeeds of course at the emperor's death.

The arms of the empire are a black eagle with two heads, hovering with expanded wings in a field of gold; and over the heads of the eagle is seen the imperial crown. 24
Arms of the
empire.

The diet of the empire consists of the emperor, the nine electors, the ecclesiastical and secular princes, and the deputies of imperial cities. The electors are divided into spiritual and temporal. The spiritual electors are, the archbishops of Mentz, Triers, and Cologne; and the secular, those of Bohemia, Palatine, Brandenburg, Saxony, Bavaria, and Hanover. The spiritual electors are such of course as soon as they are chosen to their sees by their respective chapters. In the reign of Henry IV. the right of election is said to have been introduced. Till the peace of Westphalia there were only seven electors, when an eighth was added; and, in 1692, a ninth, in favour of the illustrious house of Brunswick Lunenburg, now in possession of a much higher and infinitely more valuable dignity, viz. the crown of Great Britain. The spiritual are styled by the emperor, *highly worthy nephews*; the temporal, *most illustrious uncles*. By the other members of the empire, the spiritual, who were not born princes, are styled, *your electoral grace*; but such as were, and also the temporal electors, have the appellation of, *your electoral serenity*. Foreign kings style the temporal electors, and those of the spiritual who were princes born, *brothers*. The spiritual are also styled, *highly and most worthy*; and the temporal, *most illustrious*.

The elector of Mentz is arch-chancellor of the holy Roman empire in Germany, and director of the electoral college. This prince notifies the death of an 25
Powers of
the electors.

23
Powers of
the emper-
or.

The elector of Treves is the arch-chancellor of the holy Roman empire in Gaul and the kingdom of Arles; but this at present is only a bare title. At an election of the king of the Romans, he has the first voice; and, before the election, takes the oath of the elector of Mentz.

The elector of Cologne is arch-chancellor of the holy Roman empire in Italy. At an election of a king of the Romans, he has the second voice; and he crowns the emperor, when the coronation is at Aix-la-Chapelle, and in the archbishopric of Cologne.

The king and elector of Bohemia is arch-bearer of the holy Roman empire, precedes all the temporal electors whatsoever, and has the third voice in the electoral college.

The elector of Bavaria is arch-fewer of the holy Roman empire. At the coronation he carries the *monde* before the emperor, ranks next to Bohemia, places four silver dishes, weighing twelve marks, on the imperial table, and serves up the first course.

The elector of Saxony is arch-marshal of the holy Roman empire. He also, when there is no emperor, is one of the vicars of the empire. At the diets, and on other solemn occasions, he carries the sword of state before the emperor; and, at the coronation, he rides into a heap of oats, and fills a silver measure with that grain. During the holding of the diets, he has jurisdiction over all electoral and other officers of the states of the empire, as also in criminal matters. When the see of Mentz is vacant, he holds the directory of the diet, and the right of protection over the imperial city of Mullhausen, and all trumpeters throughout the Roman empire.

The elector of Brandenburg is arch-chamberlain of the holy Roman empire; carries the sceptre before the emperor, which he bears also in his coat of arms; presents the emperor with water in a silver basin in order to wash himself; may proceed with respect to his fiefs, principalities, and lands, as with allodial estates; and, at his own pleasure, impose new tolls, and erect mills on all rivers.

The elector Palatine was formerly arch-fewer, but since the treaty of Westphalia arch-treasurer. This house has the right of protection over all the braziers of a large district, and throughout all Germany is protector of the order of St. John; can raise nobles and gentlemen to the degree of counts; and has the right of vengery, by virtue of which, all illegitimate persons, and others of foreign countries, who within a year and a day have no succeeding lord, may be made bondsmen in such places as are subject to his jurisdiction; so that they must bind themselves to the duties of the

electorate, and to the payment of a certain tribute and mortuaries.

When the elector of Bavaria was put under the ban of the empire in 1706, the Palatine recovered the office of arch-fewer, and the elector of Brunswick-Lunenbourg obtained the office of arch-treasurer, by which he still files himself, till another suitable arch-office be conferred on him. He enjoys the alternate succession in the bishopric of Osnaburg, together with some other rights and privileges.

Without the privity of these electors, the emperor can do nothing with regard to leagues and wars of the empire, alienations and mortgages of lands belonging to it, &c. At their investiture they pay no fees, and a new-elected emperor must immediately confirm their privileges and dignities. The diets are held by the emperor, with the consent of the electors; and, at their desire, each elector enjoys a right of appointing two chamber-court assessors, and their electorates have an unlimited privilege *de non appellando*. They may meet together, and hold what are called *electoral diets*. A subject may be guilty of treason against them; and their whole electorates descend to their first-born. By the imperial capitulation, their envoys are to take place of princes in person.

Next to the electors are the princes of the empire, who are also partly spiritual, and partly temporal. The spiritual are archbishops, bishops, abbots, provosts, abbesses, the masters of the Teutonic order, and of St John; but of these, some have each a voice, and others vote by colleges. The temporal princes are dukes, marquises, counts, viscounts, and barons; of which, as among the spiritual, the higher have single voices, but the lower vote by colleges.

Not only all those princes who have seat and voice in the diet, but many others, are vested with sovereign power in their respective territories, or at least are under very few restraints. They are, indeed, more free and absolute than some crowned heads; but still they are subject to the general laws of the empire, and sworn not to engage in any wars or alliances to the prejudice of the emperor and empire. But here it is to be observed, that many have titles of nobility though they are no sovereigns, nor have any seat in the diets: some, however, have a seat, that do not hold immediately of the emperor; or, which is the same, are immediately subject to some other prince, and only mediately to the emperor. The Franks, in imitation of the Romans, reduced all Germany into provinces, over which they placed governors with different titles. They were generally of noble families; and, if there was no material objection against it, their sons were appointed to succeed them: from whence these governors came at length to insist on a right of succeeding their ancestors, and refused to pay homage to the German emperors, every one taking upon him to exercise regal power in his province; from whence have sprung up so many petty sovereigns in the empire. These officers were either *herzogen* or dukes, to whom were committed the government of the larger districts; *graffen*, or earls, who had the care of smaller parts; *pfaltz-graven*, *palgraves*, or counts-palatine, who administered justice when in the verge of the court; *landgraver*, who were set over provinces; *margraves*, or marquises, who were charged with

Germany.

with the care of the marches or borders; and *burggraves*, who were governors of the royal castles and forts. The third college of the diet is that of the free or imperial cities, *i. e.* such as are governed by magistrates of their own, and stand immediately under the emperor and empire. Some of these are wholly Catholic, others entirely Lutheran, and others again mixed. Within their territory they exercise supreme power; and are divided into two benches, the Rhenish and Saxonian. As the princes of the empire took advantage of the necessities or indulgence of the German emperors, to erect the governments they held in capacity of viceroys or governors, into independent principalities and states, so did the cities now called *free* and *imperial*. The emperors, frequently wanting supplies of money to carry on wars, or for other occasions, borrowed large sums of the wealthy trading towns, and paid them again in munificent grants and privileges, making them free states, and independent of the governors of the provinces where they stood: accordingly, these cities, like the princes, exercise all kinds of sovereign power that are consistent with the general laws of the empire; they make laws, constitute courts of justice, coin money, raise forces, and enter into alliances and confederacies; only acknowledging the emperor for their supreme lord, and contributing their share towards the common defence of the empire.

27
Powers of
the diet.

The diet meets at Ratibon on the emperor's summons, and any of the princes may send their deputies thither in their stead. The diet makes laws, raises taxes, determines differences between the several princes and states, and can relieve subjects from the oppressions of their sovereign: and there are two supreme councils, called the *aulic council*, and the *chamber of Witzlar*, to which any of the princes and states, or their subjects, may appeal, when they apprehend themselves aggrieved. The empire was anciently divided into ten circles; which division was confirmed by the emperor Charles V. who settled the portion which every circle, and every prince and member of each circle, should contribute towards the ordinary and extraordinary taxes of the empire. This was entered in a register, called a *matriculation-book*, which is kept by the elector of Mentz. The taxes are either ordinary or extraordinary. The former is what is styled the *chamber-terms*, or the money which each state of the empire is to contribute annually for maintaining the chamber-judiciary of the emperor and empire. The latter are called *Roman months*, which are a certain rate of money or troops settled by the states of the empire, and granted sometimes to the emperor; as for instance, for the support of the emperor, or of the army of the empire, or the forts thereof, or for the war against the Turks, the expenses of an embassy of the empire, &c. By the matricula settled by Charles V. twelve florins were to be paid monthly in lieu of every horseman, and four for every foot soldier. Afterwards it was enacted, that sixty florins should be advanced in lieu of every trooper wanting, and twelve for every footman; and these payments obtained the name of *Roman months*, because the forces or money abovementioned were at first applied towards the forming a body of horse and foot for six months, to conduct the emperor in

his journey to Rome to receive the papal coronation.

Besides the diet, there are yearly meetings of the states of one, two, or three of the circles that lie nearest to one another, called from thence *corresponding circles*; of which there are three classes: first, the Upper Rhine, Lower Rhine, and Westphalia; secondly, the Upper and Lower Saxony; and, thirdly, Franconia, Suabia, and Austria. That of Upper Saxony assembles usually at Leipzig; that of Franconia at Nuremberg; and that of Suabia at Ulm. They treat of the regulation of their coin, the public peace, their treasure, magazines, fortifications, and commerce, rectifying the matricula, putting the decrees of the empire in execution, and appointing judges of the imperial chamber of Witzlar or Spire, and of the aulic council at Vienna; and have power of enacting laws which are not inconsistent with the constitution of the empire. In every circle there are one or two directors, who summon the states of the circle, and have the command of the militia when embodied, regulating their march, quarters, &c. and putting the decrees of the empire in execution, when any prince or member refuses to comply with their resolutions. It is to be observed here, that the Protestant states of the empire, in the diets, are called the *evangelic body*, and have a director, viz. the elector of Saxony. Besides the higher nobility, or high *adel* of the empire, consisting of princes, counts, &c. there is the lower *adel*, or rank of knighthood, which is very numerous in Germany.

28
Annual
meetings of
the states.

With regard to the character of the ancient Germans, they are described to us by the Greek and Roman writers, as resembling the Gauls, and differing from other nations by the largeness of their stature, ruddy complexion, blue eyes, and yellow bushy hair, haughty and threatening looks, strong constitutions, and being proof against hunger, cold, and all kinds of hardship.

29
Character
of the ancient
Germans.

Their native disposition displayed itself chiefly in their martial genius, and in their singular fidelity. The former of these they did indeed carry to such an excess, as came little short of downright ferocity: but, as to the latter, they not only valued themselves highly upon it, but were greatly esteemed by other nations for it; inasmuch that Augustus, and several of his successors, committed the guard of their persons to them, and almost all other nations either courted their friendship and alliance, or hired them as auxiliaries: though it must be owned, at the same time, that their extreme love of liberty, and their hatred of tyranny and oppression, have often hurried them to treachery and murder, especially when they have thought themselves ill used by those who hired them; for, in all such cases, they were easily stirred up, and extremely vindictive. In other cases, Tacitus tells us, they were noble, magnanimous, and beneficent, without ambition to aggrandize their dominions, or invading those from whom they received no injury; rather choosing to employ their strength and valour defensively, than offensively; to preserve their own, than to ravage their neighbours.

Their friendship and intercourse was rather a compound of honest bluntness and hospitality, than of wit, humour, or gallantry. All strangers were sure

Germany. to meet with a kind reception from them, to the utmost of their ability: even those who were not in a capacity to entertain them, made it a piece of duty to introduce them to those who could; and nothing was looked upon as more scandalous and detestable, than to refuse them either the one or the other. They do not seem, indeed, to have had a taste for grand and elegant entertainments; they affected in every thing, in their houses, furniture, diet, &c. rather plainness and simplicity, than sumptuousness and luxury. If they learned the Romans and Gauls the use of money, it was rather because they found it more convenient than their ancient way of bartering one commodity for another; and then they preferred those ancient coins which had been stamped during the times of the Roman liberty, especially such as were either milled or cut in the rims, because they could not be so easily cheated in them, as in some others, which were frequently nothing but copper, or iron, plated over with silver. This last metal they likewise preferred before gold, not because it made a greater show, but because it was more convenient for buying and selling: And as they became, in time, more feared by, or more useful to, the Romans; so they learned how to draw enough of it from them to supply their whole country, besides what flowed to them from other nations.

As they despised superfluities in other cases, so they did also in the connubial way: every man was contented with one wife, except some few of their nobles, who allowed themselves a plurality, more for show than pleasure; and both were so faithful to each other, and chaste, true, and disinterested, in their conjugal affections, that Tacitus prefers their manners, in this respect, to those of the Romans. The men sought not dowries from their wives, but bestowed them upon them. Their youth, in those cold climates, did not begin so soon to feel the warmth of love, as they do in hotter ones: it was a common rule with them, not to marry young; and those were most esteemed who continued longest in celibacy, because they looked upon it as an effectual means to make them grow tall and strong; and to marry, or be concerned with a woman, before they were full twenty-years old, was accounted shameful wantonness. The women shared with their husbands not only the care of their family, and the education of their children, but even the hardships of war. They attended them in the field, cooked their victuals for them, dressed their wounds, stirred them up to fight manfully against their enemies, and sometimes have by their courage and bravery recovered a victory when it was upon the point of being snatched from them. In a word, they looked upon such constant attendance on them, not as a servitude, like the Roman dames, but as a duty and an honour. But what appears to have been still an harder fate upon the ancient German dames was, that their great Odinus excluded all those from his *valhalla*, or paradise, who did not, by some violent death, follow their deceased husbands thither. Yet notwithstanding their having been anciently in such high repute for their wisdom, and supposed spirit of prophecy, and their continuing such faithful and tender helpmates to their husbands, they sunk, in time, so low in their esteem, that, according to the

old Saxon law, he that hurt or killed a woman, was to pay but half the fine that he should have done if he had hurt or killed a man.

There is scarcely any one thing in which the Germans, though so nearly allied in most of their other customs to the Gauls, were yet more opposite to them than in their funerals. Those of the latter were performed with great pomp and profusion; those of the former were done with the same plainness and simplicity which they observed in all other things: the only grandeur they affected in them was, to burn the bodies of their great men with some peculiar kinds of wood; but then the funeral pile was neither adorned with the cloaths and other fine furniture of the deceased, nor perfumed with fragrant herbs and gums: each man's armour, that is, his sword, shield, and spear, were flung into it, and sometimes his riding-horse. The Danes, indeed, flung into the funeral-pile of a prince, gold, silver, and other precious things, which the chief mourners, who walked, in a gloomy guise, round the fire, exhorted the bystanders to fling liberally into it in honour of the deceased. They afterwards deposited their ashes in urns, like the Gauls, Romans, and other nations; as it plainly appears, from the vast numbers which have been dug up all over the country, as well as from the sundry dissertations which have been written upon them by several learned moderns of that nation. One thing we may observe, in general, that, whatever sacrifices they offered for their dead, whatever presents they made to them at their funerals, and whatever other superstitious rites they might perform at them, all was done in consequence of those excellent notions which their ancient religion had taught them, the immortality of the soul, and the bliss or misery of a future life.

It is impossible, indeed, as they did not commit anything to writing till very lately, and as none of the ancient writers have given us any account of it, to guess how soon the belief of their great Odin, and his paradise, was received among them. It may, for aught we know, have been older than the times of Tacitus, and he have known nothing of it, by reason of their scrupulous care in concealing their religion from strangers; but as they conveyed their doctrines to posterity by songs and poems, and most of the northern poets tell us that they have drawn their intelligence from those very poems which were still preserved among them; we may rightly enough suppose, that whatever doctrines are contained in them, were formerly professed by the generality of the nation, especially since we find their ancient practice so exactly conformable to it. Thus, since the surest road to this paradise was, to excel in martial deeds, and to die intrepidly in the field of battle; and since none were excluded from it but base cowards, and betrayers of their country; it is natural to think, that the signal and excessive bravery of the Germans flowed from this ancient belief of theirs: and, if their females were so brave and faithful, as not only to share with their husbands all the dangers and fatigues of war, but, at length, to follow them, by a voluntary death, into the other world; it can hardly be attributed to anything else but a strong persuasion of their being admitted to live with them in that place of bliss. This belief, therefore, whether received originally from the old Celtes,

³⁰
Their funerals.

³¹
Their belief of a future state.

Germany.

or afterwards taught them by the since deified Odin, seems, from their general practice, to have been universally received by all the Germans, though they might differ one from another in their notions of that future life.

The notion of a future happiness obtained by martial exploits, especially by dying sword in hand, made them bewail the fate of those who lived to an old age, as dishonourable here, and hopeless hereafter: upon which account, they had a barbarous way of sending them into the other world, willing or not willing. And this custom lasted several ages after their receiving Christianity, especially among the Prussians and Venidi; the former of whom, it seems, dispatched, by a quick death, not only their children, the sick, servants, &c. but even their parents, and sometimes themselves: and among the latter we have instances of this horrid parricide being practised even in the beginning of the 14th century. All that need be added is, that, if those persons, thus supposed to have lived long enough, either desired to be put to death, or, at least, seemed cheerfully to submit to what they knew they could not avoid, their exit was commonly preceded with a fast, and their funeral with a feast; but if they endeavoured to shun it, as it sometimes happened, both ceremonies were performed with the deepest mourning. In the former, they rejoiced at their deliverance, and being admitted into bliss; in the latter, they bewailed their cowardly excluding themselves from it. Much the same thing was done towards those wives, who betrayed a backwardness to follow their dead husbands.

We must likewise observe, that, in these funerals, as well as in all their other feasts, they were famed for drinking to excess; and one may say of them, above all the other descendants of the ancient Celtes, that their hospitality, banquets, &c. consisted much more in the quantity of strong liquors, than in the elegance of eating. Beer and strong mead, which were their natural drink, were looked upon as the chief promoters of health, strength, fertility, and bravery; upon which account, they made no scruple to indulge themselves to the utmost in them, not only in their feasts, and especially before an engagement, but even in their common meals.

The modern Germans in their persons are tall, fair, and strong built. The ladies have generally fine complexions; and some of them, especially in Saxony, have all the delicacy of features and shape that are so bewitching in a certain island of Europe.

Both men and women affect rich dresses, which in fashion are the same as in France and England; but the better sort of men are excessively fond of gold and silver lace, especially if they are in the army. The ladies at the principal courts differ not much in their dresses from the French and English, only they are not so excessively fond of paint as the former. At some courts they appear in rich furs; and all of them are loaded with jewels, if they can obtain them. The female part of the burghers families, in many German towns, dress in a very different manner, and some of them inconceivably fantastic, as may be seen in many prints published in books of travels: but in this respect they are gradually reforming, and many of them make quite a different appearance in their dresses from

what they did thirty or forty years ago. As to the peasantry and labourers, their dresses as in other parts of Europe, according to their employments, convenience, and opulence. In Westphalia, and most other parts of Germany, they sleep between two featherbeds, or rather the upper one of down, with sheets stitched to them, which by use becomes a very comfortable practice. The most unhappy part of the Germans are the tenants of little needy princes, who squeeze them to keep up their own grandeur; but, in general, the circumstances of the common people are far preferable to those of the French.

The Germans are naturally a frank, honest, hospitable people, free from artifice and disguise. The higher orders are ridiculously proud of titles, ancestry, and shew. The Germans, in general, are thought to want animation, as their persons promise more vigour and activity than they commonly exert, even in the field of battle. But when commanded by able generals, especially the Italians, such as Montecuculi and prince Eugene, they have done great things, both against the Turks and the French. The imperial arms have seldom made any remarkable figure against either of those two nations, or against the Swedes or Spaniards, when commanded by German generals. This possibly might be owing to the arbitrary obliquity of the court of Vienna; for in the two last wars the Austrians exhibited prodigies of military valour and genius.

Industry, application, and perseverance, are the great characteristics of the German nation, especially the mechanical part of it. Their works of art would be incredible were they not visible, especially in watch and clock making, jewellery, turnery, sculpture, drawing, painting, and certain kinds of architecture. The Germans have been charged with intemperance in eating and drinking; and perhaps not unjustly, owing to the vast plenty of their country in wine and provisions of every kind. But those practices seem now to be wearing out. At the greatest tables, though the guests drink pretty freely at dinner, yet the repast is commonly finished by coffee, after three or four public toasts have been drank. But no people have more feasting at marriages, funerals, and birth-days.

The German nobility are generally men of so much honour, that a sharper in other countries, especially in England, meets with more credit if he pretends to be a German, than of any other nation.

The merchants and tradesmen are very civil and obliging. All the sons of noblemen inherit their fathers titles, which greatly perplexes the heralds and genealogists of that country. This perhaps is one of the reasons why the German husbands are not quite so complaisant as they ought otherwise to be to their ladies, who are not entitled to any pre-eminence at the table; nor indeed do they seem to affect it, being far from either ambition or loquacity, though they are said to be somewhat too fond of gaming. From what has been premised, it may easily be conceived, that many of the German nobility, having no other hereditary estate than a high-sounding title, easily enter into their armies, and those of other sovereigns. Their fondness for title is attended with many other inconveniences. Their princes think that the cultivation of their lands, tho' it may treble their revenue,

Germany.

32
Remarkable for drinking to excess.

33
Character of the modern Germans.

is below their attention; and that, as they are a species of beings superior to labourers of every kind, they would demean themselves in being concerned in the improvement of their grounds.

The domestic diversions of the Germans are the same as in England; billiards, cards, dice, fencing, dancing, and the like. In summer, people of fashion repair to places of public resort, and drink the waters. As to their field-diversions, besides their favourite one of hunting, they have bull and bear-beating, and the like. The inhabitants of Vienna live luxuriously, a great part of their time being spent in feasting and carousing; and in winter, when the several branches of the Danube are frozen over, and the ground covered with snow, the ladies take their recreations in sledges of different shapes, such as griffins, tygers, swans, scollop-shells, &c. Here the lady sits, dressed in velvet lined with rich furs, and adorned with laces and jewels, having on her head a velvet cap; and the sledge is drawn by one horse, flag, or other creatures let off with plumes of feathers, ribbons, and bells. As this diversion is taken chiefly in the night-time, servants ride before the sledge with torches, and a gentleman sitting on the sledge behind guides the horse.

GERMEN, the feed-bud; defined by Linnaeus to be the base of the pistillum, which contains the rudiments of the seed; and, in progress of vegetation, swells and becomes the seed-vessel.

In assimilating the vegetable and animal kingdoms, Linnaeus denominates the feed-bud the *ovarium* or *uterus* of plants; and affirms its existence to be chiefly at the time of the dispersion of the male-dust by the antheræ; as, after its impregnation, it becomes a seed-vessel.

GERMEN, by Pliny and the ancient botanists, is used to signify a bud containing the rudiments of the leaves. See GEMMA.

GERMINATIO, among botanists, comprehends the precise time which the seeds take to rise after they have been committed to the soil.—The different species of seeds are longer or shorter in rising, according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mullard, kidney-beans, turneps, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; radish and beet, in six; barley, in seven; orach, in eight; purslane, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chestnut, peony, horned-poppy, hyppocum, and ranunculus scabatus, in one year; rose-bush, cornel-tree, hawthorn, medlar, and hazel-nut, in two. The seeds of some species of orchis, and of some hiliaceous plants, never rise at all. Of seeds, some require to be sowed almost as soon as they are ripe, otherwise they will not sprout or germinate. Of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years.—Mr Adanson asserts, that the sensitive plant retains that virtue for thirty or forty years.

Air and water are the agents of germination. The humidity of the air alone makes several seeds to rise that are exposed to it. Seeds too are observed to rise in water, without the intervention of earth: but water, without air, is insufficient.—Mr Homberg's experiments on this head are decisive. He put several seeds

under the exhausted-receiver of an air-pump, with a view to establish something certain on the causes of germination. Some of them did not rise at all; and the greatest part of those which did, made very weak and feeble productions.

Thus it is for want of air that seeds which are buried at a very great depth in the earth, either thrive but indifferently, or do not rise at all.

They frequently preserve, however, their germinating virtue for many years, within the bowels of the earth; and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants, which had not been seen there in the memory of man.

Were this precaution frequently repeated, it would doubtless be the means of recovering certain species of plants which are regarded as lost; or which perhaps, never coming to the knowledge of botanists, might hence appear the result of a new creation.

Some seeds require a greater quantity of air than others. Thus purslane, which does not rise till after lettuce in the free air, rises before it *in vacuo*; and both prosper but little, or perish altogether, whilst cresses vegetate as freely as in the open air.

GERVAISE, (or GERVASE), of Tilbury, a famous English writer of the 13th century; thus named from his being born at Tilbury on the Thames. He was nephew to Henry II. king of England; and was in great credit with Otto IV. emperor of Germany, to whom he dedicated a Description of the world, and a Chronicle. He also composed a history of England, that of the Holy Land, and other works.

GERUND, is grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as *nom. amandum*, *gen. amandi*, *dat. amando*, *accus. amandum*, *abl. amando*. The word is formed of the Latin *gerundivus*, and that from the verb *gerere*, "to bear."

The *gerund* expresses not only the time, but also the manner, of an action; as, "he fell in running post."—It differs from the participle, in that it expresses the time, which the participle does not; and from the tense properly so called, in that it expresses the manner, which the tense does not.

Grammarians are much embarrassed to settle the nature and character of the *gerunds*. It is certain they are not verbs, nor distinct moods of verbs, in regard they do not mark any judgment, or affirmation of the mind, which is the essence of a verb. And, beside, they have cases; which verbs have not. Some, therefore, will have them to be adjectives passive, whose substantive is the infinitive of the verb: on this footing they denominate them *verbal nouns*, or names formed of verbs, and retaining the ordinary regimen thereof. Thus, say they, *tempus est legendi libros*, or *librorum*, is as much as to say, *tempus est ut legere libros*, vel *librorum*. But others stand up against this decision.

GESNER (Conrad), a celebrated physician and naturalist, was born at Zurich in 1516. Having finished his studies in France, he travelled into Italy, and taught medicine and philosophy in his own country with extraordinary reputation. He was acquainted with the languages; and excelled so much in natural history, that he was furnished the *Pliny of Germany*.

Gestation

Ghent.

many. He died in 1566, leaving many works behind him; the principal of which are, 1. A history of animals, plants, and fossils; 2. *Bibliotheca Universalis*; 3. A Greek and Latin lexicon.

GESTATION, among physicians. See **PREGNANCY**.

GESTRICIA, a province of Sweden, bounded by Helsingia on the north, by the Bothnic gulph on the east, by Upland on the south, and by Dalecarlia on the west.

GESTURE, in rhetoric, consists chiefly in the proper action of the hands and face. See **DECLAMATION**, n° xii. and **ORATORY**, n° 130, 131.

GETHIN (Lady Grace), an English lady of uncommon parts, was the daughter of Sir George Norton of Abbots-Leigh in Somersetshire, and born in the year 1676. She had all the advantages of a liberal education; and became the wife of Sir Richard Gethin, of Gethin-Grott in Ireland. She was mistress of great accomplishments, natural and acquired, but did not live long enough to display them to the world; for she died in the 21st year of her age. She was buried in Westminster-abbey, where a beautiful monument with an inscription is erected over; and, for perpetuating her memory, provision was made for a sermon to be preached in Westminster-abbey, yearly, on Ash-Wednesday for ever. She wrote; and left behind her, in loose papers, a work, which, soon after her death, was methodized, and published under the title of "*Reliquiæ Gethinianæ*:" or, Some remains of "the most ingenious and excellent lady, Grace lady "Gethin, lately deceased. Being a collection of choice "discourses, pleasant apophthegms, and witty sentences. Written by her, for the most part, by way "of essay, and at spare hours." Lond. 1700, 4to; with her picture before it.

GEUM, **AVENS**, or *Herb-Bennet*; a genus of the pentagynia order, belonging to the icosaandra class of plants. There are five species, of which the most remarkable are, 1. The arbutum, with thick fibrous roots of an aromatic taste, rough, serrated leaves, and upright, round, hairy stalks terminated by large yellow flowers, succeeded by globular fruit. 2. The rivale, with a very thick, fleshy, and fibrous root, hairy leaves, and upright stalks, 10 or 12 inches high, terminated by purple flowers nodding on one side. Of this there are varieties with red and with yellow flowers.—Both these are natives of Britain, and are easily propagated either by the root or seed. The roots of the first, gathered in the spring before the stem comes up, and infused in ale, give it a pleasant flavour, and prevent its growing four. Infused in wine, they have a stomachic virtue. The taste is mildly astringent and aromatic, especially when the plant grows in warm dry situations; but in moist shady places, it hath little virtue. Cows, goats, sheep, and swine, eat the plant; horses are not fond of it.—The powdered root of the second species will cure tertian agues, and is daily used for that purpose by the Canadians. Sheep and goats eat the plant; cows, horses, and swine, are not fond of it.

GHEENT, a city of the Austrian Netherlands, capital of the province of Flanders. It is seated on four navigable rivers, the Scheld, the Lys, the Lieve, and the Moere, which run through it, and divide it into

canals. These form 26 little isles, over which there are 300 bridges; among which there is one remarkable for a statue of brass of a young man who was obliged to cut off his father's head; but as he was going to strike, the blade flew into the air, and the hilt remained in his hand, upon which they were both pardoned. There is a picture of the whole transaction in the town-house. Ghent is surrounded with walls and other fortifications, and is tolerably strong for a place of its circumference. But all the ground within the walls is not built upon. The streets are large and well paved, the market-places spacious, and the houses built with brick. But the Friday's market-place is the largest, and is remarkable for the statue of Charles V. which stands upon a pedestal in the imperial habit. That of Cortere is remarkable for a fine walk under several rows of trees. In 1737 a fine opera-house was built here, and a guard-house for the garrison. Near the town is a very high tower, with a handsome clock and chimies. The great bell weighs 11,000 pounds.

This town is famous for the pacifications signed here, in 1526, for settling the tranquillity of the Seventeen Provinces, which was afterwards confirmed by the king of Spain. It was taken by Lewis XIV. in 1678, who afterwards restored it. The French took possession of it again after the death of Charles II. of Spain. In 1706, it was taken by the duke of Marlborough; and by the French, in 1708; but it was retaken the same year. Last of all, the French took it by surprise after the battle of Fontenoy; but at the peace of Aix la Chapelle, it was rendered back. This is the birth-place of John of Gaunt. It is very well seated for trade, on account of its rivers and canals. It carries on a great commerce in corn; and has linen, woollen, and silk manufactures. E. Long. 4. O. N. Lat. 51. 24.

GIAGH, in chronology, a cycle of 12 years; in use among the Turks and Cathayans.

Each year of the giagh bears a name of some animal: the first, that of a mouse; the second, that of a bullock; the third, of a lynx or leopard; the fourth, of a hare; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They also divide the day into 12 parts, which they call *giaghs*, and distinguish them by the name of some animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIALLOLINO, in natural history, a fine yellow pigment much used under the name of **NAPLES YELLOW**.

GIANT, a person of extraordinary bulk and stature.

The romances of all ages have furnished us with so many extravagant accounts of giants of incredible bulk and strength, that the existence of such people is now generally disbelieved. It is commonly thought, that the stature of man hath been the same in all ages; and some have even pretended to demonstrate the impossibility of the existence of giants mathematically. Of these our countryman M^r Laurin hath been the most explicit.

"In general, (says he), it will easily appear, that the efforts tending to destroy the cohesion of beams arising from

Ghent

Giant.

Giant.

from their own gravity only, increase in the quadruplicate ratio of their lengths; but that the opposite efforts tending to preserve their cohesion, increase only in the triplicate proportion of the same lengths. From which it follows, that the greater beams must be in greater danger of breaking than the lesser similar ones; and that though a lesser beam may be firm and secure, yet a greater similar one may be made so long, that it will necessarily break by its own weight. Hence Galileo justly concludes, that what appears very firm, and succeeds very well in models, may be very weak and infirm, or even fall to pieces by its own weight, when it comes to be executed in large dimensions according to the model.

"From the same principle he argues, that there are necessary limits in the operations of nature and art, which they cannot surpass in magnitude. Were trees of a very enormous size, their branches would fall by their own weight. Large animals have not strength in proportion to their size; and if there were any land-animals much larger than those we know, they could hardly move, and would be perpetually subject to the most dangerous accidents. As to the animals of the sea, indeed, the case is different; for the gravity of the water in a great measure sustains those animals; and in fact, these are known sometimes to be vastly larger than the greatest land-animals. Nor does it avail against this doctrine to tell us, that bones have sometimes been found which were supposed to have belonged to giants of immense size; such as the skeletons mentioned by Strabo and Pliny, the former of which was 60 cubits high, and the latter 46: for naturalists have concluded on just grounds, that in some cases these bones had belonged to elephants; and that the larger ones were bones of whales, which had been brought to the places where they were found by the revolutions of nature that have happened in past times. Though it must be owned, that there appears no reason why there may not have been men who have exceeded by some feet in height the tallest we have seen."

It will easily be seen, that arguments of this kind can never be conclusive; because, along with an increase of stature in any animal, we must always suppose a proportional increase in the cohesion of the parts of its body. Large works sometimes fail when constructed on the plan of models, because the cohesion of the materials whereof the model is made and of the large work are the same; but a difference in this respect will produce a very remarkable difference in the ultimate result. Thus, suppose a model is made of fir-wood, the model may be firm and strong enough; but a large work made also of fir, when executed according to the plan of the model, may be so weak that it will fall to pieces with its own weight. If, however, we make use of iron for the large work instead of fir, the whole will be sufficiently strong, even though made exactly according to the plan of the model. The like may be said with regard to large and small animals. If we could find an animal whose bones exceeded in hardness and strength the bones of other animals as much as iron exceeds fir, such an animal might be of a monstrous size, and yet be exceedingly strong. In like manner, if we suppose the flesh and bones of a giant to be greatly superior in hardness and strength to the

Giant.

bones of other men, the great size of his body will be no objection at all to his strength. The whole of the matter, therefore, concerning the existence of giants, must rest on the credibility of the accounts we have from those who pretend to have seen them, and not on any arguments drawn *a priori*.

In the scripture we are told of *giants*, who were produced from the marriages of the *sons of God* with the *daughters of men*. But of this passage no sufficient explanation hath yet been found: nor can we be sure that the word translated *giants* does there imply any extraordinary stature; seeing in other places it is explained by *falling away, revolting, or transgressing*. In other places of scripture, however, giants, with their dimensions, are mentioned in such a manner that we cannot possibly doubt; as in the case of Og king of Bashan, and Goliath. In a memoir read before the Academy of Sciences at Rouen, M. Le Cat gives the following account of giants that are said to have existed in different ages.

"Profane historians have given seven feet of height to Hercules their first hero; and in our days we have seen men eight feet high. The giant who was slain in Rouen, in 1735, measured eight feet some inches. The emperor Maximin was of that size; Skenkiss and Platerus, physicians of the last century, saw several of that stature; and Goropius faw a girl who was ten feet high.—The body of Orestes, according to the Greeks, was eleven feet and a half; the giant Galbarr, brought from Arabia to Rome under Claudius Cæsar, was near ten feet; and the bones of Secondilla and Pusio, keepers of the gardens of Salust, were but six inches shorter. Funnam, a Scotman, who lived in the time of Eugene II. king of Scotland, measured eleven feet and a half: and Jacob le Maire, in his voyage to the frighths of Magellan, reports, that, on the 17th of December 1615, they found at Port Desire several graves covered with stones; and having the curiosity to remove the stones, they discovered human skeletons of ten and eleven feet long. The chevalier Scory, in his voyage to the Pike of Teneriffe, says, that they found in one of the sepulchre caverns of that mountain the head of a Guanche which had 80 teeth, and that the body was not less than 15 feet long. The giant Ferragus, slain by Orlando nephew of Charlemagne, was 18 feet high. Rioland, a celebrated anatomist, who wrote in 1614, says, that some years before there was to be seen in the suburbs of St Germain the tomb of the giant Iforet, who was 20 feet high. In Rouen, in 1509, in digging in the ditches near the Dominicans, they found a stone-tomb containing a skeleton whose skull held a bushel of corn, and whose shin-bone reached up to the girdle of the tallest man there, being about four feet long, and consequently the body must have been 17 or 18 feet high. Upon the tomb was a plate of copper, whereon was engraved, "In this tomb lies the noble and puissant lord, the chevalier Ricon de Vallenmont, and his bones." Platerus, a famous physician, declares, that he saw at Lucerne the true human bones of a subject which must have been at least 19 feet high. Valence in Dauphiné boasts of possessing the bones of the giant Bucart, tyrant of the Vivarais, who was slain by an arrow by the count De Cabillon his vassal. The Dominicans had a part of the shin-bone, with the articulation near

Giant.

of the knee, and his figure painted in fresco, with an inscription, shewing that this giant was 22 feet and a half high, and that his bones were found in 1705, near the banks of the Morderi, a little river at the foot of the mountain of Crussol, upon which (tradition says) the giant dwelt.

"January 11. 1613, some masons digging near the ruins of a castle in Dauphiné, in a field which (by tradition) had long been called *the giant's field*, at the depth of 18 feet discovered a brick-tomb 30 feet long, 12 feet wide, and 8 feet high; on which was a grey stone, with the words *Theutobochus Rex* cut thereon. When the tomb was opened, they found a human skeleton entire, 25 feet and a half long, 10 feet wide across the shoulders, and five feet deep from the breast-bone to the back. His teeth were about the size each of an ox's foot, and his shin-bone measured four feet. —Near Mazarino, in Sicily, in 1516, was found a giant 30 feet high; his head was the size of an hog's head, and each of his teeth weighed five ounces. Near Palermo, in the valley of Mazara, in Sicily, a skeleton of a giant 30 feet long was found, in the year 1548; and another of 33 feet high, in 1550; and many curious persons have preserved several of these gigantic bones.

"The Athenians found near their city two famous skeletons, one of 34 and the other of 36 feet high.

"At Totu, in Bohemia, in 758, was found a skeleton, the head of which could scarce be encompassed by the arms of two men together, and whose legs, which they still keep in the castle of that city, were 26 feet long. The skull of the giant found in Macedonia, September 1691, held 210 pounds of corn.

"The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt these facts; but thinks the bones were those of elephants, whales, or other enormous animals.

"Elephants bones may be shewn for those of giants; but they can never impose on connoisseurs. Whales, which, by their immense bulk, are more proper to be substituted for the largest giants, have neither arms nor legs; and the head of that animal hath not the least resemblance to that of a man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been seen by anatomists, and by them have been reputed real human bones, the existence of giants is proved."

With regard to the credibility of all, or any of these accounts, it is difficult to determine any thing. If, in any castle of Bohemia, the bones of a man's leg 26 feet in length are preserved, we have indeed a decisive proof of the existence of a giant, in comparison of whom most others would be but pigmies. Nor indeed could these bones be supposed to belong to an elephant; for an elephant itself would be but a dwarf in comparison of such an enormous monster. But if these bones were really kept in any part of Bohemia, it seems strange that they have not been frequently visited, and particular descriptions of them given by the learned who have travelled into that country.—It is certain, however, that there have been nations of men considerably exceeding the common stature. Thus, all the Roman historians inform us, that the Gauls and Germans exceeded the Italians in size, and it appears that the Italians in those days were of much the same stature with the people of the present age. Among

Vol. V.

these northern nations, it is also probable, that there would be as great differences in stature, as there are among the present race of men. If that can be allowed, we may easily believe that some of these barbarians might be called *giants*, without any great impropriety. Of this superiority of size, indeed, the historian Florus gives a notable instance in Teutobochus, above-mentioned, king of the Teutones; who being defeated and taken prisoner by Marius, was carried in triumph before him at Rome, when his head reached above the trophies that were carried in the same procession.

But whether these accounts are credited or not, we are very certain, that the stature of the human body is by no means absolutely fixed. We are ourselves a kind of giants in comparison of the Laplanders; nor are these the most diminutive people to be found upon the earth. The abbe la Chappe, in his journey into Siberia in order to observe the last transit of Venus, passed through a village inhabited by people called *Wotacks*, neither men nor women of whom were above four feet high. The accounts of the Patagonians also, which cannot be entirely discredited, render it very probable, that somewhere in South America there is a race of people very considerably exceeding the common size of mankind, and consequently that we cannot altogether discredit the relations of giants handed down to us by ancient authors; though what degree of credit we ought to give them, is not easy to be determined.

GIANTS-Causeway, a vast collection of Basaltic pillars in the county of Antrim in Ireland. See the article BASALTIC.

The principal or grand causeway, for there are several less considerable and scattered fragments of similar workmanship, consists of a most irregular arrangement of many hundred thousands of columns of a black kind of rock, hard as marble: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarce any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, may be about 20 feet; they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand, was never yet discovered. This grand arrangement extends nearly 200 yards, visible at low water; how far beyond, is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway, which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width; which has been the cause of such wild and dissimilar representations of this causeway, which different accounts have exhibited. The highest part of this causeway is the narrowest at the

18 Y

very

Giant.

very foot of the impending cliff, from whence the whole projects, where, for four or five yards, it is not above ten or fifteen feet wide. The columns of this narrow part incline from a perpendicular a little to the westward, and form a slope on their tops, by the very unequal height of the columns on the two sides, by which an ascent is made at the foot of the cliff, from the head of one column to the next above, *gradatim*, to the top of the great causeway, which, at the distance of half a dozen yards from the cliff, obtains a perpendicular position, and, lowering in its general height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade, that may be easily walked on, rather inclining to the water's edge. But from high water-mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff, it turns a little to the east for 20 or 30 yards, and then links into the sea. The figure of these columns is almost unexceptionably pentagonal, or composed of five sides; there are but very few of any other figure introduced: some few there are of three, four, and six sides, but the generality of them are five-sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are alike. Nor is the composition of these columns or pillars less deserving the attention of the curious spectator. They are not of one solid stone in an upright position; but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like ball and socket, or like the joints in the vertebrae of some of the larger kind of fish, the one end at the joint having a cavity, into which the convex end of the opposite is exactly fitted. This is not visible, but by disjoining the two stones. The depth of the concavity or convexity is generally about three or four inches. And what is still farther remarkable of the joint, the convexity, and the correspondent concavity, is not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the column will admit; and, consequently, as the angles of these columns are, in general, extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagonal, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still farther very remarkable, likewise, that the articulations of these joints are frequently inverted; in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length, also, of these particular stones, from joint to joint, is various: in general, they are from 18 to 24 inches long; and, for the most part, longer toward the bottom of

the columns than nearer the top, and the articulation of the joints something deeper. The size, or diameter, likewise, of the columns is as different as their length and figure; in general, they are from 15 to 20 inches in diameter. There are really no traces of uniformity or design discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns above water, there are others just by, of equal height, that are more or less convex or concave, which shew them to have been joined to pieces that have been washed or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made as even as might be; and the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon it and continually removing some of the upper stones and exposing fresh joints. And farther, as these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may, with reason, be inferred of the interior columns, whose tops only are visible. Yet what is very extraordinary, and equally curious, in this phenomenon, is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either on the sides or angles. And it is really a most curious piece of entertainment to examine the close contexture and nice insertion of such an infinite variety of angular figures as are exhibited on the surface of this grand parade. From the infinite dissimilarity of the figure of these columns, this will appear a most surprising circumstance to the curious spectator; and would incline him to believe it a work of human art, were it not, on the other hand, inconceivable that the wit or invention of man should construct and combine such an infinite number of columns, which should have a general apparent likeness, and yet be so universally dissimilar in their figure, as that, from the minutest examination, not two in ten or twenty thousand should be found, whose angles and sides are equal among themselves, or of the one column to those of the other. That it is the work of nature, there can be no doubt to an attentive spectator, who carefully surveys the general form and situation, with the infinitely various figuration of the several parts of this causeway. There are no traces of regularity or design in the outlines of this curious phenomenon; which, including the broken and detached pieces of the same kind of workmanship, are extremely scattered and confused, and, whatever they might originally, do not, at present, appear to have any connection with the grand or principal causeway, as to any supposable design or use in its first construction, and as little design can be inferred from the figure or situation of the several constituent parts. The whole exhibition is, indeed, extremely confused, dissimilar, and destitute of every appearance

Giant,
Gibbous.

ance of use or design in its original construction. But what, beyond dispute, determines its original to have been from nature, is, that the very cliffs, at a great distance from the causeway, especially in the bay to the eastward, exhibit, at many places, the same kind of columns, figured and jointed in all respects like those of the grand causeway: some of them are seen near to the top of the cliff, which in general, in these bays to the east and west of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, near a hundred rods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting, in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and, being longest in the middle of the arrangement, shortening on either hand in view, they have obtained the appellation of *organs*, from a rude likeness, in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns that now appears, is really the original exterior line, to the seaward, of this collection. But how far they extend internally into the bowels of the incumbent cliff, is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for besides the many pieces that are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly shew them to be in an oblique position, and about half-way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from their original upright, to their present inclining or oblique position, by the sinking or falling of the cliff.

GIBBOUS, a term in medicine, denoting any protuberance or convexity of the body, as a person haunched or hump-backed.

Infants are much more subject to gibbosity than adults, and it oftener proceeds from external than internal causes. A fall, blow, or the like, frequently thus distorts the tender bones of infants. When it proceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebrae; though the spine may be inflected forward, and the vertebrae thrown out by a too strong and repeated action of the abdominal muscles. This, if not timely redressed, grows up and fixes as the bones harden, till in adults it is totally irremediable: but when the disorder is recent, and the person young, there are hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally on the gibbous part; and

this by long wearing may set all right. The surgeons, however, have a different instrument, which they call a *crofs*; much more efficacious, though not quite so convenient in the wearing. By the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with hungary-water, spirit of lavender, or the like, and defended with a strengthening plaster.

GIBBOUS, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned, or falcated; and the light one lunched out, convex, or gibbous.

GIELLINS, or GIBELINS, a famous faction in Italy, opposite to another called the GUELPHS.

These two factions ravaged and laid waste Italy for a long series of years; so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The Gibelins stood for the emperor against the pope: but concerning their origin and the reason of their names, we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Fredrick II.'s being excommunicated by the pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf. See (*History of*) ITALY.

GIBET, a machine in manner of a gallows, whereon notorious criminals, after execution, are hung in irons or chains, as spectacles in *terrorem*. See GALLOWs. —The word in French, *gibet*, properly denotes what we call gallows: it is supposed to come originally from the Arabic *gibel*, “mount, or elevation of ground;” by reason *gibets* are usually placed on hills or eminences.

GIBBET. See GIBET.

GIBRALTAR, a famous promontory, or rather peninsula, of Spain, lying in N. Lat. 35° 50', W. Long. 5° 35'. To the ancients it was known by the name of *Calpe*, and was also called one of the *Pillars of Hercules*; by the Arabians it is called *Gebel Tarek*, that is, the Mount of Tarek, from *Tarek*, the name of the Saracen general who conquered Spain in the beginning of the eighth century. The whole is an immense rock, rising perpendicularly about 440 yards, measuring, from north to south, about two English miles, but not above one in breadth from east to west. —The town lies along the bay on the west side of the mountain on a decline; by which, generally speaking, the rains pass through it, and keep it clean. The old town was considerably larger than the new, which at present consists of between 4 and 500 houses. Many of the streets are narrow and irregular: the buildings are of different materials; some of natural stone out of the quarries, some of a facitious or artificial stone, and a few of brick. The people are supplied with fresh provisions chiefly from the coast of Barbary, with fruit,

Gibbous
Gibraltar.

roots, and vegetables, of all sorts from thence, or from their own gardens. Besides what is properly called the town, there are several spacious and commodious public edifices erected; such as barracks for the soldiers, with apartments for their officers, magazines of different kinds, storehouses for provisions, &c. The inhabitants, exclusive of the British subjects dependent on the garrison, or who reside there from other motives, consist of some Spaniards, a few Portuguese, a considerable number of Genoese, and about as many Jews; making in the whole, according to Dr Campbell, between two and three thousand, without reckoning the garrison; though some make them much fewer. The town may be said to have two ports; the first lying to the north, and is proper only for small vessels; the other is very commodious for large vessels, and has a fine stone quay. The bay is very beautiful and capacious, being in breadth about five miles, and in depth eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at an hundred fathoms depth, so that a Squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise to the subsistence of the inhabitants, by supplying them with plenty of fish.

The strait of Gibraltar, through which the ocean passes into the Mediterranean, thereby dividing Europe from Africa, runs from west to east about 13 leagues. In this strait there are three remarkable promontories or capes on the Spanish side, and as many opposite to them on the Barbary side. The first of these, on the side of Spain, is cape Trefalgar, opposite to which is cape Spartel; and in the neighbourhood of this stood the fortrefs of Tangier, once in the possession of the British. The next on the Spanish side is Tarifa; and over against it lies Malabata, near the town of Alcafar, where the straits are about five leagues broad. Lastly, Gibraltar, facing the mountain of Abyla, near the fortrefs and town of Ceuta, which make the eastern entry of the straits.

The fortrefs of Gibraltar was formerly thought to be impregnable; but, in 1704, it was proposed by the two English Admirals Sir John Leake and Sir George Rooke, and by Prince George of Hesse Darmstadt, to attempt the reduction of it. The fleet entered the bay on the 21st of July; the prince landed a body of troops on the Ithmus, between the bay and the Mediterranean; the fleet cannonaded the town from the bay; and a detachment of English seamen having debarked at Europa point, with some loss, carried the outworks. This made such an impression on the inhabitants and the garrison, that the governor (the Marquis de Salinas) capitulated; and the Prince of Hesse took possession of the place on the 24th of the same month, with the loss of less than 100 men. The Spaniards, extremely sensible of the loss they had sustained, immediately sent an army of 10,000 men, under the command of the Marquis le Villadarias, to besiege it; and at the same time the Count de Thoulouse, who commanded the French fleet in the Mediterranean, put to sea in order to co-operate with the Spaniards. This produced the battle of Malaga, August 13th 1704, in which the French were defeated; though Sir George Rooke was in no condition to prosecute his victory, on account of his want of ammuni-

tion. The siege, however, went on, and the place was so much pressed, that if Sir John Leake, who was sent to its relief, had arrived one day later, the place had been inevitably lost. Five hundred Spaniards had bound themselves by an oath, either to become masters of Gibraltar, or to perish in the attempt. They had accordingly concealed themselves in some of the caves, of which there are many in the southern part of the promontory. The mountain had also at that time many trees upon it, by which the Spaniards ascended, and which were on that account afterwards cut down by the garrison. The enterprize of the Spaniards, however, did not succeed; for, having attempted to scale the walls, they were all to a man destroyed. Marshal de Tessé then joined the Spanish army, with a considerable body of French troops, and the siege was continued for six months longer; when the French fleet being defeated by Sir John Leake*, they were forced to turn the siege into a blockade. The excellent conduct, however, of Sir John Leake, and the Prince of Hesse Darmstadt, obliged them at last to abandon the enterprize. On the conclusion of the war, the fortrefs of Gibraltar was ceded to Britain, but without any territory; and ever since the Spaniards have fortified lines on the Ithmus, to prevent any communication between the garrison and the country. They have ever since continued to behold it with a jealous eye, and have meditated several attempts against it. In 1727 they again besieged it in form with a great army: but having made very little progress during four months, which they consumed before it, a cessation of arms took place; and no further attempt has been made till the present year (1779.)

The possession of Gibraltar is of very great consequence to Britain. It not only gives us the command of the Straits, and their navigation: but affords refreshment and accommodation to our fleets in time of war, and to our merchantmen at all times; which, to a maritime power, is of very great advantage. From its situation, it divides both the kingdoms of France and Spain; that is, it hinders a ready communication by sea between the different parts of these kingdoms. This, of course, hinders the conjunction of the fleets and squadrons with each other, or at least renders it so difficult as to be a perpetual check upon these ambitious powers. It awes also the piratical states of Barbary, and in like manner the emperor of Morocco; inasmuch, that our commerce is more safe than that of any other European power, which gives us great advantages in point of freight. It is otherwise highly favourable to our trade in the Mediterranean and Levant. It procures us the respect of the Italian and other powers; who, though far distant from Britain, must consider this as an instance of her power to hurt or assist them. It also saves us the expence of squadrons and convoys, upon any disputes or disturbances that may happen among those powers, and which would otherwise be necessary for the protection of our navigation.

GIBSON (RICHARD), an English painter, commonly called the *Dwarf*, was originally page to a lady at Mortlake; who, observing that his genius led him to painting, had the generosity to get him instructed in the rudiments of that art. He devoted himself to Sir Lely's manner, and copied his pictures

* See Leake.

Gibson.

to admiration, especially his portraits: his paintings in water-colours were also esteemed. He was in great favour with Charles I. who made him his page of the back-stairs; and he had the honour to instruct in drawing queen Mary and queen Anne when they were princesses. He married one Mrs Anne Shepherd, who was also a dwarf; on which occasion king Charles I. honoured their marriage with his presence, and gave away the bride. Mr Waller wrote a poem on this occasion, intitled "The Marriage of the Dwarfs;" in which are these lines:

"Design or chance makes others wive,
 "But nature did this match contrive;
 "Eve might as well have Adam fled,
 "As he deny'd her little bed.
 "To him, for whom heav'n seem'd to frame
 "And measure out this only dame."

Mr Fenton, in his notes on this poem, observes that he had seen this couple painted by Sir Peter Lely; and that they were of an equal stature, each being three feet ten inches high. However, they had nine children, five of which arrived at maturity; these well proportioned, and of the usual standard of mankind. But what nature denied this couple in stature, she gave them in length of days: for Mr Gibson died in the 75th year of his age; and his wife, having survived him almost 20 years, died in 1709, aged 89.

GIBSON (Dr Edmund), bishop of London, was born in Westmoreland, in 1669. He applied himself early and vigorously to learning, and displayed his knowledge in several writings and translations, which recommended him to the patronage of archbishop Tenison. He was appointed domestic chaplain to his Grace; and we soon after find him rector of Lambeth, and archdeacon of Surry. Becoming thus a member of the convocation, he engaged in a controversy, which was carried on with great warmth by the members of both houses, and defended his patron's rights, as president, in eleven pamphlets; he then formed and completed his more comprehensive scheme of the legal duties and rights of the English clergy, which was at length published under the title of *Codex Juris Ecclesiastici Anglicani*, in folio. Archbishop Tenison dying in 1715, and Dr Wake bishop of Lincoln being made archbishop of Canterbury, Dr Gibson succeeded the latter in the see of Lincoln, and in 1720 was promoted to the bishoprick of London. He now not only governed his diocese with the most exact regularity, but by his greater care promoted the spiritual affairs of the Church of England colonies in the West-Indies. He was extremely jealous of the least of the privileges belonging to the church; and therefore, though he approved of the toleration of the Protestant Dissenters, he continually guarded against all the attempts made to procure a repeal of the corporation and test acts; in particular, his opposition to those licentious assemblies called *masquerades*, gave great umbrage at court, and effectually excluded him from all further favours. He spent the latter part of his life in writing and printing pastoral letters, visitation-charges, occasional sermons, and tracts against the prevailing immoralities of the age. His pastoral letters are justly esteemed as the most masterly productions against infidelity and enthusiasm. His most celebrated work, the *Codex*, has been already mentioned. His other publications are, 1. An edition of Drummond's

Poemata Middiana, and James V. of Scotland's *Cantilena Rustica*, with notes. 2. The *Chronicon Saxonum*, with a Latin translation, and notes. 3. *Reliquiae Spelmanianae*, the posthumous works of Sir Henry Spelman, relating to the laws and antiquities of England. 4. An edition of *Quintilian de Arte Oratoria*, with notes. 5. An English translation of Camden's *Britannia*, with additions, two volumes folio: and, 5. A number of small pieces, that have been collected together and printed in three volumes folio.—His intense application to study impaired his health; notwithstanding which, he attained the age of 79. He expired in September 1748, after an episcopate of near 33 years.

With regard to bishop Gibson's private life and character, he was in every respect a perfect economist. His abilities were so well adapted to discharge the duties of his sacred function, that, during the incapacity of archbishop Wake, the transaction of ecclesiastical affairs was committed to the bishop of London. He was a true friend to the established church and government, and as great an enemy to persecution. He was usually consulted by the most learned and exalted personages in church and state, and the greatest deference was paid to his judgment. He possessed the social virtues in an eminent degree; his beneficence was very extensive; and had such generosity, that he freely gave two thousand five hundred pounds, left him by Dr Crow, who was once his chaplain, to Crow's own relations, who were very poor.

GIFT, *Donum*, in law, is a conveyance which passeth either lands or goods; and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken strictly, it is applicable only to lands and tenements given in tail; but *gift*, and *grant*, are too often confounded.

GIGG, GIGA, or JIGG; a gay, brisk, and sprightly composition; and yet in full measure, as well as the allemande, which is more serious.—Menage takes the word to arise from the Italian *giga*, a musical instrument mentioned by Dante.

GILAN, or GHILAN, a considerable province of Asia, in Persia, lying on the side of the Caspian sea, and to the S. W. of it. It is supposed to be the Hyrcania of the ancients. It is very agreeably situated, having the sea on one side, and high mountains on the other; and there is no entering in but through narrow passes, which may easily be defended. The sides of the mountains are covered with many sorts of fruit-trees, and in the highest parts of them there are deer, bears, wolves, leopards, and tigers; which last the Persians have a method of taming, and hunt with them as we do with dogs.—Gilan is one of the most fruitful provinces of all Persia; and produces abundance of silk, oil, wine, rice, and tobacco, besides excellent fruits. The inhabitants are brave, and of a better complexion than the other Indians, and the women are accounted extremely handsome. Resht is the capital town.

GILBERT, or GILBERD, (William), a physician, was born at Colchester, in the year 1540, the eldest son of the recorder of that borough. Having spent some time in both universities, he went abroad; and

Gibson
Gilbert.

and at his return settled in London, where he practised with considerable reputation. He became a member of the college of physicians, and physician in ordinary to Queen Elizabeth, who, we are told, gave him a pension to encourage him in his studies. From his epitaph it appears that he was also physician to King James I. He died in the year 1603, aged 63; and was buried in Trinity-church in Colchester, where a handsome monument was erected to his memory. His books, globes, instruments, and fossils, he bequeathed to the college of physicians, and his picture to the school-gallery at Oxford. He wrote, 1. *De magnetis, magneticisque corporibus, et de magno magnetis tellure, physiologia nova*; London 1600, folio. 2. *De mundo nostro sublimitari, philosophia nova*; Amsterdam 1651, 4to. He was also the inventor of two mathematical instruments for finding the latitude at sea without the help of sun, moon, or stars. A description of these instruments was afterwards published by Thomas Blondeville in his *Theoriques of the planets*.

GILBERT (Sir Humphrey), a brave officer, and skilful navigator, was born about the year 1539, in Devonshire, of an ancient and honourable family. Though a second son, he inherited a considerable fortune from his father. He was educated at Eaton, and afterwards at Oxford; where probably he did not continue long, as he hath escaped the industrious Anthony Wood. It seems he was intended to finish his studies in the Temple; but, being introduced at court by his aunt Mrs Catharine Ashley, then in the queen's service, he was diverted from the study of the law, and commenced soldier. Having distinguished himself in several military expeditions, particularly that to Newhaven in 1563, he was sent over to Ireland to assist in suppressing a rebellion; where, for his signal services, he was made commander in chief and governor of Munster, and knighted by the lord deputy, Sir Henry Sidney, on the first day of the year 1570. He returned soon after to England, where he married a rich heiress. Nevertheless, in 1572, he failed with a squadron of nine ships, to reinforce Colonel Morgan, who at that time meditated the recovery of Flushing.

Probably on his return to England he resumed his cosmographical studies, to which he was naturally inclined: for, in the year 1576, he published his book on the North-west passage to the East Indies; and as Martin Frobisher failed the same year, probably it was in consequence of this treatise. In 1578, he obtained from the queen a very ample patent, empowering him to discover and possess in North America any lands then unsettled. He sailed to Newfoundland, but soon returned to England without success: nevertheless, in 1583, he embarked a second time with five ships, the largest of which put back on account of a contagious distemper on board. Our general landed on Newfoundland on the third of August, and on the fifth took possession of the harbour of St John's. By virtue of his patent, he granted leases to several people; but, though none of them remained there at that time, they settled afterwards in consequence of these leases: so that Sir Humphrey deserves to be remembered as the real founder of our vast American empire. On the 20th of August, he put to sea again, on board a small sloop; which on the 29th foundered in a hard gale of wind. Thus perished Sir Humphrey Gilbert; a man

of quick parts, a brave soldier, a good mathematician, a skilful navigator, and of a very enterprising genius. We learn also, that he was remarkable for his eloquence, being much admired for his patriotic speeches both in the English and Irish parliaments. He wrote "A discourse to prove a passage by the north-west to Cathaja and the East Indies, printed Lond. 1576." This treatise, which is a masterly performance, is preserved in Hakluyt's collection of voyages, vol. iii. p. 11. The style is superior to most, if not to all, the writers of that age; and shews the author to have been a man of considerable reading. He mentions, at the close of this work, another treatise, on Navigation, which he intended to publish: it is probably lost.

GILBERTINES, a religious order founded in England by St Gilbert, in the reign of Henry I. The nuns followed the rule St Benedict, and the monks that of Augustin. There were many monasteries of this order in different parts of England.

GILCHRIST (Dr Ebenezer), an eminent Scots physician, was born at Dumfries in 1707. He began the study of medicine at Edinburgh, which he afterwards prosecuted at London and Paris. He obtained the degree of doctor of medicine from the university of Rheims; and in the year 1732, he returned to the place of his nativity, where he afterwards constantly resided, and continued the practice of medicine till his death.

It may with justice be said, that few physicians of the present century have exercised their profession in a manner more respectable or successful than Dr Gilchrist; and few have contributed more to the improvement of the healing art. Having engaged in business in an early period of life, his attention was wholly devoted to observation. Endowed by nature with a judgment acute and solid, with a genius active and inventive, he soon distinguished himself by departing, in various important particulars, from established but unsuccessful modes of practice. Several of the improvements which he introduced have procured him great and deserved reputation, both at home and abroad.

His practice, in ordinary cases, was allowed to be judicious, and placed him high in the confidence and esteem of the inhabitants of that part of the country where he lived. But his usefulness was not confined to his own neighbourhood. On many occasions he was consulted by letter from the most distant parts of the country.

In different collections are to be found several of his performances, which prove that he had something new and useful to offer upon every subject to which he applied himself. But those writings which do him the greatest honour, are two long dissertations on Nervous Fevers, in the Medical Essays and Observations published by a Society in Edinburgh; and a treatise on the use of Sea-voyages in medicine, which first made its appearance in the year 1757, and was afterwards re-printed in 1771. By means of the former, the attention of physicians was first turned to a species of fever which is now found to prevail universally in this country; and the liberal use of wine, which he was the first among the moderns to recommend, has since been adopted in these fevers by the most judicious physicians of the present age, and has probably contributed

Gild
Gilding

not a little to the success of their practice. His treatise on Sea-voyages points out in a manner so clear, and so much on the sure footing of experience, their utility in various distempers, particularly in consumptions, that there is now a prospect of our being able to employ a remedy in this untractable disease much more efficacious than any hitherto in use. Dr Gilchrist died in 1774.

GILD, or GUILD. See GUILD.

GILDAS (surnamed *the Wise*), was born in Wales, in the year 511. Where he was educated is uncertain; but it appears from his own writings that he was a monk. Some writers say that he went over to Ireland; others, that he visited France and Italy. They agree however in asserting, that after his return to England, he became a celebrated and most assiduous preacher of the gospel. Du Pin says he founded a monastery at Venetia in Britain. Gildas is the only British author of the sixth century, whose works are printed; they are therefore valuable on account of their antiquity, and as containing the only information we have concerning the times of which he wrote. His *History of Britain* is, however, a very stilly performance, and his style obscure and inelegant.

GILDING, the art of spreading or covering a thing over with gold, either in leaf or liquid. The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny assures us, that the first gilding seen at Rome, was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, gild the very walls, vaults, &c. of their houses.

We need not doubt but they had the same method with us, of beating gold, and reducing it into leaves; though it should seem they did not carry it to the same height, if it be true which Pliny relates, that they only made 750 leaves of four fingers square out of a whole ounce. Indeed he adds, that they could make more; that the thickest were called *bractæ Prænestinae*, by reason of a statue of the goddess Fortune at Præneste gilt with such leaves; and that the thinner sort were called *bractæ quæstoriae*.

The modern gilders do also make use of gold-leaves of divers thicknesses; but there are some so fine, that a thousand do not weigh above four or five drachms. The thickest are used for gilding on iron, and other metals; and the thinnest, on wood. But we have another advantage over the ancients, in the manner of using or applying the gold: the secret of painting in oil, discovered of late ages, furnishes us with means of gilding works that shall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire, but with whites of eggs, or size; neither of which will endure the water: so that they could only gild such places as were sheltered from the moisture of the weather.

The Greeks called the composition on which they applied their gilding on wood, *leucophæum* or *leucopho-*

rum; which is described as a sort of glutinous, compound earth, serving, in all probability, to make the gold stick, and bear polishing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed upon.

The lustre and beauty of gold have occasioned several inquiries and discoveries concerning the different methods of applying it to different substances. Hence the art of gilding is very extensive, and contains many particular operations and various management.

A colour of gold is given by painting and by varnishes, without employing gold; but this is a false kind of gilding. Thus a very fine golden colour is given to brads and to silver, by applying upon these metals a gold-coloured varnish, which, being transparent, shews all the brilliancy of the metals beneath. Many ornaments of brads are varnished in this manner, which is called *gold lacquering*, to distinguish them from those which are really gilt. Silver-leaves thus varnished are put upon leather, which is then called *gilt leather*. See LACQUER.

Amongst the false gilding may also be reckoned those which are made with thin leaves of copper or brads, called *Dutch-leaf*. In this manner are made all the kinds of what is called *gilt paper*.

In the true gilding, gold is applied to the surface of bodies. The gold intended for this purpose ought in general to be beat into thin leaves, or otherwise divided into very fine parts.

As metals cannot adhere well merely by contact to any but to other metallic substances, when gold is to be applied to the surface of some unmetallic body, that surface must be previously covered with some gluey and tenacious substance, by which the gold shall be made to adhere. These substances are in general called *size*. Some of these are made of vegetable and animal glues, and others of oily, gluey, and drying matters. Upon them the leaves of gold are applied, and pressed down with a little cotton or a hare's foot; and when the whole is dry, the work is to be finished and polished with a hard instrument, called a *dogs-tooth*, to give lustre.

When the work is required to be capable of resisting rain or moisture, it ought to be previously covered with a composition of drying oil and yellow ochre ground together; otherwise a water-size may be used, which is prepared by boiling cuttings of parchment or white leather in water, and by mixing with this some chalk or whiting: several layers of this size must be laid upon the wood, and over these a layer of the same size mixed with yellow ochre. Lastly, another mixture, called *gold size*, is to be applied above these; upon which the gold-leaves are to be fixed. This gold size, the use of which is to make the gold-leaf capable of being burnished, is composed of tobacco-pipe clay, ground with some ruddle or black lead, and tempered with a little tallow or oil of olives. The edges of glasses may be gilt by applying, first, a very thin coat of varnish, upon which the gold-leaf is to be fixed; and when the varnish is hardened, may be burnished. This varnish is prepared by boiling powdered amber with linseed oil in a brads vessel to which a valve is fitted, and by diluting the above solution with four or five times its quantity of oil of turpentine; and that it may dry sooner, it may be ground with some white lead.

6
Of gilding
metals.

The method of applying gold upon metals is entirely different. The surface of the metal to be gilt is first to be cleaned; and then leaves are to be applied to it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver-leaf is fixed and burnished upon brass in the making of what is called *French plate*, and sometimes also gold-leaf is burnished upon copper and upon iron.

Gold is applied to metals in several other manners. One of these is by previously forming the gold into a paste or amalgam with mercury. In order to obtain a small amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one.

With this amalgam the surface of the metal to be gilded is to be covered; then a sufficient heat is to be applied to evaporate the mercury; and the gold is lastly to be burnished with a blood-stone.

This method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam; and is also preferable for its colour, which more resembles that of gold than the colour of copper. When the metal to be gilt is wrought or chased, it ought to be previously covered with quicksilver, before the amalgam is applied, that this may be easier spread: but when the surface of the metal is plain, the amalgam may be applied directly to it. The quicksilver or amalgam is made to adhere to the metal by means of a little aquafortis, which is rubbed on the metallic surface at the same time, by which this surface is cleaned from any rust or tarnish which might prevent the union or adhesion of the metals. But the use of the nitrous acid in this operation is not, as is generally supposed, confined merely to cleanse the surface of the metal to be gilt from any rust or tarnish it may have acquired; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam; and when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates upon its surface copper, from a solution of blue vitriol. When the metal to be gilt is thus covered over with a thin precipitated coat of mercury, it readily receives the amalgam. In this solution and precipitation of mercury, the principal use of the nitrous acid in the process of gilding appears to consist. The amalgam being equally spread over the surface of the metal to be gilt, by means of a brush, the mercury is then to be evaporated by a heat just sufficient for that purpose; for if it be too great, part of the gold may also be expelled, and part of it will run together, and leave some of the surface of the metal bare: while the mercury is evaporating, the piece is to be, from time to time, taken from the fire, that it may be examined, that the amalgam may be spread more equally by means of a brush, that any defective parts of it may be again co-

7
Use of the
nitrous acid
in gilding.

vered, and that the heat may not be too suddenly applied to it: when the mercury is evaporated, which is known by the surface being entirely become of a dull yellow colour, the metal must then undergo other operations, by which the fine gold-colour is given to it. First, the gilded piece of metal is rubbed with a scratch-brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called *gilding wax*, and is again exposed to the fire till the wax be burnt off. This wax is composed of bees-wax, sometimes mixed with some of the following substances; red ochre, verdegriese, copper-scales, slum, vitriols, borax: but, according to Dr Lewis, the saline substances alone are sufficient, without any wax. By this operation the colour of the gilding is heightened; and this effect seems to be produced by a perfect distillation of some mercury remaining after the former operation. This distillation is well effected by this equable application of heat. The gilt surface is then covered over with a saline composition consisting of nitre, alum, or other vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of nitre (which is disengaged by the vitriolic acid of the alum or other vitriolic salt during the exposure to heat) acting upon any particles of copper which may happen to lie on the gilded surface. Lastly, some artists think that they give an additional lustre to their gilt-work by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter, as the sulphur, or turmeric, remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

Iron cannot be gilt by amalgamation, unless, as it is said, it be previously coated with copper by dipping in a solution of blue vitriol. Iron may also receive a golden coat from a saturated solution of gold in aqua-regia, mixed with spirit of wine, the iron having a greater affinity with the acid, from which it therefore precipitates the gold. Whether any of these two methods be applicable to use, is uncertain: but the method commonly employed of fixing gold upon iron is that above-mentioned, of burnishing gold-leaf upon this metal when heated so as to become blue; and the operation will be more perfect, if the surface has been previously scratched or grained.

Another method is mentioned by authors of gilding upon metals, and also upon earthen ware, and upon glass; which is, to fuse gold with regulus of antimony, to pulverize the mass which is sufficiently brittle to admit that operation, to spread this powder upon the piece to be gilt, and expose it to such a fire that the regulus may be evaporated, while the gold remains fixed. The inconveniences of this method, according to Dr Lewis, are, that the powder does not adhere to the piece, and cannot be equally spread; that part of the gold is dissipated along with the regulus; that glass is fusible with the heat necessary for the evaporation of regulus of antimony; and that copper

Gilding.

Gilding.

is liable to be corroded by the regulus, and to have its surface rendered uneven.

8
Improvements
by
Dr Lewis.

On the subject of gilding by amalgamation Dr Lewis has the following remarks. "There are two principal inconveniences in this business: One, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them: the other, the loss of the mercury; for tho' part of it is said to be detained in cavities made in the chimney for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might in good measure be avoided, by means of a furnace of a due construction. If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door or other apertures beneath the grate closed, and the mouth of the furnace left open; the current of air, which otherwise would have entered beneath, enters now at the top, and, passing down thro' the grate to the chimney, carries with it completely both the vapour of the fuel, and the fumes of such matters as are placed upon it: the back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable: the upper end of the chimney may reach above a foot and a half higher than the level of the fire: over this is to be placed a larger tube, leaving an interval of an inch or more all round between it and the chimney, and reaching to the height of 10 or 12 feet, the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which, falling down to the bottom, is there catch'd in a hollow rim formed by turning inwards a portion of the lower part, and conveyed, by a pipe at one side, into a proper receiver.

"Mr Hellot communicates, in the Memoirs of the French Academy for the year 1745, a method of making raised figures of gold on works of gold or silver, found among the papers of Mr du Fay, and of which Mr du Fay himself had seen several trials. Fine gold in powder (such as results from the parting of gold and silver by aquafortis, is directed to be laid in a heap on a levigating stone, a cavity made in the middle of the heap, and half its weight of pure mercury put into the cavity: some of the fetid spirit, obtained from garlic root by distillation in a retort, is then to be added, and the whole immediately mingled and ground with a muller, till the mixture is reduced into an uniform grey powder. The powder is to be ground with lemon juice to the consistence of paint, and applied on the piece previously well cleaned and rubbed over with the same acid juice: the figures drawn with it may be raised to any degree by repeating the application. The piece is exposed to a gentle fire till the mercury is evaporated so as to leave the gold yellow, which is then to be pressed down, and rubbed with the finger and a

little band, which makes it appear solid and brilliant: after this it may be cut and embellished. The author observes, that being of a spongy texture, it is more advisable to cut it with a chisel than to raise it with a graver; that it has an imperfection of being always pale; and that it would be a desirable thing to find means of giving it colour, as by this method ornaments might be made of exquisite beauty and with great facility. As the paleness appears to proceed from a part of the mercury retained by the gold, I apprehend it might be remedied by the prudent application of a little warm aquafortis, which, dissolving the mercury from the exterior part, would give at least a superficial high colour: if the piece is silver, it must be defended from the aquafortis by covering it with wax. Instruments or ornaments of gold, stained by mercury, where the gold is connected with subtilances incapable of bearing fire, may be restored to their colour by the same means.

"The foregoing process is given entirely on the authority of the French writer. I have had no experience of it myself, but have seen very elegant figures of gold raised upon silver, on the same principle, by a different procedure. Some cinnabar was ground, not with the distilled spirit, but with the expressed juice of garlic, a fluid remarkably tenacious. This mixture was spread all over the polished silver; and when the first layer was dry, a second, and after this a third was applied. Over these were spread as many layers of another mixture, composed chiefly of asphaltum and linseed oil boiled down to a due consistence. The whole being dried, with a gentle heat, on a kind of wire-grate, the figures were traced and cut down to the silver so as to make its surface rough: the incisions were filled with an amalgam of gold, raised to different heights in different parts according to the nature of the design; after which a gentle fire, at the same time that it evaporated the mercury, destroyed the tenacity of the gummy juice, so that the coating, which served to confine the amalgam, and as a guide in the application of it, was now easily got off. The gold was then pressed down and embellished as in the former method; and had this advantage, that the surface of the silver under it having been made rough, it adhered more firmly, so as not to be in danger of coming off, as M. du Fay says the gold applied in his way sometimes did. The artist, however, found the process so troublesome, that though he purchased the receipt for a considerable sum, he has laid the practice aside."

Finally, some metals, particularly silver, may be gilt in the following manner:

Let gold be dissolved in aqua-regia. In this solution pieces of linen are to be dipt, and burnt to black ashes. These ashes being rubbed on the surface of the silver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the ashes is to be washed off; and the surface of the silver, which in this state does not seem to be gilt, is to be burnished with a blood-stone, till it acquire a fine colour of gold. This method of gilding is very easy, and consumes a very small quantity of gold. Most gilt ornaments upon fans, snuff-boxes, and other toys of much show and little value, are nothing but silver gilt in this manner.

Methods
of gilding
glass.

Gold may also be applied to glass, porcelain, and other vitrified matters. As the surface of these matters is very smooth, and consequently is capable of a very perfect contact with gold leaves, these leaves adhere to them with some force, although they are not of metallic nature. This gilding is so much more perfect, as the gold is more exactly applied to the surface of the glass. The pieces are then to be exposed to a certain degree of heat, and burnished slightly to give them lustre.

A more substantial gilding is fixed upon glass, enamel, and porcelain, by applying to these substances powder of gold mixed with a solution of gum arabic, or with some essential oil, and a small quantity of borax; after which a sufficient heat is to be applied to soften the glass and the gold, which is then to be burnished. With this mixture any figures may be drawn. The powders for this purpose may be made, 1. By grinding gold-leaf with honey, which is afterwards to be washed away with water. 2. By distilling to dryness a solution of gold in aqua-regia. 3. By evaporating the mercury from an amalgam of gold, taking care to stir well the mass near the end of the process. 4. By precipitating gold from its solution in aqua-regia by applying to it a solution of green vitriol in water, or some copper, and perhaps some other metallic substances.

GILL, a measure of capacity, containing a quarter of an English pint.

GILLS, in ichthyology. See BRANCHIÆ.

GILOLO, a large island of the pacific ocean, lying between 1° S. Lat. and 2° N. Lat. and between 125° and 128° E. Long. It belongs to the Dutch; but does not produce any of the fine spices, tho' it lies in the neighbourhood of the spice-islands. The natives are fierce and cruel savages.

GILPIN (Bernard), rector of Houghton, distinguished by his extraordinary piety and hospitality, was descended from an ancient and honourable family in Westmoreland, and born in 1517. As he was bred in the Catholic religion, so he for some time defended it against the reformers, and at Oxford held a disputation with Hooper afterward bishop of Worcester and martyr for the Protestant faith; but was staggered in another disputation with Peter Martyr, and began seriously to examine the contested points by the best authorities. Thus, being presented to the vicarage of Norton in the diocese of Durham, he soon resigned it, and went abroad to consult eminent professors on both sides; and after three years absence returned a little before the death of queen Mary, satisfied in the general doctrines of the reformation. He was kindly received by his uncle Dr Tontall, bishop of Durham; who soon after gave him the archdeaconry of Durham, to which the rectory of Essington was annexed. When repairing to his parish, tho' the persecution was then at its height, he boldly preached against the vices, errors, and corruptions of the times, especially in the clergy, on which a charge consisting of 13 articles was drawn up against him, and presented in form to the bishop. But Dr Tontall found a method of dismissing the cause in such a manner as to protect his nephew, without endangering himself, and soon after presented him to the rich living of Houghton le Spring. He was a second time accused to the bishop, and again protected; when his

enemies, enraged at this second defeat, laid their complaint before Dr Bonner, bishop of London; who immediately gave orders to apprehend him. Upon which Mr Gilpin bravely prepared for martyrdom; and ordering his house-steward to provide him a long garment, that he might make a decent appearance at the stake, set out for London. Luckily, however, he broke his leg on the journey; which protracted his arrival until the news of the queen's death freed him from all further apprehensions. Being immediately set at liberty, he returned to Houghton, where he was received by his parishioners with the sincerest joy.

Upon the deprivation of the Popish bishops, he was offered the see of Carlisle, which he declined; and confining his attention to his rectory, discharged all the duties of his function in the most exemplary manner. To the greatest humanity and courtesy, he added an unwearied application to the instruction of those under his care. He was not satisfied with the advice he gave in public, but used to instruct in private; and brought his parishioners to come to him with their doubts and difficulties. He had a most engaging manner towards those whom he thought well-disposed: nay, his very reproof was so conducted, that it seldom gave offence; the becoming gentleness with which it was urged, made it always appear the effect of friendship. Thus, with unceasing assiduity, did he employ himself in admonishing the vicious, and encouraging the well-intentioned; by which means, in a few years, he made a greater change in his neighbourhood, than could well have been imagined. A remarkable instance, what reformation a single man may effect, when he hath it earnestly at heart!

But his hopes were not so much in the present generation, as in the succeeding. It was an easier task, he found, to prevent vice, than to correct it; to form the young to virtue, than to amend the bad habits of the old. He employed much of his time, therefore, in endeavouring to improve the minds of the younger part of his parish; suffering none to grow up in ignorance of their duty; but pressing it as the wisest part to mix religion with their labour, and amidst the cares of this life to have a constant eye upon the next. He attended to every thing which might be of service to his parishioners. He was very assiduous in preventing all law-suits among them. His hall is said to have been often thronged with people, who came to him about their differences. He was not indeed much acquainted with law; but he could decide equitably, and that satisfied; nor could his sovereign's commifion have given him more weight, than his own character gave him.

His hospitable manner of living was the admiration of the whole country. He spent in his family every fortnight 40 bushels of corn, 20 bushels of malt, and a whole ox; besides a proportionable quantity of other kinds of provision. Strangers and travellers found a cheerful reception. All were welcome that came; and even their beasts had so much care taken of them, that it was humorously said, "If a horse was turned loose in any part of the country, it would immediately make its way to the rector of Houghton's."

Every Sunday, from Michaelmas till Easter, was a sort of public day with him. During this season he expected to see all his parishioners and their families.

For

Gilpin.

For their reception, he had three tables well covered: the first was for gentlemen, the second for husbandmen and farmers, and the third for day-labourers. This piece of hospitality he never omitted, even when losses, or a scarcity of provision, made its continuance rather difficult to him. He thought it his duty, and that was a deciding motive. Even when he was absent from home, no alteration was made in his family-expenditures: the poor were fed as usual, and his neighbours entertained.

But notwithstanding all this painful industry, and the large scope it had in so extended a parish, Mr Gilpin thought the sphere of his benevolence yet too confined. It grieved him extremely, to see every where in the parishes around him, so great a degree of ignorance and superstition, occasioned by the shameful neglect of the pastoral care in the clergy of those parts. These bad consequences induced him to supply, as far as he could, what was wanting in others. For this purpose, every year he used regularly to visit the most neglected parishes in Northumberland, Yorkshire, Cheshire, Westmoreland, and Cumberland; and that his own parish in the mean time might not suffer, he was at the expence of a constant assistant. In each place he stayed two or three days; and his method was, to call the people about him, and lay before them, in as plain a way as possible, the danger of leading wicked, or even careless lives; explaining to them the nature of true religion; instructing them in the duties they owed to God, their neighbour, and themselves; and shewing them how greatly a moral and religious conduct would contribute to their present as well as future happiness.

As Mr Gilpin had all the warmth of an enthusiast, though under the direction of a very calm and sober judgment, he never wanted an audience, even in the wildest parts; where he roused many to a sense of religion, who had contracted the most inveterate habits of inattention to every thing of a serious nature. And wherever he came, he used to visit all the gaols and places of confinement; few in the kingdom having at that time any appointed minister. And by his labours, and affectionate manner of behaving, he is said to have reformed many very abandoned persons in those places. He would employ his interest likewise for such criminals whose cases he thought attended with any hard circumstances, and often procured pardons for them.

There is a tract of country upon the border of Northumberland, called *Redf-dale* and *Time-dale*, of all barbarous places in the north, at that time the most barbarous. Before the Union, this place was called the *debateable land*, as subject by turns to England and Scotland, and the common theatre where the two nations were continually acting their bloody scenes. It was inhabited by a kind of desperate banditti, rendered fierce and active by constant alarms: they lived by theft, used to plunder on both sides of the barrier; and what they plundered on one, they exposed to sale on the other; by that means escaping justice. And in this dreadful country, where no man would even travel that could help it, Mr Gilpin never failed to spend some part of every year.

He generally chose the Christmas holidays for his journey, because he found the people at that season

most disengaged, and most easily assembled. He had set places for preaching, which were as regularly attended as the assize-towns of a circuit. If he came where there was a church, he made use of it: if not, of barns, or any other large building; where great crowds of people were sure to attend him, some for his instructions, and others for his charity.—This was a very difficult and laborious employment. The country was so poor, that what provision he could get, extreme hunger only could make palatable. The inclemency of the weather, and the badness of the roads through a mountainous country, and at that season covered with snow, exposed him likewise often to great hardships. Sometimes he was overtaken by the night, the country being in many places desolate for several miles together, and obliged to lodge out in the cold. At such times, we are told, he would make his servant ride about with his horses, whilst himself on foot used as much exercise as his age and the fatigues of the preceding day would permit. All this he cheerfully underwent; esteeming such services well compensated by the advantages which he hoped might accrue from them to his uninstructed fellow-creatures.

The disinterested pains he took among these barbarous people, and the good offices he was always ready to do them, drew from them the warmest and sincerest expressions of gratitude. Indeed, he was little less than adored among them, and might have brought the whole country almost to what he pleased. One instance that is related, shews how greatly he was revered. By the carelessness of his servant, his horses were one day stolen. The news was quickly propagated, and every one expressed the highest indignation at the fact. The thief was rejoicing over his prize, when, by the report of the country, he found whose horses he had taken. Terrified at what he had done, he instantly came trembling back, confessed the fact, returned the horses, and declared he believed the devil would have seized him directly, had he carried them off, knowing them to have been Mr Gilpin's.

We have already taken notice of Mr Gilpin's uncommonly generous and hospitable manner of living. The value of his rectory was about 400*l.* a year: an income, indeed, at that time very considerable, but yet in appearance very unproportionate to the generous things he did: indeed, he could not have done them, unless his frugality had been equal to his generosity. His friends, therefore, could not but wonder to find him, amidst his many great and continual expences, entertain the design of building and endowing a grammar-school: a design, however, which his exact economy soon enabled him to accomplish, though the expence of it amounted to upwards of 500*l.* His school was no sooner opened, than it began to flourish; and there was so great a resort of young people to it, that in a little time the town was not able to accommodate them. He put himself, therefore, to the inconvenience of sitting up a part of his own house for that purpose, where he seldom had fewer than twenty or thirty children. Some of these were the sons of persons of distinction, whom he boarded at easy rates: but the greater part were poor children, whom he not only educated, but clothed and maintained: he was at the expence likewise of boarding in the town many other poor children. He used to bring several every

year from the different parts where he preached, particularly Readf-dale and Tine-dale; which places he was at great pains in civilizing, and contributed not a little towards rooting out that barbarism which every year prevailed less among them.

As to his school, he not only placed able masters in it, whom he procured from Oxford, but himself likewise constantly inspected it. And, that encouragement might quicken the application of his boys, he always took particular notice of the most forward: he would call them *his own scholars*, and would send for them often into his study, and there instruct them himself. One method used by him to fill his school, was a little singular. Whenever he met a poor boy upon the road, he would make trial of his capacity by a few questions; and if he found it such as pleased him, he would provide for his education. And besides those whom he sent from his own school to the universities, and there wholly maintained, he would likewise give to others, who were in circumstances to do something for themselves, what farther assistance they needed. By which means he induced many parents to allow their children a liberal education, who otherwise would not have done it. And Mr Gilpin did not think it enough to afford the means only of an academical education to these young people, but endeavoured to make it as beneficial to them as he could. He still considered himself as their proper guardian; and seemed to think himself bound to the public for their being made useful members of it, as far as it lay in his power to make them so. With this view he held a punctual correspondence with their tutors; and made the youths themselves frequently write to him, and give him an account of their studies. So solicitous indeed was he about them, knowing the many temptations to which their age and situation exposed them, that once every other year he generally made a journey to the universities, to inspect their behaviour. And this uncommon care was not unrewarded; for many of his scholars became ornaments to the church, and exemplary instances of piety.

To the account that hath been already given of Mr Gilpin's hospitality and benevolence, the following particulars may be added. Every Thursday throughout the year, a very large quantity of meat was dressed wholly for the poor; and every day they had what quantity of broth they wanted. Twenty-four of the poorest were his constant pensioners. Four times in the year a dinner was provided for them; when they received from his steward a certain quantity of corn, and a sum of money; and at Christmas they had always an ox divided among them.

Wherever he heard of any in distress, whether of his own parish, or any other, he was sure to relieve them. In his walks abroad, he would frequently bring home with him poor people, and send them away clothed as well as fed. He took great pains to inform himself of the circumstances of his neighbours, that the modesty of the sufferer might not prevent his relief. But the money best laid out was, in his opinion, that which encouraged industry. It was one of his greatest pleasures to make up the losses of his laborious neighbours, and prevent their sinking under them. If a poor man had lost a beast, he would lend him another in his room: or if any farmer had had a

bad year, he would make him an abatement in his tythes.—Thus, as far as he was able, he took the misfortunes of his parish upon himself; and, like a true shepherd, exposed himself for his flock. But of all kinds of industrious poor, he was most forward to assist those who had large families: such never failed to meet with his bounty, when they wanted to settle their children in the world.

In the distant parishes where he preached, as well as in his own neighbourhood, his generosity and benevolence were continually shewing themselves; particularly in the desolate parts of Northumberland. "When he began his journey," says an old manuscript life of him, "he would have ten pounds in his purse; and, at his coming home, he would be twenty nobles in debt, which he would always pay within a fortnight after."—In the gaols he visited, he was not only careful to give the prisoners proper instructions, but used to purchase for them likewise what necessaries they wanted.

Even upon the public road, he never let slip an opportunity of doing good. He has often been known to take off his cloak, and give it to an half-naked traveller: and when he has had scarce money enough in his pocket to provide himself a dinner, yet would he give away part of that little, or the whole, if he found any who seemed to stand in need of it.—Of this benevolent temper, the following instance is preserved. One day returning home, he saw in a field several people crowding together; and judging something more than ordinary had happened, he rode up, and found that one of the horses in a team had suddenly dropped down, which they were endeavouring to raise; but in vain, for the horse was dead. The owner of it seemed much dejected with his misfortune; and declaring how grievous a loss it would be to him, Mr Gilpin bade him not be disheartened: "I'll let you have, (says he) 'honest man, that horse of mine,' and pointed to his servant's.—"Ah! master, (replied the countryman) my pocket will not reach such a beast as that." "Come, come, (said Mr Gilpin) take him, take him; and when I demand my money, then thou shalt pay me."

This worthy and excellent divine, who merited and obtained the glorious titles of the *Father of the Poor*, and the *Apostle of the North*, died in 1583, in the 66th year of his age.

GILTHEAD, in ichthyology. See SPARUS.

GIN. See GENEVA.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved that goes over the wheel at the top: one end of this rope is seized to an iron-monkey, that hooks to a bettie of different weights, according to the pile they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground: then the monkey's own weight overhauls the windlafs, in order for its being hooked again to the beetle.

GINKGO, the MAIDEN-HAIR TREE, is a native of Japan, where it is also known by the names of *Ginan* and *Iiso*. It rises with a long, erect, thick and branched

Ginkgo
Giorgione.

branched stem, to the size of a walnut-tree. The bark is ash-coloured, the wood brittle and smooth, the pith soft and fungous. The leaves are large, expanded from a narrow bottom into the figure of a maiden-hair leaf, unequally parted, streaked, without fibres or nerves; both surfaces having the same appearance, and supported upon footstalks, which are compressed upon the upper surface, and extended into the substance of the leaf. From the uppermost shoots hang the flowers in long catkins that are filled with the fertilizing powder; and to which succeeds the fruit, adhering to a thick fleshy pedicle, which proceeds from the bottom of the leaves. This fruit is either exactly or nearly round, and of the appearance and size of a damask plum. The substance surrounding the fruit is fleshy, juicy, white, very harsh, and adheres so firmly to the inclosed nut, as not to be separated from it, except by putrefaction. The nut, properly termed *Gineau*, resembles the pistachia nut, especially a Persian species named *bergies pistai*; but is almost double in size, and of the figure of an apricot stone. The shell is somewhat white, woolly, and brittle; and incloses a white loose kernel, having the sweetness of an almond, along with a degree of harshness. These kernels taken after dinner are said to promote digestion, and to give relief in furberis; whence they never fail to make part of the dessert in great feasts and anniversary entertainments.—Many of these plants have been reared by Mr James Gordon at his nursery near Mile-end. They seem to be very hardy, and thrive in this country in the open air.

GINGER, the root of a species of amomum. See AMOMUM.

GINGIVÆ, the gums. See GUMS.

INGLYMUS, in anatomy. See ANATOMY, n^o 2, d.

GINSENG. See PANAX.

GIOIA (Flavio), of Amalfi, in the kingdom of Naples, the celebrated mathematician; who, from his knowledge of the magnetic powers, invented the mariner's compass, by which the navigation of the Europeans was extended to the most distant regions of the globe: before this invention, navigation was confined to coasting. The king of Naples being a younger branch of the royal family of France, he marked the north point with a fleur de lis, in compliment to that country. It is said the Chinese knew the compass long before; be this as it may, the Europeans are indebted to Gioia for this invaluable discovery. He flourished A.D. 300.

GIRAFFE, in zoology. See CERVUS.

GIRALD (Barry), or *Giraldus Cambrensis*. See BARRY.

GIORGIONE, so called from his comely aspect, was an illustrious Venetian painter, born in 1478. He received his first instructions from Giovanni Bellini; but studying afterwards the works of Leonardo da Vinci, he soon surpassed them both, being the first among the Lombards who found out the admirable effects of strong lights and shadows. Titian became his rival in this art; and was so careful in copying the life, that he excelled Giorgione in discovering the delicacies of nature, by tempering the boldness of his colouring. The most valuable piece of Giorgione in oil is that of Christ carrying his cross, now in the

church of San Rovo in Venice; where it is held in great veneration. He died of the plague young, in 1511.

GIOSEPPINO, an eminent painter, so called by way of contraction from *Gioseppe d'Arpino*, the town of Naples, where he was born in 1560. Being carried to Rome very young, and employed by painters then at work in the Vatican to grind their colours, he soon made himself master of the elements of design, and by degrees grew very famous. His wit and humour gained him the favour of popes and cardinals, who found him business in plenty. Gregory XIII. shewed him great respect; and Lewis XIII. of France made him a knight of the order of St Michael. By the force of a happy genius he acquired a light and agreeable manner of delineating; though it is remarked by De Piles, that he degenerated into a style which neither partook of true nature, nor of the antique. His battles in the capitol are the most esteemed of all his pieces. He died at Rome in 1640.

GIOTTO, an ingenious painter, sculptor, and architect of Florence, born in 1276. He was the disciple of Cimabue; but far superior to his master in the air of his heads, the attitude of his figures, and in the tone of his colouring; but could not express liveliness in the eyes, tenderness in the flesh, or strength in the muscles of his naked figures. He was principally admired for his works in mosaic; the best of which is over the grand entrance of St Peter's church at Rome. The observation of Alberti on that piece is, that in the ship of Giotto, the expression of fright and amazement of the disciples at seeing St Peter walk upon the water is so excellent, that each of them exhibits some characteristic sign of his terror. His death happened in 1336, and the city of Florence honoured his memory with a statue of marble over his tomb.

GIRALDI (Lilio Gregorio), an ingenious critic, and one of the most learned men that modern Italy has produced, was born at Ferrara in 1479. He was at Rome when it was plundered by the emperor Charles V.; and having thus lost all he had, and being tormented by the gout, he struggled through life with ill fortune and ill health. He wrote, nevertheless, 17 performances, which were collected and published at Basil in 2 vols folio in 1580, and at Leyden in 1696. Authors of the first rank have bestowed the highest eulogies on Giraldus; particularly Casaubon and Thuanus.

GIRALDI (John Baptist Cintio), an Italian poet of the same family with the foregoing Lilio, was born in 1504. He was secretary to the duke of Ferrara, and afterwards became professor of rhetoric at Pavia. He died in 1573. His works, which consist chiefly of tragedies, were collected and published at Venice by his son Celfo Giraldi, in 1583; and some scruple not to rank him among the best tragic writers Italy has produced.

GIRARDON (Francis), a celebrated French architect and sculptor, born at Troyes, in 1627. Lewis XIV. being informed of his great talents, sent him to Rome with a pension of 1000 crowns. At his return into France, he laboured for the royal palaces, and the gardens of Versailles and Trianon; where there are many of his works executed in bronze and in marble, from the designs of Charles le Brun. The mausoleum

Giosepchino
Giraldon.

Gironne
Gladiators.

of cardinal de Richlieu, in the Sorbonne, and the equestrian statue of Lewis XIV. at the Place de Vendôme, where the statue and horse are cast in one piece, pass for his most excellent performances. Girardon was professor, rector, and chancellor, of the Academy of Painting and Sculpture; and had the post of inspector-general of all the works done in sculpture. He died in 1715.

GIIRONNE, or GIRONNY, in heraldry, a coat of arms divided into girones, or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GITTITH, a Hebrew word occurring frequently in the Psalms, and generally translated *wine-presser*. The conjectures of interpreters are various concerning this word. Some think it signifies a sort of musical instrument; others, that the psalms with this title were sung after the vintage; lastly, others, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion, that it was given to the class of young women or songstresses of Gath to be sung by them; Psal. viii. 1. lxxxi. 1. lxxiv. 1. Dr Hammond thinks that the psalms with this title were all set to the same tune, and made on Goliath the Gittite.

GIULA, a strong town of Upper Hungary, on the frontiers of Transylvania. It was taken by the Turks in 1566, and retaken by the Imperialists in 1695. It is seated on the river Kereszban, in E. Long. 21. 1. N. Lat. 46. 25.

GIUSTANDEL, a large and strong town of Turkey in Europe, and in Macedonia, with a Greek archbishop's see. It is seated near the lake Ochrida, in E. Long. 20. 50. N. Lat. 41. 10.

GLACIES MARIE. See *Lapis Specularis*.

GLACIS, in building, an easy insensible slope or declivity.

The descent of the glacis is less steep than that of the talus. In gardening, a descent sometimes begins in talus, and ends in glacis.

The glacis of the cornice, is an easy imperceptible slope in the cymatium, to promote the descent and draining off the rain-water.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the campaign or field.

GLADE, in gardening and agriculture, an opening and light passage made through a wood, by lopping off the branches of trees along that way.

GLADIATORS, in antiquity, persons who fought, generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like our prize-fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asiatics; and we find that even the high-priests had their ludi pontificales, and ludi sacerdotales. As from the earliest ages of antiquity we read that it was customary to sacrifice prisoners of war to the manes of the great men that fell in the engagement, in process of time they came to sacrifice slaves at the funerals of all persons of condition; but as it would have appeared barbarous to cut their throats like beasts, they were appointed to fight with each other, and to do their best to save their own lives by killing their adversary.

Hence arose the masters of arms called *laniffæ*, and men learned to fight. These laniffæ bought slaves to train up to this cruel trade, whom they afterwards sold to such as had occasion to exhibit shews. Junius Brutus, who expelled the kings, was the first that honoured the funeral of his father with these inhuman diversions at the sepulchre of the deceased: but afterwards they were removed to the circus and amphitheatres; and other persons, besides slaves, would hire themselves to this infamous office.

They were all first sworn that they would fight till death; and if they failed, they were put to death, either by fire, swords, clubs, whips, &c. It was usual with the people, or emperor, to grant them life when they shewed no signs of fear. Augustus decreed that it should always be granted them.

From slaves and freed-men, the wanton sport spread to persons of rank, as we find in Nero's time. And Domitian exhibited combats of women in the night-time. We also read, that dwarfs encountered with one another. Constantine the Great first prohibited these combats in the East; but the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths in the year 500.

When any person designed to entertain the people with a show of gladiators, he set up bills in the public places, giving an account of the time, the number and names of the combatants, and the circumstances whereby they were to be distinguished; each having his several badge, which generally was a peacock's feather: they also gave notice what time the show would last; and sometimes gave representations of these things in painting, as is practised among us by those who have any thing to show at fairs, &c.

Upon the day appointed for the show, in the first place the gladiators were brought out all together, and obliged to take a circuit round the arena in a very solemn and pompous manner. After this they proceeded *paria componere*, to match them by pairs, in which great care was taken to make the matches equal. The first sort of weapons they made use of were slaves, or wooden foils called *rudes*; and the second were effective weapons, as swords, poinards, &c.

The first were called *arma luforia*, or *exercitoria*; the second, *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited.

They began to fence or skirmish with the first, which was to be the prelude to the battle; and from thence, when well warmed, they advanced to the second, with which they fought naked. The first part of the engagement was called *ventilare*, *preludare*; and the second *dimicare ad certum*, or *versus armis pugnare*.

When any received a remarkable wound, either his adversary or the people used to cry out, *Habet, Hoc habet*. If the vanquished surrendered his arms, it was not in the victor's power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant this boon. The two signs of favour and dislike given by the people were, *premere pollicem*, and *vertere pollicem*; the former of which M. Dacier takes to be a clenching of the fingers of both hands between one another, and so holding the two thumbs upright close together, was a sign of

of the people's admiration of the courage shewn by both combatants; and at the same time for the conqueror to spare his antagonist's life: but the contrary motion, or bending back of the thumbs, signified the dissatisfaction of the spectators, and authorised the victor to kill the other combatant downright for a coward. The emperor saved whom he liked, if he was present at the solemnity, in the same manner.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and oftentimes a sum of money, perhaps gathered up among the spectators: but the most common rewards were the pileus and the rudis. The former was given only to such gladiators as were slaves, for a token of obtaining their freedom. But the rudis seems to have been bestowed both on slaves and freemen; with this difference, that it procured the former no more than a discharge from any further performance in public, upon which they commonly turned lanista: but the rudis, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty. See PILEUS, RUDIS, and LANISTA.

GLADIOLUS, CORN-FLAG; a genus of the monogynia order, belonging to the pentandria class of plants. There are ten species, of which the most remarkable is the communis, or common gladiolus. This hath a round, compressed, tuberous root; long sword-shaped leaves; an erect flower-stalk, two or three feet high; the top garnished with several pretty large flowers of a red or white colour, having each six petals. They appear in May and June, and are succeeded by plenty of seed in August. The plants are very hardy, and will thrive in any soil or situation. They are propagated by offsets from the roots.

GLAMORGANSHIRE, by the Welsh called *Gwalad Morganwg* or *Vorganwg*, i. e. the county of *Morganwg*; a county of South Wales, bounded on the south by the Severn sea, on the north by Brecknockshire, on the east by Monmouthshire, and on the west by Caermarthenshire. It extends in length 48 miles, in breadth 27; and in circumference about 116. On the north side, where there are mountains covered with snow a great part of the year, the air is sharp, and the soil very indifferent; but, on the south side, as the country approaches nearer to a level, the soil grows better, producing plenty both of corn and groats. Its commodities are black cattle, sheep, coals, lead, fish, and butter. The chief rivers of this country are the Rhymney or Renny, the Taff, the Ogmore, the Avon, the Cleddagh, and the Tavye. This country was formerly full of castles, most of which are now fallen to decay. It hath many small harbours on the coast for exporting coals and provisions. Of the former it sends large quantities both to England and Ireland; but of the latter, to England almost solely, especially butter. It sends two members to parliament, one for the shire, and one for the borough of Cardiff the capital.

GLAND, in anatomy, may be defined a circumscribed apparatus of the soft parts, whose office is to secrete a certain juice, and throw it out of the immediate circulation.

The glands are roundish bodies, seated in the cellular membrane, generally near the large vessels; their

substance is firm, and of various colours. Sylvius was the first who divided the glands into conglobate and conglomerate. Malpighi added what he calls the folliculus or simple gland; instances of which are the small glands behind the ears, but the most remarkable are those in the fauces.

Dr Nicholls divides the glands into sinuous, tubular, and equal. What he means by *sinuous* gland is, when each little gland hath its own excretory duct, through which it transmits its liquor to a common basin, as the kidneys; his *tubular* is the same as the conglobate gland of Sylvius, of which the testes are an instance. By an *equal* gland he means where the vessels are branched, as in the liver.

Ruych proves by subtle injections, that the substance of the glands is vascular, consisting of a ramifying artery, partly terminating in a vein, and partly in an excretory duct.

Mr Hewson says, that the little corpora globosa, which most modern anatomists call cryptæ and folliculæ, are nothing but convoluted arteries.

The glands are often disordered by becoming large and indurated. When they are swelled and hard, they are said to be *indurated*; if they grow harder, they are said to be *scirrhus*: if, when hard, they become painful, they are *incipient* or *ocult* cancers; if their hardness and pain continue long, they are called *carcinomata*, or *inveterate ocult* cancers; and if the skin breaks, they are called *ulcerated* cancers *.

GLANDERS. See FARRIERY, § xii.

GLANDORP (Matthias), a learned physician, born in 1595, at Cologne, in which town his father was a surgeon. After receiving a doctor's degree at Padua, and visiting the principal towns of Italy, he settled at Bremen in 1618, where he practised physic and surgery with so much success, that he was made physician to the republic, and to the archbishop. He published at Bremen, *Speculum chirurgorum, Methodus medendi paronychie, Tractatus de polypo narium affectu gravissimo, and Gazophylacium polyposum fonticulisimo*; which four pieces were collected and published, with his life prefixed, at London, in 4to. 1729. Glandorp died young; and it must suggest a high opinion of his abilities, that, notwithstanding the great improvements in all branches of science, his works should be deemed worthy a republication 100 years after his death.

GLANVIL (Joseph), a learned, ingenious, but fanciful and credulous, writer in the 17th century, was born at Plymouth in 1636, and bred at Oxford. He became a great admirer of Mr Baxter, and a zealous person for a commonwealth. After the restoration, he published *The vanity of dogmatizing*; was chosen a fellow of the Royal Society; and, taking orders in 1662, was presented to the vicarage of Frome-Selwood in Somersetshire. This same year he published his *Lux Orientalis*; in 1665, his *Scythis Scientifica*; and in the year following, *Some philosophical considerations touching the being of witches and witchcraft*, and other pieces on the same subject. In 1660, he published *Plus ultra*; or, *The progress and advancement of knowledge since the days of Aristotle*. He likewise published *A seasonable recommendation and defence of reason*; and *Philosophia Pia*; or, *A discourse of the religious temper and tendencies of the experimental phi-*

philosophy. In 1678 he was made a prebendary of Worcester, and died in 1680.

GLARIS, one of the cantons of Switzerland, is bounded on the east, partly by the Grisons, and partly by the territory of Sargans; on the north, by the bailiwick of Gaster, and by the lake Wahlenstätt; on the east, by the canton of Schwitz; and on the south, by part of the canton of Uri, and part of the league of the Grisons. It is a mountainous country, being entirely within the Alps. Near the village Ober-Urnen there is a famous mineral spring; which is sometimes hot and sometimes cold. The lake Wahlenstätt is bounded by high rocks and mountains, through one of which a road is cut. Towards the top of one of these there is a large hole, through which the sky may be seen.

GLARIS, a town of Switzerland, capital of the canton of the same name. It is situated in a plain, at the foot of high craggy mountains. The streets are large, and the houses kept in good repair. It has some public buildings; among which are two churches, one in the middle of the town, and the other without, upon an eminence. On this eminence there is a cavern, with grotesque figures formed by the water that drops therein. The general assemblies of the country are held here on the first Sundays in May, where all the males above the age of sixteen are obliged to appear. Both the Calvinists and the Roman-Catholics are tolerated in this town, and they have divine service by turns in the same church. It is situated on the river Lint, E. Long. 9° 13'. N. Lat. 47° 6'.

GLASGOW, a large city of Lanarkshire or Clydesdale in Scotland, situated in W. Long. 4° 30'. N. Lat. 55° 50'.

Concerning the foundation of this city we have no authentic records. The word in the Gaelic language signifies a *gray-smith*; from whence it may perhaps be inferred, that some spot in the most ancient part of the city was originally the residence of some blacksmith, who had become eminent in his profession, so that the place went by his name.

Bishopric of
Glasgow,
when
founded.

In the year 560, a bishopric is said to have been founded here by Saint Mungo, or Kentigern, supposed to be the son of Thamates, daughter of Loth king of the Picts; but in what state the town at that time was, is altogether uncertain. Most probably the priests and disciples who attended St Kentigern, would contribute considerably towards its advancement: the aged and infirm, who were unfit for the purposes of war, or such as were religiously inclined, would come and settle round the habitation of the holy man, in order to have the benefit of his prayers; and as a number of miracles were said to have been wrought at his tomb, the same causes would still contribute to the increase of the town.

History has not informed us of the name of the prince who founded and endowed the bishopric of Glasgow in favour of St Kentigern. But from an abstract of the life of Kentigern (contained in Mr Innes's Critical Essay on the Ancient Inhabitants of Scotland) which was written in the 12th century, we learn, that the saint being ill used by Marken or Marcus, one of the kings of the Britons, retired into Wales. On the invitation of Roderic, however, one of Marken's successors, he returned to

Glasgow, and enjoyed the see till 601, when he died. He was buried in the church of Glasgow, where his monument is still to be seen; and we find him marked among the saints of the Roman calendar, January 13th 578.

The immediate successors of Kentigern were Baldebre and Conwal. The first established a religious house at Inchinnan, the second went into Lothian to preach to the Saxons; and both of them are ranked as saints in the Roman calendar, Baldebre on the 6th of March 608, and Conwal on the 18th of May 612. From this time, however, till the 1115 we have no distinct accounts concerning the city or bishopric of Glasgow. We find then, that David I. king of Scotland made an attempt to retrieve the people from a state of gross barbarity into which they were fallen, and restored to the church those lands of which they had been robbed. The only account we have of the transactions with regard to Glasgow, during that period, is in the inquisition made by David concerning the church-lands of Glasgow, and is as follows.—“This church, by the divine appointment, admitted St Kentigern into the bishopric, who furnished large draughts of knowledge to those thirsting after heavenly things, &c. But a fraudulent destroyer, employing his common wiles, brought in, after a long series of time, unaccountable scandals into the Cumbrian church. For after St Kentigern and many of his successors were removed to heaven, various disturbances every where arising, not only destroyed the church and her possessions, but, wasting the whole country, drove the inhabitants into exile. These good men being destroyed, various tribes of different nations flocking in from several quarters, possessed the fore-said deserted country; but being of different origins, and varying from each other in their language and customs, and not easily agreeing among themselves, they followed the manners of the Gentiles, rather than those of the true faith. The inhabitants of which unhappy and abandoned country, though living like brutes, the Lord, who chooseth that none should perish, vouchsafed to visit in mercy, &c.”

From the year 1116 to the reformation, the records of the bishopric are tolerably complete. The most remarkable particulars furnished by them are the following.

In 1136, John Achaius, chosen bishop of Glasgow by David I. built and adorned a part of the cathedral, which he solemnly consecrated on the 9th of July. The king was present at the ceremony; and bestowed on the church the lands of Perdey, now Patrick. This prelate also divided the diocese into the two archdeanries of Glasgow and Teviotdale; and established the offices of dean, subdean, chancellor, treasurer, sacrist, chanter, and successor; and settled a prebendary upon each of them, out of the donations he received from the king.

In 1174, Joceline, abbot of Melrose, was elected bishop, and consecrated by Eskilus, bishop of Lundun in Denmark. The Pope's legate for that kingdom, on the 1st of June 1175. He rebuilt the cathedral, or rather made an addition to the church already built by John Achaius. He also procured a charter from William, king of Scotland, erecting Glasgow into a royal borough, and likewise a charter for a royal borough.

Glasgow. a fair to be held there annually for eight days.

In 1335, John Lindlay, bishop of Glasgow, was killed in an engagement at sea with the English, as he was returning home from Flanders. His successor, William Rae, built the stone bridge over the Clyde. In the time of Matthew Glendonings, who was elected bishop in 1387, the great spire of the church, which had been built only of wood, was consumed by lightning. The bishop intended to have built another of stone; but was prevented by death, in 1408, from accomplishing his purpose. His successor, William Lauder, laid the foundation of the vestry of the cathedral, and built the great tower of stone, as far as the first battlement. The great tower of the episcopal palace was founded about the year 1437, on which bishop Cameron expended a great deal of money.

In 1447, William Turnbull, a son of the family of Bedrule in Roxburghshire, was chosen bishop. He obtained from king James II. in 1450, a charter erecting the town and the patrimony of the bishops into a regality. He also procured a bull from pope Nicholas V. for erecting an university within the city, which he endowed, and on which he also bestowed many privileges. He died in 1454, leaving behind him a most excellent character. The establishment of the college contributed more than any thing that had been formerly done towards the enlargement of the town. Before this time the town seems to have been inconsiderable. Mr Gibson* is of opinion, that the number of its inhabitants did not exceed 1500. But though the establishment of the university greatly increased the number of inhabitants, it in fact destroyed the freedom of the town. Bishop Turnbull seems to have made a point of it with king James II. that the city of Glasgow, with the bishops' forest, should be erected into a regality in his favour; which was accordingly done at the time above-mentioned; and this at once took away all power from the citizens, and transferred it to the bishop. As the powers of the bishop, however, were reckoned by Turnbull insufficient to convey to the members of the university all that freedom which he wished to bestow upon them, he therefore obtained from the king a great many privileges for them; and afterwards he himself, with the consent of his chapter, granted them many more.

The good effects of the establishment of the college were very soon obvious in Glasgow. The number of inhabitants increased exceedingly; the high street, from the convent of the black friars, to where the cross is now placed, was very soon filled up; the ancient road which led to the common, being too far distant for the convenience of the new inhabitants, the Gallows-gate was begun to be built. Soon after, the collegiate church of the blessed Mary (now the Tron-church) being founded by the citizens, occasioned the Tron-gate street to be carried to the westward as far as the church. The rest of the city increased gradually towards the bridge, by the building of the Salt-market street. The burrough-roads, and the cattle that grazed on the commons, were now found insufficient to maintain the increased number of inhabitants; for which reason a greater degree of attention than formerly was paid to the fishing in the river. Many poor people subsisted themselves by this occu-

Vol. V.

pation: they were incorporated into a society; and in order that they might be at hand to prosecute their business, they built a considerable part of the street now called the *Bridge-gate*, but at that time *Fibbers-gate*.

Notwithstanding all this, however, the city of Glasgow did not for a long time attain the rank among the other towns of Scotland, which it holds at present. In 1556, it held only the 11th place among them, as appears by queen Mary's taxation. The introduction of the reformed religion proved for some time prejudicial to the opulence of the city. The money which had formerly been expended among the citizens by the bishop and his clergy, was now diverted into other channels: the advantages resulting from the university were also for a time lost; for as the reformers generally despised human learning, the college was in a manner deserted.

In the time of the civil wars, Glasgow suffered severely. To the mischiefs attending intestine discord, were added a pestilence and famine; and to complete their misfortunes, a violent fire broke out in June, which destroyed the greatest part of the Saltmarket, Tron-gate, and High-street. The fronts of the houses at that time were mostly of wood, so that they became an easy prey to the flames. The fire continued with great violence for the space of 18 hours; by which, a great many of the inhabitants were ruined, the habitations of almost 1000 families being totally destroyed. On this account collections were made through different parts of the country; and to prevent such accidents for the future, the fronts were built with free stone, which abounds in the neighbourhood.

By the charter given to bishop Turnbull in 1450, the citizens had been deprived of the power of electing their own magistrates, which was thenceforth exercised by the bishop; which, however, was not done without some resistance on the part of the inhabitants. After the reformation was introduced into Scotland, we find this power exercised by the citizens, the bishop, the earl of Lennox, and others. The idea that the town was a bishop's burgh, and not a royal free burgh, gave occasion to this unsettled manner of appointing the magistracy; and though, in 1633, they were declared to be a royal free burgh by the parliament, yet their freedom of election was afterwards disturbed by the privy-council, by Cromwell, and the duke of York. But on the 4th of June 1690, the town was declared free by a charter of William and Mary; and in confirmation of this charter it was inserted in the act of parliament, dated June 14th the same year, that they should have power to elect their own magistrates as fully and freely, in all respects, as the city of Edinburgh, or any other royal burgh within the kingdom; which freedom of election still continues.

By the assentment of the burghs in 1695, we find the city of Glasgow reckoned the second in Scotland in point of wealth, which place it still continues to hold. To account for this great increase of wealth, we must observe, that for a long time, even before the restoration of Charles II. the inhabitants of Glasgow had been in possession of the sale both of raw and refined sugars for the greatest part of Scotland; they had a privilege of distilling spirits from their molasses,

Glasgow. free of all duty and excise; the herring-fishery was also carried on to what was at that time thought a very considerable extent; they were the only people in Scotland who made soap; and they sent annually some hides, linen, &c. to Bristol, from whence they brought back in exchange, a little tobacco, sugar, and goods of the manufacture of England, with which they supplied a considerable part of the kingdom. From the year 1707, however, in which the union between Scotland and England took place, we may date the prosperity of Glasgow. By the union, the American trade was laid open to the inhabitants: and so sensible were they of their advantageous situation, that they began almost instantly to prosecute that commerce; an assiduous application to which, ever since, hath greatly contributed to raise the city to that pitch of affluence and splendor which it now enjoys. The city was now greatly enlarged; and as the community were sensible of the inconvenience that attended the want of a sufficiency of water in the river, for carrying on their commerce, they resolved to have a port of their own, nigher the mouth of the river. At first, they thought of making their harbour at Dumbarton: but as this is a royal borough, the magistrates opposed it; because they thought that the influx of sailors and others, occasioned by the harbour, would be so great, that a scarcity of provisions would be occasioned. The magistrates and town-council of Glasgow, therefore, purchased some lands on the south side of the river Clyde for this purpose; and so expeditious were they in making their harbour, and rearing their town, that in 1710 a bailie was appointed for the government of Port-Glasgow. It is now a very considerable parish, and lies 14 miles nigher the mouth of Clyde than Glasgow.

7
Erection of
Port-Glas-
gow.

In 1725, Mr Campbell, the member of parliament for Glasgow, having given his vote for having the malt-tax extended over Scotland, a riot ensued among the lower class of people. In this disturbance, Mr Campbell's furniture was destroyed, and some excisemen were maltreated for attempting to take an account of the malt. General Wade, who commanded the forces in Scotland, had sent two companies of soldiers, under the command of Captain Buthell, to prevent any disturbance of this kind. Captain Buthell drew up his men in the street, where the multitude pelted them with stones. They endeavoured to disperse, by firing with powder only: but this expedient failing, he ordered his men to load their pieces with ball; and, without the sanction of the civil authority, commanded them to fire four different ways at once. By this discharge about 20 persons were killed and wounded; which enraged the multitude to such a degree, that having procured some arms, they pursued Buthell and his men to the castle of Dumbarton, about five miles distant.

11
Disturbance
about the
excise-bill.

General Wade being informed of this transaction, assembled a body of forces, and being accompanied by Duncan Forbes, lord advocate, took possession of the town: the magistrates were apprehended, and carried prisoners to Edinburgh; but on an examination before the lords, their innocence clearly appeared, upon which they were immediately dismissed. Buthell was tried for murder, convicted, and condemned; but, instead of suffering the penalties of law, he was

indulged with a pardon, and promoted in the service. Mr Campbell petitioned the House of Commons for an indemnification of his losses: a bill was passed in his favour; and this, together with some other expenses incurred in the affair, cost the town 9000 l. ster.

During the time of the rebellion in 1745, the citizens of Glasgow gave proof of their attachment to revolution principles, by raising two battalions, of 600 men each, for the service of government. This piece of loyalty, however, had like to have cost them dear. The rebels, in their journey fourth, took a resolution to plunder and burn the city; which would probably have been done, had not Mr Cameron of Lochiel threatened, in that case, to withdraw his clan. A heavy contribution, however, was laid on. The city was compelled to pay 5000 l. in money, and 500 l. in goods; and on the return of the rebels from England, they were obliged to furnish them with 12,000 linen shirts, 6000 cloth coats, 6000 pairs of shoes, 6000 pairs of hose, and 6000 bonnets. These goods, with the money formerly paid them, the expense of raising and subsisting the two city-battalions, and the charge of maintaining the rebel army in free quarters for ten days, cost the community about 14,000 l. sterling; 10,000 l. of which they recovered in 1749, by an application to parliament.

About the year 1750, a very considerable change took place in the manner of living among the inhabitants of Glasgow. Till this time, an attentive industry, and a frugality bordering upon parsimony, had been their general characteristic; the severity of the ancient manners prevailed in its full vigour; But now, when an extensive commerce and increased manufactures had produced wealth, the ideas of the people were enlarged, and schemes of trade and improvement were adopted, which people would formerly have been denominated madmen if they had undertaken; a new stile was introduced in living, dress, building, and furniture; wheel-carriages were set up, public places of entertainment were frequented; and an assembly-room, ball-room, and playhouse, were built by subscription; and from this time we may date all the improvements that have taken place, not only in Glasgow, but all over the west of Scotland. The best method, however, of estimating the growing improvement of any town, is by the frequency of their applications for assistance to parliament; we shall therefore enumerate the acts of parliament which have been passed in favour of the city of Glasgow since the year 1750. In 1753, an act passed for repairing several roads leading into the city of Glasgow.—In 1756, an act for erecting and supporting a light-house in the island of Little Cumray, at the mouth of the Clyde, and for rendering the navigation of the frith and river more safe and commodious.—In 1759, an act for improving the navigation of the river Clyde to the city of Glasgow, and for building a bridge across the river from the city to the village of Gorbells.—In 1767, the people of Glasgow having proposed to make a small cut or canal from the frith of Forth to that of Clyde, for the convenience of their trade to the eastern side of the island, several gentlemen at Edinburgh, and throughout different parts of the kingdom, proposed that this canal should be executed upon a much larger scale than what had been originally projected. An act was accordingly obtained,

and the canal executed in the manner described under the article CANAL.—In 1770, another act was obtained for improving the navigation of the river, and for building the bridge from the city to the village of Gorbells, being an amendmēt of the former act for that purpose.—In 1771, an act for making and widening a passage from the Salt-market to St Andrew's church; for enlarging and completing the church-yard of that church, and likewise for building a convenient exchange or square in the city; also for amending and explaining the former act relative to the navigation of the Clyde.—An act for making and maintaining a navigable canal and waggon-way from the collieries in the parishes of Old and New Monkland, to the city of Glasgow.

This last canal, which was undertaken with a view to reduce the price of coals, has not been attended with the desired effect. The other improvements have been productive of very great advantages: and it may be confidently asserted, that since the year 1750 a total change has been effected in the city of Glasgow and all round it; the manners of the people have undergone an alteration greatly for the better; a spirit of industry and activity has been raised, and now pervades every order of men; commerce has been increased; manufactures carried on to a considerable extent, and still increasing; every person is employed; not a beggar is to be seen in the streets; the very children are busy.

14
Description
of the city.

Such is the present flourishing state of the city of Glasgow, which for its beauty and elegance exceeds every other city in Scotland. The most ancient part of it stands on a rising ground. The foundation of the cathedral is 104 feet higher than the bed of the river; and the descent from the high ground reaches to about 100 yards below the college. The rest of the city is built upon a plain. The city reaches from north to south, *i. e.* from the Stable-green port, to the fourth end of the Gorbells, 2000 yards; from east to west, *i. e.* from the Gallowgate toll-bar to Grahamestown toll-bar, 3160 yards. The streets are clean and well paved; the medium breadth of the principal ones is 52 feet; and several of them intersecting one another at right angles, produce a very fine effect. The houses, excepting a very few, are built of free-stone well hewed; few of them exceed four floors in height; and many of them are in an exceeding good taste, inasmuch that Mr Pennant pronounces Glasgow to be the best second-rate city he had ever seen. The most remarkable public buildings are,

15
Of the ca-
thedral.

1. *The Cathedral, or High Church*, is a magnificent building, and its situation greatly to its advantage, as it stands higher than any part of the city. It has been intended to form a cross, though the traverse part has never been finished. The great tower is founded upon four large masonry pillars, each of them about 30 feet in circumference. The tower itself is 25½ feet square within; and is surrounded by a ballustrade, within which rises an octangular spire terminated by a vane. The tower upon the west end is upon the same level, but appears not to have been finished, though it is covered over with lead. In this tower is a very large bell 11 feet 4 inches in diameter. The principal entry was from the west; the gate 11 feet broad at the base,

and 17 feet in height. The west end of the choir is now appropriated for a place of divine worship; and is divided from the remaining part by a stone-partition, which is inclosed by another stone-wall parting it from the nave. It is impossible to form an adequate idea of the awful solemnity of the place occasioned by the loftiness of the roof and the range of pillars by which the whole is supported.

The nave of the church rises four steps higher than the choir; and on the west side stood the organ-loft, formerly ornamented with a variety of figures, but now defaced. The pillars here are done in a better taste than those in the choir, and their capitals are ornamented with fruits. The arched roof of the altar is supported by five pillars, over which was a fine terrace walk, and above it a large window of curious workmanship, but now shut up. On the north side of the altar is the vestry, being a cube of 28 feet, the roof arched and vaulted at top, and supported by one pillar in the centre of the house. Arched pillars from every angle terminate in the grand pillar, which is 19 feet high. The lower part of the fourth cross is made use of as a burying place for the clergy of the city; and is by much the finest piece of workmanship in the whole building. It is 55 feet long, 28 broad, and 15 high; arched and vaulted at top, and supported by a middle range of pillars, with their capitals highly ornamented; corresponding to which are columns adjoining to the walls, which as they rise, spring into semi-arches, and are every where met at acute angles by their opposites, and are ornamented with carvings at the closing and crossing of the lines. At the east end of the choir you descend by flights of steps upon each side into passages which, in former times, were the principal entries to the burying vault which is immediately under the nave. It is now made use of as a parish-church for the barony of Glasgow; and is full of pillars, some of them very maffy, which support the arched roof: but it is a very uncomfortable place for devotion. The space under the altar and vestry, though now made use of as a burying place by the heritors of the barony, was formerly, according to tradition, employed for keeping of the relics; and indeed, from the beautiful manner in which this place is finished, one would imagine that it had not been destined for common use. Here is shewn the monument of St Mungo, or Kentigern, with his figure lying in a cumbent posture.

The whole length of the cathedral within the walls is 284 feet; its breadth 65; the height of the choir, from the floor to the canopy, 90 feet; the height of the nave, 85 feet; the height of the middle tower, 220 feet. This fabric was begun by John Achaius in 1123, and consecrated in 1136; and continued by succeeding bishops till such time as it was finished in the manner in which it stands at present. The wealth of the see of Glasgow, however, was not sufficient for so great an undertaking, so that they were obliged to have recourse to all the churches of Scotland for assistance in it. Near the cathedral is the ruin of the castle or bishop's palace.

2. *St Andrew's Church* was begun by the community in 1739, and finished in 1756. It is the finest piece of modern architecture in the city; and is built after the model of St Martins in the fields, London,

Glasgow.

16
St. An-
drew's
church.

whose architect was the famous Gibbs. The length of the church is 104 feet, and its breadth 66. It has a fine arched roof, well ornamented with figures in stucco, and sustained by stone-columns of the Corinthian order. Correspondent to the model, it has a place for the altar on the east, in which is a very ancient Venetian window; but the altar-place being feated makes this end appear to no great advantage. The fronts of the galleries and the pulpit are done in mahogany in a very elegant manner. The spire by no means corresponds with the rest of the building; and, instead of being an ornament, disgraces this beautiful fabric. Its height is 170 feet.

17
The col-
lege.

3. *The College.* The front of this building extends along the east side of the high street, and is upwards of 330 feet long. The gate at the entrance is decorated with rustics, and over it are the king's arms. The first court is 88 feet long and 44 broad. The west side is elevated upon stone pillars, on which are placed pilasters supporting the Doric entablature, and ornamented with arches forming a piazza. Above these is the public hall; the ascent to which is by a double flight of steps inclosed by a handsome stone balustrade, upon the right of which is placed a lion, and on the left an unicorn, cut in free stone. The spire stands on the east side, is 135 feet high, and has a very good clock. Under this is the gateway into the inner and largest court, which is 103 feet long and 79 broad. Over the entry, in a niche, is a statue of Mr Zacharias Boyd, who was a benefactor to the university. On the east side of the court is a narrow passage leading into a handsome terrace walk, gravelled, 122 feet long by 64 feet broad. This walk is inclosed to the east by an iron pallisade, in the centre of which is a gate leading into the garden. This last consists of seven acres of ground, laid out in walks for the recreation of the students. On the south side of the walk stands the library; a very neat edifice, well constructed for the purpose intended, and containing a very valuable collection of books.

18
Town-
ouic, &c.

5. *The Town-House and Assembly-Hall.* This is a magnificent and extremely elegant building. The front is adorned with a range of Ionic pilasters; the top of the building is ornamented with a balustrade and handsome vases; the front is elevated on strong rusticated pillars adorned with arches, forming a piazza for merchants and others to shelter themselves from the weather when met upon business. The assembly-hall is a neat room, and is finished in a good taste, though too small for the city; its length is 47 feet, its breadth and height 24. The town-hall is a very spacious and lofty apartment, 52 feet long by 27 broad, and 24 in height. It is finished in a very grand manner; the ceiling is divided into different compartments well ornamented. In it are full-length portraits of king James VI. and VII. Charles I. and II. William and Mary, queen Anne, king George I. II. and III. and Archibald duke of Argyle in his judiciary robes. The two last are by Ramsay. Opposite to the front of this building is the exchange, which is well paved with free stone, and inclosed from the street by stone pillars. Upon it is an equestrian statue of king William III. placed upon a lofty pedestal, and surrounded with an iron rail.

19
Guild-hall.

5. *The Guild-Hall, or Merchants House.* This building is situated upon the south side of Bridge-gate street; and is in length 82 feet, in breadth 31.

The great hall, which is the whole length and breadth of the building, is so capacious, that it is better adapted for the reception of great and numerous assemblies than any other in the city. This house is adorned with a very elegant spire 200 feet high.

20
Town's ho-
spital.

6. *The Town's Hospital* is a very neat building, consisting of two wings and a large front: the length 156 feet, the breadth of the centre 30 feet, and the depth of the wings 68 feet. Behind the building is an infirmary 127 feet long by 25 feet broad, the ascent to which is by a flight of steps. The lower part of this building is appointed for the reception of lunatics. The area between the buildings is large, which, with the agreeable open situation of the hospital on the river, must conduce to the health of the inhabitants.

21
New bridge

7. *The New Bridge* is built in an elegant manner. It is 32 feet wide; with a commodious foot-way for passengers, five feet broad on each side, raised above the road made for carriages, and paved with free stone. This bridge is about 500 feet in length; and consists of seven arches, the faces of which are wrought in rustic, with a strong block-cornice above. The arches spring but a little way above low-water mark; which, tho' it renders the bridge stronger than if they sprung from taller piers, diminishes its beauty. Between every arch there is a small circular one: these break the force of the water when the river rises to a flood, and add to the strength of the whole. The parapet-wall or breast-work is cut out in the Chinese taste; and the two ends are finished off with a sweep.

22
Markets,
&c.

8. *The Markets in King's Street* are justly admired, as being the completest of their kind in Britain. They are placed on both sides of the street. That on the east side, appropriated entirely for butcher-meat, is 112 feet in length, and 67 in breadth. In the centre is a spacious gateway, decorated on each side with coupled Ionic columns set upon their pedestals, and supporting an angular pediment. At the north end is a very neat hall belonging to the incorporation of butchers, the front ornamented with rustics and a pediment. The markets upon the west side of the street consist of three courts, set apart for fish, mutton, and cheefe. The whole of the front is 173 feet, the breadth 46 feet; in the centre of which, as on the opposite side, is a very spacious gateway of the Doric order, supporting a pediment. This is the entry to the mutton-market. Each of the other two has a well-proportioned arch faced with rustics for their entrance. All these markets are well paved with free stone; have walks all round them; and are covered over for shelter by roofs standing upon stone piers, under which the different commodities are exposed to sale. They have likewise pump-wells within, for cleaning away all the filth; which render the markets always sweet and agreeable.

9. *The Guard-House* is a very handsome building, with a piazza formed by arches, and columns of the Ionic order set upon their pedestals. The entablature supports at Attic course, in which are oval port-holes ornamented with palm-branches.

10. *The Herb-Market*, is neat and commodious; in length 130, and in breadth 41 feet. The principal entry is decorated with coupled Ionic columns, supporting an angular pediment. It is laid out in the same manner with the markets in King's-street.

The most remarkable public charities in Glasgow are,

1. *Muir-*

Glasgow.

23
Public cha-
rities.

1. *Muirhead's or St Nicholas's Hospital.* This was originally appointed to subsist 12 old men and a chaplain: but its revenues have, from some unknown causes, been lost; so that no more of them now remains than the paltry sum of 139l. 2s. 5d. Scots money, 128 l. of which is annually divided among four old men annually, at the rate of 2 l. 13s. 4d. each.

2. *Hutcheson's Hospital,* was founded and endowed in 1639 by George Hutcheson of Lamb-hill, notary-public, and Mr Thomas Hutcheson his brother, who was bred a preacher, for the maintenance of old men and orphans. The funds of this hospital were afterwards increased by James Blair merchant in Glasgow, in 1710; and by subsequent donations, the managers now have it in their power to give away above 900l. Sterling in pensions, from 5 l. 10s. to 10 l. per pensioner.

3. *The Town's Hospital* was opened for the reception of the poor on the 15th of November 1733. The funds from whence this hospital is subsisted are, the general session, the town-council, the trades house and merchants house, the interest of money belonging to their funds, which are sums that have been mortified for the use of the house. These supplies, however, are found insufficient to defray the expences of the house; for which reason an assessment is annually made upon the inhabitants in the following manner. The magistrates nominate 12, 14, or sometimes more gentlemen of known integrity and character, who have a list laid before them of all the inhabitants in town. This list they divide into 16 or 18 columns. Each of these columns contains the names of such inhabitants as carry on trade to a certain extent, or are supposed to be well able to pay the sum affixed to the particular column in which their names are inserted. If it is necessary to raise 500l. for instance, then each name, in every separate column, is valued at as much as the fortunes of the persons in each particular column are supposed to be. If 1000l. or more is to be raised, it is only continuing a proportional increase through the whole of the columns. The highest sum that ever was thus raised, was 12 s. 6d. upon every thousand pounds that each person was supposed to be worth. The number of people maintained in this hospital are about 620.

24
Members of
the univer-
sity.

The university of Glasgow owes its origin, as we have already observed, to bishop Turnbull. The institution consisted at first of a rector, a dean of faculty, a principal who taught theology, and three professors of philosophy; and, soon after this, the civil and canon laws were taught by some clergymen. From the time of its establishment in 1450 to the reformation in 1560, the college was chiefly frequented by those who were intended for the church; its members were all ecclesiastics, and its principal support was derived from the church. The reformation brought the university to the verge of destruction: masters, students, and servants, all forsook it. The magistrates were so sensible of the loss which the community had sustained by this desertion, that they endeavoured to restore it in 1572, by bestowing upon it considerable funds, and prescribing a set of regulations for its management. These, however, proved insufficient; for which reason king James VI. erected it anew, by a charter called the *Nova Erectio*, in 1577, and bestowed upon it the tithes of the

parish of Govan. The persons who were to compose the new university were, a principal, three professors of philosophy, four students bursars, one oeconomus, a principal's servant, a janitor, and cook.

Since the year 1577, the funds of the university have been considerably increased by the bounty of kings and the donations of private persons. The professors have therefore also been increased; so that at present the university of Glasgow consists of a chancellor, rector, dean of faculty, principal, and 13 professors, together with bursars, &c. The archbishop of Glasgow was formerly chancellor of the university *ex officio*; at present, the chancellor is chosen by the rector, dean of faculty, principal, and masters.

The chancellor, as being the head of the university, is the fountain of honour, and in his name are all academical degrees bestowed. The office of rector is to exercise that academical jurisdiction in disputes among the students themselves, or between the students and citizens, which is bestowed upon the greater part of the universities in Europe. He is chosen annually in the *comitia*; that is, in a meeting in which all the students, as well as the other members of the university, have a voice. Immediately after his admission, he has been in use to choose certain persons as his assessors and counsellors in his capacity of judge; and, in former periods, it was customary to name the ministers of Glasgow, or any other gentlemen who had no connection with the university; but, for a great while past, the rector has constantly named the dean of faculty, the principal, and masters for his assessors; and he has always been, and still is, in the daily practice of judging in the causes belonging to him, with the advice of his assessors. Besides these powers as judge, the rector summons and presides in the meetings of the university for the election of his successor; and he is likewise in use to call meetings of the professors for drawing up addresses to the king, electing a member to the general assembly, and other business of the like kind.

The dean of faculty has, for his province, the giving directions with regard to the course of studies; the judging, together with the rector, principal, and professors, of the qualifications of those who desire to be created masters of arts, doctors of divinity, &c., and he presides in meetings which are called by him for these purposes. He is chosen annually by the rector, principal, and masters.

The principal and masters, independent of the rector and dean, compose a meeting in which the principal presides; and, as they are the persons for whose behalf chiefly the revenue of the college was established, the administration of that revenue is therefore committed to them.

The revenue arises from the tithes of the parish of Govan, granted by king James VI. in 1557; from the tithes of the parishes of Renfrew and Kilbride, granted by the same monarch in 1617, and confirmed by king Charles I. on the 28th of June 1630; from the tithes of the parishes of Calder, Old and New Monkland, conveyed to them by a charter from Charles II. in 1670; from a tack of the archbishopric; and from several donations received from private persons.

The college of Glasgow, for a very considerable time after its erection, followed the mode of public teaching which is common even to this day in Oxford

and

and Cambridge, and in many other universities throughout Europe; that is, each professor gave a few lectures every year, *gratis*, upon the particular science which he professed: but, in place of this, the professors have, for a great while past, adopted the mode of private teaching; that is, they lecture and examine two hours every day during the session, viz. from the 30th of October to the 10th of June; a method which comes much cheaper to the student, as he has it in his power, if he is attentive, to acquire his education without being under the necessity of employing a tutor. They have also private classes, in which they teach one hour per day. The fixed fee for a public class is 1 l. 11 s. 6 d. per session; the fixed fee for a private one is 1 l. 1 s. per d°. The number of students who have attended this college for several years past, has been upwards of 500 each season.

25
History of
the trade of
Glasgow.

The trade of Glasgow is said to have been first promoted by one Mr William Elphinstone in 1420. This trade was most probably the curing and exporting of salmon; but the first authentic document concerning Glasgow as a trading city is in 1546. Complaints having been made by Henry VIII. king of England, that several English ships had been taken and robbed by vessels belonging to Scotland, an order of council was issued, discharging such captures for the future; and among other places made mention of in this order is the city of Glasgow. The trade which at that time they carried on could not be great. It probably consisted of a few small vessels to France loaded with pickled salmon; as this fishery was, even then, carried on to a considerable extent, by Glasgow, Renfrew, and Dumbarton. Between the year 1630 and 1660, a very great degree of attention seems to have been paid to inland commerce by the inhabitants of Glasgow. Principal Baillie informs us, that the increase of Glasgow arising from this commerce was exceedingly great. The exportation of salmon and of herrings was also continued and increased. In the war between Britain and Holland during the reign of Charles II. a privateer was fitted out in Clyde to cruise against the Dutch. She was called the *Lion of Glasgow*, Robert McAllan commander; and carried five pieces of cannon, and 60 hands.

A spirit of commerce appears to have arisen among the inhabitants of Glasgow between the year 1660 and 1707. The citizens who distinguished themselves most during this period were Walter Gibson and John Anderlon. Gibson cured and packed in one year 300 lasts of herrings, which he sent to St Martins in France on board of a Dutch vessel, called the *St Agate*, of 450 tons burthen; his returns were brandy and salt. He was the first who imported iron from Stockholm into Clyde. Anderlon is said to have been the first who imported white-wines.

Whatever their trade was at this time, it could not be considerable: the ports to which they were obliged to trade lay all to the eastward: the circumnavigation of the island would therefore prove an almost unsurmountable bar to the commerce of Glasgow; and of consequence the people on the east coast would be possessed of almost all the commerce of Scotland. The union with England opened a field for commerce for which the situation of Glasgow was highly advantageous. Since that time the commerce of the east

coast has declined, and that of the west increased to an amazing degree. No sooner was the treaty of union signed, than the inhabitants of Glasgow began to prosecute the trade to Virginia and Maryland; they chartered vessels from Whitehaven, sent out cargoes of goods, and brought back tobacco in return. The method in which they at first proceeded in this trade, was certainly a very prudent one. A supercargo went out with every vessel. He bartered his goods for tobacco, until such time as he had either sold all his goods, or procured as much tobacco as was sufficient to load his vessel. He then immediately set out on his return; and if any of his goods remained unsold, he brought them home with him. While they continued to trade in this way, they were of great advantage to the country, by the quantity of manufactures which they exported; their own wealth began to increase; they purchased ships of their own; and, in 1718, the first vessel of the property of Glasgow crossed the Atlantic. Their imports of tobacco were now considerable, and Glasgow began to be looked upon as a considerable port; the tobacco-trade at the ports of Bristol, Liverpool, and Whitehaven, was observed to dwindle away; the people of Glasgow began to send tobacco to these places, and to undersell the English even in their own ports. Thus the jealousy of the latter was soon excited, and they took every method in their power to destroy the trade of Glasgow. The people of Bristol presented remonstrances to the commissioners of the customs at London against the trade of Glasgow, in 1717. To these remonstrances the merchants of Glasgow sent such answers to the commissioners as convinced them that the complaints of the Bristol merchants were without foundation. But in 1721, a most formidable confederacy was entered into by almost all the tobacco-merchants in South Britain against the trade of Glasgow. Those of London, Liverpool, and Whitehaven, presented severally to the Lords of the Treasury, petitions, arraigning the Glasgow merchants of frauds in the tobacco trade. To these petitions the Glasgow people gave in replies; and the lords of the treasury, after a full and impartial hearing, were pleased to dismiss the cause with the following sentence: "That the complaints of the merchants of London, Liverpool, and Whitehaven, were groundless; and that they proceeded from a spirit of envy, and not from a regard to the interest of trade, or of the king's revenue."

But the malice of these gentlemen did not stop here. They brought their complaints into the house of commons. Commissioners were sent to Glasgow in 1722, who gave in their reports to the house in 1723. The merchants sent up distinct and explicit answers to these reports; but such was the interest of their adversaries, that these answers were disregarded. New officers were appointed at the ports of Greenock and Port-Glasgow, whose private instructions seem to have been, to ruin the trade if possible, by putting all imaginable hardships upon it. In short, every species of persecution, which malice assisted by wealth and interest could invent, were put in practice to destroy the trade of Glasgow; and they in part succeeded. It languished till the year 1735; but after that began to revive, though even after its revival it was carried on but slowly for a considerable space of time.

With

Glasgow.

26
Manufac-
tures of
Glasgow.

With regard to the manufactures of Glasgow, Mr Gibbon is of opinion that the commerce to America first suggested the idea of introducing them, in any considerable degree at least. The first attempts in this way were about the year 1725, and their increase for some time was very slow, nor did they begin to be considerable till great encouragement was given by the legislature to the linen manufacture in Scotland. The first causes of the success of this manufacture were the act of parliament in 1748, whereby the wearing of French cambrics was prohibited under severe penalties; that of 1751, allowing weavers in flax or hemp to settle and exercise their trades any where in Scotland free from all corporation-dues; and the bounty of three-halfpence per yard on all linsens exported at and under 18d. per yard. Since that time a spirit of manufacture has been excited among the inhabitants of Glasgow; and great variety of goods, and in very great quantity, have been manufactured. Checks, linen, and linen and cotton, are manufactured to a great extent. Printed linsens and cottons were begun to be manufactured in 1738; but they only made garments till 1754, when handkerchiefs were first printed. There is no manufacture more upon the increase in Glasgow than this; nor can any branch be more beneficial to the country, as the cloths on which they print are all made in Scotland; whereas at London, and through the greatest part of England, the cloths they print upon are all imported from Germany.

A manufactory of ribbons has been very lately introduced into Glasgow; and though this branch of business is yet in its infancy, they are made equal in quality to those in England, and rather cheaper.

Incels were first made here about the year 1732. The engine-ooms used at that time were so inconvenient, and took up so much time in making the goods, that the Dutch, who were the only people possessed of the large incels, were almost solely in possession of this manufacture. Mr Hervey, who began this branch in Glasgow, was so sensible of the disadvantages under which it laboured, that he went over to Holland; and, in spite of the care and attention which the Dutch took to conceal their methods of manufacturing, he brought over with him from Harlem two of their looms, and one of their workmen. This Dutchman remained some years in Glasgow; but on some disgust he went to Manchester, and instructed the people there in the method of carrying on the manufacture.

In 1757, carpets were begun to be made, and are now carried on to a considerable extent. Hunters cloths, English blankets, and other goods of the same kind, are also made; and, with proper attention, these manufactures certainly will succeed.

Besides these, a great variety of articles are manufactured at Glasgow, of which our limits will not permit us to enter into a detail, such as soap, refining of sugar, iron-mongery, brass, jewellery, &c.—Types for printing are made in this city by Dr Wilson and Sons, perhaps superior to any others in Europe. Printing of books was first begun here by George Anderlon about the year 1638. But there was no good printing in Glasgow till the year 1735; when Robert Urie printed several books in a very elegant manner. The highest perfection, however, to which printing hath yet been carried in this place, or perhaps in any other, was by the

late Robert and Andrew Foulis, (who began in the year 1740;) as the many elegant and splendid editions of books printed by them in different languages sufficiently testify. The same gentlemen also established an academy of painting; but the wealth of Scotland being unequal to the undertaking, it hath been since given up.

The government of the city of Glasgow is vested in a provost and three bailies, a dean of guild, deacon-conveener, and a treasurer, with a common council of 13 merchants and 12 mechanics. The provost and two of the bailies must, by the set of the burgh, be elected from the merchant rank, and the other bailie from the trades rank, *i. e.* the mechanics. The provost is, from courtesy and custom, styled *lord provost*. He is properly lord of the police of the city, president of the community, and is *ex officio* a justice of the peace for both the burgh and county.

The revenue of Glasgow amounts to about L. 6000 Sterling *per annum*. It arises from a duty upon all grain and meal brought into the city, (this tax is denominated *the ladder*); from the rents of lands and houses the property of the community; from an impost of two pennies Scots upon every Scots pint of ale or beer brewed, inbrought, or sold, within the city; from certain dues payable out of the markets; from the rents of the seats in churches; from the dues of crannage at the quay, at the weigh-house, tonnage on the river, pontage on the bridge, statute-work within the burgh, &c. The number of inhabitants is computed to be about 43,000.

GLASS, a transparent, brittle, facitious body, produced from sand melted in a strong fire with fixed alkaline salts, lead, flags, &c. till the whole becomes perfectly clear and fine. The word is formed of the Latin *glafum*, a plant called by the Greeks *glafis*, by the Romans *vitrum*, by the ancient Britons *gudum*, and by the English *wasad*. We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with *glafum*, *gudum*, *vitrum*, &c. *i. e.* with the blue colour procured from this plant. And hence, the facitious matter we are speaking of came to be called *glafi*; as having always somewhat of this bluishness in it.

At what time the art of glafs-making was first invented, is altogether uncertain. Some imagine it to have been invented before the flood: but of this we have no direct proof, though there is no improbability in the supposition; for we know, that it is almost impossible to excite a very violent fire, such as is necessary in metallurgic operations, without vitrifying part of the bricks or stones wherewith the furnace is built. This indeed might furnish the first hints of glafs-making; tho' it is also very probable, that such imperfect vitrifications would be observed a long time before people thought of making any use of them.

Neri traces the antiquity of glafs as far back as the time of Job. That writer, speaking of the value of wisdom, chap. xxviii. verse 17, says, that gold and crystal cannot equal it. But this word, which Neri will have to signify facitious glafs, is capable of a great many different interpretations, and properly signifies only whatever is beautiful or transparent. Dr Merret will have the art to be as ancient as that of pottery or the

Glasgow.
Glasf.27
Govern-
ment, reve-
nue, &c. of
the city.History of
glafs-making.

Glasf.

the making of bricks, for the reasons already given, viz. that by all vehement heats some imperfect vitrifications are produced. Of this kind undoubtedly was the fossil glass mentioned by Ferant. Emperor. to have been found under-ground where great fires had been. But it is evident, that such imperfect vitrifications might have passed unnoticed for ages; and consequently we have no reason to conclude from thence, that the art of glass-making is of such high antiquity.

The Egyptians boast, that this art was taught them by their great Hermes. Aristophanes, Aristotle, Alexander, Aphroditeus, Lucretius, and St John the divine, put it out of all doubt that glass was used in their days. Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea; who being obliged to continue there, and dress their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to ashes, its salts mixed and incorporated with the sand, or stones fit for vitrification, and thus produced glass; and that this accident, being known, the people of Sidon, in that neighbourhood, essayed the work, and brought glass into use; since which time the art has been continually improving. Be this as it will, however, the first glass-houses mentioned in history were erected in the city of Tyre, and here was the only staple of the manufactory for many ages. The sand which lay on the shore for about half a mile round the mouth of the river Belus was peculiarly adapted to the making of glass, as being neat and glittering; and the wide range of the Tyrian commerce gave an ample vent for the productions of the furnace. It appears, however, that before the conquest of Britain by the Romans, glass-houses had been erected in this island, as well as in Gaul, Spain, and Italy. Hence, in many parts of the country are to be found annulets of glass, having a narrow perforation and thick rim, denominated by the remaining Britons *gleineu naidreedb*, or *glass adders*, and which were probably in former times used as amulets by the druids *. It can scarcely be questioned that the Britons were sufficiently well versed in the manufacture of glass, to form out of it many more useful instruments than the glass-beads. History indeed assures us, that they did manufacture a considerable quantity of glass vessels. These, like their annulets, were most probably green, blue, yellow, or black, and many of them curiously streaked with other colours. The process in the manufacture would be nearly the same with that of the Gauls or Spaniards. The sand of their shores being reduced to a sufficient degree of fineness by art, was mixed with three fourths of its weight of their nitre (much the same with our kelp), and both were melted together. The metal was then poured into other vessels, where it was left to harden into a mass, and afterwards replaced in the furnace, where it became transparent in the boiling, and was afterwards figured by blowing, or modelling in the lath, into such vessels as they wanted.

It is not probable that the arrival of the Romans would improve the glass manufactory among the Britons. The taste of the Romans at that time was just the reverse of that of the inhabitants of this island. The former preferred silver and gold to glass for the composition of their drinking vessels. They made indeed

great improvements in their own at Rome, during the government of Nero. The vessels then formed of this metal rivalled the bowls of porcelain in their clearness, and equalled the cups of crystal in their transparency. But these were by far too costly for common use; and therefore, in all probability, were never attempted in Britain. The glass commonly made use of by the Romans was of a quality greatly inferior; and, from the fragments which have been discovered at the stations or towns of either, appear to have consisted of a thick, sometimes white, but mostly blue-green, metal.

With regard to the theory of vitrification, we are almost totally in the dark. In general, it seems to be that state, in which solid bodies are, by the vehement action of fire, fitted for being dissipated, or carried off in vapour. In all vitrifications, there is a plentiful evaporation; and if any solid substance is carried off in vapour by the intense heat of a burning speculum, a vitrification is always observed previously to take place. The difference, then, between the state of fusion and vitrification of a solid body we may conceive to be, that in the former the element of fire acts upon the parts of the solid in such a manner as only to disjoin them, and render the substance fluid; but, in vitrification, the fire not only disjoins the particles, but combines with them in a latent state, into a third substance; which, having now as much fire as it can contain, can receive no further change from that element, except being carried off in vapour.

But, though we are unable to effect this change upon solid bodies without a very violent heat, it is otherwise in the natural processes. By what we call *crystallization*, nature produces more perfect glasses than we can make with our furnaces. These are called *precious stones*; but in all trials they discover the essential properties of glass, and not of stones. The most distinguishing property of glass is its resisting the force of fire, so that this element cannot calcine or change it as it does other bodies, but can only melt it, and then carry it off in vapours. To this last all the precious stones are subject. The diamond (the hardest and most ponderous of them all) is dissolvable in a less degree of heat than what would dissipate common glass. Nor can it be any objection to this idea, that some kinds of glass are capable of being converted into a kind of porcelain by a long-continued cementation with certain materials. This change happens only to those kinds of glass which are made of alkaline salt and sand; and Dr Lewis hath shewn that this change is produced by the dissipation of the saline principle, which is the least fixed of the two. Glass, therefore, we may still consider as a substance upon which the fire, has no other effect than either to melt, or dissipate it in vapour.

The other properties of glass are very remarkable, Remarkable some of which follow.

1. It is one of the most elastic bodies in nature. If the force with which glass-balls strike each other be reckoned 16, that wherewith they recede by virtue of their elasticity will be nearly 15.

2. When glass is suddenly cooled, it becomes exceedingly brittle; and this brittleness is sometimes attended with very surprising phenomena. Hollow bells made of unannealed glass, with a small hole in them, silver

will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be stopped with a finger. Lately, however, some vessels made of such annealed glass have been discovered, which have the remarkable property of resisting very hard strokes given from without, though they shiver to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. Those glasses may be made of any shape; all that needs be observed in making them is, that their bottoms be thicker than their sides. The thicker the bottom is, the easier do the glasses break. One whose bottom is three fingers breadth in thickness, flies with as much ease at least as the thinnest glass. Some of these vessels have been tried with strokes of a mallet sufficient to drive a nail into wood tolerably hard, and have held good without breaking. They have also resisted the shock of several heavy bodies let fall into their cavities, from the height of two or three feet; as musket-balls, pieces of iron, or other metal, pyrites, jasper, wood, bone, &c. But this is not surprising, as other glasses of the same shape and size will do the same: but the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the glass only from the height of three inches, in about two seconds the glass flies, and sometimes at the very moment of the shock; nay, a bit of flint no larger than a grain, dropped into several glasses successively, though it did not immediately break them, yet when set by, they all flew in less than three quarters of an hour. Some other bodies produce the same effect with flint; as sapphire, diamond, porcelain, hard tempered steel, also marbles such as boys play with, and likewise pearls.

These experiments were made before the Royal Society; and succeeded equally when the glasses were held in the hand, when they were rested on a pillow, put in water, or filled with water. It is also remarkable, that the glasses broke upon having their bottoms slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing. If the glasses are every where extremely thin, they do not break in these circumstances.

5
Attempts
to account
for it.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into the vessels cause a concussion which is stronger than the cohesive force of the glass, and consequently that a rupture must ensue. But why does not a ball of iron, gold, silver, or copper, which are perhaps a thousand times heavier than the flint, produce the same effect? Is it because they are not elastic? But surely iron is more elastic than the end of one's finger.—Mr Euler has endeavoured to account for these appearances from his principles of percussion. He thinks that this experiment entirely overthrows the opinion of those who measure the force of percussion by the *vis viva*, or absolute apparent strength of the stroke. According to his principles, the great hardness and angular figure of the flint, which makes the space of contact with the glass extremely small, ought to cause an impression on the glass vastly greater than lead, or any other metal; and this may account for the flint's breaking the vessel, though the bullet, even falling from a considerable height, does no damage.—Hollow cups made of green bottle-glass, some of them three

inches thick at the bottom, were instantly broken by a shiver of flint, weighing about two grains, though they had resisted the shock of a musket-ball from the height of three feet.

That Mr Euler's theory cannot be conclusive more than the other, must appear evident from a very slight consideration. It is not by angular bodies alone that the glasses are broken. The marbles with which children play are round, and yet they have the same effect with the angular flint. Besides, if it was the mere force of percussion which broke the glasses, undoubtedly the fracture would always take place at the very instant of the stroke; but we have seen, that this did not happen sometimes till a very considerable space of time had elapsed. It is evident, therefore, that this effect is occasioned by the putting in motion some subtle fluid with which the substance of the glass is filled; and that the motions of this fluid, when once excited in a particular part of the glass, soon propagate themselves through the whole or greatest part of it, by which means the cohesive power becomes at last too weak to resist them. There can be little doubt that the fluid just now mentioned is that of electricity. It is known to exist in glass, in very great quantity; and it also is known to be capable of breaking glasses, even when annealed with the greatest care, if put into too violent a motion. Probably the cooling of glass hastily may make it more electric than is consistent with its cohesive power, so that it is broken by the least increase of motion in the electric fluid by friction or otherwise. This is evidently the case when it is broken by rubbing with the finger; but why it should also break by the mere contact of flint and the other bodies abovementioned, has not yet been satisfactorily accounted for.

6
Rotation of
glass-tubes
before a
fire.

A most remarkable phenomenon also is produced in glass tubes placed in certain circumstances. When these are laid before a fire in an horizontal position, having their extremities properly supported, they acquire a rotatory motion round their axis, and also a progressive motion towards the fire, even when their supports are declining from the fire, so that the tubes will move a little way uphill towards the fire. When the progressive motion of the tubes towards the fire is stopped by any obstacle, their rotation still continues. When the tubes are placed in a nearly upright posture, leaning to the right hand, the motion will be from east to west; but if they lean to the left hand, their motion will be from west to east; and the nearer they are placed to the perfectly upright posture, the less will the motion be either way.

If the tube is placed horizontally on a glass plane, the fragment, for instance, of coach window-glass, instead of moving towards the fire, it will move from it, and about its axis in a contrary direction to what it had done before; nay, it will recede from the fire, and move a little up-hill when the plane inclines towards the fire.—These experiments are recorded in the philosophical transactions †. They succeeded best with † No 476. §. 1. tubes about 26 or 22 inches long, which had in each end a pretty strong pin fixed in cork for an axis.

7
Attempts to account
for it.

The reason given for these phenomena, is the swelling of the tubes towards the fire by the heat, which is known to expand all bodies. For, say the adopters of this hypothesis, granting the existence of such a

Glasf.

swelling, gravity must pull the tube down when supported near its extremities, and a fresh part being exposed to the fire, it must also swell out and fall down, and so on.—But, without going farther in the explanation of this hypothesis, it may be here remarked, that the fundamental principle on which it proceeds is false: for though fire indeed makes bodies expand, it does not increase them in weight; and therefore the sides of the tube, though one of them is expanded by the fire, must still remain in *equilibrio*; and hence we must conclude, that the causes of these phenomena remain yet to be discovered.

4. Glasf is less dilatable by heat than metalline substances, and solid glasf-ticks are less dilatable than tubes. This was first discovered by Col. Roy, in making experiments in order to reduce barometers to a greater degree of exactness than hath hitherto been found practicable; and since his experiments were made, one of the tubes 18 inches long, being compared with a solid glasf-rod of the same length, the former was found by a pyrometer, to expand four times as much as the other, in a heat approaching to that of boiling oil.—On account of the general quality which glasf has of expanding less than metal, M. de Luc recommends it to be used in pendulums: and he says it has also this good quality, that its expansions are always equable, and proportioned to the degrees of heat; a quality which is not to be found in any other substance yet known.

5. Glasf appears to be more fit for the condensation of vapours than metallic substances. An open glasf filled with water, in the summer-time, will gather drops of water on the outside, just as far as the water in the inside reaches; and a person's breath blown on it, manifestly moistens it. Glasf also becomes moist with dew, when metals do not. See Dew.

6. A drinking-glasf partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glasf is more or less full; and will make the liquor frisk and leap. See HARMONICA.

7. Glasf is possessed of very great electrical virtues. See ELECTRICITY, *passim*.

Materials for Making of GLASS. The materials whereof glasf is made, we have already mentioned to be salt and sand or stones. The salt here used, is procured from a sort of ashes, brought from the Levant, called *polverine*, or *rochetta*; which ashes are those of a sort of water-plant called *kali*, cut down in summer, dried in the sun, and burnt in heaps, either on the ground, or on iron gates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use. It may also be procured from common kelp, or the ashes of the *fucus vesiculosus*. See Kelp, and Fucus in *The APPENDIX*.

To extract the salt, these ashes, or polverine, are powdered and sifted, then put into boiling water, and there kept till one third of the water be consumed; the whole being stirred up from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted: then the vessel is filled up with new water, and boiled over again, till one half be consumed; what remains is a sort of lee, strongly impregnated with salt. This lee, boiled over again in fresh coppers, thickens in about twenty-four hours,

and shoots its salt; which is to be ladled out, as it shoots, into earthen pans, and thence into wooden vats to drain and dry. This done, it is grossly pounded, and thus put in a sort of oven, called *calcar*, to dry. It may be added, that there are other plants, besides *kali*, and *fucus*, which yield a salt fit for glasf: such are the common way-thistle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c. In some kinds of glasf, however, litharge, common pearl-ashes, and nitre, are used in great quantity.

The sand or stone, called by the artists *tarso*, is the second ingredient in glasf, and that which gives it the body and firmness. These stones, *Agricola* observes, must be such as will fuse; and of these such as are white and transparent are best; so that crystal challenges the precedence of all others.

At Venice they chiefly use a sort of pebble, found in the river Tefino, resembling white marble, and called *cugolo*. Indeed Ant. Neri assures us, that all stones which will strike fire with steel, are fit to vitrify: but Dr Merret shews, that there are some exceptions from this rule. Flints are admirable; and when calcined, powdered, and searched, make a pure white crystalline metal: but the expence of preparing them makes the masters of our glasf-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used; which should be white, and small, and well washed, before it be applied: such is usually found in the mouths and sides of rivers. Our glasf-houses are furnished with a fine sand for crystal, from Maidstone; the same with that used for sand-boxes, and in scouring; and with a coarser for green glasf, from Woolwich. For crystal glasf, to 200 lb of tarso, pounded fine, they put 130 lb of salt of polverine; then mix them together, and put them into the *calcar*, a sort of reverberatory furnace, being first well heated. Here they remain baking, frying, and calcining, for five hours, during which the workman keeps mixing them with a rake, to make them incorporate: when taken out, the mixture is called *frit*, or *bolitto*.

It may be further observed, that glasf might be made by immediately melting the materials without thus calcining and making them frit; but the operation would be much more tedious.

A glasf much harder than any prepared in the common way may be made by means of borax, in the following manner. Take four ounces of borax, and an ounce of fine white sand, reduced to powder, and melt them together in a large close crucible set in a wind-furnace, keeping a strong fire for half an hour; then take out the crucible, and, when cold, break it; and there will be found at the bottom, a hard, pure glasf, capable of cutting common glasf almost like a diamond. This experiment duly varied, says Dr Shaw, may lead to some considerable improvements in the art of making glasf, enamels, and artificial gems. It shews us an expeditious method of making glasf without the use of fixed salts, which has generally been thought an essential ingredient in glasf, and which is the ingredient that gives common glasf its softness; and it is not yet known, whether calcined crystal, or other substances being added to this salt, instead of sand, it might not make a glasf approaching to the

nature of a diamond.

Kinds of GLASS. Of theſe materials we have many ſorts of glaſs made, which may principally be diſtinguiſhed according to their beauty: as the cryſtal flint-glaſs, the cryſtal white-glaſs, the green-glaſs, and the bottle-glaſs. Again, theſe ſeveral ſorts are diſtinguiſhed by their ſeveral uſes: as plate or coach glaſſes, looking-glaſſes, optic-glaſſes, &c. which are made of the firſt fort. The ſecond fort includes crown-glaſs, toys, phials, drinking glaſſes, &c. The third fort is well known by its colour, and the ſecond by its form.

Balar-coloured GLASS is made thus: Put into a pot cryſtal frit, thrice waſhed in water; tinge this with manganese prepared into a clear purple: to this add alumen cativum ſifted fine in ſmall quantities, and at ſeveral times; this will make the glaſs grow yellowiſh, and a little reddiſh, but not blackiſh, and always diſſipates the manganese. The laſt time you add manganese, give no more of the alumen cativum, unleſs the colour be too full. Thus will the glaſs be exactly of the colour of the balas-ruby.

Red GLASS. A blood-red glaſs may be made in the following manner: Put fix pounds of glaſs of lead, and ten pounds of common glaſs, into a pot glazed with white glaſs: when the whole is boiled and refined, add, by ſmall quantities, and at ſmall diſtances of time, copper calcined to a redneſs, as much as, on repeated proofs, is found ſufficient: then add tartar in powder by ſmall quantities at a time, till the glaſs is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

A much finer red, however, may be communicated to glaſs by means of gold, of which Dr Lewis gives the following account. "The tinging of glaſs and enamels by preparations of gold appears to have been firſt attempted about the beginning of the laſt century. Libavius, whoſe works compoſe a valuable body of the chemical knowledge of his own time, conjectures, in one of his traſacts entitled *Alchymia*, printed in 1606, that the colour of the ruby proceeds from gold, and that gold diſſolved and brought to redneſs might be made to communicate a like colour to facitious gems or glaſs: Neri, in his *Art of Glaſs* dated 1611, gives a proceſs on this principle, which he ſays was found to ſucceed: he directs the gold to be diſſolved in aqua regia, the menſtrum to be evaporated or drawn off by diſtillation, more aqua regia added, and the abſtraction repeated five or fix times: the remaining matter is to be calcined till it becomes purple, and then mixed with a proper quantity of the ſineſt white or cryſtal glaſs. But though this proceſs may be ſuppoſed to have ſometimes proved ſucceſſful, it doubtleſs very often miſcarried; inſomuch that the introduction of this deſirable colour into the glaſs was very little known for many years after.

"Glauber, in the ſecond part of his *Philophical Furnaces* published in 1648, gives another method of producing a red colour by gold in a matter which is of the vitreous kind, though not perfect glaſs. When powdered flint or ſand is well ground with four times its weight of fix alkaline ſalt, the mixture melts in a moderately ſtrong fire, and when cold looks like glaſs, but on account of its over-proportion of alka-

line ſalt it runs into a liquid ſtate on being expoſed to the air: on adding this liquor to ſolution of gold in aqua regia, the acid, which held the gold diſſolved, unites with the alkali which held the flint diſſolved, and the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple: this powder being mixed with three or four times its weight of the alkaline ſolution of flint, the mixture dried, and kept melted in a ſtrong fire for an hour, a maſs is obtained, of a transparent ruby colour, and of a vitreous appearance; though ſtill ſoluble in water, or by the moiſture of the air, on account of the redundance of ſalt.

"Boyle, in his treatiſe on the Porofity of Bodies, and in the appendix to his *Sceptical Chemiſt* published in 1680, mentions an experiment, in which a like colour was introduced into glaſs without fuſion. A mixture of gold and mercury having been kept in diſſolution for ſome months, the fire was at laſt immoderately increaſed, inſomuch that the glaſs burſt with a violent exploſion: the lower part of the glaſs was found tinged throughout of a transparent red colour, which ſeemed, he ſays, to emulate that of a not common ruby.

"About the ſame time Caſſius diſcovered the precipitation of gold by tin, and that glaſs might be tinged of a ruby colour by melting it with this precipitate. I can give no further account of his experiments, having never had the good fortune to meet with his treatiſe.

"The proceſs was ſoon after brought to perfection by Kunckel, who ſays he prepared the ruby glaſs in large quantity, and ſold it for about forty ſhillings an ounce; and that he made a chalice of it for the elector of Cologn, weighing no leſs than 24 pounds, a full inch thick, and of an uniform fine colour throughout. He has nowhere communicated the proceſs he followed, but ſome uſeful obſervations relating to it are diſperſed through his writings: he ſays, that one part of the precipitate by tin is ſufficient to give a ruby colour to twelve hundred and eighty parts of glaſs, and a ſenſible redneſs to upwards of nineteen hundred parts: that the ſucceſs is by no means conſtant, and that, after long practice, he ſtill frequently failed: that oftentimes the glaſs comes out of the fire colourleſs as cryſtal, and receives its ruby colour on being afterwards expoſed to a ſmoky flame, inſomuch that he imagines the diſcovery of the ruby glaſs did not ariſe from ſimply melting the gold precipitate with glaſs, but from the ſubſequent ſoftening and working of the glaſs in the flame of a lamp, in the uſe of which Caſſius was very converſant: that the addition of nitre and ſal ammoniac calls forth the colour, and that the colour produced by ſal ammoniac is more beautiful than that by nitre, but quickly diſappears on a continuance of the fire.

"Orſchal, in a treatiſe entitled *ſol ſine veſte*, gives a proceſs, by which he ſays he obtained a very fine ruby. He directs the purple precipitate, made by tin, to be ground with fix times its quantity of Venetian glaſs in a very fine powder, and this compound to be exquisitely mingled with the frit or vitreous compoſition to be tinged: his frit conſiſts of equal parts of borax, nitre, and fix alkaline ſalt, and four times as much calcined ſlint as of each of the ſalts; but in

Glas.

what proportion the gold precipitate is to be mixed with the fritt, and in what manner the fusion is to be performed, he does not mention. He reports that he had found the muddy matter, obtained in polishing gold by a pumice stone, to impart likewise a ruby colour to glasses.

" Grummet, who had been operator to Kunckel in making the red glass, published a tract in opposition both to him and Orfclal, under the title of *Sol non sine vesle*; in which he observes, that the furnace ought to be so constructed, that the operator may have full liberty of examining the glass in the fire, and of removing it as soon as it appears to have acquired the proper colour: he says the enamellers obtain a ruby colour, by melting, with a large proportion of Venice glass, the brownish powder precipitated from solution of gold in aqua regia by fixt alkaline salts. But he imagines that the gold is nowise concerned in the production of the colour. Venice glass, and most of the finer colourless kinds of glass, have an addition of manganese, without which it would be very difficult to render them perfectly void of colour: the manganese communicates at first a purplish hue, which on continuing the fire disappears, and at the same time suppresses or discharges any other tinge that the glass may be impregnated with: the addition of a little nitre revives the purplish colour of the manganese; and Grummet is of opinion that the colour with which glass becomes tinged, by the admixture of preparations of gold, is no other than that of the manganese extricated by the nitrous salt which the gold has retained in its precipitation. He affirms, that the same purplish red colour will be obtained on melting Venice glass with an eighth part of nitre, without any gold; that in a hundred repetitions of this experiment, it scarcely fails once; and that neither nitre nor the gold-precipitate were found to give any thing of the admired colour to those kinds of glass which have no manganese in their composition.

" The colours which manganese imparts to glass, it belongs not to this place to examine: but that precipitates of gold will communicate, in certain circumstances, a purplish red colour, I have several times experienced; having myself tinged of this colour fritts composed of calcined flint, nitre and borax, without the addition of manganese or of glasses containing it. Though gold, dissolved in common aqua regia, exhibits its own yellow colour; yet, when the menstruum is separated by fire to a certain point, or when the gold is precipitated by tin, or when it is precipitated by alkaline salts and afterwards moderately heated, or when gold is barely divided by mechanical means into subtile powder, and exposed for some time, in mixture with earthy bodies, to a slight heat, it assumes, in different circumstances, a violet colour, a purple, or a red verging to purple: in a strong fire, these colours vanish, and the gold melts into a mass of its original appearance. All these colours I have introduced into glass by preparations of gold; and I have found them to be nearly as perishable in the fire when the coloured gold-powder was thus diffused through the glass, as when exposed to the fire by itself: when the fire was raised to any great degree, and the glass made to flow thin, there was generally a button of revived gold collected at the bottom.

Glas.

" A solution of gold in aqua regia being inspissated to dryness in the bottom of a Florence flask, and the heat further increased till the gold resumed its proper colour, the lower part of the glass was by this simple process tinged purplish: pieces of it being exposed to the flame of a lamp, they became in some parts violet coloured, in some of a bright purple, and in others purplish red; and the parts which in one position looked violet or purplish, in another appeared red.

" A colour nearly of the same kind is impressed on glass by gold-leaf in some electrical experiments; a fact which we are obliged to Mr Franklin for the first knowledge of. A narrow strip of gold-leaf being placed between two slips of glass, with both the ends hanging out a little, and the glass well tied round with silk thread, a strong electrical explosion is made to pass through the gold-leaf. On examining the glass, the gold-leaf, he observes, will be found missing in several places, and instead of it a reddish stain on both the glasses, exactly similar on both in the minutest stroke, though sometimes spread a little wider than the breadth of the leaf: the stain appears to have penetrated into the substance of the glass, so as to be protected by it from the action of aqua regia. I have had this experiment several times repeated with plate-glass; and found it tinged, as above described, in some parts violet, in some purplish, and in some reddish: the colours could not be scraped off, and resisted aqua regia and spirit of salt. If the electric explosion is made very strong, the glass commonly flies in pieces, with such force, that it is necessary for the operator to have his face screened from them.

" The preparation of gold which has been principally recommended for tinging glass is Cassius's precipitate by solution of tin. To obtain this precipitate of the due colour, a good deal of care is necessary both in dissolving the tin and in diluting the solutions. A mixture of two parts of aqua fortis and one of spirit of salt, is supposed to be the best menstruum for the tin: into this mixture some fine block-tin, granulated, is to be let fall, grain by grain, waiting till one grain is dissolved before another is dropt in, that the dissolution may go on slowly, without any heat or discharge of fumes. The gold is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been hit; if the colour appears dull, a greater quantity of water must be added for the rest of the solutions. After the mixture has deposited its red matter, and become clear, a little more of the tin-solution is to be dropt in, for discovering, and precipitating, any gold that may still remain in it: the liquor being then poured off, the precipitate is washed and dried.

" Kunckel mentions another purple gold-powder, made nearly like that of Neri already mentioned, by inspissating solution of gold to dryness, abstracting from it fresh aqua regia three or four times till the matter looks almost like oil, then precipitating with strong alkaline ley, and washing the precipitate with water. By dissolving this powder in spirit of salt, and precipitating again, it becomes, he says, extremely

ly

Glaifs. ly fair, and in this state he directs it to be mixed with a due proportion of Venice glass.

“ Hellot describes a preparation which in mixture with Venice glass was found to give a beautiful purple enamel. Equal parts of solution of gold, and of solution of zinc in aqua regia, are mixed together; and a volatile spirit, prepared from sal ammoniac by quicklime, added to the mixture in sufficient quantity to precipitate the two metals. The precipitate is to be gradually heated, till it acquires a violet colour: it does not fulminate, making only a slight dull decrepitation without any of its particles flying about.

“ Though a purple, or a red colour approaching to that of the ruby, may by the foregoing means be baked upon glass or enamels, and introduced into the mass by fusion, the way of equally diffusing such a colour through a quantity of fluid glass is still a secret.

“ I was once, many years ago, fortunate enough to succeed, at a glass-house, in a small pot of glass, of which a salver was blown of a fine ruby red: the tinging matter was the precipitate of gold by tin; the particulars of the process cannot now be recollected. I have since tried the remainder of the same preparation, with common flint glass, with green glass, with various frits composed of flint, borax, pure fixt alkaline salt, nitre, sal ammoniac. When flint was used, it was several times made red-hot, and quenched in water, to render it more easily pulverable: both the flint and glasses were powdered in an iron mortar, and the powders well washed with diluted oil of vitriol, to extract such particles of iron as they might have worn off in the trituration; the gold precipitate was ground with the other ingredients, in agate or glass mortars; its proportion was varied from an eighth part to an eight hundredth of the vitreous materials; and the fire was continued, in a wind furnace, from six to thirty hours. All the glasses came out considerably coloured; some of a deep dusky yellow; some of a fine pale transparent yellow; some of a brown colour, greatly resembling that which the glass mentioned below acquired under a muffle; some appeared yellowish or brownish when looked down upon, and of a purple-violet or reddish purple when held between the eye and the light: some had specks and veins of a fine red; no one was either red or purple throughout. Several of these glasses were melted again and again, by themselves, and with the addition of more vitreous matter: some were worked in the flame of a lamp: some were laid in a mixture of powdered charcoal and foot, and made red-hot in a close crucible; and others being laid in the same manner, the fire was increased till they melted. The colours were by these means altered; but did not become uniform, or more approaching to the ruby colour than before: some pieces, which had at first very considerable specks of a ruby lustre, lost them on a repetition of the fusion.

“ At the same time that these experiments were tried, the same kinds of vitreous compositions, mixed with different metallic preparations, were exposed to the fire in different parts of the same furnace, and were all found to receive beautiful and uniform colours. To what cause the miscarriage of those with gold was owing; whether the success, in regard to this metal,

is influenced by the quantity of the matter, by the unsteadiness of the heat in a small furnace, by the fusibility of the vitreous composition, by the metallic matter being ground with the ingredients before their exposure to the fire, or added to them in fusion, by the continuance of the fire, by the fluid matter being kept unmoved or stirred with an iron rod, by the crucible being covered or open, or other like circumstances; or whether the admixture of a little manganese, though gold will certainly give a ruby colour without it, does not contribute to secure the success; I have not yet discovered. The proportion of the gold precipitate to the vitreous matter is perhaps of principal importance. Solution of gold, as we have seen already, produces no redness with tin unless diluted with a very large quantity of water, in which circumstance the whole mixture acquires that beautiful colour which we here want to transfer from the watery fluid into fluid glass. It should seem, therefore, that the quantity of gold precipitate, for communicating the admired colour to a certain volume of glass, ought to be the same with that which communicated a like colour to an equal volume of water in the precipitation: a quantity extremely minute, and much less than that employed in any of my experiments.

“ I have lately been favoured with some pieces of glass, in greatest part colourless, with one or two large red spots, several small streaks of violet, and some of a light brownish yellow. The person from whom I received them informs me, “ that he had found, that in a heat not very strong, under a muffle, the glass becomes of an opaque brown, and, if then polished, appears variegated like a fine pebble.” I exposed a colourless piece to the flame of a lamp, impelled by a blow-pipe; and on working it about, sometimes in the smoke, and sometimes in the flame, found it change to a true ruby-red, perfectly transparent, and free from veins of any other colour. Another piece, kept for two hours under a close muffle, in such a heat as made it just soft enough to bend and receive an impression, became on the surface green, brown, and pale yellow in different parts, greatly resembling the coat of some pebbles: in this state, looked through against the sun, it appeared of a beautiful ruby-colour, and on breaking it, the internal part was found throughout of an uniform dark-red when looked down upon, and of the ruby-red when placed between the eye and the light. A large piece being continued under the muffle for four hours, its figure was found scarcely altered, the coat was much thicker, and beautifully veined with various colours, which were all lost in a glorious red when the piece was viewed between the light.

“ All I have been able to learn in regard to the preparation of this glass is, that the quantity made at once is about six cwt.; that the tinging matter is mixed with the vitreous materials before they are put into the melting-pot, the mixture being brought to the glass-house in tubs; that the matter is not stirred in fusion; and that it is kept no longer in the fire than is necessary for perfecting the glass, which, as soon as fine, is cast into a kind of bricks. Some imagine that this glass has no mixture of calx of lead, of which a large proportion is used in the composition of the

Glaifs.

en frame, with truffles for the convenience of moving to the annealing furnace; into which, strewed with sand, the new plate is shoved, where it will harden in about ten days. After this, the glass needs only to be ground, polished, and foliated for use.

Grinding and Polishing of Plate-Glass. Glass is made transparent by fire; but it receives its lustre by the skill and labour of the grinder and polisher, the former of whom takes it rough out of the hands of the maker.

In order to grind plate-glass, they lay it horizontally upon a flat stone table (fig. 3.) made of a very fine-grained free-stone: and for its greater security they plaster it down with lime or stucco; for otherwise the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This stone table is supported by a strong frame A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground, is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel to which this plank is fastened, and from the weights laid upon it to promote the grinding or triture of the glasses. The whole is covered with a wheel, B, made of hard light wood, about six inches in diameter; by pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen, who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the work advanceth, till at last they must pour in the powder of smalt. As the upper or incumbent glass polishes and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a *mill* by the artists, and is used only in the largest-sized glasses; for in the grinding of the lesser glasses, they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glass to an exact plainness, it is turned over to the polisher; who, with the fine powder of tripoli-stone, or emery, brings it to a perfect evenness and lustre. The instrument made use of in this branch is a board, c, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist in working this roller, is assisted with a wooden hoop or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

Painting in Glass. The ancient manner of painting in glass was very simple: it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called *Mosaic work*. See *MOsaic*.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther

than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, basilics, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree; having first laid on the colours.

This art, however, has frequently met with much interruption, and sometimes been almost totally lost; of which Mr Walpole gives us the following account, in his *Anecdotes of Painting in England*.

"The first interruption given to it was by the reformation, which banished the art out of churches; yet it was in some measure kept up in the escutcheons of the nobility and gentry, in the windows of their seats. Towards the end of queen Elizabeth's reign it was omitted even there; yet the practice did not entirely cease. The chapel of our Lady at Warwick was ornamented anew by Robert Dudley earl of Leicester, and his countess, and the cipher of the glass-painter's name yet remains, with the date 1574: and in some of the chapels at Oxford the art again appears, dating itself in 1622, by the hand of no contemptible master.

"I could supply even this gap of 48 years by many dates on Flemish glass; but nobody ever supposed that the secret was lost so early as the reign of James I. and that it has not perished since, will be evident from the following series reaching to the present hour.

"The portraits in the windows of the library at All Souls, Oxford. In the chapel at Queen's college there are twelve windows dated 1518. P. C. a cipher on the painted glass in the chapel at Warwick, 1574. The windows at Wadham-college; the drawing pretty good, and the colours fine, by Bernard Van Linde, 1622. In the chapel at Lincoln's-Inn, a window, with the name of *Bernard*, 1623. This was probably the preceding Van Linde. In the church of St Leonard, Shoreditch, two windows by Baptista Sutton, 1634. The windows in the chapel at University-college, Hen. Giles *pinxit*, 1637. At Christ-church, Isaac Oliver, aged 84, 1700. Window in Merton-chapel, William Price, 1700. Windows at Queen's New-college, and Maudlin, by William Price, the son, now living, whose colours are fine, whose drawing is good, and whose taste in ornaments and mosaic is far superior to any of his predecessors; is equal to the antique, to the good Italian masters, and only surpassed by his own singular modesty.

"It may not be unwelcome to the curious reader to see some anecdotes of the revival of taste for painted glass in England. Price, as we have said, was the only painter in that style for many years in England. Afterwards one Rowell, a plumber at Reading, did some things, particularly for the late Henry earl of Pembroke; but Rowell's colours soon vanished. At last he found out a very durable and beautiful red; but he died in a year or two, and the secret with him. A man at Birmingham began the same art in 1756 or 1757, and fitted up a window for lord Lyttelton, in the church of Hagley; but soon broke. A little after him,

Glas. him, one Peckitt at York began the same business, and has made good proficiency. A few lovers of that art collected some dispersed panes from ancient buildings, particularly the late lord Cobham, who erected a Gothic temple at Stowe, and filled it with arms of the old nobility, &c. About the year 1753, one Asciotti, an Italian, who had married a Flemish woman, brought a parcel of painted glass from Flanders, and sold it for a few guineas to the honourable Mr Bateman, of Old Windsor. Upon that I sent Asciotti again to Flanders, who brought me 450 pieces, for which, including the expence of his journey, I paid him 36 guineas. His wife made more journeys for the same purpose; and sold her cargoes to one Palmer, a glazier in St Martin's-lane, who immediately raised the price to one, two, or five guineas for a single piece, and fitted up entire windows with them, and with mosaics of plain glass of different colours. In 1761, Paterfon, an auctioneer at Essex-house in the Strand, exhibited the two first auctions of painted glass, imported in like manner from Flanders. All this manufacture consisted in rounds of scripture-stories, stained in black and yellow, or in small figures of black and white; birds and flowers in colours, and Flemish coats of arms."

The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce: reduce them to powder, and mix them.* For blue, take powder of blue, one pound; sal nitre, half a pound; mix them and grind them well together. For carnation, take red chalk, eight ounces; iron scales, and litharge of silver, of each two ounces; gum arabic, half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, take red-lead, one pound; scales of copper, one pound; and flint, five pounds: divide them into three parts; and add to them as much sal nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, take silver, an ounce; antimony, half an ounce; melt them in a crucible; then pound the mass to powder; and grind it on a copper plate; add to it yellow oker, or brick-dust calcined again, fifteen ounces; and grind them well together with water. For purple, take minium, one pound; brown stone, one pound; white flint, five pounds: divide them into three parts, and add to them as much sal nitre as one of the parts; calcine, melt, and grind it as you did the green. For red, take jet, four ounces; litharge of silver, two ounces; red chalk, one ounce; powder them fine, and mix them. For white, take jet, two parts; white flint, ground on a glass very fine, one part; mix them. For yellow, take Spanish brown, ten parts; leaf-silver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not

go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glass, though already coloured, they could shew other kind of colours where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till such time as they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By these means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights, and heightnings, on all kinds of colour.

The first thing to be done, in order to paint or stain glass, in the modern way, is to design, and even colour the whole subject on paper. Then they choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts; and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again: which done, applying every part of the design upon the glass intended for it, they copy, or transfer, the design upon this glass with the black colour diluted in gum-water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black; and repeat it several times, according as the shades are desired to be heightened; with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in the respective places with a wooden point, or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow,

Glaſs,
Glaſton-
bury.

Glaſton-
bury
Glaucoma.

low, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard muſt always be had not to lay colour on colour, or lay on a new lay, till ſuch time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glaſs, and incorporates therewith by the fire; the reſt, and particularly the blue, which is very difficult to uſe, remaining on the ſurface, or at leaſt entering very little. When the painting of all the pieces is finiſhed, they are carried to the furnace, or oven, to anneal, or bake the colours.

The furnace here uſed is ſmall, built of brick, from 18 to 30 inches ſquare. At fix inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three ſquare bars of iron, which traſverſe the furnace, and divide it into two parts. Two inches above this partition, is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a ſquare earthen pan, fix or ſeven inches deep, and five or ſix inches leſs every way than the perimeter of the furnace. On the one ſide hereof is a little aperture, through which to make trials, placed directly oppoſite to that of the furnaces deſtined for the ſame end. In this pan are the pieces of glaſs to be placed, in the following manner: Firſt, the bottom of the pan is covered with three ſtrata, or layers, of quicklime pulveriſed; theſe ſtrata being ſeparated by two others of old broken glaſs, the deſign whereof is to ſecure the painted glaſs from the too intense heat of the fire. This done, the glaſſes are laid horizontally on the laſt or uppermoſt layer of lime.

The firſt row of glaſs they cover over with a layer of the ſame powder, an inch deep; and over this they lay another range of glaſſes, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the furnace with tiles, on a ſquare table of earthen ware, cloſely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to ſerve as chimneys. Things thus diſpoſed, there remains nothing but to give the fire to the work. The fire for the firſt two hours muſt be very moderate, and muſt be increaſed in proportion as the coction advances, for the ſpace of ten or twelve hours; in which time it is uſually completed. At laſt the fire, which at firſt was charcoal, is to be of dry wood, ſo that the flame covers the whole pan, and even iſſues out at the chimneys.

During the laſt hours, they make eſſays, from time to time, by taking out pieces laid for the purpoſe through the little aperture of the furnace and pan, to ſee whether the yellow be perfect, and the other colours in good order. When the annealing is thought ſufficient, they proceed with great haſte to extinguiſh the fire, which otherwiſe would ſoon burn the colours, and break the glaſſes.

GLASS of Antimony. See CHEMISTRY, n° 454.

GLASS of Lead. See GLAZING.

GLASTONBURY, a town of Somerſetſhire in England; ſeated in W. Lon. 2. 46. N. Lat. 51. 15. — It is noted for a famous abbey, ſome magnificent

ruins of which are ſtill remaining; but they are every day diminiſhing for the ſake of the ſtones. However, the curious ſtructure called the *Abbot's kitchen* is ſtill pretty entire, and is of a very unuſual contrivance. The monks pretend that it was the reſidence of Joſeph of Arimathea, and of St Patrick; but for this aſſertion they produce no good authority. The king of the Weſt Saxons erected a church here, which he and the ſucceeding kings enriched to ſuch a degree, that the abbot lived like a prince, had the title of *lord*, and ſat among the barons in parliament; and no perſon, not even a biſhop or prince, durſt ſet foot on the iſle of Avalon, in which the abbey ſtands, without his leave. The revenue of the abbey was above 40,000 l. per ann. beſides ſeven parks well ſtocked with deer. The laſt abbot, (Richard Whiting,) who had 100 monks, and 300 domeſtics, was hanged in his pontificals, with two of his monks, on the Tor, a high hill in the neighbourhood, for reſuſing to take the oath of ſupremacy to Henry VIII. and ſurrender his abſeiy when required. Edgar and many other Saxon kings were buried here; and, as ſome will have it, Arthur the Britiſh king.—The ſtory of the Glaſtonbury thorn, and of its budding always upon Chriſtmas-day, is well known: however, that circumſtance is falſe; though, if the winter is mild, it always buds about the latter end of December, but later if the weather is fevere.

GLATZ, a handſome and ſtrong town of Bohemia, and capital of a county of the ſame name. It is ſeated on the river Neiſſe; and* has ſtrong fortifications, with a caſtle built upon a mountain. The county was ceded to the king of Pruſſia by the queen of Hungary in 1742; and is about 45 miles in length, and 25 in breadth. It has mines of pit-coal, ſilver, and iron; good quarries, plenty of cattle, and fine ſprings of mineral water. The town is ſituated in E. Lon. 15. 16. N. Lat. 50. 25.

GLAUBER (John Rhodolphus), a celebrated German chemiſt, who flouriſhed about the year 1646. He wrote a great number of different treatiſes on chemiſtry, ſome of which have been tranſlated into Latin and French. All his works have been collected into one volume, entitled, *Glauberus concentratus*, which has been tranſlated into Engliſh, and was printed at London, in folio, in 1689.

GLAUBER's Salt. See CHEMISTRY, n° 124.

GLAUCUS, a marine god, or deity of the ſea. There are a great many fabulous accounts of this divinity: but the poetical hiſtory of him is, that, before his deſecation, he was a fiſherman of the town of Anthedon, who, having one day taken a conſiderable number of fiſhes, which he laid upon the bank, on a ſudden perceived, that theſe fiſhes, having touched a kind of herb that grew on the ſhore, received new ſtrength, and leaped again into the ſea: upon the ſight of which extraordinary accident, he was tempted to taſte of the herb himſelf, and preſently leaped into the ſea after them, where he was metamorphoſed into a Triton, and became one of the ſea-gods.

GLAUCOMA, or GLAUCOSIS, from γλαυκος, a ſky-blue colour. Mr Sharp, in his *Operations of Surgery*, p. 158—163, ſays, that the *glaucoma* of the ancient Greeks is the *ſuſſio* of the Latins, and the *cataraſt*.

Glucos
||
Glazing.Glazing,
Gleaning.

cataract of the present times. See (Index subjoined to) MEDICINE and SURGERY. Mr St Yves says, it is a *cataract* accompanied with a *gutta serena*; according to which nothing need be added, except that, in such a case, the operation and all other means are ineffectual, except to ease pain, and to mend the figure of the eye.

GLAUCUS, in ichthyology. See *SQUALUS*.

GLAZIER, an artificer who works in glass.—The principal part of a glazier's business consists in fitting panes of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same.

GLAZING, the crusting over earthen ware by a vitreous substance, the basis of which is lead.

For making a pure glass of lead, the following receipt will be found to answer: Put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps. Continue this for several hours, till the powder becomes of a fair yellow; then take it out and sift it fine. This is called *calcined lead*.—Take of this calcined lead, 15 pounds; and crystalline or other frit, 12 pounds: mix these as well as possible together; put them into a pot, and set them in a furnace for 10 hours; then cast the whole, which will now be perfectly melted, into water; separate the loose lead from it, and return the metal into it; and after standing in fusion 12 hours more, it will be fit for use.

The workers of common earthen ware, however, are not at the trouble of thus previously making a pure glass of lead. Their usual composition for glazing their ware is formed of sand, wood-ashes, lead-ashes, and salt. The ware, after being turned on the wheel, and dried in the open air, is covered over with this composition by means of a brush; and when set in the furnace the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel.

The various colours for glazing are the same with those for tinging glass, which we have already described. A black colour is given with manganese or iron. The proportions, however, are not exactly ascertained, nor are there any receipts published concerning these things on which we can much depend. In the Philosophical Transactions we have the following receipt for a fine gold-coloured glazing, communicated to the Royal Society by Mr Heinhus of Petersburg. Take of litharge three parts, of sand or calcined flint one part; mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and moisten it when in subtile powder with a well-saturated solution of silver, which make into a paste. Put this paste into a crucible, and cover it. Give at first a gentle degree of fire, then increase and continue it till you have a perfect glass which will be green. Pound this glass again, and reduce it to a fine powder: moisten this powder with some beer, so that by means of an hair-pencil you may apply it upon the vessels. Those that are painted or covered over with this glazing must be first well heated, then put under a muffle; and as soon as the glass runs you must smoke them, and take out the vessels. This prepa-

ration owes its colour to the silver in it; the precipitates of which, spread upon a glass plate, have the property of staining it yellow by ignition, without fusion. When used in glazing vessels, however, they must be held over the smoke of burning vegetables, in order to call forth the beautiful colour.

A red or green tinge may be given to glazings by means of copper. The red colour appears first; but by a continuation of the fire, it is changed into a green. The finest red colour, however, that can be given to glazings, is that prepared from the solution of gold in aqua regia, as mentioned under the article GLASS.—The finest blue is always given by means of zaffre or smalt. A purplish colour, as well as a brown or black, may also be given by manganese; but a mixture of the materials for red and blue will undoubtedly produce the finest colour. The colouring materials for glazings, therefore, in short are the following.

Red—Gold or copper.

Yellow—Silver, iron.

Green—Copper.

Blue—Zaffre or smalt.

Black—Manganese.

White—Calc of tin.

Each of these materials mixed up in a proper quantity with any composition that readily vitrifies, will form a glazing of the desired colour upon any kind of earthen ware. The proportions in which they are to be used may easily be determined by a few trials.—Stone ware is glazed by another method, viz. the vitrification of a small part of the substance of the ware itself, by the fumes of salt thrown into the furnace when the vessels are intensely heated. See STONE WARE.—The application of different colours to it, however, is equally easy with the former.

The Romans had a method of glazing their earthen vessels, which in many respects appears to have been superior to ours. The common brown glazing easily scales off, cracks, and in a short time becomes disagreeable to the eye. Besides, it is very easily destroyed by acids; nor can vessels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is also very destructive to the human body; and if acids are unwarily put into vessels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be seen upon urns dug up in several places, appears to have been made of some kind of varnish; and Pliny gives us a hint that it was made of bitumen. He tells us that it never lost its beauty, and that at length it became customary to glaze over statues in this manner. As this varnish sunk deep into the substance of the ware, it was not subject to those cracks and flaws which disfigure our vessels; and as it was not liable to be corroded by acids, it could not be liable to any of the accidents which may ensue from the use of vessels glazed with lead.

GLEANING, the act of gathering or picking up the ears of corn left behind after the field has been reaped and the crop carried home. By the customs of some countries, particularly those of Melun and Estampes, all farmers and others are forbid, either by themselves or servants, to put any cattle into the fields, or prevent the gleaning in any manner whatever for

Glebe
Gliffon.

Glifter,
Globe.

the fpace of 24 hours after the carrying off the corn, under penalty of confiscation.

GLEBE, among miners, fignifies a piece of earth in which is contained fome mineral ore.

GLEBE, in law, the land belonging to a parifh-church befides the tithes.

GLECHOMA, **GROUND-IVY**; a genus of the angiofpermia order, belonging to the didymia clafs of plants. There are three fpecies; the moft remarkable of which is the hederacea, or common ground-ivy, which is fo well known that it requires no defcription. Many virtues were formerly attributed to this plant, which it is now found not to be poffeffed of. Some, however, it has. The leaves are thrown into the vat with ale to clarify it and give it a flavour. Ale thus prepared is often drank as an antifeorbutic. The expreffed juice mixed with a little wine, and applied morning and evening, deftroys the white fpecks upon horfes eyes. The plants that grow near it do not flourifh. It is faid to be hurtful to horfes if they eat much of it. Sheep eat it, horfes are not fond of it; cows, goats, and fwine, refufe it.

GLÉDITSIA, **TRIPLE-THORNED ACACIA**; a genus of the diœcia order, belonging to the polygamia clafs of plants. There is but one fpecies, which rifes with an upright trunk 30 or 40 feet high, branching out regularly with many long triple thorns, and clofely garnifhed with doubly pinnated leaves, each leaf confifting often of near 200 fmall leaves or foliola. The flowers are amentaceous, and of a greenifh colour proceeding from the fides of the branches, and fucceeded by broad feed-pods near a foot and an half long.— This plant is a native of South America, but will thrive in this country in any fituation. They are propagated by feeds, which are annually procured from America by the feedfmen.

GLEET, in medicine, the flux of a thin limpid humour from the urethra. See (the *Index* fubjoined to) **MEDICINE**.

GLICAS, or **GLYCAS**, (Michael), a Greek hiftorian about the middle of the 15th century, lived in Sicily, and wrote Annals of what paffed from the creation of the world to the death of Alexis Comnenus, in 1118. Leondavius added to it a fifth part, which carries it down to the taking of Conftantinople. Glिकास was alfo the author of feveral ufeful and curious letters.

GLENODES, the name of two cavities, or fmall depreflions, in the inferior part of the firft vertebra of the neck.

GLIRES, the name of Linnæus's fourth order of mammalia. See **ZOOLOGY**.

GLIS, in zoology. See **SCIURUS**.

GLISSON (Francis), a learned English phyfician in the 17th century, was educated at Cambridge, and was made regius professor of that univerfity. In 1634, he was admitted a fellow of the college of phyficians in London. During the civil wars, he praftifed phyfic at Colchefter, and afterwards fettled in London. He greatly improved phyfic by his anatomical diffections and obfervations, and made feveral new difcoveries of fingular ufe towards eftablifhing a rational praftice. He wrote, 1. *De rachitide*, &c. 2. *De lymphæductis nuper repertis*; with the *Anatonica prolegomena*, & *Anatomia hepatis*. 3. *De natura fubftantia emerge-*

tica; feu *de via vitæ nature*, ejufque tribus primis facultatibus, &c. quarto. 4. *Tractatus de ventriculo & inteftinis*, &c. The world is obliged to him for the *capula communis*, or *vagina portæ*.

GLISTER, in furgery. See **CLYSTER**.

GLOBE, in geometry, a round or fpherical body, more ufually called a *sphere*. See **SPHERE**.

GLOBE, is more particularly ufed for an artificial fphere of metal, plafter, paper, or other matter; on whole convex furface is drawn a map, or representation, either of the earth, or heavens, with the feveral circles conceived thereon. See **GEOGRAPHY**.

Globes are of two kinds, *terreftrial* and *celeftial*; each of very confiderable ufe, the one in aftronomy, and the other in geography; to perform many of the operations thereof, in an eafy, fenfible manner, fo as to be conceived without any knowledge of the mathematical grounds of thofe arts.

The fundamental parts, common to both globes, are an axis, representing that of the world; and a fpherical fhell, or cover, which makes the body of the globe, on whole external furface the representation is drawn. See **AXIS**, **POLE**, &c.

Globes, we have obferved, are made of divers materials, viz. filver, brafs, paper, plafter, &c. Thofe commonly ufed, are of plafter, and paper: The conftruction whereof is as follows:

Conftruction of GLOBES.—A wooden axis is provided, fomewhat lefs than the intended diameter of the globe; and into the extremes hereof two iron wires are driven, for poles: this axis is to be the beam, or bafis of the whole ftructure.

On the axis are applied two fpherical, or rather hemifpherical caps, formed on a kind of wooden mould or block.—Thefe caps confift of paltboard, or paper, laid one lay after another, on the mould, to the thicknefs of a crown-piece; after which, having flood to dry and embody, making an incifion along the middle, the two caps thus parted are flipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on thofe of the mould: and to fix them in their new place, the two edges are fewed together with pack-thread, &c.

The rudiments of the globe thus laid, they proceed to ftrengthen and make it fmooth and regular. In order to this, the two poles are hafped in a metalline femicircle, of the fize intended; and a kind of plafter, made of whitening, water, and glue, heated, melted, and incorporated together, is daubed all over the paper-furface. In proportion as the plafter is applied, the ball is turned round in the femicircle, the edge whereof pares off whatever is fuperfluous and beyond the due dimension, leaving the reft adhering in places that are fhort of it. After fuch application of plafter, the ball ftands to dry; which done, it is put again in the femicircle, and frefh matter applied: thus they continue alternately to apply the compofition, and dry it, till fuch time as the ball every where accurately touches the femicircle; in which ftate it is perfectly fmooth, regular, firm, &c.

The ball thus finifhed, it remains to paffe the map or defcription thereon: in order to this, the map is projected in feveral gores, or gullefts; all which join accurately on the fpherical furface, and cover the whole

Globularia
||
Glocester.

whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus palled on, there remains nothing but to colour and illuminate the globe; and to varnish it, the better to resist dust, moisture, &c.—The globe itself thus finished, they hang it in a brais meridian, with an hour-circle, and a quadrant of altitude; and thus fit it into a wooden horizon.

For the uses, &c. of the globes, see GEOGRAPHY, n° 33. 35, &c. ASTRONOMY, n° 168, 320. and Plate XLVIII. fig. 2.

GLOBULARIA, **GLOBULAR BLUE DAISY**; a genus of the monogynia order, belonging to the tetrandria class of plants. There are several species; but only one is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It hath broad thick radical leaves, three parted at the ends, upright stalks from about six to ten or twelve inches high, garnished with speared-shaped leaves, and the top crowned by a globular head of fine blue flowers composed of many florets in one cup. It flowers in June, and makes a good appearance; but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLOBULE, a diminutive of globe, frequently used by physicians in speaking of the red particles of the blood. See **Blood**.

GLOCESTER, the capital of Gloucestershire in England. It is an ancient city, and by Antoninus is called *Glevum*, or *Glevium*, which Camden thinks was formed from the British *Caer-Glowe*, signifying a fair city. It was built by the Romans to curb the Silures; and a colony was placed there, called *Colonia Glevum*. It stands upon the bank of the Severn; and, except on the side next the river, is surrounded by a wall. Towards the south there was anciently a castle built in the time of William the Conqueror, the remains of which is now the common gaol for debtors and felons. Ceaulin, king of the West Saxons, first took it from the Britons in 570; but it afterwards became subject to the Mercians. The present cathedral was erected by Aldred, archbishop of York, and bishop of Worcester, after the conquest, but hath been greatly improved and adorned since. In the fourth life Edward II. lies interred in an alabaster tomb; and not far from him, in the middle of the choir, Robert Curt-hose, eldest son of William the Conqueror. This city suffered much in the barons wars, was plundered by Edward the son of Henry III. and not long after almost entirely destroyed by an accidental fire. King John made it a borough; and Henry III. who was crowned here, a corporation. Richard III. made it a county of itself, adding two hundreds to it, and gave it his sword and cap of maintenance. It had once eleven parish-churches; but five of them were demolished when it was besieged by Charles I. against whom it had shut its gates. In the reign of Charles II. its walls were pulled down, and two hundreds taken from its county by act of parliament. It was erected into an episcopal see by Henry VIII. on the suppression of the abbey of St Peter, with a dean and six prebends. A-

Glocester
shire.

bout the time of the conquest, its chief business seems to have been forging of iron; for in Doomsday book it is said, that the only tribute required of it was so many ires, or bars of iron. At present it has ten incorporated companies, a stone-bridge over the river, with a key and wharf; but though it is well situated for trade, yet its traffic is not considerable, having been much impaired by the neighbourhood of Bristol. One of its chief manufactures now is pin-making. Several parliaments were anciently held here, particularly by Richard II. and III.; and in the town are many crosses and statues of the kings of England. By a charter from Charles II. it is governed by a steward, mayor, recorder, twelve aldermen, a town-clerk, two sheriffs chosen yearly out of twenty-six common-council men, a sword-bearer, and four sergeants at mace. Camden says, the Roman-way, that extends from St David's in Wales to Southampton, passes through this city. It gives title of duke to the second brother of his present majesty George III.

GLOCESTERSHIRE, a county of England, is bounded on the west by Monmouthshire and Herefordshire, on the north by Worcestershire, on the east by Oxfordshire and Warwickshire, and on the south by Wiltshire and part of Somersetshire. It is sixty miles in length, twenty-six in breadth, and one hundred and sixty in circumference; containing eight hundred thousand acres, twenty-nine hundreds, one city, twenty-five market-towns; and sends eight members to parliament, viz. two for the county, two for the city of Gloucester, two for Cirencester, and two for Tewksbury. It lies in the diocese that takes its name from the capital, and in the Oxford circuit. The air of the county is very wholesome, but the face of it is very different in different parts: for the eastern part is hilly, and is called *Cotteswold*; the western woody, and called the *Forest of Dean*; and the rest is a fruitful valley, through which runs the river Severn. This river is in some places between two and three miles broad; and its course through the country, including its windings, is not less than seventy miles. The tide of flood, called the *Boar*, rises very high, and is very impetuous. It is remarkable, that the greatest tides are one year at the full-moon, and the other at the new; one year the night-tides, and the next the day. This river affords a noble conveyance for goods and merchandise of all sorts, to and from the county; but it is watered by several others, as the Wye, the Avon, the Isis, the Leden, the Frome, the Stroud, and Windrush, besides lesser streams, all abounding with fish, the Severn in particular with salmon, conger-eels, and lampreys. The soil is in general very fertile, though pretty much diversified, yielding plenty of corn, pasture, fruit, and wood. In the hilly part of the county, or Cotteswold, the air is sharper than in the lowlands; and the soil, though not so fit for grain, produces excellent pasture for sheep; so that of the four hundred thousand that are computed to be kept in the county, the greater part are fed here. Of these sheep the wool is exceeding fine; and hence it is that this shire is so eminent for its manufacture of cloth, of which fifty thousand pieces are said to have been made yearly, before the practice of clandestinely exporting English wool became so common. In the

shire
||
Gloriosa.

vale, or lower part of the county, through which the Severn passes, the air and soil are very different from those of the Cotswold: for the former is much warmer, and the latter richer, yielding the most luxuriant pastures; in consequence of which, numerous herds of black cattle are kept, and great quantities of that excellent cheese, for which it is so much celebrated, made in it. The remaining part of the county, called the *Forest of Dean*, was formerly almost entirely over-run with wood, and extended twenty miles in length, and ten in breadth. It was then a nest of robbers, especially towards the Severn; but now it contains many towns and villages, consisting chiefly of miners, employed in the coal-pits, or in digging for or forging iron ore, with both which the forest abounds. These miners have their particular laws, customs, courts, and judges; and the king, as in all royal forests, has a swain-mote, for the preservation of the vert and venison. This forest was anciently, and is still noted for its oaks, which thrive here surprisingly; but as there is a prodigious consumption of wood in the forests, it is continually dwindling away. There were so many religious houses in the county before the reformation, that it gave occasion to the proverb, "As sure as God is in Gloucestershire."

GLOGAW, a strong and considerable town of Germany, in Silesia, and capital of a duchy of the same name. It is not very large, but is well fortified on the side of Poland. It has a handsome castle, with a tower, in which several counsellors were condemned by Duke John, in 1498, to perish with hunger. Besides the Papists, there are a large number of Protestants and Jews. It was taken by assault, by the king of Prussia, in 1741, and the garrison made prisoners. After the peace in 1742, the king of Prussia settled the supreme court of justice here, it being, next to Breslaw, the most populous place in Silesia. It is seated on the river Oder, in E. Lon. 15. 13. N. Lat. 51. 40.

GLOGAW the LESS, a town of Silesia, in the duchy of Opelen, now in possession of the king of Prussia. It is two miles S. E. of Great Glogaw, and forty-five N. W. of Breslaw. E. Lon. 16. 15. N. Lat. 51. 38.

GLORIA PATRI, among ecclesiastical writers. See DOXOLOGY.

GLORIOSA, **SUPERB LILY**; a genus of the monogynia order, belonging to the hexandria class of plants. There is but one species, a native of Malabar. It hath a thick, fleshy, tuberos root, sending forth from its centre declinated round stalks growing eight or ten feet long, and garnished with very long narrow leaves running out into a point, terminated by a long tendril. From the upper part of the stalks proceed large flame-coloured drooping flowers, consisting of six widely-spreading reflexed petals. It flowers in June and July, and is of admirable beauty whence; its name of *Gloriosa*, or *Superb Lily*.—This plant being a native of a very warm climate, requires the protection of a hot-house in this country. The flower-stalks shoot forth in March or April; which being long and trailing, must have tall racks placed for their support. The plants are propagated by offsets, which are produced in tolerable plenty, and may be separated any

time after the stalks decay, or in spring before new ones arise.

GLOSS, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language or any other. See the article COMMENTARY. The word, according to some, comes from the Greek γλῶσση, "tongue;" the office of a *gloss* being to explain the text, as that of the tongue is to discover the mind.

Gloss is likewise used for a literal translation, or an interpretation of an author in another language word for word.

Gloss is also used in matters of commerce, &c. for the lustre of a silk, stuff, or the like.

GLOSSARY, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's Latin and Greek Glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his Parochial Antiquities.

CLOSSOPETRA, in natural history, a genus of extraneous fossils, so called from their having been supposed the tongues of serpents turned into stone; though they are really the teeth of sharks, and daily found in the mouths of those fishes, where-ever taken.

The several sizes of teeth of the same species, and the several different species of sharks, furnish us with a vast variety of these fossil-teeth. Their usual colours are black, bluish, yellowish, or brown. In shape they are usually somewhat approaching to triangular; some are simple, and others have a smaller point on each side the large one. Many of them are quite straight; but they are frequently met with crooked and bent in all the different directions, some inwards, some outwards, and some sideways. They are also of various sizes; the larger ones being four or five inches long, and the smaller less than a quarter of an inch. They are found with us in the strata of blue clay, and are very plentiful in the clay-pits of Richmond, and some other places; but they are nowhere so common as in the island of Malta.

GLOTTIS, in anatomy, the narrow slit at the upper part of the apera arteria, which is covered by the epiglottis when we hold our breath and when we swallow. The glottis, by its dilatation and contraction, modulates the voice. See ANATOMY, n° 380.

GLOVE, a covering for the hand and wrist.

Gloves, with respect to commerce, are distinguished into leathern-gloves, silk-gloves, thread-gloves, cotton-gloves, worsted-gloves, &c. Leathern-gloves are made of chamois, kid, lamb, doe, elk, buff, &c.

To throw the glove, was a practice or ceremony very usual among our forefathers; being the challenge, whereby another was defied to single combat.—It is still retained at the coronation of our kings; when the king's champion casts his glove in Westminster-hall. See CHAMPION.

Fayn supposes the custom to have arose from the eastern nations, who in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove*, what the common version renders by *sheep*. He adds, that the Rabbins interpret by *glove*, that passage in the civiith Psalm, *In Idumeam extendam calcamentum*

Glofa
||
Glove

calceamentum meum, "Over *Edm* will I cast out my shoe."—Accordingly, among us, he who took up the *glove*, declared thereby his acceptance of the challenge; and as a part of the ceremony, continues *Favyn*, took the *glove* off his own right-hand, and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side, to meet at the time and place which should be appointed by the king, parliament, or judges.—The same author asserts, that the custom which still obtains of blessing *gloves* in the coronation of the kings of France, is a remain of the eastern practice of giving possession with the *gloves*, l. xvi. p. 1017, &c.

Anciently it was prohibited the judges to wear gloves on the bench. And at present in the stables of most princes, it is not safe going in without pulling off the gloves.

GLOW-WORM, a small insect, remarkable for its shining in the dark. See *CICINDELA*.

The male and female of this species differ greatly from each other. The male has wings, and is a small fly: the female has no wings, but is a large crawling worm.—The body of the male is oblong, and somewhat flattened; the wings are shorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light issuing from it, and is not commonly supposed to be at all akin to the glow-worm. The female is what we expressly call by this name. This is a very slow-paced animal, somewhat resembling a caterpillar: the head is small, flat, hard, black, and sharp towards the mouth. It has short antennæ, and six moderately long legs. The body is flat, and is composed of twelve rings, whereas the body of the male consists only of five. It is of a dusky colour, with a streak of white down the back. It is often seen in the day-time, but is not known till dark; at which time it is easily distinguished by the glowing light, or lambent flame, that is seen near the tail, issuing from the under part of the body. It is commonly met with under hedges; and if carefully taken up may be kept alive many days upon fresh turfs of grass, all which time it will continue to shine in the dark.

The light of this little insect is so strong, that it will shew itself through several substances in which the creature may be put up; a thin pill-box easily shews it through, and even though lined with paper the light is not impeded by both. The creature is sluggish, and appears dead in the day-time; and its light is not distinguishable even if carried into a darkened room, unless the creature be turned upon its back and disturbed, so as to be put in motion, and then it is, but very faint: after sun-set the light returns, and with it the life and motion of the creature. The motion and light of this insect indeed seem in some measure to depend upon one another: it never shines but when its body is in some sort of motion; and when it shines most, the body is extended to one third more than its length in the day-time. In the time of brightest shining it will sometimes of a sudden turn its body about, and the light will not be longer than the head of a pin; and, on being touched, she will then immediately extend herself, and the light will become as large and as bright as ever.

Flying Glow-Worm, (*cicindela volans*.) In the war-

mer months of the year, this creature is sometimes caught in our houses flying to the flame of a candle; and examined in the dark is found to be luminous at these times, tho' perhaps less or not at all so at others; which may be a reason of its not being known though caught in the fields; and to this it may be owing, that many who have described this creature, have thought it not a native of Britain. Without wings, it is frequently enough found in form of the common glow-worm, and then always shines. *Aldrovandus* informs us, that it lays eggs which in a short time hatch small worms; and that these afterwards become flies, by the same sort of change which happens to butterflies and other species of winged insects. *Mouffet*, and *Thomas Bartholine*, give much the same description with *Aldrovandus*, but allow the male only to have wings. *Julius Scaliger*, however, contradicts this, and affirms that he has caught them both winged in the act of generation; but this is not acknowledged even by all those who have quoted the abovementioned passage from *Scaliger*. Mr *Waller*, in the philosophical transactions, confirms *Scaliger's* account, having observed them in the same manner in the act of copulation both winged; only with this difference, that the female was the larger of the two, which is the case with many other insects. The male and female in this winged state both shine in hot weather, and their light is so vivid that it may easily be seen even when there is a candle in the room. The vibrations of this light are irregular, and its colour greenish. The luminous parts are two small specks under the tail at the end, and the light continues in these some time after the tail is cut off; but then gradually goes out. The parts of insects continue alive in some degree for a considerable time after they are separated from the rest of the body; and probably the light of the tail of this animal continues just as long as this sort of life remains in it.

The use of this light seems to be to direct the animal in its course, and in the taking of its prey; and to this purpose it is admirably placed. The tail is easily bent under the belly, and then throws the light full upon any object about or under the head of the animal; and the eyes are placed, not on the upper part, but on the under side of the head; so that they have all the advantages of it, while the light in this part is not offensive to the eyes, as it naturally would have been if carried before the head. Upon occasion the insect can cover this light, so that its enemies cannot take the advantage in order to pursue it.

The insect is of the beetle kind, of a brown or dusky colour. It has hard case or shell wings, as the other beetles have; and, when these are expanded, there appears a pair of very large membranaceous ones. Its head is covered with a sort of shield or broad-brimmed hat; under this hat are placed the eyes, which are black and large, and are moveable, so that the creature can upon occasion thrust them forward to the sides of the hat or covering of the head. It has two hairy antennæ; and its legs are like those of the common fly, hard, shelly, and hairy. Its eyes afford an elegant object for the microscope, being composed of an infinite number of lenses, like those of the libellæ and other insects.

GLUKSTADT, a strong and considerable town of Germany,

Glue.

Germany, in the circle of Upper Saxony, and duchy of Holstein, with a strong cattle, and subject to Denmark. It is seated on the river Elbe, near its mouth; E. Long. 9. 15. N. Lat. 52. 53.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uses they are designed for, as the common glue, glove-glue, and parchment-glue; whereof the two last are more properly called *size*.

The common or strong glue is chiefly used by carpenters, joiners, cabinet-makers, &c.

It is made of the skins of animals, as oxen, cows, calves, sheep, &c.; and the older the creature is, the better is the glue made of its hide. Indeed whole skins are but rarely used for this purpose, but only the shavings, parings, or scraps of them; or the feet-sinews, &c. That made of whole skins, however, is undoubtedly the best; as that made of sinews is the very worst.

The Method of Making GLUE. In making glue of parings, they first steep them two or three days in water: then, washing them well out, they boil them to the consistence of a thick jelly; which they pass, while hot, through ozier-baskets, to separate the impurities from it; and then let it stand some time, to purify it further: when all the filth and ordures are settled to the bottom of the vessel, they melt and boil it a second time. They next pour it into flat frames or moulds; whence it is taken out pretty hard and solid, and cut into squares pieces or cakes. They afterwards dry it in the wind, in a sort of coarse net; and at last string it, to finish its drying.

The glue made of sinews, feet, &c. is managed after the same manner; only with this difference, that they bone and scour the feet, and do not lay them to steep.

Of this commodity there is a very great exportation from England; the English glue being universally allowed to be the best in Europe, partly from the excellency of the materials, and partly from the skill of the manufacturers. Next to this is the Flanders glue. In both countries it is made by the tanners from fragments of good skins dried with much care. In France it is a separate trade: and the glue-makers pick up their materials as they can, from the several dealers in skins, and boiling these with cow-heels make their glue; which as they purchase every thing, must render it dear, as well as of an inferior quality. The duty on exportation is ten-pence, and on importation three shillings and ten-pence, on every hundred weight.

The best glue is that which is made from the skin of the oldest beast, especially if a bull's hide is used. Experience likewise shews that glue is considerably improved in quality by keeping after it is made; and the surest way to try its goodness is to lay a piece to steep three or four days, and if it swell considerably without melting, and when taken out resumes its former driness, it is excellent.

A glue that will hold against fire or water, it is said, may be made thus: Mix a handful of quicklime with four ounces of linseed oil; boil them to a good thickness; then spread it on tin-plates in the shade, and it will become exceeding hard, but may be easily

dissolved over a fire, as glue, and will effect the business to admiration.

Neumann observes, that glue dissolved in a solution of lapis calaminaris in spirit of nitre, and afterwards inspissated, forms an extremely slippery tenacious mass, which might be of use for entangling flies, caterpillars, and other insects, if it was not too expensive.

Method of Preparing and Using GLUE. Set a quart of water on the fire, then put in about half a pound of good glue, and boil them gently together till the glue be entirely dissolved and of a due consistence. When glue is to be used, it must be made thoroughly hot; after which, with a brush dipped in it, besmear the faces of the joints as quick as possible: then clapping them together, slide or rub them lengthwise one upon another, two or three times, to settle them close; and so let them stand till they are dry and firm.—Mr Boyle gives a receipt for preparing a fine strong glue from isinglass in the following manner: Steep the isinglass for 24 hours in common brandy. When the menstruum has opened and mollified the isinglass, they must be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, suffered to cool, turns into a strong jelly. Then strain it, whilst hot, through a clean linen-cloth, into a vessel to be kept close stopped. A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong; so that pieces of wood glued together with it will separate elsewhere rather than in the place where they are joined. See ISINGLASS.

GLUME, *Gluma*, among botanists. See BOTANY, p. 1293.

GLUTEUS, in anatomy. See there, *Table of the muscles*.

GLYCINE, KNOBBED-ROOTED LIQUORICE-VETCH; a genus of the decandria order, belonging to the diadelphia class of plants. There is but one species commonly cultivated in our gardens, viz. the frutescens, or Carolina kidney-bean tree. This hath shrubby climbing stalks, twining round any support, 15 or 20 feet high, adorned with pinnated leaves of three pair of foliicles terminated by an odd one, and from the axillas clusters of large bluish-purple flowers, succeeded by long pods like those of the climbing kidney-bean. It flowers in June and July, but the seeds do not ripen in this country. It is easily propagated, either by seeds imported from America, where it is native, or by layers.—The stalks and roots of the abrus, another species of glycine which grows in Egypt and the Indies, are very sweet to the taste. Herman affirms that the juice obtained from them by decoction is little inferior to liquorice; whence its name of *wild-liquorice* in those parts of America where it is native.

GLYCYRRHIZA, LIQUORICE; a genus of the decandria order, belonging to the diadelphia class of plants. There are two species. 1. The glabra, or common liquorice, hath a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth pods.

The root of this is the useful part, which is replete with

Glue
||
Glycyrrhiza.

Glycyrrhiza.

with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. 2. The echinata, or prickly-podded liquorice, is nearly like the common sort, only the seed-pods are prickly.

Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other.

The roots are perennial; but the stalks rise in spring, and decay in autumn.

They delight in a deep light soil, in which the roots will run down three or four feet deep, and attain a large size, if permitted to stand three or four years. From the main root smaller ones run off horizontally; and from these horizontal roots, that run near the surface, cuttings for sets or young plants are taken for propagation, which are generally procured at the time when the liquorice is taken up for use, being fit in three years after planting.

Where large quantities are required for sale, they may be cultivated in fields, as practised in many parts of England; vast quantities are also raised in the kitchen-gardens about London, where, by the richness and depth of the ground, the roots attain their utmost perfection in length and bulk.

The length and thickness of the roots is a principal consideration to the planter, as they are always sold by weight.

Propagation and culture. Their propagation is, as above observed, effected by cuttings of the small roots issuing from the sides of the main ones, near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is, any time, in open weather, from October till March, though from the middle of February till the middle of March is rather the most successful season for planting.

An open situation is the most suitable for a plantation of these plants.

Particular regard should also be had to the soil: it ought to be of a light, loose temperature, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

Having fixed on the ground, let it be trenched three spades deep, if the depth of proper soil will admit; then having your sets ready, proceed to plant them by line and dibble, planting the sets a foot distance in each row; putting them perpendicular into the ground, with the tops about an inch under the surface; and let the rows be a foot and a half asunder; though the London gardeners seldom allow more than twelve inches between row and row. These gardeners also sow a crop of onions on the same ground the first year; which, as the onions root but slender, and spread but little at top, may be done without any detriment to the liquorice, nor that to the onions, as it does not rise above ten or twelve inches high the first summer; observing to keep the ground clean from weeds during that season by hoeing. If there is a crop of onions, use the small hoe, cutting out the onions to four or five inches distance, clearing away such as grow

immediately close to the liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface and destroy all weeds effectually; and in autumn cut down the decayed stalks of the liquorice, and nothing more is necessary to be done till spring; when, in February or March, give a slight digging between the rows; during spring and summer, keep down all weeds by broad-hoeing; and in autumn, when the stalks are in a decaying state, cut them down to the surface of the earth.

In three years after planting, the roots of the liquorice will be fit to take up: and the proper season for this is, any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to thrive and diminish in weight.

In taking them up, the small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale. It is of advantage to sell them as soon as possible after they are taken up, before they lose much of their weight. They are sold to the druggists, from about twenty to thirty or forty shillings per hundred weight, and an acre of ground has produced three thousand and upwards, which has been sold for more than sixty pounds; but the price is commonly in proportion to the goodness of the roots.

The common liquorice is cultivated in most countries of Europe for the sake of its root. That which is cultivated in Britain is preferable to such as comes from abroad; this last being generally mouldy, which this root is very apt to become, unless kept in a dry place. The powder of liquorice usually sold is often mingled with flour, and probably too often with substances not quite so wholesome: the best sort is of a brownish yellow colour (the fine pale yellow being generally sophisticated), and of a very rich sweet taste, much more agreeable than that of the fresh root. Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks *adipson*. Galen takes notice, that it was employed in this intention in hydropic cases, to prevent the necessity of drinking. Mr Fuller, in his *Medicina Gymnastica*, recommends this root as a very useful pectoral; and says it excellently softens acrimonious humours, at the same time that it proves gently detergent: and this account is warranted by experience. An extract is directed to be made from it in the shops; but this preparation is chiefly brought from abroad, though the foreign extract is not equal to such as is made with proper care among ourselves.

GLYPH, in sculpture and architecture, denotes any canal or cavity used as an ornament.

GNAPHALUM, CUDWEED, GOLDS-LOCKS, ETERNAL FLOWER, &c. a genus of the polygamia superflua order, belonging to the syngenesia class of plants. There are 41 species; the most remarkable of which are, 1. The margaritaceum, or pearly white eternal flower, hath creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves; herbaceous, thick, woolly stalks, a foot and an half high, branching outward, garnished with long acute pointed white woolly leaves, and termina-

Glycyrrhiza
Gnaphalium.

ted by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The *plantaginifolium*, hath large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches high, terminated by a corymbus of white flowers in June, July, &c. 3. The *stæchas* hath a shrubby stalk, dividing into slender branches three feet long, terminated by corymbose clusters of yellow flowers, appearing in May and June. 4. The *orientale*, or oriental goldlocks, hath three varieties, with yellow, gold-coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The *odoratissimum*, or sweet-scented eternal flower, hath shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright yellow flowers, changing to a dark yellow. 6. The *arboresum*, or tree *gnaphalium*, hath a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers.

The first three sorts are hardy, and will thrive in any soil or situation. The two first increase exceedingly by their roots; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender; and therefore should be kept in pots, to be sheltered in a green-house or garden-frame in winter. Others may be planted in the full ground, in a dry and warm situation, especially the oriental kind and varieties, and likewise the sweet-scented kind; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer-months. All these are propagated by slips, or cuttings of their shoots.—The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

GNAT, in zoology. See *Musca*.

There is no species of insects so particularly troublesome to mankind as the gnats. Others give more pain with their stings, but it is only by accident that we are struck by them; but the gnats thirst for our blood, and follow us about in whole companies for it. There are many marshy places in our country where the legs and arms are all the summer swelled to an enormous size by the bitings of these insects, and in many other countries they are yet more troublesome than with us.

All the naturalists have of late years employed the microscope to examine the parts of this little animal; and Swammerdam, Hooke, Bonanni, Lewenhock, &c. have given very good accounts and very valuable drawings of the creature.

The trunk of the gnat, or the instrument with which it strikes the flesh and sucks the blood from animal bodies, is of a very curious construction. The piercer, or, more properly, the piercers of this instrument are all entirely hid in the sheath of the instrument which makes what we call the *trunk*, and is the only part naturally offered to our view. This trunk appears to be cylindric in the greatest part of its length; and is covered with scales not unlike those on the nerves of the creature's wings, and resembling small leaves. Near its end it has a little swelling, where there is an oblong button broader at its insertion than

at its point: the end of this button is furnished with an aperture out of which the creature occasionally thrusts a fine point. Many naturalists have observed this point. Swammerdam considered it as a single pointed body formed to pierce the skin; but Lewenhock discovered that it was made up of a vast number of pointed bodies. There is no occasion, however, for all the accuracy of Swammerdam, nor all the power of the magnifying-glasses of Lewenhock, to discover that this is a complex body; a common small magnifying glass and a little attention will at any time discover it.

If a gnat is held by the corcelet between the fingers, and a little squeezed, the trunk will frequently be seen to open lengthwise on each side; sometimes only a little way, at others almost its whole length; and a fine glossy reddish filament shews itself at the opening of this case. This filament is bent and turned inwards, and one very soon distinguishes that it is indeed a congeries of a great number of filaments: these one may easily separate in some measure, from one another by any pointed instrument; and very often the filament of itself separates into several in the bending. It is plain, therefore, that the instrument destined to pierce the skin and suck the blood is of a complex structure; that what we might naturally take for this instrument, is only its case or sheath; and that this case or sheath, instead of a plain cylindric body is really a composition of two semi-cylindric ones, which the animal has the power of separating from one another on proper occasions.

The best way to get a regular sight of the trunk of this creature and of the manner of using it, is to suffer a gnat to settle upon the hand, and not to disturb him in the operation; but, with a magnifying glass in the other hand, to observe all his motions. In this case, we may first observe a small and slender point thrust out of the case, and the animal try several different parts of the skin with this sharp instrument. When this is done, it chooses that part which is most easily pierced, and where there lies a vessel underneath capable of furnishing as much blood as it will have occasion to suck. As soon as it has made its choice, the wound is immediately given: and since the point of the compound piercer cannot be protruded so far out of the case as it is necessary it should be to strike to a proper depth, the use of the slit in this case is seen; for while the button at the end of this remains firmly applied to the orifice of the wound, where the piercer is introduced, and supports that feeble and delicate instrument from bending, the case opens at the slit, and its two sides bend to give room to the piercer to penetrate; and, at length, when the piercer is sunk to its utmost depth, the two extremities of each piece touch, and the two sides are brought close together.

The several species of gnats have great variety in their trunks. One of them deserves to be remarked, as having no need of the button at the end of the case, common to all the rest, to support it while it enters the flesh. This has a case on which it rests itself as on a seventh leg; from which it darts a piercer, which without any support is of sufficient strength to penetrate the flesh, and do its office for the animal. This species of gnat has two very long beards placed above its trunk, and terminated by an end covered

covered with white scales. What remains of these beads is covered with brown scales, the body of the gnat also is brown, and the coracel reddish.

Though it is easy to find that the trunk of a gnat is composed of several pieces, yet it is by no means easy to say what the precise number of them is. The best microscopes often shew the whole a single body, its several parts being so extremely well joined; and when they have been found to be more than one, it is yet extremely difficult to say how many they are. Lwenhoeck believed them to be four in number; and Swammerdam, who at first believed the whole to be a single filament, afterwards thought he discovered six pieces going to its composition.

After separating the piercer of the gnat wholly from its sheath, if it be cut transversely near its base, or insertion in the head, and the section laid upon the plate of a microscope, and there touched with an extremely fine pointed instrument, it may be divided into four, and sometimes into five separate pieces. Two of these may be often seen to come out of a third as out of a canal or tube. The seeming necessity of a tube in this instrument for sucking the blood, has made many ready to persuade themselves that they have actually seen one: but if we follow the analogy of nature in her other works, we shall find there is no absolute necessity for such an organization in this part; since, in the gad-fly, the several pieces of which the piercer is composed are of themselves able to form a tube for the conveying of the blood.

Out of the immense number of gnats that one sees in summer, few can have any chance, even once in their lives, of sucking the blood of the larger animals; the rest, however, are by no means doomed to perpetual famine: the herbs of the field afford them a sufficient nourishment; for the gnats, like many other insects, are partly carnivorous, and partly otherwise, feeding equally on flesh and vegetables.

The wings of gnats are of a very curious structure, and worthy of an attentive observation. It is well known, that, on touching the wings of butterflies, a coloured powder is left upon the fingers; which, tho' to the naked eye it appears a mere shapeless dust, yet when examined by the microscope is found to consist of beautiful and very regularly figured bodies resembling feathers and scales. The generality of flies have nothing of this kind; but a close examination of the wings of the gnat will shew that they are not wholly destitute of them: they are bestowed much more sparingly indeed upon the gnat than on the butterfly; but they are arranged with great regularity.

The wings of the gnat, like those of most other insects, are of a cartilaginous substance, friable, and transparent like a flake of talc; and the circumference and many parts of the inner surface of the wing are strengthened by slender but firm ribs, which are divaricated into several ramifications. These appear to us to be mere fibril fibres; but they are probably hollow, and perform the office of vessels for the carrying of fluids or air necessary to the support of the wing, as well as to strengthen it. In the wings of butterflies there are similar ribs, but they are there all hid by the scales; but it is not so in the gnat; for in its wings, as in those of the other flies, these ribs seem naked. The assistance of the microscope, however, shews that they

are not absolutely so in the wings of gnats, but these nerves or ribs, with their several ramifications, look like as many stalks of a plant covered with small oblong leaves. The several scales that are attached to these ribs make acute angles with them, and are directed towards the end of the wing. The number of these scales is very small in comparison with those of the butterfly-clas; but they make a slighter and more elegant ornament. There are some species which have the intermediate spaces of the wing also adorned with these scales; but they are in these only thinly scattered. The intermediate spaces of the wings, when they have no scales are finely wrought and pointed: the inner edges of the wings are always bordered with a row of scales in form of a fringe; which, in some species, is composed of scales all of the same size, and in others is made up of many various lengths; and the exterior edge of the wing, which is surrounded by a rib much thicker and stronger than the interior, is not fringed with a series of scales, but is beset at proper distances with a kind of prickles.

The ordinary shape of the wings of the gnats is that of an oblong battledoor, one end of which is broader and the other more pointed. The narrower end is that from which goes the stalk by which it adheres to the rib. The other end is sometimes more, sometimes less round, and is sometimes a little hollowed in the middle. Some of these are much longer in proportion to their breadth than others; and some of them have their extremity formed into an open crescent. All have a number of fine lines running longitudinally through the whole scale.

GNAT-WORM, in natural history, a small aquatic insect produced from the egg of a gnat, and which is after its several changes again transformed into a gnat.

These worms do not frequent rivers, but ditches, ponds, and other stagnant waters; where they are found in vast abundance from the middle of May till towards the beginning of winter. This is the reason why watery and marshy places are found most to abound with gnats, and why the wet summers are found to produce the greatest numbers of them; because in dry seasons the ponds and ditches where they are to pass their worm-state are dried up, and the worms killed. These are creatures, however, that one need not go far to seek; since one need only expose a vessel of water in a garden, or any open place, in the summer time, and sooner or later it will not fail to produce plenty of them.

Before they arrive at their full growth, though they are then but small, they are easily found; because they are under a necessity of coming often to the top of the water by having occasion for frequent respiration; and to do this, they are obliged to keep the end of a small pipe they are furnished with from the last ring of their body above water. The end of this pipe is hollow and indented, and forms a sort of funnel upon the surface of the water. It is of the length of about three rings of the body, and is somewhat thicker at its insertion than at its extremity.

The worm is of the third class of those which are transformed into two-winged flies; that is, it has no legs, and has a head of a constant and invariable figure; and has no teeth or moveable jaws formed to play against one another. Their body is long, and their

head is somewhat detached from the first ring, to which it is fastened by a sort of neck. This first ring is the longest and largest of all, and seems a sort of corcelet to the worm. The creature has eight rings besides this. These grow smaller as they approach the hinder extremity.

While the worm is young, the body is whitish or greenish; but when it is at its full growth, and draws near the time of its change, it becomes greyish. The great transparency of the body of this worm gives a fine view of what passes within it; and it is at any time easy to see the motion of the intestines by which the food is pushed on towards the anus. The two principal tracheæ are also seen very distinctly in this creature. They are two white tubes placed in a direction parallel to one another, and run from the first ring to the tube of respiration.

This worm several times changes its skin in the course of its life. After three changes of this kind, which usually happen in the space of three weeks, it undergoes a fourth, in which the old skin is as easily thrown off as before; but the animal now appears in a new form, viz. that of a nymph. It is now shorter and rounder than before; and the body is so bent, that the tail is now applied to the under part of the head: this, however, is only its form in a voluntary state of rest, for it can yet move; and, when it pleases, extends its tail, and swims as swiftly as before.

All the parts of the future gnat may be seen in this nymph; the skin of it is extremely thin and transparent, yet sufficiently tough and firm for the use for which it is intended. It is uncertain how long the animal lives in this nymph state; but after the time is accomplished, its change into the gnat is very quick, and attended with great danger to the animal, since multitudes of them are drowned in the act of getting out.

GNESNA, a large and strong town of Great Poland, of which it is capital, and in the palatinate of Calish, with an archbishop's see, whose prelate is primate of Poland, and viceroy during the vacancy of the throne. It was the first town built in the kingdom, and formerly more considerable than at present. E. Lon. 18.20. N. Lat. 52.28.

GNOMES, *gnomi*, certain imaginary beings, who, according to the cabalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See FAIRY.

GNOMON, in dialling, the style, pin, or cock of a dial; which, by its shadow, shews the hour of the day. The gnomon of every dial represents the axis of the world. See DIAL and DIALLING. The word is Greek, *γνομων*, which literally implies something that makes a thing known; by reason that the style or pin indicates or makes the hour known.

GNOMON, in geometry. If, in a parallelogram ABCD (Pl. CXL. fig. 8. n° 1.) the diameter AC be drawn; also two lines EF, HI, parallel to the sides of the parallelogram, and cutting the diameter in one and the same point G, so that the parallelogram is, by these parallels, divided into four parallelograms; then are the two parallelograms DG, BG, through which the diameter does not pass, called *complements*; those through which the diameters pass, EH, FI,

are called the *parallelograms about the diameter*; and a gnomon consists of the two complements, and either of the parallelograms about the diameter, viz. GD+HE+FI, or GD+FI+GB.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle ABC are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC:AB::radius:tangent of the angle C.

By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See QUADRANT.

By the same instrument the height of any object GH may be found: for as DE, the distance of the observer's eye from the gnomon, is to DE, the height of the style; so is FH, the distance of the observer's eye from the object, to GH, its height.

GNOMON of a Globe; the index of the hour-circle. GNOMONICS, the art of dialling. See DIALLING.

GNOSTICS, (from the Greek *γινωσκω*, I know,) in church-history, Christian heretics so called; it being a name which almost all the ancient heretics affected to take, that they might express the new knowledge and extraordinary light to which they made pretensions.

St Epiphanius ascribes the origin of the Gnostics to Simon Magus; and says, that they acknowledged two principles, a good and a bad. They supposed there were eight different heavens, each of which was governed by its particular prince. The prince of the seventh heaven, whom they named *Sabaoth*, created the heavens and the earth, the six heavens below him, and a great number of angels. In the eighth heaven they placed their *Barbelo* or *Barbero*, whom they sometimes called the *father*, and sometimes the *mother of the universe*. All the Gnostics distinguished the creator of the universe from God who made himself known to men by his son, whom they acknowledged to be the Christ. They denied that the Word was made flesh; and asserted that Jesus Christ was not born of the Virgin Mary; that he had a body only in appearance, and that he did not suffer in reality. They neither believed a resurrection nor a judgment to come; but imagined that those who had been instructed in their maxims would return into the world, and pass into the bodies of hogs, and other like animals. They had several apocryphal books, as the *Gospel of St Philip*; the *Revelation of Adam*; the *Gospel of Perfection*, &c.

GOA, a large and strong town of Asia, in the peninsula on this side the Ganges, and on the Malabar coast. It was taken by the Portuguese in 1508, and is the chief town of all the settlements the Europeans have in India. It stands in an island about 12 miles in length, and six in breadth; and the city is built on the north side of it, having the convenience of a fine salt-water river, capable of receiving ships of the greatest burthen, where they lie within a mile of the town. The banks of the river are beautified with a great number of handsome structures; such as churches, castles,

caffles, and gentlemen's houfes. The air within the town is unwholefome, for which reason it is not fo well inhabited now as it was formerly. The viceroy's palace is a noble building; and ftands at a fmall diftance from the river, over one of the gates of the city, which leads to a fpacious ftreet, terminated by a beautiful church. This city contains a great number of handfome churches, convents, and cloifters, with a ftately large hofpital; all well endowed, and kept in good repair. The market-place takes up an acre of ground; and in the fhops about it may be had the produce of Europe, China, Bengal, and other countries of lefs note. Every church has a fet of bells, fome of which are continually ringing. Their religion is the Roman Catholic, and they have a fevere inquisition. There are a great many Indian converts; but they generally retain fome of their old cuftoms, particularly they cannot be brought to eat beef. However, there are many Gentoo's in the city, who are tolerated, becaufe they are more induftrious than the Chriftians, and better artifts. The clergy are very numerous, and illiterate; but the churches are finely embellifhed, and have great numbers of images. The houfes are large, and make a fine fhew; but within they are but poorly furnifhed. The inhabitants are contented with greens, fruits, and roots; which, with a little bread, rice, and filh, is their principal diet, though they have hogs and fowls in plenty. However, they are very much addifted to women; and are generally weak, lean, and feeble. Captain Hamilton flood on a hill near the city, and counted above 80 churches, convents, and monafteries; and he was told, that there were about 30,000 priefts and monks. The body of St Francis Xavier is buried in St Paul's church; and, as they pretend, performs a great many miracles. It is remarkable, that none of the churches, except one, have glafs windows; for they make ufe of clear oyster-shells inftead of glafs, and all their fine houfes have the fame. Goa itfelf has few manufactures or productions; their beft trade being in arrack. The river's mouth is defended by feveral forts and batteries, well planted with large cannon on both fides; and there are feveral other forts in different places. It is 250 miles N. by W. of Cochinchina. E. Lon. 74. o. N. Lat. 15. 31.

GOAL. See GAO.

GOAT, in zoology. See CAPRA.

GOAT's-Beard, in botany. See TRAGOPOGON.

GOAT-Sucker, in ornithology. See CAPRIMULGUS.

GOBELIN (Giles), a famous French dyer, in the reign of Francis I. difcovered a method of dying a beautiful fcarlet, and his name has been given ever fince to the fineft French fcarlets. His houfe, in the fuburb of St Marcel at Paris, and the river he made ufe of, are ftill called the *Gobelins*. An academy for drawing, and a manufactory of fine tapeftries, were erected in this quarter in 1666; for which reason the tapeftries are called the *Gobelins*.

GOBIUS, in ichthyology, a genus of fifhes belonging to the order of thoracii. They have two holes between the eyes, four rays in the membrane of the gills, and the belly-fins are united in an oval form. There are eight fpecies, principally diftinguifhed by the number of rays in their fins.

GOD, one of the many names of the Supreme

Being. See CHRISTIANITY; METAPHYSICS, n° 6. 222 - 230.; and MORAL PHILOSOPHY, n° 161, &c.

GODDARD (Jonathan), an eminent phyfician and chemift, and one of the firft promoters of the Royal Society, was born about the year 1617. He was elected a fellow of the college of phyficians in 1646, and appointed reader of the anatomical lecture in that college in 1647. As he took part againft Charles I. accepted the wardfhip of Meiton-college, Oxford, from Oliver Cromwell when chancellor, and fat fole representative of that univerfity in Cromwell's parliament, he was removed from his wardfhip in a manner difgraceful to him by Charles II. He was however then profeffor of phyfic at Grefham college, to which he retired, and continued to attend thofe meetings that gave birth to the Royal Society; upon the firft eftablifhment of which, he was nominated one of the council. Being fully perfuaded that the preparation of medicines was no lefs the phyfician's duty than the prefcribing them, he contently prepared his own; and in 1668 publifhed a treatife recommending his example to general practice. He died of an apopleftic fit in 1674; and his memory was preferred by the drops that bore his name, otherwife called *Gutta Anglicana*, the feeret of which he fold to Charles II. for 5000 l. and which Dr Lifter affures us was only the volatile fpirit of raw filk rectified with oil of cinnamon or fome other effential oil. But he claims more particular regard, if what bifhop Seth Ward fays be true, that he was the firft Englifhman who made that noble aftronomical inftrument, the telefcop.

GODDESS, a heathen deity of the female fex.

The ancients had almoft as many goddeffes as gods: fuch were, Juno the goddefs of air, Diana the goddefs of woods, &c. and under this character were reprefented the virtues, graces, and principal advantages of life; truth, juftice, piety, liberty, fortune, victory, &c.

It was the peculiar privilege of the goddeffes to be reprefented naked on medals; for it was fuppofed that the imagination muft be awed and reftained by the confideration of the divine character.

GODEAU (Anthony), bifhop of Grasse and Vence in France, was born at Dreux in 1605. He was a very voluminous writer, both in profe and verfe; but his principal works are, 1. *An ecclefiaftical hiftory*, 3 vols. folio, containing the firft eight centuries only, as he never finifhed more. 2. *Translation of the Pfalms into French verfe*; which was fo well approved, that even thofe of the reformed religion preferred it to that of Marat. He died in 1671.

GODFATHERS and GODMOTHERS, perfons who, at the baptifm of infants, anfwer for their future conduct, and folemnly promife that they will renounce the devil and all his works, and follow a life of piety and virtue; and by this means lay themfelves under an indifpenfable obligation to inftruct them, and watch over their conduct.

This cuftom is of great antiquity in the Chriftian church; and was probably inftituted to prevent children being brought up in idolatry, in cafe their parents died before they arrived at years of difcretion.

The number of godfathers and godmothers is reduced to two, in the church of Rome; and three, in the church of England; but formerly they had as many as they pleafed.

GODFREY

GODFREY (of Bouillon), prince of Lorrain, a most celebrated crusader, and victorious general. He was chosen general of the expedition which the Christians undertook for the recovery of the Holy Land and sold his dukedom to prepare for the war. He took Jerusalem from the Turks in 1099; but his piety, as historians relate, would not permit him to wear a diadem of gold in the city where his Saviour had been crowned with thorns. The sultan of Egypt afterwards sent a terrible army against him; which he defeated, with the slaughter of above 100,000 of the enemy. He died in 1160.

GODOLPHIN (John), an eminent English civilian, was born in the island of Scilly in 1617, and educated at Oxford. In 1642-3, he was created doctor of civil law; in 1653, he was appointed one of the judges of the admiralty; and at the Restoration, he was made one of his majesty's advocates. He was esteemed as great a master of divinity, as of his own faculty; and published, 1. *The holy limbeck*. 2. *The holy labour*. 3. *A view of the admirals jurisdiction*. 4. *The orphan's legacy*. 5. *Repertorium canonicum, &c.* He died in 1678.

GODWIN (Francis), successively bishop of Landaff and Hereford, was born in 1567. He was eminent for his learning and abilities; being a good mathematician, an excellent philosopher, a pure Latinist, and an accurate historian. He understood the true theory of the moon's motion, a century before it was generally known. He first started those hints afterwards pursued by bishop Wilkins, in his *Secret and swift messenger*; and published *A catalogue of the lives of English bishops*. He has nevertheless been accused as a great simoniac, for omitting no opportunity of disposing of preferments in order to provide for his children. He died in 1648.

GODWIN (Thomas), a learned English writer born in 1517, was master of the free-school at Abingdon in Berkshire; where he educated a great many youths, who became eminent both in church and state. His works shew him to have been a man of great learning; such as, *Historia Romane antologia*, *Synopsis antiquitatum Hebraicarum*, *Moses & Aaron*, *Floriolum Phrasicon*, &c. He died in 1642.

GODWIT, in ornithology. See **SCOLOPAX**.

GOES, or **TER GOES**, a strong and considerable town of the United Provinces, in Zealand, and capital of the island of South-Beveland. It communicates with the sea by a canal; and is 10 miles east of Middelburg, and 30 north of Ghent. E. Lon. 3. 50. N. Lat. 51. 33.

GOGMAGOG-HILLS, are hills so called, three miles from Cambridge, remarkable for the intrenchments and other works cast up here: whence some suppose it was a Roman camp; and others, that it was the work of the Danes.

GOITO, a town of Italy, in the duchy of Mantua, taken by the Germans in 1701, and by the prince of Hesse in 1706. It is seated on the river Mincio, between the lake of Mantua and that of Garda, 10 miles north-west of Mantua. E. Lon. 11. o. N. Lat. 45. 16.

GOLCONDA, a kingdom of Asia, in the peninsula on this side the Ganges. It is bounded on the north by that of Orissa, on the west by that of Ba-

lagate, on the south by Bijnagar, and on the east by the gulph of Bengal. It abounds in corn, rice, and cattle; but that which renders it most remarkable are the diamond-mines, they being the most considerable in the world: they are usually purchased of the black merchants, who buy parcels of ground to search for these precious stones in. They sometimes fail in meeting with any, and in others they find immense riches. They have also mines of salt, fine iron for sword-blades, and curious calicoes and chintzes. It is subject to the Great Mogul; and has a town of the same name, seated at the foot of a mountain, being one of the largest in the East-Indies. It is about six miles in circumference; and was formerly the residence of the kings, till it was conquered by the Great Mogul. It is now much frequented by the European merchants. E. Lon. 79. 10. N. Lat. 16. 30.

GOLD, the most precious of all the metals.

For an account of the places where gold is found in greatest quantities; the methods of extracting it from the ore, and afterwards purifying it; with an account of its different phenomena in combination with other metals; see the article **METALLURGY**. An account of its chemical properties, solution in different menstrua, &c. is given under **CHEMISTRY**, n° 194, 236, 348.—For its effects on glass, see the article **GLASS** and **VITRIFICATION**.

GOLD is the most fixed of all the metals; and it hath been generally believed, till very lately, that it was absolutely fixed in every degree of fire which could be excited by human art. Some chemists indeed pretended to have evaporated, calcined, and even vitrified gold, by exposing it to the focus of a good burning-glass; but as their experiments did not appear to have all the authenticity that was necessary, the opinion fell into discredit; and this the more readily that gold is found to resist the most violent furnace fires without any loss. Mr Macquer, however, in the last additions to his *Chemical Dictionary*, hath found, that this metal, when exposed to the heat of a good burning-glass, loses in weight considerably, and that even in a very short time. He held some very fine gold in the focus of a large burning-glass, at several times, at half an hour each time, sometimes in a hollow piece of charcoal, or in vessels made of earthen ware and porcelain; and whenever the air was very clear, and the sun bright, a very sensible smoke arose to the height of three or four inches. To know the nature of this smoke, a cold silver-plate was exposed to it; by which means, some of the vapour appeared on the silver like a tarnish a little less white, but not sensibly yellow. But when this part of the silver was rubbed with a burnisher, it appeared so evidently to be gilded, that none could doubt the evaporation of the metal. At this experiment several members of the Academy of Sciences were present.

The experiments with regard to the calcination and vitrification of gold were also tried by Mr Macquer, in presence of Messrs Montigny, Cadet, Lavoisier, and Brillon. The glass employed was that of Tschirnhausen, the same which had formerly been employed by Mr Homberg. Gold of 24 carats fine was exposed to the focus of this glass several times, by half an hour at a time, on vessels made of a very refractory porcelain earth.—When the gold was melted,

which

which happened in the space of a few seconds, it took a spherical form as nearly as its gravity would permit, and had nearly the consistence of quicksilver. The melted mass soon acquired a rotatory motion round its axis, sometimes in one direction, and sometimes in another, according to the direction of the focus upon the metal; (which, by-the-by, is a very curious appearance, and seems difficult to be accounted for). A smoke arose as in the former experiments. On the surface of the melted gold, spots evidently vitrified were formed, which separated from the metal. These afterwards united into a dark violet-coloured mass, of a greater curvature than the melted gold, in which they were found to be set, as jewels in a ring; and produced nearly the same appearance that the transparent cornea has on the globe of the eye; that is, as the segment of a small sphere joined to the surface of a large one. On a mass of liquid gold, of about half an inch diameter, he obtained, after four hours calcination, a button of this violet glass, whose diameter exceeded two lines; and this glass was observed gradually to increase as the gold diminished. Yet, though this very much resembles the vitrification of the gold, Mr Macquer doth not take upon him to assert that it certainly is so; seeing it may arise from the vessels on which the gold is supported, and which were coloured purple to a considerable distance, and besides were sprinkled with many small particles of gold undecomposed, easily distinguishable by a microscope; and in the violet glass also, many similar particles were observable. To determine the matter accurately, the experiment ought to be continued till all the particles of the metal be certainly either vitrified or evaporated.—Though this experiment, however, is hitherto equivocal when the heat of burning-glasses is made use of, it certainly succeeds with a strong flash of electric fire. See ELECTRICITY, n° 113.

Method of Recovering Gold from Gilt Works. The solubility of gold and the indissolubility of silver in aqua regia affords a principle on which gold may be separated from the surface of silver; and, on this foundation, different processes have been contrived, of which the two following appear to be the best.—Some powdered sal ammoniac, moistened with aqua fortis into the consistence of a paste, is spread upon the gilt silver, and the piece heated, till the matter smokes, and becomes nearly dry: being then thrown into water, it is rubbed with a scratch brush, composed of fine brass-wire bound together, by which the gold easily comes off. The other way is, by putting the gilt silver into common aqua regia, kept so hot as nearly to boil, and turning the metal frequently till it becomes all over black: it is then to be washed with a little water, and rubbed with the scratch brush, to get off what gold the aqua regia may have left. This last method appears preferable to the other; as the same aqua regia may be made to serve repeatedly till it becomes saturated with the gold, after which the gold may be recovered pure by precipitation with solution of vitriol, as directed under the article METALLURGY.

For separating gold from gilt copper, some direct a solution of borax to be applied on the gilt parts, but nowhere else, with a pencil, and a little powdered sulphur to be sprinkled on the places thus moistened; the principal use of the solution of borax seems

to be to make the sulphur adhere; the piece being then made red hot, and quenched in water, the gold is said to be so far loosened, as to be wiped off with a brush. Others mix the sulphur with nitre and tartar, and form the mixture with vinegar into a paste, which is spread upon the gilt parts.

Schlutter recommends mechanical means, as being generally the least expensive, for separating gold from the surface both of silver and copper. If the gilt vessel is round, the gold is conveniently got off by turning it in a lathe, and applying a proper tool, a skin being placed underneath for receiving the shavings: he says it is easy to collect into two ounces of shavings, all the gold of a gilt vessel weighing thrice as many pounds. Where the figure of the piece does not admit of this method, it is to be properly fixed, and scrapers applied, of different kinds, according to its size and figure; some large, and furnished with two handles, one at each end; others small and narrow, for penetrating into depressed parts. If the gold cannot be got off by either of these ways, the file must be had recourse to, which takes off more of the metal underneath than the turning tool or the scraper, particularly than the former. The gold scrapings, or filings, may be purified from the silver or copper they contain, by the methods described under the article METALLURGY.

The editors of the *Encyclopédie* give a method of recovering the gold from wood that has been gilt on a water-fire: this account is extracted from a memoir on the same subject, presented to the Academy of Sciences by M. de Montamy. The gilt wood is steeped for a quarter of an hour, in a quantity of water, sufficient to cover it, made very hot: the fire being thus softened, the wood is taken out, and scrubbed, piece by piece, in a little warm water, with short stiff bristle brushes of different sizes, some small for penetrating into the carvings, and others large for the greater dispatch in flat pieces. The whole mixture of water, fire, gold, &c. is to be boiled to dryness, the dry matter made red hot in a crucible to burn off the fire, and the remainder ground with mercury, either in a mortar, or, where the quantity is large, in a mill.

GOLD-Coast. See GUINEA.

GOLD-Wire, a cylindrical ingot of silver, superficially gilt or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See WIRE-DRAWING.

It may be observed, that, before the wire be reduced to this excessive fineness, it is drawn through above an hundred and forty different holes; and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

GOLD-Wire flattened, is the former wire flattened between two rollers of polished steel, to fit it to be spun on a slock, or to be used flat, as it is, without spinning, in certain stuffs, laces, embroideries, &c. See STUFF, &c.

GOLD-Thread, or *Spun-gold*, is flattened gold, wrapped or laid over a thread of silk, by twisting it with wheel and iron-bobbins.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two, is rendered quite flat, but without losing any thing of its gilding; and is rendered so exceedingly thin and flexible, that it is easily spun on silk-thread, by means of a hand-wheel, and so wound on a spool or bobbin. See *WIRE-DRAWING*.

GOLD-Leaf, or *Beaten Gold*, is gold beaten with a hammer into exceeding thin leaves, so that it is computed, that an ounce may be beaten into sixteen hundred leaves, each three inches square, in which state it takes up more than 159,052 times its former surface. See *GOLD-LEAF*.

It must be observed, however, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire drawers to gild their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. See *GILDING*.

GOLD-Brocade. See *BROCADE*.

Fulminating-GOLD. See *CHEMISTRY*, n° 356.—Since that article was printed, however, we are informed by Mr Macquer, that fulminating gold may be made without any nitrous acid. Of consequence, the conjecture there given concerning the cause of its explosion cannot be true in as far as the nitrous ammoniacal salt is concerned; though possibly the fixed air contained in the calx of gold may considerably contribute towards it.—Mr Bergman, whom Mr Macquer quotes, found that he could prepare fulminating gold at any time, by applying volatile alkali to it when in a greatly divided state. He doth not indeed tell us whether the alkali used, was in a caustic or mild state, (*i. e.* whether it was deprived of its fixed air or not): but though the experiment should even be found to succeed with caustic alkali, still the explosion might depend on fixed air; because caustic volatile alkalies are found either to imbibe, or generate this kind of air, even though excluded from the atmosphere in the most careful manner; and hence the complaint among druggists, that alkaline spirits, made with quicklime, do not keep equally well with others. See *ALKALINE SPIRITS*.

Shell-GOLD, that used by the illuminers, and where-with we write gold-letters. It is made of the parings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aqua fortis, they put it in shells, where it sticks. To use it, they dilute it with gum-water, or soap water.

GOLD-Finch, in ornithology. See *FRINGILLA*.

These are feed-birds of very curious colours, and which, were they not so common in this country, would probably be very much esteemed.

They are usually taken about Michaelmas, and soon become tame; but they differ very much in their song.—They frequently breed in the upper part of plum-trees, making their nests of the moss that grows upon apple-trees, and of wool; quilting the inside with all sorts of hairs they find upon the ground. They breed

three times a-year; and the young are to be taken with the nest at about ten days old, and fed as follows:—Pound some hemp-feed very fine in a mortar; then sift it through a sieve, and add to it as much wheat-bread as hemp-feed; and likewise a little flower of canary-seeds: then with a small stick or quill, take up as much as the bigness of a white-pea, and give them several times a-day. This ought to be made fresh every day: for if it is suffered to sour, it will spoil their stomachs, causing them to cast up their meat; which if they do, it is very probable that they will die.—These young birds must be carefully kept warm till they can feed themselves, for they are very tender. In feeding, be sure to make your bird clean his bill and mouth. If any of the meat falls upon his feathers, take it off, or else he will not thrive. Such as eat hemp-feed, to purge them, should have the seeds of melons, succory, and mercury; or else let them have lettuce and plantane for that purpose. When there is no need of purging, give them two or three times a week a little sugar or loam in their meat, or at the bottom of the cage; for all seeds have an oiliness, so that if they have not something to absorb it, in length of time it fouls their stomachs, and brings on them a flux, which is very dangerous.

GOLD-Fish. See *CYPRINUS*.

GOLDEN, something that has a relation to gold, or consists of gold.

GOLDEN Calf, was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness, to worship, during Moses's absence into the mount; and which that legislator, at his return, burnt, grinded to powder, and mixed with the water the people were to drink of; as related in Exod. xxxii. The commentators have been divided on this article: the pulverizing of gold, and rendering it potable, is a very difficult operation in chemistry. Many, therefore, suppose it done by a miracle: and the rest, who allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process. Moses could not have done it by simple calcination, nor amalgamation, nor antimony, nor calcination; nor is there one of those operations that quadrates with the text.

M. Stahl has endeavoured to remove this difficulty. The method Moses made use of, according to this author, was by dissolving the metal with hepatic sulphur; only, instead of the vegetable alkali, he made use of the Egyptian natron, which is common enough throughout the east. See *CHEMISTRY*, n° 359.

GOLDEN Fleece, in the ancient mythology, was the skin, or fleece of the ram, upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; and which being sacrificed to Jupiter, was hung upon a tree in the grove of Mars, guarded by two brazen-hoof'd bulls, and a monstrous dragon that never slept; but was taken and carried off by Jason and the Argonauts.

Many authors have endeavoured to shew that this fable is an allegorical representation of some real history, particularly of the philosopher's stone. Others have explained it, by the profit of the wool-trade to Colchis, or the gold which they commonly gathered there with fleeces in the rivers.

Order of the GOLDEN FLEECE, is a military order instituted

Golden,
Goldingen.

instituted by Philip the Good, duke of Burgundy, in 1429. It took its denomination from a representation of the *golden fleece*, borne by the knights on their collars, which consisted of flints, and steels. The king of Spain is now grand master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir, wrote on the fleece of a sheep.

Oliver de la Marche writes that he had suggested to Philip I. archduke of Austria, that the order was instituted by his grandfather Philip the Good, duke of Burgundy, with a view to that of Jason; and that John Germain, bishop of Chalons, chancellor of the order, upon this occasion made him change his opinion, and assured the young prince that the order had been instituted with a view to the fleece of Gideon. William bishop of Tournay, chancellor likewise of the order, pretends that the duke of Burgundy had in view both the golden fleece of Jason, and Jacob's fleece, *i. e.* the speckled sheep belonging to this patriarch, according to agreement made with his father-in-law Laban. Which sentiment gave birth to a great work of this prelate, in two parts: in the first, under the symbol of the fleece of Jason, is represented the virtue of magnanimity, which a knight ought to possess; and under the symbol of the fleece of Jacob, he represents the virtue of justice.

Paradin is of the same mind, and tells us that the duke designed to insinuate that the fabulous conquest which Jason is said to have made of the *golden fleece* in Colchis, was nothing else but the conquest of virtue, which gains a victory over those horrible monsters vice and our evil inclinations.

GOLDEN NUMBER, in chronology, a number shewing what year of the moon's cycle any given year is. See **ASTRONOMY**, n° 304—307.

GOLDEN-ROSE. The pope annually consecrates a golden-rose on the fourth Sunday in Lent, which is sent to princesses, or to some church, as a mark of his peculiar affection.

GOLDEN RULE, in arithmetic, a rule or praxis, of great use and extent in the art of numbers; whereby we find a fourth proportional to three quantities given.

The *golden rule* is also called the *Rule of Three*, and *Rule of Proportion*. See its nature and use under the article **ARITHMETIC**, n° 13.

GOLDINGEN, a town of Poland in the duchy of Courland, with a handsome castle, seated on the river Weia, in E. Long. 22. 31. N. Lat. 56. 48.

GOLDSMITH, or, as some choose to express it, *silversmith*, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures, are cast in a mould, and afterwards polished and finished: plates, or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and

their mouldings are beat, not cast. The business of Goldsmith's the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted; but there are now invented flattening-mills, which reduce metals to the thinness that is required, at a very small expence. The goldsmith is to make his own moulds; and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy, to be able to assay mixed metals, and to mix the alloy.

The goldsmiths in London employ several hands under them for the various articles of their trade: such are the jeweller, the snuff-box and toy maker, the silver-turner, the gilder, the burnisher, the chaffer, the refiner, and the gold-beater. See the articles **JEWELLER**, &c.

GOLDSMITHS are superior tradesmen: their wares must be assayed by the wardens of the company of this name in London, and marked; and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of York, Exeter, Bristol, &c. are places appointed for the assaying wrought-plate of goldsmiths; also a duty is granted on silver-plate of six-pence an ounce, &c. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting 10 l.; and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken and defaced; and the fees for assaying are particularly limited.

GOLDSMITH (Oliver), a celebrated English writer, was born at Roscommon in Ireland, in the year 1731. His father, who possessed a small estate in that county, had nine sons, of which Oliver was the third. He was originally intended for the church; and with that view, after being well instructed in the classics, was, with his brother the Rev. Henry Goldsmith, placed in Trinity college, Dublin, about the latter end of the year 1749. In this seminary of learning he continued a few years, when he took a bachelor's degree; but, his brother not being able to obtain any preferment after he left the college, Oliver, by the advice of Dean Goldsmith of Cork, turned his thoughts to the study of physic; and, after attending some courses of anatomy in Dublin, proceeded to Edinburgh in the year 1751, where he studied the several branches of medicine under the different professors in that university. His beneficent disposition soon involved him in unexpected difficulties; and he was obliged precipitately to leave Scotland, in consequence of engaging himself to pay a considerable sum of money for a fellow-student.

A few days after, about the beginning of the year 1754, he arrived at Sunderland, near Newcastle, where he was arrested at the suit of a taylor in Edinburgh, to whom he had given security for his friend. By the good offices of Laughlin MacLaine, Esq; and Dr. Sleight, who were then in the college, he was soon delivered out of the hands of the bailiff; and took his passage on board a Dutch ship to Rotterdam, where, after a short stay, he proceeded to Brussels:

Goldsmith. he then visited great part of Flanders; and after passing some time at Strasbourg and Louvain, where he obtained a degree of bachelor in physic, he accompanied an English gentleman to Berne and Geneva.

It is undoubtedly fact, that this ingenious, unfortunate man, travelled on foot most part of his tour. He had left England with very little money; and, being of a philosophical turn, and at that time possessing a body capable of sustaining every fatigue, and a heart not easily terrified at danger, he became an enthusiast to the design he had formed of seeing the manners of different countries. He had some knowledge of the French language, and of music, and he played tolerably well on the German flute; which, from an amusement, became at some times the means of subsistence. His learning produced him a hospitable reception at most of the religious houses; and his music made him welcome to the peasants of Flanders and other parts of Germany. "Whenever I approached," he used to say, "a peasant's house towards night-fall, I played one of my most merry tunes; and that procured me not only a lodging, but subsistence for the next day: but in truth, (his constant expression), I must own, whenever I attempted to entertain persons of a higher rank, they always thought my performance odious, and never made me any return for my endeavours to please them."

On Mr Goldsmith's arrival at Geneva, he was recommended as a proper person for a travelling tutor to a young man, who had been unexpectedly left a considerable sum of money by his uncle Mr S—, formerly an eminent pawnbroker near Holborn. This youth, who had been articled to an attorney, on receipt of his fortune, determined to see the world; and, on his engaging with his preceptor, made a proviso, that he should be permitted to govern himself; and Goldsmith soon found his pupil understood the art of directing in money-concerns extremely well, as avarice was his prevailing passion. His questions were usually how money might be saved, and which was the least expensive course of travel; whether any thing could be bought that would turn to account when disposed of again in London? Such curiosities on the way as could be seen for nothing he was ready enough to look at; but, if the sight of them was to be paid for, he usually asserted, that he had been told they were not worth seeing. He never paid a bill that he would not observe how amazingly expensive travelling was; and all this, though he was not yet twenty-one. During Goldsmith's continuance in Switzerland, he assiduously cultivated his poetical talent, of which he had given some striking proofs while at the college of Edinburgh. It was here he sent the first sketch of his delightful poem, called the Traveller, to his brother the clergyman in Ireland, who, giving up fame and fortune, had retired, with an amiable wife, to happiness and obscurity, on an income of only 40 l. a year.

From Geneva Mr Goldsmith and his pupil visited the south of France; where the young man, upon some disagreement with his preceptor, paid him the small part of his salary which was due, and embarked at Marseilles for England. Our wanderer was left once more upon the world at large, and passed through a variety of difficulties in traversing the greatest part of

France. At length his curiosity being fatiated, he Goldsmith. bent his course towards England, and arrived at Dover, the beginning of the winter, in the year 1758. When he came to London, his stock of cash did not amount to two livres. An entire stranger in this metropolis, his mind was filled with the most gloomy reflections on his embarrassed situation. With some difficulty he discovered that part of the town in which his old acquaintance Dr Sleight resided. This gentleman received him with the warmest affection, and liberally invited him to share his purse till some establishment could be procured for him. Goldsmith, unwilling to be a burden to his friend, a short time after eagerly embraced an offer which was made him to assist the late Rev. Dr Milner, in instructing the young gentlemen at the academy at Peckham; and acquitted himself greatly to the doctor's satisfaction for a short time: but, having obtained some reputation by the criticisms he had written in the Monthly Review, Mr Griffith, the proprietor, engaged him in the compilation of it; and, resolving to pursue the profession of writing, he returned to London, as the mart where abilities of every kind were sure of meeting distinction and reward. As his finances were by no means in a good state, he determined to adopt a plan of the strictest economy, and took lodgings in an obscure court in the Old Bailey, where he wrote several ingenious little pieces. The late Mr Newberry, who at that time gave great encouragement to men of literary abilities, became a kind of patron to our young author; and introduced him as one of the writers in the Public Ledger, in which his Citizen of the World originally appeared, under the title of "Chinese Letters."

Fortune now seemed to take some notice of a man she had long neglected. The simplicity of his character, the integrity of his heart, and the merit of his productions, made his company very acceptable to a number of respectable families; and he emerged from his shabby apartments in the Old Bailey, to the polished air of the Temple, where he took handsome chambers, and lived in a genteel style. The publication of his Traveller, and his Vicar of Wakefield, was followed by the performance of his comedy of the Good-natured Man at Covent-Garden theatre, and placed him in the first rank of the poets of the present age.

Among many other persons of distinction who were desirous to know him, was the duke of Northumberland; and the circumstance that attended his introduction to that nobleman is worthy of being related, in order to shew a striking trait of his character. "I was invited," said the Doctor (as he was then universally called) "by my friend Mr Piercy, to wait upon the duke, in consequence of the satisfaction he had received from the perusal of one of my productions. I dressed myself in the best manner I could; and, after studying some compliments I thought necessary on such an occasion, proceeded to Northumberland-house, and acquainted the servants that I had particular business with his Grace. They shewed me into an antichamber; where, after waiting some time, a gentleman, very elegantly dressed, made his appearance. Taking him for the duke, I delivered all the fine things I had composed, in order to compliment him on the honour he had done me: when, to my great

great astonishment, he told me, I had mistaken him for his master, who would see me immediately. At that instant, the duke came into the apartment; and I was so confuted on the occasion, that I wanted words, barely sufficient to express the sense I entertained of the duke's politeness, and went away exceedingly chagrined at the blunder I had committed."

Another feature in his character we cannot help laying before the reader. Previous to the publication of his *Deserted Village*, the bookseller had given him a note for one hundred guineas for the copy, which the doctor mentioned, a few hours after, to one of his friends; who observed, it was a very great sum for so short a performance. "In truth," replied Goldsmith, "I think so too; I have not been easy since I received it; therefore I will go back and return him his note;" which he absolutely did, and left it entirely to the bookseller to pay him according to the profits produced by the sale of the piece, which turned out very considerable.

During the last rehearsal of his comedy, intitled, *She stoops to Conquer*, which Mr Coleman had no opinion would succeed, on the Doctor's objecting to the repetition of one of Tony Lumpkin's speeches, being apprehensive it might injure the play, the manager with great keenness replied, "Piha, my dear Doctor, do not be fearful of squibs, when we have been fitting almost these two hours upon a barrel of gunpowder." The piece, however, contrary to Mr Coleman's expectation, was received with uncommon applause by the audience; and Goldsmith's pride was so hurt by the severity of the above observation, that it entirely put an end to his friendship for the gentleman that made it.

Notwithstanding the great success of his pieces, by some of which it is asserted, upon good authority, he cleared 1800*l.* in one year, his circumstances were by no means in a prosperous situation; which was partly owing to the liberality of his disposition, and partly to an unfortunate habit he had contracted of gaming, the arts of which he knew very little of, and consequently became the prey of those who were unprincipled enough to take advantage of his simplicity.

Just before his death he had formed a design for executing an *Universal Dictionary of Arts and Sciences*, the prospectus of which he actually published. In this work several of his literary friends (particularly, Sir Joshua Reynolds, Dr Johnson, Mr Beauclerc, and Mr Garrick) had undertaken to furnish him with articles upon different subjects. He had entertained the most sanguine expectations from the success of it. The undertaking, however, did not meet with that encouragement from the booksellers which he had imagined it would undoubtedly receive; and he used to lament this circumstance almost to the last hour of his existence.

He had been for some years afflicted, at different times, with a violent strangury, which contributed not a little to embitter the latter part of his life; and which, united with the vexations which he suffered upon other occasions, brought on a kind of habitual despondency. In this unhappy condition he was attacked by a nervous fever, which, being improperly treated, terminated in his dissolution on the 4th of April 1774. His remains were privately deposited

in the Temple burial-ground.

As to his character, it is strongly illustrated by Mr Pope's line,

In wit a man, simplicity a child.

The learned leisure he loved to enjoy was too often interrupted by distresses which arose from the liberality of his temper, and which sometimes threw him into loud fits of passion: but this impetuosity was corrected upon a moment's reflection; and his servants have been known, upon these occasions, purposely to throw themselves in his way, that they might profit by it immediately after; for he who had the good fortune to be reproved, was certain of being rewarded for it. The universal esteem in which his poems were held, and the repeated pleasure they give in the perusal, is a striking test of their merit. He was a studious and correct observer of nature; happy in the selection of his images, in the choice of his subjects, and in the harmony of his versification; and, though his embarrassed situation prevented him from putting the last hand to many of his productions. His *Hermit*, his *Traveller*, and his *Deserted Village*, bid fair to claim a place among the most finished pieces in the English language.

Besides the works already mentioned, he wrote, 1. *History of the earth and animated nature*, 6 vols 8vo. 2. *History of England*, 4 vols 8vo. 3. *History of Rome*, 2 vols. 4. *Abridgements of the two last*, for the use of schools. 5. A view of experimental philosophy, 3 vols 8vo.; a posthumous work, not esteemed. 6. *Miscellanies*, &c.

GOLIUS (James), a celebrated professor of Arabic and the mathematics at Leyden, was descended from a very honourable family, and born at the Hague in the year 1596. He was put to the university of Leyden, where he studied under Erpinus; and having made himself master of all the learned languages, applied himself to the mathematics, physics, and divinity. He afterwards travelled into Africa and Asia; and became greatly esteemed by the king of Morocco, and the sultan of the Turks. He at length returned to Leyden, laden with manuscripts; and in 1624, succeeded Erpenius in the Arabic chair. As he had been an eye-witness of the wretched state of Christianity in the Mahometan countries, he was filled with the compassion of a fellow-Christian; and none ever solicited for a place of honour and profit with greater eagerness, than he for procuring a new edition of the New Testament, in the original language, with a translation into the vulgar Greek, by an Archimandrite; and as there are some of these Christians, who use the Arabic tongue in divine service, he also took care to have dispersed among them an Arabic translation of the Confession of the Protestants, together with the Catechism and Liturgy. In 1626, he was also chosen professor of mathematics; and discharged the functions of both professorships, with the greatest applause, during 40 years. He was likewise appointed interpreter in ordinary to the states for the Arabic, Turkish, Persian, and other eastern languages, for which he had an annual pension, and a present of a gold chain, with a very beautiful medal, which he wore as a badge of his office. He published, 1. *The life of Tamerlane*, written in Arabic. 2. *The history of the Saracens*, written by Elmacin. 3. *Alferganus's*

Goltzius
Gombroon

elements of astronomy, with a new version and learned commentaries. 4. An excellent Arabic lexicon. 5. A Persian Dictionary. He died in 1667.

GOLTZIUS (Henry), a famous engraver and painter, born in 1558, at Mulbreck, in the duchy of Juliers. His ill health induced him to travel; and to prevent his being known, he took the name of his man-servant, maintained by him for his skill in painting; by which stratagem he enjoyed the pleasure of hearing what was said of his works, without being known. Travelling restored his health for a while; but he relapsed, and died at Harlem in 1617. Mr Evelyn has given a strong testimony of his merit as an Engraver. As his works are very numerous, his execution must have been remarkably ready.

GOLTZIUS (Hubert), a learned German, born at Venlo in the duchy of Gueldres in 1526. His father was a painter, and himself was bred to the art under Lambert Lombard; but he did little at painting, or at least his pictures are very scarce; for having a peculiar turn to antiquities, he devoted himself to the study of medals. He travelled through Germany, France, and Italy, to make collections, as well as to draw from thence all the lights he could towards clearing up ancient history: he was the author of several excellent works, in which he was so accurate and nice, that he had them printed at his own house, under his own correction, and even engraved the plates and medals with his own hand. His veneration for Roman antiquities was so great, that he gave all his children Roman names; and married, for his second wife, the widow of the antiquarian Martinus Smetius; probably more for the sake of Smetius's medals and inscriptions, than for his own sake; and was punished accordingly by her plaguing him all his life, if he did not shorten it. He died in 1583.

GOMBAULD (John Ogier de), one of the best French poets in the 17th century, and one of the first members of the French academy, was born at St. Just de Lussac. He acquired the esteem of Mary de Medicis, and of the wits of his time. He was a Protestant, and died in a very advanced age. He wrote many works in verse and prose. His epigrams, and some of his sonnets, are particularly esteemed.

GOMBROON, by the natives called *Bander Abassi*, a city of Persia, situated in N. Lat. 27. 40. E. Long. 55. 30. The name of *Gombroon*, or *Comerong*, Captain Hamilton tells us, it had from the Portuguese; because it was remarkable for the number of prawns and shrimps caught on its coasts, by them called *comerong*. This city owes its wealth and grandeur to the demolition of Ormus, and the downfall of the Portuguese empire in the East-Indies. It is now justly accounted one of the greatest marts in the East, was built by the great shah Abas, and from him, as some think, obtained the name of *Bander-Abassi*, which signifies the court of Abas. It stands on a bay about nine leagues to the northward of the east end of the island of Kishmish, and three leagues from the famous Ormus. The English began to settle here about the year 1631, when, in consideration of their services against the Portuguese, shah Abas granted them half the customs of that port. This was confirmed by a phirmaund, and duly regarded, till the English began to neglect the services they had stipulated. Whether

the company has any emolument from the customs, at present, is what we cannot pretend to ascertain. The town is large, but its situation bad; wanting almost every thing that contributes to the happiness, and even support of life. Towards the land it is encompassed by a fort of wall; and towards the sea several small forts, with a platform, and a castle or citadel, mounted with cannon to secure it and the road from the attempts of an enemy by sea. The houses in most of the streets are so out of repair, some half down, others in a heap of rubbish, that a stranger would imagine the town had been sacked and ravaged by a barbarous people; not a vestige of the wealth really contained in the place appearing in view. The bazars and shops round them, are kept, for the most part, by Danians, whose houses are generally in good order. Most of the houses are built with earth and lime, but some of the best with stone. Many of them have a fort of ventilators at top, which contribute greatly to the health of the inhabitants in the hot seasons of the year. The most sickly months here are April, May, September, and October. With fish and mutton the inhabitants are well supplied. Rice is imported from India; and wheat is so plenty, that the poor subsist chiefly on bread and dates. The country hereabouts abounds in the most delicious fruits, as apricots, peaches, pomegranates, pears, mangoes, grapes, quavas, plumbs, sweet quinces, and water-melons. The apricots, however, are small, and extremely dangerous if eaten to excess.

Those conveniences are more than overbalanced by the scarcity of fresh water, with which the inhabitants are supplied from Affeen, a place seven miles distant, there not being a spring or well in the town. Persons of condition keep a camel constantly employed in bringing fresh and wholesome water. Captain Hamilton gives it as his opinion, that one cause of the unwholesomeness of this city is the reflection of the rays of light from a high mountain to the north of it. He says, that when the beams are reflected from this mountain, they almost fire the air, and, for two or three months in the year, render the situation intolerable. For this reason the people of condition retire into the country, to pass the heats of June, July, and August. The very fea, during this season, is affected, inasmuch that the stench is no less disagreeable than that of putrid carcases; and this is increased by the quantities of shell-fish left on the shore, from which an exhalation arises that taints gold and silver, and is less tolerable than the bilge-water of a tight ship. At Affeen the English factory have a country-house and gardens, to which they retire occasionally. Here they have whole groves of Seville orange-trees, which, though not natural to the country, thrive very well, and are always verdant, bearing ripe and green fruit, with blossoms, all at the same time. They have likewise tanks and ponds of fine fresh water, with every thing else that can moderate the heat of the climate, and render life agreeable and elegant. About ten miles from Affeen is a place called *Minoa*, where are cold and hot natural baths, reckoned infallible in the cure of all scrophulous disorders, rheumatisms, and other diseases, by bathing.

Gombroon is extremely populous, on account of the commerce carried on by the Dutch and English factories,

Gombroon

Gomera
Gomphrena.
na.

factories, as well as the natives. The English factory is close by the sea, at some distance from the Dutch, which is a commodious and fine new building. A great part of the company's profit arises from freights. As the natives have not one good ship of their own, and are extremely ignorant of navigation, they freight their goods for Surat, and other Indian marts, in English and Dutch bottoms, at an exorbitant rate. The commodities of the Gombroon market are, fine wines of different kinds, raisins, almonds, kish-mishes, prunellas, dates, pistachio-nuts, ginger, filks, carpets, leather, tutty, galbanum, ammoniac, alafatida, tracaganth, with other gums, and a variety of shop medicines. There are in a great measure the produce of Carmania, which they bring to Gombroon in caravans. The English company had once a small factory in the province of Carmania, chiefly for the sake of a fine wool produced there, and used by the hatters. The said company had once a project of carrying a breed of the Persian goats to St Helena; but whether it was executed, or what success it met with, we cannot say. Although the company pay no customs, yet they usually make a present to the shabander, to avoid the trouble he has it in his power to give them. All private traders with the company's palles, enjoy the same privileges, on paying two *per cent.* to the company, one to the agent, and one to the broker. All private trade, either by European or country ships, has long been engrossed by the company's servants.

GOMERA, one of Canary islands lying between Ferro and Teneriffe. It has one good town of the same name, with an excellent harbour, where the Spanish fleet often take in refreshments. They have corn sufficient to supply the inhabitants, with one sugar-work, and great plenty of wine and fruits. It is subject to the Spaniards, who conquered it in 1445. W. Long. 17. 10. N. Lat. 28. 0.

GOMORRAH, (anc. geog.) one of the cities of the plain or of the vale of Siddim in Judæa, destroyed together with Sodom by fire from heaven, on account of the wickedness of the people. To determine its particular situation at present, is impossible.

GOMORRO islands. See COMORA.

GOMPHOSIS, in anatomy, that kind of articulation by which the teeth are fixed in the jaw-bone. See ANATOMY, n° 2. c.

GOMPHRENA, GLORE AMARANTH, a genus of the digynia order, belonging to the pentandria class of plants. There are seven species; but only one of them is commonly cultivated in our gardens, viz. the globosa. It hath an upright stalk branching all round, two or three feet high, garnished with oval, lanceolate, and opposite leaves; and every branch and side-shoot terminated by a close globular head of flowers, composed of numerous, very small starchy florets closely covered with dry scaly calices placed *imbricatum*, persistent, and beautifully coloured purple, white, red, or striped and variegated. The flowers themselves are so small, and closely covered with the scaly calices, that they scarcely appear. The numerous closely placed scaly coverings being of a dry, firm, consistence, coloured and glittering, collected into a compact round head, about the size of an ordinary cherry, make a fine appearance. They are annual plants,

natives of India; and require artificial heat to raise and forward them to a proper growth, so that they may flower in perfection, and produce ripe seed. They flower from June to November; and if the flowers are gathered when at full growth, and placed out of the sun, they will retain their beauty several months.

GONDI (John Francis Paul), cardinal de Retz, was the son of Philip Emmanuel de Gondi, count de Joigny, lieutenant-general, &c. and was born in 1613. From a doctor of the Sorbonne, he first became coadjutor to his uncle John Francis de Gondi, whom he succeeded in 1654 as archbishop of Paris; and was finally made a cardinal. This extraordinary person has drawn his own character in his memoirs with impartiality. He was a man who, from the greatest degree of debauchery, and still languishing under its consequences, made himself adored by the people as a preacher. At the age of 23, he was at the head of a conspiracy against the life of cardinal Richelieu; he precipitated the parliament into cabals, and the people into sedition: he was, says M. Voltaire, the first bishop who carried on a civil war without the mask of religion. However, his intrigues and schemes turned out so ill, that he was obliged to quit France; and he lived the life of a vagrant exile for five or six years, till the death of his great enemy cardinal Mazarin, when he returned on certain stipulated conditions. After assisting in the conclave at Rome, which chose Clement IX. he retired from the world, and ended his life like a philosopher in 1679; which made Voltaire say, that in his youth he lived like Catiline, and like Atticus in his old age. He wrote his Memoirs in his retirement; the best edition of which is that of Amsterdam, 4 vols. 12mo. 1719.

GONORRHÆA, an effluvia of white, greenish, or differently-coloured matter from the urethra; most commonly owing to venereal infection. See (Index subjoined to) MEDICINE, and SURGERY.

GONZAGA (Lucretia), was one of the most illustrious ladies of the 16th century; and much celebrated for her wit, her learning, and her delicate style. Hortensio Lando wrote a beautiful panegyric upon her, and dedicated to her his dialogue of moderating the passions. Her beautiful letters have been collected with the greatest care. We learn from these, that her marriage with John Paul Manfrone was unhappy.—She was married to him when he was not 14 years of age, and his conduct afterwards gave her infinite uneasiness. He engaged in a conspiracy against the duke of Ferrara; was detected and imprisoned by him; but, though condemned by the judges, not put to death. She did all in her power to obtain his enlargement, but in vain; for he died in prison, having shewn such impatience under his misfortunes, as made it imagined he had lost his senses. She never would listen afterwards to any proposals of marriage, though several were made to her. All that came from her pen was so much esteemed, that a collection was made even of the notes she writ to her servants; several of which are to be met with in the edition of her letters.

GONDOLA, a sort of barge curiously ornamented, and navigated on the canals of Venice; also a passage-boat, of six or eight oars, in other parts of the coasts of Italy.

Gondi
Gondola.

Good.

GOOD, in general, whatever is apt to increase pleasure, or diminish pain in us; or, which amounts to the same, whatever is able to procure or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

Moral Good denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations. See **MORALS**.

Good Abearing, (*bonus gestus*), signifies an exact carriage or behaviour of a subject towards the king and the people, whereunto some persons upon their misbehaviour are bound: and he that is bound to this, is said to be more strictly bound than to the peace; because where the peace is not broken, the surety *de bono gestu* may be forfeited by the number of a man's company, or by their weapons.

Good Behaviour, in law, an exact carriage and behaviour to the king and his people.

A justice of the peace may, at the request of another, or where he himself sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any persons whatsoever, under the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's-bench, where such nobleman may be bound to keep the peace. Infants and feme-coverts, who ought to find surety by their friends, may be bound over to their good behaviour; as also lunatics, that have sometimes lucid intervals, and all others who break the peace, or being suspected to do it, by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. A person may be likewise bound to his good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whoremongers, common whores, cheats, libellers, &c. He who demands surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

Good-Friday, a fast of the Christian church, in memory of the sufferings and death of Jesus Christ. It is observed on the Friday in *holy or passion week*; and it is called, by way of eminence, *good*, because of the blessed effects of our Saviour's sufferings, which were a propitiatory or expiating sacrifice for the sins of the world. The commemoration of our Saviour's sufferings has been kept from the very first ages of Christianity, and was always observed as a day of the strictest fasting and humiliation. Among the Saxons it was called *Long-Friday*; but for what reason, except on account of the long fastings and offices then used, is uncertain. On Good-Friday the Pope sits on a plain form; and, after service is ended, when the cardinals wait on him back to his chamber, they are obliged to keep a deep silence, as a testimony of their sorrow. In the night of Good-Friday, the Greeks perform the obsequies of our Saviour round a great crucifix, laid on a bed of state, adorned with flowers: these the bishops distribute among the assistants, when the office is ended. The Armenians, on this day, set open a holy sepulchre, in imitation of that of mount Calvary.

Good-Hope, or *Cape of Good-Hope*, the most south-

erly promontory of Africa, where the Dutch have built a good town and fort. It is situated in the country of the Hottentots. See **HOTTENTOTS**.

Good Manners. See **MANNERS**.

GOOSE, in ornithology. See **ANAS**.

GOOSE-Andery, in ornithology. See **MERCUS**.

GOOSE-Berry, in botany. See **RIBES**.

GOOSE-Neck, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whip-staff or the wheel-rope comes, for steering the ship.

GOOSE-Wing, in the sea-language. When a ship fails before, or with a quarter-wind on a fresh gale, to make the more haste, they lanch out a boom, and sail on the lee-side; and a sail so fitted, is called a *goose-wing*.

GORCUM, a town of the United Provinces, in South Holland, which carries on a considerable trade in cheese and butter. It is situated on the rivers Lingne and Maeße, in E. Lon. 4. 55. N. Lat. 51. 49.

GORDIANUS I. (Roman general,) was for his valour and virtues, chosen emperor by the army in the reign of Maximinus, A. D. 237; but his son, whom he had associated with himself in the throne, being slain by Capellian, the governor of Mauritania for Maximinus, Gordianus killed himself the same year. See **ROME**.

GORDIANUS III. (grandson of the former), a renowned warrior, and styled *The guardian of the Roman commonwealth*. He was treacherously assassinated by Philippus, an Arabian, one of his generals; who, to the eternal disgrace of the Romans of that æra, succeeded him in the empire, A. D. 244. See **ROME**.

GORDIAN-Knot, in antiquity, a knot made in the leathers or harness of the chariot of Gordius king of Phrygia, so very intricate, that there was no finding where it began or ended. The inhabitants had a tradition, that the oracle had declared, that he who untied this knot should be master of Asia. Alexander having undertaken it, was unable to accomplish it; when fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

GORDIUS, the HAIR-WORM, a genus of insects belonging to the class of *vermes intestina*. There are two species, 1. The aquaticus, with a silflim body, of equal thickness, and smooth. It hath a pale colour, with both the ends black; and inhabits boggy places, and clay at the bottom of water. 2. The argillaceus is of an uniform yellow colour, twisted spirally, and lying flat. It is common in the intestines of herring, and other sea-fish. Aristotle remarks, that the ballerus and tillo are infested in the dog-days with a worm that torments them so much, that they rise to the top of the water, where the heat destroys them. To these worms also may probably be owing the agonies to which the bleaks are at certain times subject. See **CYPRINUS**.

GORDIUS, king of Phrygia, and father of Midas, was a poor husbandman, with two yokes of oxen, where-with he ploughed his land and drew his wain. An eagle sitting a long while upon one of his oxen, he consulted the soothsayers; a virgin bid him sacrifice

to

Goose

Gordius.

Jacob's
Law Dist.

Gordon
||
Gorget.

to Jupiter in the capacity of king. He married the virgin, who brought forth Midas. The Persians instructed by the oracle to fet the first person they met in a wain upon the throne, met Gordius, and made him king. Midas for this good fortune dedicated to Jupiter his father's cart. The knot of the yoke, they say, was so well twisted, that he who could unloose it was promised the empire of Asia; hence the proverb of *the Gordian knot* had its origin. See GORDIAN Knot.

GORDON (Thomas) noted for his translations and political writings, was born at Kirkcudbright in North-Britain. He came young to London; where he supported himself by teaching languages, until he procured employment under the earl of Oxford in queen Anne's time, but in what capacity is not now known. He first distinguished himself in the defence of Dr Hoadley in the Bangorian controversy; which recommended him to Mr Trenchard, in conjunction with whom he wrote the well-known *Cato's Letters*, upon a variety of important public subjects. These were followed by another periodical paper, under the title of *The Independent Whig*; which was continued some years after Mr Trenchard's death, by Gordon alone, against the hierarchy of the church; but with more acrimony than was shewn in *Cato's Letters*. At length Sir Robert Walpole retained him to defend his administration, to which end he wrote several pamphlets; and died first commissioner of the wine-licences in 1750. There are two other collections of tracts of his writing, *The cordial for low spirits*, and *The pillars of priesthood and orthodoxy spoken*. In his translations of *Sally's* and other works, he places the verbs at the ends of sentences, according to the Latin idiom, in a very stiff and affected manner.

GORE, in heraldry, one of the abatements, which, according to Gullim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point. See HERALDRY.

GOREE, a small island of Africa, near Cape de Verd, subject to the French. It is barren, but of great importance on account of its good trade. It was taken by the English in May 1759, and given up by the treaty of peace in 1763. E. Long. 12. 25. N. Lat. 14. 30.

GOREE, the capital town of an island of the same name in Holland, eight miles South of Briel. E. Long. 3. 50. N. Lat. 51. 55.

GORGE, in architecture, the narrowest part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar, and the annulets.

GORGE, in fortification, the entrance of the platform of any work. See FORTIFICATION.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is *gorged* with a dual coronet, &c.

Gorged is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGET, a kind of breast-plate like a half moon, with the arms of the prince thereon; worn by the officers of foot. They are to be either gilt or silver, ac-

cording to the colour of the buttons on the uniforms.

GORGONS, in antiquity. Authors are not agreed in the accounts they give of the Gorgons. Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women who inhabited that part of Libya which lay on the lake Tritonidis. We may well imagine, says that author, that they had frequent quarrels together; as being women and neighbours. He goes on to give an account of a most bloody engagement between them, wherein the Amazons had the better; three thousand of the Gorgons being made prisoners, and the rest obliged to take shelter in a wood, to which the Amazons set fire, with an intention to destroy the whole nation of Gorgons; but as the wind did not prove favourable, they were obliged to desist, and retire to their own territories. Here the Amazons, intoxicated with their victory, gave themselves up to feasting and mirth; and as the guard was very negligently kept in the night-time, the 3000 prisoners laid hold of the opportunity, and, seizing the swords of these imprudent females, massacred a great number of them; but were themselves at last overpowered and cut to pieces. Myrine, the queen of the Amazons, caused monuments to be erected to her female warriors who had been slain on this occasion; which monuments were still to be seen, says our author, in his days. These female nations are said to have been exterminated by Hercules.

Pausanias's account of the Gorgons is much to the same purpose. They were, says he, the daughters of Phorbus; after whose death one of them, named *Medusa*, reigned over the people dwelling near the lake Tritonidis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on the Gorgons, and killed the queen herself, when he came to take a view of the field of battle, he found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried home with him to shew to his countrymen the Greeks, who could not behold it without astonishment.

These accounts appear somewhat credible; but others represent the Gorgons in a very incredible manner, making them to be a kind of monstrous women, all covered over with hair, who lived in woods and forests. Others again, make them a kind of animal resembling a sheep, with such long hair on their faces, that it required their utmost efforts to clear it away before they could see any thing; but when once they had effected this, they killed all they saw with the poisonous influence of their eyes.

GORGONA, a small island of Italy, in the sea of Tuscany, and near that of Corsica, about eight miles in circumference; remarkable for the large quantity of anchovies taken near it. E. Long. 10. 0. N. Lat. 43. 22.

GORGONA, a small island of the South Sea, 12 miles West of the coast of Peru, in America. It is indifferent high land, very woody, and some of the trees are very tall and large, and proper for masts. It is about 10 miles in circumference, and has several springs and rivulets of excellent water, but is subject to constant rains. W. Long. 79. 3. S. Lat. 3. 30.

GORITIA, or GORITZ, a strong town of Germany, in the circle of Austria, and duchy of Carniola, with

Gorgons
||
Goritia.

with a castle; seated on the river Lizonzo, 20 miles north-east of Aquileia, and 70 north-east of Venice. E. Long. 13. 43. N. Lat. 46. 12.

GORLITZ, a town of Germany, in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Niesse, in E. Long. 15. 15. N. Lat. 51. 10.

GOSHAWK. See **FALCO**.

GOSLAR, a large and ancient town of Lower Saxony, and in the territory of Brunswick; it is a free imperial city, and it was here that gun-powder was first invented, by a monk as is generally supposed. It is a large place, but the buildings are in the ancient taste. In 1728, 280 houses, and St Stephen's fine church, were reduced to ashes. It is seated on a mountain, near the river Gose, and near it are rich mines of iron. The inhabitants are famous for brewing excellent beer. E. Long. 3. 37. N. Lat. 51. 55.

GOSPEL, the history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.

The word is Saxon, and of the same import with the Latin term *evangelium*, which signifies glad tidings, or good news.

This history is contained in the writings of St Matthew, St Mark, St Luke, and St John; who from thence are called *evangelists*. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSSYPIMUM, or **COTTON**, a genus of the polyandria order belonging to the monodelphia class of plants. There are four species, all of them natives of warm climates. 1. The herbaceous, or common herbaceous cotton, hath an herbaceous smooth stalk two feet high, branching upwards; five-lobed smooth leaves; and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton. 2. The hirsutum, or hairy American cotton, hath hairy stalks branching laterally two or three feet high; palmated, three and five lobed hairy leaves; and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 3. The barbadense, or Barbadoes shrubby cotton, hath a shrubby stalk branching four or five feet high, three-lobed smooth leaves, glandulous underneath; and yellow flowers succeeded by oval pods, containing seeds and cotton. 4. The arboreum, or tree-cotton, hath an upright woody perennial stalk, branching six or eight feet high; palmated, four or five lobed smooth leaves; and yellow flowers, succeeded by large pods filled with seeds and cotton.

The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. When these plants are raised in this country, they must be continually kept in a warm stove, where they will produce seeds and cotton. They are propagated by seeds. See **COTTON**.

The American Islands produce cotton shrubs of various sizes, which rise and grow up without any culture; especially in low and marshy grounds. Their

produce is of a pale red; some paler than others; but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making of hats. The little that is picked up, serves to make mattresses and pillows.

The cotton-shrub that supplies our manufactures, requires a dry and stony soil, and thrives best in grounds that have already been tilled. Not but that the plant appears more flourishing in fresh lands than in those which are exhausted; but, while it produces more wood, it bears less fruit.

A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and, if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the prospect of an advantage that will compensate the trouble.

This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth; but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being discoloured and spotted.

When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill; which is an engine, composed of two rods of hard wood, about 18 feet long, 18 lines in circumference, and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the seed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the seed contained in it.

GOTHA, a town of Germany, in the circle of Upper Saxony, and capital of a duchy of the same name. It is 15 miles west of Erford, and 15 south-east of Mulhausen. E. Long. 11. 0. N. Lat. 52. 25.

GOTHARD, one of the highest mountains of Switzerland; and from the top, where there is an hospital for monks, is one of the finest prospects in the world. It is eight miles from Aldorf.

GOTHIC, in general, whatever has any relation to the Goths; thus, we say, Gothic customs, Gothic architecture, &c.

GOTHLAND, the most southern province of Sweden, being a peninsula, encompassed on three sides by the Baltic Sea, or the channel at the entrance of it. It is divided into several parts, which are East Gothland, West Gothland, Smaland, Halland, Blekinge, and Schonen. It was a long time in the possession of the kings of Denmark, but was ceded to Sweden in 1654. The principal towns of Gothland are Calmar, Landskron,

fcröon, Christianople, Daleburg, Gothenburg, Helmat, Lunden, Malmone, and Vexio.

GOTHS, a warlike nation, and above all others famous in the Roman history, came originally out of Scandinavia, (the name by which the ancients distinguished the present countries of Sweden, Norway, Lapland, and Finmark.) According to the most probable accounts, they were the first inhabitants of those countries; and from thence sent colonies into the islands of the Baltic, the Cimbrian Cherfoneus, and the adjacent places yet destitute of inhabitants. The time of their first settling in Scandinavia, and the time when they first peopled with their colonies the abovementioned islands and Cherfoneus, are equally uncertain; though the Gothic annals suppose the latter to have happened in the time of Serug the great-grandfather of Abraham. This first migration of the Goths is said to have been conducted by their king Eric; in which all the ancient Gothic chronicles, as well as the Danish and Swedish ones, agree. Their second migration is supposed to have happened many ages after; when, the abovementioned countries being overstocked with people, Berig, at that time king of the Goths, went out with a fleet in quest of new settlements. He landed in the country of the Ulmerugians, now Pomerania, drove out the ancient inhabitants, and divided their lands among his followers. He fell next upon the Vandals, whose country bordered on that of the Ulmerugians, and overcame them; but instead of forcing them to abandon their country, he only made them share the possessions with the Goths.

The Goths who had settled in Pomerania and the adjacent parts of Germany being greatly increased, inasmuch that the country could no longer contain them, they undertook a third migration in great numbers, under Filimer surnamed the Great, their fifth prince after leaving Scandinavia; and taking their route eastward, entered Scythia, advanced to the Cimmerian Bosphorus, and, driving out the Cimmerians, settled in the neighbourhood of the Palus Meotitis. Thence in process of time, being greatly increased in Scythia, they resolved to seek new settlements; and accordingly, taking their route eastward, they traversed several countries, and at length returned into Germany.

Their leader in this expedition was the celebrated Woden, called also *Voden, Othen, Oden, Godan*, and *Guadan*. Of this Woden many wonderful things are related in the Sæco-gothic chronicles. He was king of the Afgardians, whom the northern writers will have to be the same with a people called *Aspurgians* mentioned by Strabo and Ptolemy. By Strabo they are placed near the Cimmerian Bosphorus. Aspurgia was the metropolis of a province which Strabo calls *Asia*; and Woden and his followers are styled by the ancient Gothic writers *Aise, Aisane*, and *Aisote*. The kings of Aspurgia were masters of all that part of Scythia which lay to the westward of Imaus, and was by the Latins called *Scythia intra Imaum*, or "Scythia within Imaus."

At what time Woden reigned in this country, is quite uncertain; but all historians agree, that he went out in quest of new settlements with incredible numbers of people following him. He first entered Roxolania, comprehending the countries of Prussia, Livonia, and great part of Muscovy. From thence he went

Vol. V.

by sea into the north parts of Germany; and having reduced Saxony and Jutland, he at last settled in Sweden, where he reigned till his death, and became so famous that his name reached all countries, and he was by the northern nations worshipped as a god. He is supposed to have brought with him the Runic characters out of Asia, and to have taught the northern nations the art of poetry; whence he is styled the father of the Scaldi or Scaldri, their poets, who described in verse the exploits of the great men of their nation, as the bards did among the Gauls and Britons.

The Romans distinguished the Goths into two classes; the Ostrogoths and Visigoths. These names they received before they left Scandinavia, the *Visigoths* being softened by the Latins from *Westerogothi*, or those who inhabited the Western part of Scandinavia, as the Ostrogoths were those who inhabited the eastern part of that country. Their history affords nothing of moment till the time of their quarrelling with the Romans; which happened under the reign of the emperor Caracalla, son to Severus. After that time their history becomes so closely interwoven with that of the Romans, that for the most remarkable particulars of it we must refer to the article *ROME*. After the destruction of the Roman empire by the Heruli, the Ostrogoths, under their king Theodoric, became masters of the greatest part of Italy, having overcome and put to death Odoacer king of the Heruli in 494. They retained their dominion in this country till the year 553; when they were finally conquered by Narfes, the emperor Justinian's general. See (History of) *ITALY*. The Visigoths settled in Spain in the time of the emperor Honorius, where they founded a kingdom which continued till the country was subdued by the Saracens; for a particular account of all which, see the article *SPAIN*.

The Goths were famous for their hospitality and kindness to strangers, even before they embraced the Christian religion. Nay, it is said, that from their being eminently good, they were called *Gothi* by the neighbouring nations; that name, according to Grotius and most other writers, being derived from the German word *guten*, which signifies "good." They encouraged, says Dio, the study of philosophy above all other barbarous or foreign nations, and often chose kings from among their philosophers. Polygamy was not only allowed but countenanced among them; every one being valued or respected according to the number of his wives. By so many wives they had an incredible number of children, of whom they kept but one at home, sending out the rest in quest of new settlements; and hence those swarms of people which overran so many countries. With them adultery was a capital crime, and irremissibly punished with death. This severity, and likewise polygamy, prevailed among them when they were known to the Romans only by the name of *Geter*, (their most ancient name); as appears from the poet Menander, who was himself one of that nation; and from Horace, who greatly commends the chastity of their women. Their laws fell little short of those of the ancient Romans. Their government was monarchical; their religion was much the same with that of the ancient Germans or Celtes; and their dress is described by Apollinaris Sidonius in the following words: "They are shod (says he) with high

19 F

shoes

Gothofred
Gottenburg

Gottorp
Gourgues.

shoes made of hair, and reaching up to their ankles; their knees, thighs, and legs, are without any covering; their garments of various colours scarce reaching to the knee; their sleeves only cover the top of their arms; they wear green cassocks with a red border; their belts hang on their shoulder; their ears are covered with twisted locks, they use hooked lances and missile weapons."

GOTTHOFRED, or **GODFREY**, (Denis or Dionysius) an eminent civil lawyer, born of an illustrious house at Paris, in 1549. Finding his country involved in the confusion of the leaguers, he accepted of a professor's chair at Geneva, until he was patronized and employed by Henry IV.; but being afterward stripped of his employments as a huguenot, he at length retired to Heidelberg, from whence no offers were able to detach him. He was, however, disappointed of his intention to end his days there; for the disturbances that broke out in the Palatinate obliged him, in 1621, to take refuge in Straßburg, where he died the following year. He wrote a great number of books; but his principal work is the *Corpus Juris Civilis cum notis*.

GOTTHOFRED (Thodore), son of the former, was born at Geneva, in 1580. As soon as he had finished his studies, he went to Paris; where he conformed to the Romish religion, and applied with indefatigable industry to the study of history, that of France particularly, wherein he became very eminent, as appears by his works. In 1632, the king made him one of his historiographers, with a stipend of 3000 livres; and, in 1636, he was sent to Cologne, to assist at the treaty of peace negotiating there, on the part of France, by the cardinal of Lyons. This treaty being removed to Munster, Gothofred was sent thither, where he drew up Memoirs on the subject; and continued in that city, in the king's service, to his death in 1649. His principal work is his *Account of the Ceremonial of the kings of France*.

GOTTHOFRED (James), brother of the preceding, was born at Geneva, in 1587. Applying himself to the study of the law, he obtained the professor's chair there, was made counsellor of the city, and was several times employed in France, Germany, Piedmont, and Switzerland, to negotiate their affairs in the name of the republic. He died in 1562; and his chief work is his *Codex Theodosianus, cum perpetuis commentariis, &c.*

GOTTHOFRED (Denis), son of Theodore above mentioned, was born at Paris, in 1615. He studied history, after his father's example; became as eminent in that department of knowledge; and obtained the reversion of his father's place of historiographer royal, from Lewis XIII. when he was but 25 years of age. He published his father's *Ceremonial of France*; finished his *Memoirs of Philip de Commines*; and was preparing a *History of Charles VIII.* when he died in 1681. It was published by his eldest son, Denis, in 1684.

GOTTENBURG, a rich and strong town of West Gothland, in Sweden, with a good harbour, at the mouth of the river Gothebä; which is the best situated for foreign trade of any in Sweden, as it lies without the sound. E. Lon. 11. 50. N. Lat. 57. 44.

GOTTINGEN, a considerable town of Lower

Saxony, in Germany, and in the duchy of Brunswick; formerly free and imperial, but now subject to the elector of Hanover. Here his late Majesty, George II. founded an university. It is seated on the river Leine, in E. Lon. 10. 5. N. Lat. 51. 32.

GOTTORP, a town of the duchy of Hefwick, in Denmark, and capital of the duchy of Holstein Gottorp, where the duke has a very fine palace.

GOUDA, or **TURGOW**, a considerable town of South Holland, in the United Provinces, remarkable for its stately church. It is seated on the river IJssel, in E. Lon. 4. 37. N. Lat. 52. 2.

GOVERNMENT, in general, is the polity of a state, or an orderly power constituted for the public good.

Civil government was instituted for the preservation and advancement of mens civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some sort of civil authority: but as men are seldom unanimous in the means of attaining their ends, so their differences of opinion in relation to government has produced a variety of forms of it. To enumerate them, would be to recapitulate the history of the whole earth. But, according to Montesquieu, and most other writers, they may in general be reduced to one of these three kinds. 1. The republican. 2. The monarchical. 3. The despotic.—The first is that, where the people in a body, or only a part of the people, have the sovereign power: the second, where one alone governs, but by fixed and established laws: but, in the despotic government, one person alone, without law and without rule, directs every thing by his own will and caprice. See the article *LAW*, n^o 1. 3.—10.—On the subject of government at large, see Montesquieu's *L'Esprit des Loix*, l. 2. c. 1.; Locke, ii. 129, &c. quarto edition, 1768; Sidney on Government; Sir Thomas Smith *de Repub. Angl.*; and Acherly's *Britannic Constitution*.—As to the Gothic government, its original and faults, &c. see Montesquieu's *L'Esprit des Loix*, l. 11. c. 8.—With respect to the feudal policy, how it limited government; see *FEUDAL System*.

GOVERNMENT is also a post or office, which gives a person the power or right to rule over a place a city, or a province, either supremely, or by deputation.

GOVERNMENT is likewise used for the city, country, or place to which the power of governing is extended.

GOULART (Simon), a famous minister of Geneva, was born at Senlis, in 1543; and was one of the most indefatigable writers of his time. He made considerable additions to the Catalogue of witnesses of the truth, composed by Illyricus; and acquired a great reputation by his works, the principal of which are, 1. A translation of Seneca. 2. A collection of memorable histories. 3. A translation of St Cyprian *De lapsis*. 4. Several devotional and moral treatises. He died at Geneva in 1628.

GOURD, in botany. See *CUCURBITA*.

GOURGUES (Dominique de), an illustrious French patriot, a private gentleman of Gascony. The Spaniards having inhumanly massacred a colony of Frenchmen who had settled in Florida, Gourgues took a severe revenge on them, an account of which is gi-

Gournay
Gown.

ven under the article FLORIDA. On his return, he was received with acclamations by his countrymen, but was forbid to appear at court. Queen Elizabeth invited him to command an English fleet against the Spaniards, in 1593; but he died at Tours, in his way to England.

GOURNAY, a town of France, in the duchy of Normandy and territory of Bray, celebrated for its butter-market. It is seated on the river Epte, in E. Lon. o. 33. N. Lat. 49. 25.

GOURNAY (Mary de Jars de), a lady celebrated for her learning, was the daughter of William de Jars, lord of Neuvi and Gournay. After the death of her father, she was protected by Montaigne and Cardinal Richlieu. To the daughter of the former she dedicated her *Nofegay of Pindus*; and composed several other works, the most considerable of which is *Les Avis*. She died at Paris in 1685, aged 80. The critics are divided concerning the reputation of this lady: by some she is styled the *Syren of France*; others say her works should have been buried with her.

GOUT. See (Index subjoined to) MEDICINE.

GOWER (John), one of our most ancient English poets, was cotemporary with Chaucer, and his intimate friend. Of what family, or in what country he was born, is uncertain. He studied the law, and was some time a member of the society of Lincoln's inn, where his acquaintance with Chaucer began. Some have asserted that he was a judge; but this is by no means certain. In the first year of Henry IV. he became blind; a misfortune which he laments in one of his Latin poems. He died in the year 1402; and was buried in St Mary Overie, which church he had rebuilt, chiefly at his own expence, so that he must have lived in affluent circumstances. His tomb was magnificent, and curiously ornamented. It still remains, but hath been repaired in later times. From the collar of SS, round the neck of his effigies, which lies upon the tomb, it is conjectured that he had been knighted. As to his character as a man, it is impossible, at this distance of time, to say any thing with certainty. With regard to his poetical talents, he was undoubtedly admired at the time when he wrote, though a modern reader may find it difficult to discover much harmony or genius in any of his compositions. He wrote, 1. *Speculum meditantis*, in French; in ten books. There are two copies of this in the Bodleian library. 2. *Vox clamantis*, in Latin verse; in seven books. Preferred also in the Bodleian library, and in that of All-Souls. It is a chronicle of the insurrection of the commons in the reign of Richard II. 3. *Confessio amantis*; printed at Westminster by Caxton, in 1493. Lond. 1532, 1554. It is a sort of poetical system of morality, interperfed with a variety of moral tales. 4. *De rege Henrico IV.* Printed in Chaucer's works. There are likewise several historical tracts, in manuscript, written by our author, which are to be found in different libraries; also some short poems printed in Chaucer's works.

GOWN, ROBE, a long upper garment, wore by lawyers, divines, and other graduates; who are hence called *men of the gown*, or *gownmen*.

The gown is an ample sort of garment, wore over the ordinary cloaths, hanging down to the feet.—It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they gave the name "virile gown," 1232 *virilis*, to a plain kind of gown which their youth assumed when arrived at puberty. This they particularly denominated *prætexta*. See TOGA, PRÆTEXTA, &c.

"The remarkable drefs of our British ancestors, (Mr Whitaker observes), which continued very nearly the same to the commencement of the last century among the natives of Ireland, and has actually descended to the present among the mountaineers of Scotland, and is therefore rendered very familiar to our ideas, carried in it an astonishing appearance to the Romans. And it seems to have been equally the drefs of the men and women, among the nobles of Britain. But, in a few years after the erection of the Roman-British towns in the north, and in the progress of refinement among them, this ancient habit began to be disesteemed by the chiefs of the cities, and looked upon as the badge of ancient barbarism. And the growing prejudices were soon so greatly improved, that, within twenty years only after the construction of the towns, the British fagum was actually resigned, and the Roman *toga* or "gown" assumed by many of them.

"The gown, however, never became universal in Britain. And it seems to have been adopted only by the barons of the cities and the officers of the crown; and has therefore been transmitted to us as the robe of reverence, the ensign of literature, and the mantle of magistracy. The woollen and plaided garments of the chiefs having naturally superseded the leathern vestures of their clients, the former were still wore by the generality of the Britons. And they were retained by the gentlemen of the country, and by the commonalty both in country and city. That this was the case, appears evident from the correspondent conduct of the Gauls and Britons; who kept their *Virgata Sagula* to the last, and communicated them to the Franks and Saxons. The plaided drapery of the Britons still appeared general in the streets of Manchester; and must have formed a striking contrast to the gown of the chief, the dark mantle of Italy. And it, and the ornamented buttons on the shoulder, are preserved among us even to the present moment, in the parti-coloured clothing and the tasselled shoulder-knots of our footmen."

In some universities, physicians wear a scarlet-gown.—In the Sorbonne, the doctors are always in gowns and caps. Beadles, &c. wear gowns of two or more colours.

Among the French officers, &c. they distinguish those of the *short gown* or *robe*; which are such as have not been regularly examined.—They have also barbers of the *short gown*, who are such as are obliged to practise in an inferior way to those of the long robe.

GOWN is also taken in the general for civil magistrature, or the profession opposite to that of arms. In this sense it was that Cicero said, *cedant arma togæ*.

GRAAF (Regnier de), a celebrated physician, born at Schoonhaven, in Holland, in 1641. He studied

Gown,
Grass.

Grabe,
Grace.

died phytic at Prussia. He was educated in Leyden, where he acquired great honour by publishing a treatise *De Succo Pancreatico*. He also published three pieces upon the organs of generation, both male and female; upon which subject he had a controversy with Swammerdam. He died young, in 1673; and his works, with his life prefixed, were published at Leyden in 1677, in 8vo.

GRABE (John Ernest), a very learned writer in the beginning of the 18th century, a native of Koninberg in Prussia. He was educated in the Lutheran religion; but the reading of the fathers led him into doubts. He presented to the electoral consistory at Sambia in Prussia a memorial, containing his doubts. The elector gave orders to three eminent divines to answer them. Their answers shook him a little in his resolution of embracing the Roman Catholic religion; and one of them, Spener, advised him to go to England. He went; and king William gave him a pension, which was continued by Queen Anne. He was ordained a priest of the church of England, and honoured with the degree of Doctor of Divinity by the university of Oxford; upon which occasion Dr George Smalridge pronounced two Latin orations, which were afterwards printed. He wrote, 1. *Spicilegium S. S. Patrum, ut et Hæreticorum sæculi post Christum natum*, 8vo. 2. An edition of the Septuagint, from the Alexandrian manuscript in St James's library. 3. Notes on Justin, &c.; and other works, which are esteemed by the learned.

GRACE, among divines, is taken, 1. For the free love and favour of God, which is the spring and source of all the benefits we receive from him. 2. For the work of the Spirit renewing the soul after the image of God; and continually guiding and strengthening the believer to obey his will, to resist and mortify sin, and overcome it.

GRACE is also used, in a peculiar sense, for a short prayer said before and after meat.

The proofs of the moral obligation of this ceremony, drawn from different passages of the New Testament, are so well known, that it is needless to insist on them here. Some others, drawn from the practice of different nations, and of very remote antiquity, may not be disagreeable to our readers.

1. Athenæus tells us, in his *Deipnosoph.* lib. ii. that in the famous regulation made by Amphiclyon, king of Athens, with respect to the use of wine, both in sacrifices, and at home, he required that the name of *Jupiter the Sustainer* should be decently and reverently pronounced. The same writer, in lib. iv. p. 149. quotes Hermias, an author extant in his time, who informs us of a people in Egypt, inhabitants of the city of Naucratis, whose custom it was on certain occasions, after they had placed themselves in the usual posture of eating at the table, to rise again, and kneel; when the priest or precentor of the solemnity began to chant a grace, according to a stated form amongst them; and when that was over, they joined in the meal, in a solemn sacrificial manner. Heliodorus, has a passage in his *Ethiopes* to the same purpose, that it was the custom of the Egyptian philosophers to pour out libations and put up ejaculations before they sat down to meals. Porphyry, in his treatise *De abst.* lib. iv. p. 408. gives a great character of

Grace.

the Samæan gymnosophists in Egypt, for the strictness of their life: as one article in their favour, he observes, that at the founding of a bell before their meals, which consisted only of rice, bread, fruits, and herbs, they went to prayers; which being ended, and not before, the bell sounded again, and they sat down to eating. In general, this was a religious usage or rite amongst the ancient Greeks; and derived from yet older ages, if Clement of Alexandria rightly informs us. He mentions, that these people, when they met together to refresh themselves with the juice of the grape, sung a piece of music, in imitation of the Hebrews psalms, which they called a *scholion*. Livy, lib. xxxix. speaks of it as a settled custom among the old Romans, that they offered sacrifice and prayer to the gods, at their meals and computations. But one of the fullest testimonies to our purpose is given by Quintilian, *Declam.* 301. *Adisti mensam*, says he, *ad quam cum venire capimus, Deos invocamus*; "We approached the table (at supper together), and then invoked the gods."

The Jesuit Trigantius, in his very elegant and instructive narrative of the Christian expedition of their missionaries into China, book i. p. 69. gives this account of the people there, in the particular now under consideration. "Before they place themselves for partaking of an entertainment, the person who makes it, sets a vessel, either of gold or silver, or marble, or some such valuable material, in a charger full of wine, which he holds with both his hands, and then makes a low bow to the person of chief quality or character at the table. Then, from the hall or dining room, he goes into the porch or entry, where he again makes a very low bow, and turning his face to the south, pours out this wine upon the ground, as a thankful oblation to the Lord of heaven. After this, repeating his reverential obeisance, he returns into the hall, &c."

The Turks pray for a blessing on their meat; and many more instances might be produced of infidels, who have constantly observed the like custom, in some way or other.

2. The fact, therefore, with respect to the heathen world, being thus evident; we proceed to the sentiments and behaviour of the *Jews* in this particular. Their celebrated historian *Josèphus*, giving a detail of the rites and customs of the *Essenes*, who were confessedly the strictest and most pious professors of the Jewish religion, has this remarkable passage to the present purpose: "The priest," says he, "begs a blessing before they presume to take any nourishment; and it is looked upon as a great sin to take or taste before." Then follows the thanksgiving before meat: and "when the meal," proceeds he, "is over, the priest prays again; and the company with him blest and praise God as their preserver, and the donor of their life and nourishment."

Philo, in his book *De vita contemplativa*, gives an account of a body of men and women stricter than even the *Essenes* themselves. He distinguishes them by no particular name, though his relation is very accurate and circumstantial; namely, that, on certain special occasions, before "they took their meals, they placed themselves in a proper decent order; when, lifting up their hands and eyes to heaven, they prayed to

God,

God, that he would be pleased to be propitious to them in the use of those his good creatures."

From the Hebrew ritual it appears, that the Jews had their hymns and psalms of thanksgiving, not only after eating their passover, but on a variety of other occasions, at and after meals, and even between their several courses and dishes; as when the best of their wine was brought upon the table, or their aromatic confections, or the fruit of the garden, &c. On the day of the passover was sung Psalm cxiv. *When Israel came out of Egypt, &c.*

ARITHMEUS has a passage full on the present subject. "Moses," says he, "commands, that when the Jews are going to eat or drink, the company should immediately join in sacrifice or prayer." Where Rabbi Eleazar (upon that author) met with this sentence, has been controverted. But supposing it not to be found in scriptis, it is sufficient for us to know that the Jews did constantly practise this custom, upon the foundation of an ancient and general tradition and usage. That the prophet Daniel gave thanks after meat, is evident from the Apocryphal book concerning *Bel and the Dragon*, where, ver. 38, 39, we find, that *Daniel said, Thou hast remembered me, O God! neither hast thou forsaken them who seek thee and love thee. So Daniel arose, and did eat.* Of this text Prudentius takes notice in Cathemirin. hymn iv.

*Hu famulis Daniels excitavit
In celum suum, cique fortis,
Anon reddidit, alleluia dixit.*

The much-belov'd took the repast,
And up to heav'n his eyes he cast;
By which refresh'd, he sung aloud,
Amen, and alleluia to his God

Where, by the way, it may be observed, that the poet is a little mistaken, in making the prophet give thanks after meat; whereas, according to the text, he did it before.

GRACE, or *Gracefulness*, in the human character; an agreeable attribute, inseparable from motion as opposed to rest, and as comprehending speech, looks, gesture, and loco-motion.

As some motions are homely, the opposite to *graceful*; it is to be inquired, With what motions is this attribute connected? No man appears graceful in a mask; and therefore, laying aside the expressions of the countenance, the other motions may be genteel, may be elegant, but of themselves never are graceful. A motion adjusted in the most perfect manner to answer its end, is elegant; but still somewhat more is required to complete our idea of grace or gracefulness.

What this unknown *more* may be, is the nice point. One thing is clear from what is said, that this *more* must arise from the expressions of the countenance; and from what expressions so naturally as from those which indicate mental qualities, such as sweetness, benevolence, elevation, dignity? This promises to be a fair analysis; because of all objects mental qualities affect us the most; and the impression made by graceful appearance upon every spectator of taste, is too deep for any cause purely corporeal.

The next step is, to examine what are the mental qualities, that, in conjunction with elegance of motion, produce a graceful appearance. Sweetness, cheerfulness, affability, are not separately sufficient, nor

even in conjunction. Dignity alone, with elegant motion, produce a graceful appearance; but still more graceful with the aid of other qualities, those especially that are the most exalted. See DIGNITY.

But this is not all. The most exalted virtues may be the lot of a person whose countenance has little expression: such a person cannot be graceful. Therefore to produce this appearance, we must add another circumstance, viz. an expressive countenance, displaying to every spectator of taste, with life and energy, every thing that passes in the mind.

Collecting these circumstances together, grace may be defined, "that agreeable appearance which arises from elegance of motion and from a countenance expressive of dignity". Expressions of other mental qualities are not essential to that appearance, but they heighten it greatly.

Of all external objects, a graceful person is the most agreeable.

Dancing affords great opportunity for displaying grace, and haranguing still more. See DANCING, DECLAMATION, and ORATORY.

But in vain will a person attempt to be graceful, who is deficient in amiable qualities. A man, it is true, may form an idea of qualities he is destitute of; and, by means of that idea, may endeavour to express these qualities by looks and gestures: but such studied expression will be too faint and obscure to be graceful.

AGE OF GRACE, the appellation given to the act of parliament 1696, c. 32. which allows prisoners for civil debts to be set at liberty, upon making oath that they have not wherewithal to support themselves in prison, unless they are alimented by the creditors on whose diligences they were imprisoned, within ten days after intimation made for that purpose. See LAW, Part III. N° clxxxv. 13.

DAYS OF GRACE, three days immediately following the term of payment of a bill, within which the creditor must protest if payment is not obtained, in order to entitle him to recourse against the drawer. See LAW, Part III. N° clxxxiii. 16.

GRACE is also a title of dignity given to dukes, archbishops, and in Germany to barons and other inferior princes.

GRACES, in heathen mythology, three goddesses, whose names were *Aglaia*, *Thalia*, and *Euphrosyne*; that is, *shining*, *flourishing*, and *gay*; or, according to some authors, *Pasithea*, *Euphrosyne*, and *Egiale*. Some make them the daughters of Jupiter, and Eurynome, or Eunomia, the daughter of Oceanus; but the most common opinion is, that they were the daughters of Bacchus and Venus.

They are sometimes represented dressed; but more frequently naked, to shew, perhaps, that whatever is truly graceful, is so in itself, without the aid of exterior ornaments. They presided over mutual kindness and acknowledgment; bestowed liberality, eloquence, and wisdom, together with a good grace, gaiety of disposition, and easiness of manners.

GRACCHUS (Tiberius), elected tribune of the Roman people, demanded in the senate, in their name, the execution of the Agrarian law; by which all persons possessing above 200 acres of land were to be deprived of the surplus, for the benefit of the poor citizens, amongst whom an equal distribution of them

Gracula

Grafting.

was to be made; having carried his plan into execution by violent measures, he fell a victim to his zeal, being assassinated by his own party, 133 B. C. Caius, his brother, pursuing the same steps, was killed by the consul Opimius, 121 B. C. See (history of) Rome.

GRACULA, in ornithology, a genus belonging to the order of piceæ. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is fleshy and sharpish; it has three toes before, and one behind. There are eight species, principally distinguished by their colour.

GRACULUS, in ornithology. See CORVUS.

GRADATION, in general, the ascending step by step, or in a regular and uniform manner.

GRADATION, in logic, a form of reasoning, otherwise called *SORITES*.

GRADATION, in painting, a gradual and insensible change of colour, by the diminution of the tints and shades.

GRADATION, in rhetoric, the same with CLIMAX.

GRADISKA, a strong town of Hungary in Sclavonia, on the frontiers of Croatia, taken by the Turks in 1691. It is seated on the river Save, in E. Lon. 17. 55. N. Lat. 45. 38.

GRADISKA, a strong town of Italy, in a small island of the same name on the frontiers of Friuli, in E. Lon. 13. 37. N. Lat. 46. 6. It is subject to the house of Austria.

GRADO, a strong town of Italy, in a small island of the same name, on the coast of Friuli, and in the territory of Venice. E. Lon. 13. 35. N. Lat. 45. 52.

GRADUATE, a person who has taken a degree in the university. See DEGREE.

GRÆVIUS (John George), one of the most learned writers in the 17th century. In the 24th year of his age, the elector of Brandenburg made him professor at Duisbourg. In 1658, he was invited to Deventer to succeed his former master Gronovius. In 1661, he was appointed professor of eloquence at Utrecht; and 12 years after, he had the professorship of politics and history conferred on him. He fixed his thoughts here, and refused several advantageous offers: He had, however, the satisfaction to be sought after by divers princes, and to see several of them come from Germany to study under him. He died in 1703, aged 71. His *Theſaurus antiquitatum et historiæ Italicæ*, &c. and other works, are well known.

GRAFTING, or ENGRAFTING, in gardening, is the taking a shoot from one tree, and inserting it into another in such a manner, that both may unite closely and become one tree. By the ancient writers on husbandry and gardening, this operation is called *in-cision*, to distinguish it from inoculation or budding, which they call *inferere oculis*.

Grafting hath been practised from the most remote antiquity; but its origin and invention is differently related by naturalists. Theophrastus tells us, that a bird having swallowed a fruit whole, cast it forth into a cleft or cavity of a rotten tree; where mixing with some of the putrified parts of the wood, and being washed with the rains, it budded, and produced within this tree another tree of a different kind. This led the husbandman to certain reflections, from which soon afterwards arose the art of engrafting.

Grafting.

Pliny sets the same thing in a different light: a countryman having a mind to make a pallisade in his grounds, that it might endure the longer, he bethought himself to fill up and strengthen the bottom of the pallisade, by running or waiting it with the trunks of ivy. The effect of this was, that the stakes of the pallisades taking root, became engrafted into the trunks, and produced large trees; which suggested to the husbandman the art of engrafting.

The use of grafting is to propagate any curious sorts of fruits so as to be certain of the kinds; which cannot be done by any other method: for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as is not worth the cultivating: but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be their stock or tree on which they are grafted.

The reason or philosophy of engrafting is somewhat obscure; and had not accident given the first hint, all our knowledge of nature would never have led us to it. The effect is ordinarily attributed to the diversity of the pores or ducts of the graft from those of the stock, which change the figure of the particles of the juices in passing through them to the rest of the tree.

Mr Bradley, on occasion of some observations of Agricola, suggests something new on this head. The stock grafted on, he thinks, is only to be considered as a fund of vegetable matter, which is to be filtered through the cyon, and digested, and brought to maturity, as the time of growth in the vessels of the cyon directs. A cyon, therefore, of one kind, grafted on a tree of another, may be rather said to take root in the tree it is grafted in, than to unite itself with it: for it is visible that the cyon preserves its natural purity and intent, though it be fed and nourished with a mere crab; which is, without doubt, occasioned by the difference of the vessels in the cyon from those of the stock: so that grafting may be justly compared to planting.

In prosecution of this view of that ingenious author, we add, that the natural juices of the earth, by their secretion and comminution in passing through the roots, &c. before they arrive at the cyon, must doubtless arrive there half elaborated and concocted; and so disposed for a more easy, plentiful, and perfect assimilation and nutrition; whence the cyon must necessarily grow and thrive better and faster than if it were put immediately in the ground, there to live on coarse diet and harder of digestion: and the fruit produced by this further preparation in the cyon, must be finer and further exalted than if fed immediately from the more imperfectly prepared and altered juices of the stock.

Many have talked of changing of species, or producing mixed fruits, by engrafting one tree on another of the same class; but as the graft carries the juices from the stock to the pulp of the fruit, there is little hope of succeeding in such an expectation by ever so many repeated grafts: but if, after changing the graft and stock several successive times, you set the seed of the fruit produced on the graft in a good mould, it is possible that a change may happen, and

a new mixed plant may be produced. Thus the almond and peach may, by many changes in the graftings, and by interrations of the stones of the peaches, and of the shells of the almonds, and by teribrations of the stem of the root here and there, alter their nature so much, that the coat or pulp of the almond may approach to the nature of the peach, and the peach may have its kernel enlarged into a kind of almond; and on the same principle, the curious gardener may produce many such mixed kinds of things.

Mr Du Hamel has observed, that, in grafting of trees, there is always found at the insertion of the graft, a change in the directions of fibres, and a sort of twisting or turning about of the vessels, which greatly imitates that in the formation of certain glands in animal bodies: and from thence he infers, that a new sort of vicus being formed by this means, the fruit may very naturally be so far influenced by it, as to be meliorated on the new branch; but that no such sudden and essential changes can be effected by those means, as too many of the writers on agriculture pretend. He observes, however, that this anatomical observation would not have been sufficient to convince him of the falsity of too many of these relations, had not experiment joined to confirm him in this opinion. He tried many grafts on different trees; and, for fear of error, repeated every experiment of consequence several times: but all served only to convince him of the truth of what he at first suspected. He grafted in the common way the peach upon the almond, the plum upon the apricot, the pear upon the apple, the quince, and the white thorn; one species of plum on other very different species, and upon the peach the apricot and the almond. All these succeeded alike: the species of the fruit was never altered; and in those which would not come to fruit, the leaves, the wood, and the flowers, were all the same with those of the tree from whence the graft was taken.

Authors on agriculture have also mentioned a very different sort of grafting; namely, the setting grafts of one tree upon stocks of a different genus; such as the grafting the pear upon the oak, the elm, the maple, or the plum, &c. Mr Du Hamel tried a great number of those experiments carefully, and found every one of them unsuccessful; and the natural conclusion from this was, that there must be some natural alliance between the stocks and their grafts, otherwise the latter will either never grow at all, or very soon perish.

Notwithstanding the facility with which grafts generally take on good stocks, there are many accidents and uncertainties attending them in their different periods. Some perish immediately; some, after appearing healthy for many months, and some even for years. Of these last some die without the stocks suffering any thing; others perish together with the stocks. It is very certain, that the greater part of grafted trees do not live so long as they would have done in their natural state; yet this is no unexceptionable rule: for there are some which evidently live the longer for this practice; nay, there are instances of grafts which, being placed on stocks naturally of short duration, live longer than when placed on those which are more robust and lasting. These irregularities have been but little considered hitherto, though they might

be made productive of considerable advantages.—One great requisite for the succeeding of any graft is, that it be in its own nature capable of so close and intimate an union with the substance of the stock, that it becomes as it were a natural branch of it. If all trees resembled one another in their structure and juices, the size and elasticity of their vessels, &c. probably the grafts of all trees would succeed upon another; but this is by no means the case.

Trees are well known to be composed of numerous arrangements of hollow fibres, and these are different and unequal in every species of tree. In order to the succeeding of a graft, it is plain that there must be a conformity in its vessels and juices with those of the stock; and the more nearly they agree in this, probably the better they succeed, and the farther they differ, the worse.—If there be, however, some difference in the solid parts of trees, there are evidently many more in the juices. The sap in some trees is white as milk, in others it is reddish, and in some as clear and limpid as water. In some, it is thin and very fluid; in others, thick and viscous. In the taste and smell of these juices there are also not less differences: some are sweet, some insipid, some bitter, some acid, and some fetid: the quality of the sap thus makes a very great difference in the nature of trees; but its quantity, and derivation to the parts, is scarce less observable. Of this we have familiar instances in the willow and the box; one of which will produce longer shoots in a year, than the other in 20.

Another difference yet more striking, and indeed more essential in regard to the growth of grafts than all these, is the different season of the year at which trees shoot out their leaves, or ripen their flowers. The almond-tree is in flower before other trees in general have opened their earliest buds; and when other trees are in flower, this is full of leaves, and has its fruit set before the mulberry begins to push out its earliest buttons. When we consider all these differences in trees, we cannot but wonder how it is possible for a branch of one to live upon another; and it becomes a much more perplexing question how any graft can succeed, than how such numbers come to miscarry. A graft of one pear upon another shall be seen to succeed presently as if upon its own tree; and in a fortnight will gain six inches in length, and so of some others.—This must be owing to the great similarity between the stock and the graft in all respects; and a great contrariety or difference in structure of parts will make as remarkable a difference on the other hand. An instance of this may be observed in the plum and the elm; which no art can ever make to succeed upon one another, whether the plum be grafted on the elm, or the elm upon the plum stock. These are examples of the extremes of easy growth, and of absolute decay; but there are many conjunctions of trees which seem of a middle nature between the two, and neither immediately perish, nor totally succeed. Of these, such as were grafted in autumn usually remain green the whole winter without pushing; and those which are grafted in spring remain green a month or longer, but still without shooting. Some particular ones have also been known to make a few shoots the first, or even the second sap season after the operation; but all perish at the end of these times.

times. Of this kind are the grafts of the pear-tree upon the elm, the maple, and the hornbeam, and the mulberry upon the elm and fig, with many others.

When we come to inquire into the cause of this, we find that these grafts, though unnatural, have yet had a communication with the stock by means of a few small vessels, which has been sufficient to keep them green, or even to make them shoot a little, during the great ascent of the sap: But the far greater number of the fibres have had all the while no communication, and are found putrified, dried up, or covered with a putrid juice. This has evidently happened by means of the disproportion in size between the vessels of the stock and of the graft, and the great difference between their natural juices, which are obstacles abundantly sufficient to prevent either an union of the fibres, or the introduction of new sap.

The grafts of the almond on the plum, and of the plum on the almond, always grow very vigorously for the first year, and give all the appearances imaginable of succeeding entirely; yet they always perish in the second or third year. The almond-graft upon the plum-stock always pushes out very vigorously at first; but the part of the stock immediately under the graft grows smaller and perishes, the graft absorbing too much of the juices, and the graft necessarily perishes with it. The decay of the whole generally happens early in the spring; and that plainly from the different season of the natural shooting of the two trees, the almond pushing very vigorously, and consequently draining the stock of its juices, at a time when, according to its nature, the juices are but in small quantity in it, and the sap does not begin to ascend. The grafts of the plum on the almond are, from the same cause, furnished with an abundance of sap which they have at that time no occasion for; and consequently they as certainly perish of repletion, as the other of inanition.

The peach grafted on the plum succeeds excellently, and lives longer than it would have done in a natural state; the reason seems to be, that the peach is a tender tree, shoots with great vivacity, and produces more branches than the root is able to maintain. Thus the peach trees are usually full of dead wood; and often their large branches perish, and sometimes their whole trunk. On this occasion the plum being a slow shooting tree, communicates its virtue to the graft; and the peach consequently sends out shoots which are more robust and strong, and are no more in number than the root is able to supply with nourishment, and consequently the tree is the more lasting.

The grafts, or cions, with which the grafting is effected, are young shoots of last summer's growth, for they must not be more than one year, and such as grow on the outside branches, and robust but moderate shooters; such also as are firm and well ripened, should always be chosen from healthful trees: observing, that the middle part of each shoot is always the best graft, cut at the time of grafting to five or six inches in length, or so as to have four or five good eyes or buds; but should be preserved at full length till grafting time, and then prepared as hereafter directed.

They should be collected or cut from the trees in February, in mild weather, before their buds begin to swell, or advance much for shooting: in collecting them, choose such as have not made lateral or side shoots; cut

them off at full length; and if they are not to be used as soon as they are collected, lay their lower ends in some dry earth in a warm border till grafting time, and, if severe weather should happen, cover them with dry litter.

The proper tools and other materials used in grafting, are,

A strong knife for cutting off the heads of the stocks, previous to the insertion of the graft; also a small hand-saw for occasional use in cutting off the heads of large stocks.

A common grafting-knife, or strong, sharp pen-knife, for cutting and shaping the grafts ready for insertion; also to slope and form the stocks for the reception of the grafts.

A flat grafting-chisel and small mallet for clefting large stocks, in cleft-grafting, for the reception of the graft.

A quantity of new bals-strings for bandages, for tying the grafted parts close, to secure the grafts, and promote their speedy union with the stock. And,

A quantity of grafting clay, for claying closely round the grafts after their insertion and binding, to defend the parts from being dried by the sun and winds, or too much liquified by wet, or pinched by cold; for these parts ought to be closely surrounded with a coat of clay in such a manner as effectually to guard them from all weathers, which would prove injurious to young grafts, and destroy their cementing property, so as to prevent the junction: therefore, a kind of stiff loamy mortar must be prepared of strong fat loam, or, in default thereof, any sort of tough binding clay, either of which should be laid in an heap, adding thereto about a fourth of fresh horse-dung free from litter, and a portion of cut hay, mixing the whole well together, and adding a little water: then let the whole be well beaten with a stick upon a floor, or other hard substance; and as it becomes too dry, apply more water, at every beating turning it over, always continuing to beat it well at top till it becomes flat; which must be repeated more or less according to the nature of the clay, but should be several times done the first day: next morning repeat the beating, still moistening it with water; and by thus repeating the beating six or eight times every day for two or three days, or every other day at least, for a week, it will be in proper order for use; observing, it should be prepared a week at least before it is used, but if a month the better.

The season for performing the operation of grafting is February and March: though, when the work is performed in February, it for the general part proves the most successful, more especially for cherries, plums, and pears; and March grafting is well adapted for apples.

There are different methods of grafting in practice, termed Whip-grafting---Cleft-grafting---Crown-grafting---Cheek-grafting---Side-grafting---Root-grafting---and Grafting by approach or Inarching: but Whip-grafting and Cleft-grafting are most commonly used; and Whip-grafting most of all, as being the most expeditious and successful of any.

Whip-grafting.—This being the most successful method of grafting is the most commonly practised in all the nurseries; it is always performed upon small stocks, from

from about the size of a goose-quill, to half an inch or a little more or less in diameter, but the nearer the stock and graft approach in size the better; and is called *whip-grafting*, because the grafts and stocks being nearly of a size, are sloped on one side, so as to fit each other, and tyed together in the manner of whips, or joints of angling-rods, &c. and the method is as follows.

Mawe's
Diss. of
Gardening.

Having the cions or grafts, knife, bandages, and clay ready, then begin the work by cutting off the head of the stock at some clear smooth part thereof; this done, cut one side sloping upwards, about an inch and half or near two inches in length, and make a notch or small slit near the upper part of the slope downward about half an inch long, to receive the tongue of the cion; then prepare the cion, cutting it to five or six inches in length, forming the lower end also in a sloping manner, so as exactly to fit the sloped part of the stock, as if cut from the same place, that the rinds of both may join evenly in every part; and make a slit so as to form a sort of tongue to fit the slit made in the slope of the stock; then place the graft, inserting the tongue of it into the slit of the stock, applying the parts as evenly and close as possible; and immediately tie the parts close together with a string of bafs, bringing it in a neat manner several times round the stock and graft; then clay the whole over near an inch thick on every side, from about half an inch or more below the bottom of the graft, to an inch over the top of the stock, finishing the whole coat of clay in a kind of oval globular form, rather longwise, up and down, closing it effectually about the cion, and every part, so as no sun, wind, nor wet may penetrate, to prevent which is the whole intention of claying; observing to examine it now and then, to see if it any where cracks or falls off, and if it does it must be instantly repaired with fresh clay.

This sort of grafting may also be performed, if necessary, upon the young shoots of any bearing tree, if intended to alter the sorts of fruits, or have more than one sort on the same tree.

By the middle or latter end of May, the grafts will be well united with the stock, as will be evident by the shooting of the graft; then the clay should be wholly taken away; but suffer the bafs bandage to remain some time longer until the united parts seem to swell and be too much confined by the ligature, then take the tying wholly off.

Their farther culture is directed under the respective articles, whether designed for dwarfs or standards, &c.

Cleft-grafting.—This is so called, because the stock being too large for whip-grafting is cleft or slit down the middle for the reception of the graft; and is performed upon stocks from about one to two inches diameter.

First, with a strong knife cut off the head of the stock; or if the stock is very large, it may be headed with a saw; and cut one side sloping upwards about an inch and half to the top; then proceed with a strong knife or chisel, to cleave the stock at top, cross-way the slope, fixing the knife or chisel towards the back of the slope, and with your mallet strike it, so as to cleave the stock about two inches, or long enough to admit the graft, keeping it open with the chisel; this done, prepare

the cion, cutting it to such length as to leave four or five eyes, the lower part of which being sloped on each side, wedge-fashion, an inch and half or two inches long, making one side to a thin edge, the other much thicker, leaving the rind thereon, which side must be placed outward in the stock; the cion being thus formed, and the cleft in the stock being made and kept open with the chisel, place the graft therein at the back of the stock the thickest side outward, placing the whole cut part down into the cleft of the stock, making the rind of the stock and graft join exactly; then removing the grafting chisel, each side of the cleft will closely squeeze the graft, so as to hold it fast; it is then to be bound with a ligature of bafs, and clayed over, as observed in whip-grafting, leaving three or four eyes of the cions uncovered.

If intended to graft any pretty large stocks or branches by this method, two or more grafts may be inserted in each; in this case the head must be cut off horizontally, making no slope on the side, but smooth the top, then cleave it quite a-crofs, and place a graft on each side, as the stock may be cleft in two places, and insert two grafts in each cleft; they are thus to be tied and clayed as in the other methods.

This method of grafting may be performed upon the branches of bearing trees, when intended either to renew the wood, or change the sort of fruit.

Towards the latter end of May, or the beginning of June, the junction of the graft and stock in either method will be effectually formed, and the graft begin to shoot, when the clay may be taken off, and in a fortnight or three weeks after take off also the bandages.

Crown-grafting.—This kind of grafting is commonly practised upon such stocks as are too large to cleave, and is often performed upon the large branches of apple and pear trees, &c. that already bear fruit, when it is intended to change the sorts, or renew the tree with fresh-bearing wood. It is termed *crown-grafting*, because the stock or branch being headed down, several grafts are inserted at top all around betwixt the wood and bark, so as to give it a crown-like appearance; observing, that this kind of grafting should not be performed until March, or early in April; for then the sap being in motion, renders the bark and wood of the stock much easier to be separated for the admission of the graft.

The manner of performing this sort of grafting is as follows:

First, cut off the head of the stock or branch with a saw horizontally, and pare the top smooth; then having the grafts, cut one side of each flat, and somewhat sloping, an inch and half long, forming a sort of shoulder at top of the slope to rest upon the crown of the stock; and then raising the rind of the stock with a wedge, so as to admit the cion between that and the wood two inches down, place the grafts with the flat side next the wood, thrusting it down far enough for the shoulder to rest upon the top of the stock, and in this manner may be put three, four, five, or more grafts in one large stock or branch.

When the grafts are all thus inserted, let the whole be tied tight and well clayed; observing to leave two or three eyes of each graft uncovered, by raising the clay an inch above the top of the stock, so as to throw the wet quickly off, without lodging about the grafted

Grafting. parts, which would ruin the whole work.

Crown-grafting may also be performed, by making several clefts in the crown of the stock, and inserting the grafts round the top into the clefts.

The grafts will be pretty well united with the stock, and exhibit a state of growth, by the end of May or beginning of June, and the clay may then be taken away.

Mason's
Diss.

The trees grafted by this method will succeed extremely well; but, for the first two or three years, have this inconvenience attending them, of being liable to be blown out of the stock by violent winds; which must be remedied by tying long sticks to the body of the stock or branch, and each graft tied up to one of the sticks.

Cheek-grafting.—Cut the head of the stock off horizontally, and pare the top smooth; then cut one side sloping an inch and half or two inches deep, and cut the lower part of the graft sloping the same length, making a fort of shoulder at top of the sloped part: it is then to be placed upon the sloped part of the stock, resting the shoulder upon the crown of it: bind it with bafs, and finish with a covering of clay as in the other methods.

Side-grafting.—This is done by inserting grafts into the sides of the branches without heading them down; and may be practised upon trees to fill up any vacancy, or for the purpose of variety, to have several sorts of apples, pears, plums, &c. upon the same tree.

It is performed thus. Fix upon such parts of the branches where wood is wanted to furnish the head or any part of the tree; there slope off the bark and a little of the wood, and cut the lower end of the grafts to fit the part as near as possible; then join them to the branch, and tie them with bafs, and clay them over.

Root-grafting.—This is done by Whip-grafting cions upon pieces of the root of any tree of the same genus, and planting the root where it is to remain; it will take root, draw nourishment, and feed the graft.

Grafting by Approach, or Inarching.—This sort of grafting is, when the stocks designed to be grafted, and the tree from which you intend to take the graft, either grow so near, or can be placed so near together, that the branch or graft may be made to approach the stock, without separating it from the tree, till after its union or junction with the stock; so that the branch or graft being bent to the stock, they together form a sort of arch; whence it is called Grafting by Approach, or Inarching. Being a sure method, it is commonly practised upon such trees as are with difficulty made to succeed by any of the former ways of grafting.

When intended to propagate any kind of tree or shrub by this method of grafting, if the tree, &c. is of the hardy kind, and growing in the full ground, a proper quantity of young plants for stocks must be set round it; and when grown of a proper height, the work of inarching must be performed; or, if the branches of the tree you design to graft from is too high for the stocks, in that case stocks must be planted in pots, and a slight stage must be erected around the tree, of due height to reach the branches, and the

pots containing the stocks must be placed upon the stage.

Grafting.

As to the method of performing the work: Observe, that in this method of grafting, it is sometimes performed with the head of the stock cut off, and sometimes with the head left on till the graft is united with the stock; though, by previously heading the stock, the work is much easier performed; and having no top, its whole effort will be directed to the nourishment of the graft; having, however, the stocks properly placed, either planted in the ground, or in pots around the tree to be propagated; then make the most convenient branches approach the stock, and mark on the body of the branches the parts where they will most easily join to the stock, and in those parts of each branch pare away the bark and part of the wood two or three inches in length, and in the same manner pare the stock in the proper place for the junction of the graft; then make a slit upwards in the branch, so as to form a sort of tongue, and make a slit downwards in the stock to admit it; let the parts be then joined, slipping the tongue of the graft into the slit of the stock, making the whole join in an exact manner, and tie them closely together with bafs, and afterwards cover the whole with a due quantity of clay, as before directed in the other methods.

After this, let a stout stake be fixed, if possible, for the support of each graft, to which let that part of the stock and graft be fastened, which is necessary to prevent their being disjoined by the wind.

The operation being performed in spring, let them remain in that position about four months, when they will be united, and the graft may then be separated from the mother-tree. In doing this, be careful to perform it with a steady hand, so as not to loosen or break out the graft, sloping it off downwards close to the stock; and if the head of the stock was not cut down at the time of grafting, it must now be done close to the graft, and all the old clay and bandage must also be cleared away, and replaced with new, to remain a few weeks longer.

Observe, however, that if you shall think the grafts are not firmly united with the stock in the period of time above-mentioned, let them remain another year till autumn, before you separate the grafts from the parent-tree.

By this kind of grafting, you may raise almost any kind of tree or shrub, which is often done by way of curiosity, to ingraft a fruit-bearing branch of a fruit-tree upon any common stock of the same fraternity or genus, whereby a new tree bearing fruit is raised in a few months. This is sometimes practised upon orange and lemon trees, &c. by grafting bearing-branches upon stocks raised from the kernels of any of the same kind of fruit, or into branches of each other, so as to have orange, lemons, and citrons, all on the same tree.

An anonymous author has given us in a treatise, published at Hamburg, under the title *Amenitates Hortensæ Novæ*, a new method of grafting trees, so as to have very beautiful pyramids of fruit upon them, which will exceed in beauty, flavour, and quantity, all that can be otherwise produced. This, he says, he had long experienced, and gives the following method

Graham.

thod of doing it. The trees are to be transplanted in autumn, and all their branches cut off. Early in the following summer the young shoots are to be pulled off, and the buds are then to be ingrafted into them in an inverted direction. This, he says, adds not only to the beauty of the pyramids, but also makes the branches more fruitful. There are to be closely connected to the trunk, and to be fastened in with the common ligature: they are to be placed circularly round the tree, three buds in each circle, and these circles at six inches distance from one another. The old trees may be grafted in this manner, the success having been found very good in those of twenty years standing; but the most eligible trees are those which are young, vigorous, and full of juice, and are not above a finger or two thick. When these young trees are transplanted, they must be fenced round with pales to defend them from the violence of the wind; and there must be no dung put to them till they are thoroughly rooted, for fear of rotting them before the fibres strike. The buds ingrafted must be small, that the wounds made in the bark to receive them, not being very large, may heal the sooner; and if the buds do not succeed, which will be perceived in a fortnight, there must be others put in their place. The wound made to receive these buds must be a straight cut, parallel to the horizon; and the piece of bark taken out must be downward, that the rain may not get in at the wound. In the autumn of the same year, this will be a green and flourishing pyramid; and the next summer it will flower, and ripen its fruit in autumn.

GRAHAM (James), Marquis of Montrose, was comparable to the greatest heroes of antiquity. He undertook, against almost every obstacle that could terrify a less enterprising genius, to reduce the kingdom of Scotland to the obedience of the king; and his success was answerable to the greatness of the undertaking. By valour, he in a few months almost effectuated his design; but, for want of supplies, was forced to abandon his conquests. After the death of Charles I. he, with a few men, made a second attempt, but was immediately defeated by a numerous army. As he was leaving the kingdom in disguise, he was betrayed into the hands of his enemy, by the Lord Aston, his intimate friend. He was carried to his execution with every circumstance of indignity that wanton cruelty could invent; and hanged upon a gibbet 30 feet high, with the book of his exploits appended to his neck. He bore this reverse of fortune with his usual greatness of mind, and expressed a just scorn at the rage and insult of his enemies. We meet with many instances of valour in this active reign; but Montrose is the only instance of heroism. He was executed May 21st, 1650. See BRITAIN, n° 137, 143, 165.

GRAHAM (Sir Richard), lord viscount Preston, eldest son of Sir George Graham of Netherby, in Cumberland, Bart. was born in 1648. He was sent ambassador by Charles II. to Lewis XIV. and was master of the wardrobe and secretary of state under James II. But when the Revolution took place, he was tried and condemned, on an accusation of attempting the restoration of that prince; though he obtained a pardon by the queen's intercession. He spent the remainder of his days in retirement, and published an ele-

gant translation of *Boethius on the consolation of philosophy*. He died in 1695.

GRAHAM (George), clock and watch maker, the most ingenious and accurate artist in his time, was born in 1675. After his apprenticeship, Mr Tompion received him into his family, purely on account of his merit; and treated him with a kind of parental affection as long as he lived. Beside his universally acknowledged skill in his profession, he was a complete mechanic and astronomer; the great mural arch in the observatory at Greenwich, was made for Dr Halley, under his immediate inspection, and divided by his own hand: and from this incomparable original, the best foreign instruments of the kind are copies made by English artists. The sector by which Dr Bradley first discovered two new motions in the fixed stars, was of his invention and fabric: and when the French academicians were sent to the north to ascertain the figure of the earth, Mr Graham was thought the fittest person in Europe to supply them with instruments; those who went to the south were not so well furnished. He was for many years a member of the Royal Society, to which he communicated several ingenious and important discoveries; and regarded the advancement of science more than the accumulation of wealth. He died in 1751.

GRAHAM'S DYKE. See ANTONINUS'S WALL.

GRAIN, corn of all sorts, as barley, oats, rye, &c. See CORN, WHEAT, &c.

GRAIN is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight Troy.

A grain-weight of gold-bullion is worth two-pence, and that of silver but half a farthing.

GRAIN also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, means contrary to the fibres of wood, &c.

GRAIN (Baptist le), master of the requests in ordinary to Mary de Medicis queen of France's household, wrote *The history of Henry the Great*, and of *Louis XIII.* from the beginning of his reign to the death of the marshal d'Ancre in 1617. This history is reckoned to be wrote with impartiality, and the spirit of a true patriot; and contains many things not to be found any where else. He vigorously asserts the edict that had been granted to the reformed.

GRAMINÆ, GRASSES; one of the seven tribes or natural families, into which all vegetables are distributed by Linnaeus in his *Philosophia Botanica*. They are defined to be plants which have very simple leaves, a jointed stem, a husky calix termed *gluma*, and a single seed. This description includes the several sorts of corn as well as grasses. In Tournefort they constitute a part of the fifteenth class, termed *apetalæ*; and in Linnaeus's sexual method, they are mostly contained in the second order of the third class, called *triandria digynia*.

This numerous and natural family of the grasses, has engaged the attention and researches of several eminent botanists. The principal of these are, Ray, Monti, Micheli, and Linnaeus.

M. Monti, in his *Catalogus stirpium agri Bononiensis*, *gramina ac hujusmodi affinia completens*, printed at Bononia in 1719, divides the grasses, from the dis-

Grain
Gramina.

position of their flowers, as Theophrastus and Ray had divided them before him, into three sections or orders—These are, 1. Grasses having flowers collected in a spike. 2. Grasses having their flowers collected in a panicle or loose spike. 3. Plants that in their habit and external appearance are allied to the grasses.

This class would have been natural if the author had not improperly introduced sweet-rush, juncus, and arrow-headed grass, into the third section. Monti enumerates about 306 species of the grasses, which he reduces under Tournefort's genera; to these he has added three new genera.

Scheuchzer, in his *Aristographia*, published likewise in 1719, divides the grasses, as Monti, from the disposition of their flowers into the five following sections. 1. Grasses with flowers in a spike, as phalaris, anthoxanthum, and frumentum. 2. Irregular grasses, as schoenanthus and cornucopiae. 3. Grasses with flowers growing in a simple panicle or loose spike, as reed and millet. 4. Grasses with flowers growing in a compound panicle, or diffused spike, as oats and poa. 5. Plants by their habit nearly allied to the grasses, as cypress-grass, scirpus, linagrostis, rush, and Scheuchzeria.

Scheuchzer has enumerated about four hundred species, which he describes with amazing exactness.

Micheli has divided the grasses into six sections, which contain in all, forty-four genera, and are arranged from the situation and number of the flowers.

GRAMINA, the name of the fourth order in Linnaeus's fragments of a natural method, consisting of the numerous and natural family of the grasses, viz. agrostis; aira; alopecurus, or fox-tail grass; anthoxanthum, or vernal grass; aristida; arundo, or reed; avena, or oats; bobartia; briza; bromus; cinna; cornucopiae, or horn-of-plenty grass; cynosurus; dactylis; elymus; festuca, or fescue-grass; hordeum, or barley; lagurus, or hare's-tail grass; lolium, or darnel; lygeum, or hooded matweed; melica; mileum, or millet; nardus; oryza, or rice; panicum, or panic-grass; paspalum; phalaris, or canary-grass; phleum; poa; saccharum, or sugar-cane; secale, or rye; stipa, or winged spike-grass; triticum, or wheat; uniola, or sea-side oats of Carolina; coix, or Job's tears; olyra; pharus; tripsacum; zea, Indian Turkey wheat, or Indian corn; zizania; ægilops, or wild fescue-grass; andropogon; apluda; cenchrus; holcus, or Indian millet; ischæmum. See BOTANY, p. 1305, col. 2.

GRAMMAR.

1. **GRAMMAR** is the art of speaking or of writing any language with propriety.

2. Grammar considered as an *Art*, necessarily supposes the previous existence of language; and as its design is to teach any language to those who are ignorant of it, it must be adapted to the genius of that particular language of which it treats.—A just method of grammar, therefore, supposing a language introduced by custom, without attempting any alterations in it, furnishes certain observations called *rules*, to which the methods of speaking used in this language may be reduced; this collection of rules is what is called a *grammar* of any particular language. For the greater distinctness with regard to these rules, grammarians have usually divided this subject into four distinct heads, viz. *ORTHOGRAPHY, or the art of combining letters into syllables, and syllables into words; ETYMOLOGY, or the art of deducing one word from*

another, and the various modifications by which the sense of any one word can be diversified; SYNTAX, or what relates to the construction or due disposition of the words of a language into sentences or phrases; and PROSODY, or that which treats of the quantities and accents of syllables, and the art of making verses.

3. But grammar considered as a *Science*, views language in itself: neglecting particular modifications, or the analogy which words may bear to each other, it examines the analogy and relation between words and things; distinguishes between those particulars which are *essential* to language, and those which are only *accidental*; and thus furnishes a certain standard by which different languages may be compared, and their several excellencies or defects pointed out. This is what is called *PHILOSOPHIC or UNIVERSAL GRAMMAR*.

OF UNIVERSAL GRAMMAR.

4. **IT** is not necessary here to inquire how language was originally invented, to trace the various changes it may have undergone, or to examine whether any one language may be considered as the original from which all others have been derived: it is sufficient for our purpose to observe, that all mankind, however diversified in other respects, agree in the common use of language; from which it appears, that language is not merely accidental and arbitrary, but founded in the nature of things, and within the reach of all mankind. It is therefore an object worthy of a philosophic inquiry, to discover the foundations upon which this universal fabric has been raised.

5. The design of speech is to publish to others the thoughts and perceptions of our mind. The most acute feelings of man, as well as of every other ani-

mal, are expressed by simple inarticulate sounds, which, as they tend to the preservation of the individual, are universally understood. These inarticulate but significant sounds, therefore, constitute a natural and universal language, which man, as a mere sensitive being, partakes in common with the other animals. But as man is not only endowed with sensation, but with the faculty of reasoning, simple inarticulate sounds are insufficient for expressing all the various modifications of thought, or for communicating to others a chain of argumentation: it was therefore necessary to call in the aid of *articulation*; which by modifying these simple sounds, and by fixing a particular meaning to these modifications, forms the language peculiar to man, and which distinguishes him from all other animals, and enables him to communicate with facility all

all that diversity of ideas with which his mind is stored. These sounds, thus modified and having a determinate meaning, are called **WORDS**; and as all language is composed of significant words variously combined, a knowledge of them is necessary previous to our acquiring an adequate idea of language.

6. But, as it is by words that we express the various ideas which occur to the mind, it is necessary to examine how ideas themselves are suggested, before we can ascertain the various classes into which words may be distributed. With this view, therefore, let us suppose a reasonable being, devoid of every prepossession whatever, placed upon this globe. His attention would, in the first place, be directed to the various objects which he saw existing around him: these he would naturally endeavour to distinguish from one another, and give them names, by means of which the idea of them might be recalled when the objects themselves were absent. This is one copious source of words; and forms a natural class which must be common to every language, and which is distinguished by the name of **NOUNS**. And as these nouns are the names of the several substances which exist, they have likewise been called **SUBSTANTIVES**.

7. It would likewise be early discovered, that every one of these substances was endowed with certain qualities or attributes, to express which another class of words would be requisite. Thus, *to be weighty*, is a quality of matter; *to think*, is an attribute of man. Therefore, in every language, words have been invented to express the various qualities of the several objects which exist. These may all be comprehended under the general denomination of **ATTRIBUTIVES**.

8. These two classes of words must comprehend all things that exist: for whatever exists, must of necessity be either a substance, or the attribute of some substance; and hence these two classes must comprehend all those words which are significant of themselves, and may be called **WORDS SIGNIFICANT OF THEMSELVES**. If any other words occur, they can only be significant in so far as they tend to explain or connect the words of the two former classes.

9. But, although these words form the basis or matter of a language, in the same manner as stones form the matter of a building; yet, as stones cannot be arranged into a regular structure without a cement to bind and connect them, so these original words stand in need of others to connect them, before they can be made to express all the variety of our ideas. Another order of words, therefore, was necessary, which, although not of themselves significant, yet, when joined with others, might acquire a meaning. These form a second general class of words, that may be called **WORDS NOT OF THEMSELVES SIGNIFICANT**, and which cannot acquire any meaning but so far as they serve either to **EXPLAIN** or **CONNECT** the others.

10. Hence, therefore, all words which can possibly be invented, may be divided into two general classes; those that are **SIGNIFICANT OF THEMSELVES**, and those that are **NOT**. Words which are significant of themselves, are either expressive of the names of substances, and therefore called **SUBSTANTIVES**; or, of qualities, which we call **ATTRIBUTIVES**. Words which are not significant of themselves, must acquire a meaning either as defining or connecting others, which we shall

arrange under the two classes of **DEFINITIVES** and **CONNECTIVES**, each of which shall be examined in their order.

CHAPTER I. OF SUBSTANTIVES.

11. **SUBSTANTIVES** may be divided into two classes, viz. those which are primary, commonly called **NOUNS**; and those of a secondary order, which are often substituted for nouns, and are hence called **PRONOUNS**; each of which we shall consider separately.

SECT. I. Of Substantives of the First Order, called **NOUNS**.

12. **NOUNS** are all those words by which objects or substances are denominated, and which distinguish them from one another, by names applicable to each, without marking either quantity, quality, action, or relation. And as all the objects which exist must be either in the same state that they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, this naturally suggests a division of nouns into **NATURAL**, as *man, vegetable, tree, &c.*; **ARTIFICIAL**, as *house, ship, watch, &c.*; **OF ABSTRACT**, as *whiteness, temperance, &c.*

13. But the diversity of objects being so great as to render it impossible for any person to know the distinct names of every individual, therefore it has been found expedient to arrange them under certain general classes, the names of which may be more easily acquired, so that by referring any unknown object to the class to which it belongs, we in some measure supply the want of proper names. Hence, therefore, each of the above species of nouns are divided into those which denote genera, species, and individuals. Thus, in natural substances, *animal, vegetable, and fessile*, denote genera; *man, dog, tree, metal*, are species; and *Alexander, Caesar, oak, gold*, are individuals. In artificial substances, *edifice* is a genus; *house, tower, church*, are species; and *the Vatican, Tron-church, and Herriot's-hospital*, individuals. In abstract substances, *motion* is a genus; *flight and course*, are species; *the flight of Mahomet, the course of a grey-hound*, are individuals. Each of these general classes might be subdivided into many smaller; but as these lesser divisions can only relate to the particular genius of different languages, it does not fall within our plan to consider them. We therefore proceed to take notice of the accidents which accompany nouns. Of which kind may be reckoned *number* and *gender*.

14. As nouns are the names of *substances*, and as there may be many substances of the same kind, therefore nouns must be adapted to express whether there is one or more of those objects of which we speak. Nouns, therefore, in every language, admit of a certain variation to denote this circumstance, which is called *number*. Thus, in the English language, when we speak of a single place of habitation, we call it *a house*; but if of more, we call them *houses*. In the first of these cases the noun is said to be in the *singular*, and in the last case the *plural* number: nor does the English, or any other language except the Greek, admit of any other variation but these two: and altho' the Greek language admits of a particular variation of the

Of nouns.

the noun called the *dual* number, which is a plural limited to two objects; yet this cannot be considered as essential to language; and it is perhaps doubtful whether this variation ought to be considered as an elegance or a defect in that language.

15. But although number be a natural accident of nouns, it can only be considered as essential to those which denote genera or species, as it does not descend to individuals. Thus we say, *animal*, or *animals*, *vegetables*, and *soffits*; as also *man*, or *men*, *dogs*, *trees*, &c. But we only say, *Xenophon*, *Cæsar*, *Bucephalus*, &c. in the singular. Nor do these admit of a plural, excepting when we consider any proper name as a general appellation under which many others are arranged, when it is no longer the name of an individual, but that of a species, and as such admits of a plural; as the *Alexanders*, the *Ptolemies*, the *Howards*, the *Pelham*s, the *Montague*s, &c. The reason of all which will be obvious, if we consider, that every genus may be found whole and entire in each of its species; for *man*, *horse*, and *dog*, are each of them an entire and complete *animal*: and every species may be found whole and entire in each of its individuals; for *Socrates*, *Plato*, and *Xenophon*, are each of them completely and entirely a *man*. Hence it is, that every genus, though *ONE*, is multiplied into *MANY*; and every species, though *ONE*, is also multiplied into *MANY*, by reference to those beings which are their subordinates. But as no individual has any such subordinates, it can never in strictness be considered as *MANY*, and so is truly an *INDIVIDUAL* as well in nature as in name, and therefore cannot admit of number.

16. Besides number, another accident of nouns is gender, the nature of which may be thus explained: As nouns are the names of the various objects in nature; and as the distinction of sex is perceptible among all those objects which are animated, and as those which are inanimate cannot admit of any sex at all; therefore all the beings which can become the objects of our speculation, may be considered as either *males* or *females*, or such as admit of *no* sex, and therefore may be said to be neuter, or of *neither* sex. Hence, therefore, grammarians have made a threefold distinction of nouns, into *masculine genders*, or those which denote *males*; *feminine*, or those which denote *females*; and *neuters*, which denote those substances that admit of no sex. But, although the origin of genders is thus so clear and obvious; yet every language that we know of, except the English, deviates from the order of nature, and often attributes sex to those substances which are totally incapable of any: nay, some languages are so particularly defective in this respect, as to class every object inanimate as well as animate under either the *masculine* or *feminine* gender, as they admit of no gender for those that are of neither sex. This is the case with the French, Italian, and Spanish. But the English, strictly following the order of nature, puts every noun which denotes a male animal, and no others, in the *masculine* gender; every name of a female animal, in the *feminine*; and every animal whose sex is not obvious, or known, as well as every inanimate object whatever, in the *neuter* gender. Nor does this rule admit of any exceptions; although poets take the liberty of personifying any objects they think pro-

Of nouns.

per, and endow them with whatever sex suits their purpose best; which serves admirably to distinguish between the cool language of philosophy, and the enthusiasm of poetry.

17. Although *Cases* are not necessary accidents of nouns; yet as they have been often considered as such, it will perhaps be deemed proper to take some notice of them.—As natural objects remain the same, altho' observed from many different points of view, they are not in their own nature altered, although they may be connected with others in many different ways: their names therefore ought to remain unchanged, although their relations to other words may be varied. However, there are certain circumstances in which nouns may be considered with respect to their relation to, and connection with, other words, which occur more frequently than others. Some languages (particularly the Greek and Latin) express *some* of these circumstances by a variation of the original noun, which variations are called *CASES*. But the English, and almost all the modern languages of Europe, have followed the order of nature, and allow the noun to remain the same, expressing its relation and connection with other words by the help of distinct words called *prepositions*.—Which of these methods is best, it is not our present purpose to inquire. See *LANGUAGE*.

18. It has been supposed the English nouns admit of one variation which answers to the genitive case of the Latins.—Thus the word *Alexander* is an English noun in its proper form, and in that case which in Latin would be called the *Nominative*. The variation which they called the *Genitive Case*, is expressed in English by adding the preposition *of* before the noun; thus, *of Alexander*. But the same meaning may be conveyed by the word *Alexander's*; for the meaning is the same, if I say the house of *Alexander*, or *Alexander's* house. This, therefore, has been called a true inflection of the original noun. However, although this opinion has been adopted by all grammarians, it appears to have been adopted without sufficient examination, as will be evident from the following considerations.

There are certain circumstances in which this supposed genitive cannot be substituted instead of the other: for I may say, I speak of *Alexander*, I write of *Cæsar*, I think of *Pompey*; but I cannot say, I speak *Alexander's*, I write *Cæsar's*, or I think *Pompey's*. Hence these two are not in all cases synonymous terms; and therefore one of them must be considered as only accidentally coinciding with the other in particular circumstances.

Again, every one of these supposed genitives can with propriety assume all the various signs of the different *cases* in the English language; for we may say simply, as in the nominative case, *Alexander's* house; but we can also say, *of Alexander's* house, *to*, *with*, *from*, *in*, *by*, or *for Alexander's* house, &c. If this then be a real genitive, it requires the sign of the genitive, as well as of the other cases, to explain it; which would be an absurdity too great to be admitted.—But it may be asked, If these are not genitives, to what class of words can they be referred?

In answer to this, it has been already observed, that the variety of substances is so great, that it is

im-

impossible for any person to know the names of every one of them; and therefore, they have been arranged under the several orders of genera and species. We now further observe, that as the individuals are so exceedingly numerous, it would be impossible even to invent proper names for each, and far less would it be possible to make these names be known to every person who might accidentally see them: therefore, when we want to ascertain any individual object, and distinguish it from all the other individuals of the same species, we are obliged to have recourse to particular epithets, or definitives, to ascertain that individual.—Thus, I see a particular house which I want to distinguish from other houses: this has no particular name of its own: I must therefore ascertain it in the best manner I can: and as the shortest is always the best, we most naturally denominate it from its owner or possessor if we know him; and therefore call it *Alexander's*, *James's*, or *John's*, house.—Here then we see, that the words *Alexander's*, *James's*, and *John's*, do not stand as nouns, but as articles or definitives serving to ascertain and point out the individuality of the noun with which they are joined, and are much nearer allied to adjectives than to substantives. These, therefore, like other articles, do not alter the case of the noun; so that the term *Alexander's house*, is as much the proper name of a particular house, as *Alexander* or *James* are the proper names of particular men, and of consequence may be varied through the different cases as well as the other.—It is surprising, that this idea never occurred to grammarians; for *St Peter's* at Rome, and *St Paul's* at London, are as truly the proper names of these two noble edifices, as the *Rotundo* or the *Circus* are the proper names of two other structures.—We may therefore safely conclude, that the English language admits of no cases at all, and that the only essential accidents of nouns are gender and number.

SECT. II. Of Substantives of the Second Order, called PRONOUNS.

19. ALL conversation passes between individuals. When these individuals are unknown to each other, how shall the one speaker address the other when he knows not his name; or how explain himself by his own name, of which the other is wholly ignorant? This might perhaps have been at first effected by pointing; but as it behoved this method to be extremely inconvenient and defective, it was necessary that a particular class of words should be invented for this purpose; and as these words always supply the place of a noun, they have been called PRONOUNS;—the nature of which may be explained as follows.

20. Suppose the parties conversing to be wholly unacquainted, and the subject of the conversation to be the speaker himself: here, to supply the place of pointing, the inventors of language have furnished the speaker with the pronoun *I*; *I write*, *I desire*: and as the speaker is always principal with respect to his own discourse, they have therefore called this the *pronoun* of the first person.

Again, suppose the subject of the conversation to be the party addressed: here, for similar reasons, they invented the pronoun *THOU*, *THOU writest*, *THOU walkest*; and as the party addressed is next in dignity to the

speaker, or at least comes next with reference to the discourse, they therefore called this the *pronoun* of the second person.

But as the subject of the conversation may be some third object different from either the speaker or the party addressed, another pronoun was necessary; and as this object might be either a *male* or a *female*, or a *neuter*, it was necessary to have one pronoun for each of the genders, *HE* for the *masculine*, *SHE* for the *feminine*, and *IT* for the *neuter*: and this, in distinction to the former, was called the *pronoun* of the third person.—Hence the distribution of pronouns into *persons*.

21. We have already seen that nouns admit of number; pronouns, which are their substitutes, likewise admit of number. There may be many speakers of the same sentiment, as well as one who including himself speaks the same sentiment with many; speech may likewise be addressed to many at a time as well as to one; and the subject of the discourse may likewise be many; therefore the pronoun of every one of the *persons* must admit of number, to express this singularity or plurality. Hence, therefore, the pronoun of the first person *I*, has the plural *we*; that of the second person *thou*, has the plural *you*; and that of the third person *he*, *she*, or *it*, has the plural *they*, which is equally applied to all the three genders.

22. With regard to gender, we do not find in any language that the pronouns of the *First* or *Second persons* admit of any distinction in this respect: nor was it necessary that they should; as the speaker and party addressed are usually present with one another, this distinction is generally obvious from dress and external appearance. But this is not the case with regard to the pronoun of the *Third person*; of whose character and distinctions we often know no more than what we learn from the discourse itself; and hence it is, that in almost all languages the pronoun of the third person admits of genders, as we have already seen the English admits of the triple distinction of masculine, feminine, and neuter.—The utility of which threefold distinction will be best shewn by an example. Supposing there was no such distinction, and that we should read in any history *HE* caused *HIM* to destroy *HIM*, and were told that the pronoun which is here thrice repeated stood each time for something different; that is to say, for a man, for a woman, and for a city, whose names were *Alexander*, *Thais*, and *Persopolis*. Taking the pronoun thus divested of its genders, it does not appear which of the three was destroyed, which the destroyer, or which the cause that moved to the destruction. But there is no ambiguity when we hear the genders distinguished; and when, instead of the ambiguous sentence, *he* caused *him* to destroy *him*, we are told with the proper distinctions that *she* caused *him* to destroy *it*. Then we know with certainty, that the promoter was the *woman*, that her instrument was the *hero*, and that the subject of her cruelty was the unfortunate city.—From this example we would be surprised how the *Italian*, *French*, and *Spanish*, could express themselves with precision or elegance, with no more than two variations of this person.

23. From the same causes, as a distinction of gender is unnecessary in the pronouns of the first and second persons, we see the reason why a single pronoun to each person, an *I* for the first, and a *THOU* for the second,

Pronouns.

are sufficient for all the purposes of language, as these are always supposed present and obvious. But it is not so with respect to the third person, as the various relations of different objects made it necessary to have not *one*, but *many*; such as, *HE, SHE, IT, THIS, THAT, OTHER, SOME, ALL, ANY, &c.*

24. Although we have said that there is only one pronoun for each of the first and second persons, yet the English reader may perhaps be puzzled with finding two distinct words applied to each; *I* and *ME*, for the first person; *THOU* and *THEE*, for the second. The learned reader will at once see that these two words *ME* and *THEE* are equivalent to the *accusative* case of the Latin pronoun: but, in order to make the meaning of this as plain as possible without embarrassing ourselves about unnecessary terms, we shall only observe, no effect can be produced without a cause, and no action can be performed without producing some effect. The same person may in different circumstances be either the active and efficient cause *of*, or the passive subject who suffers *by*, an action: some languages have therefore formed different words to express the same object in these different circumstances. Thus in the Latin sentences, *Brutus amavit Cassium*, Brutus loved Cassius; and *Cassius amavit Brutum*, Cassius loved Brutus; the word *Brutus* in the first, and *Cassius* in the second, is the form which the noun assumes when it is used as the efficient cause; and *Brutum* and *Cassium* the forms which the same nouns assume when they are represented as the passive subjects. This last, then, is what was called the *accusative* case of the noun, and the first was called the *nominative*. We have already seen, that the English noun admits of no cases, the active subject always preceding the verb, and the passive following it; as is plain from the above sentences, where *Brutus* and *Cassius* remain unchanged in both situations; and the same might be observed of all other modern languages: yet the English and all modern languages admit of a different word to express the different fate of the pronouns. Thus, we say, *I esteem THEE, I admire HIM, I love HER*: in all of which sentences, *I* the pronoun of the first person, is the *active*; and *THEE* of the second person, and *HIM* and *HER* of the third, are the *passive* subjects, and are therefore expressed by the words *THEE, HIM, and HER*. But if the case be reversed, and the pronoun of the first person becomes the passive subject, and the others the active, they assume a different form; thus, *THOU esteamest, HE admires, SHE loves*—*ME*. Hence, therefore, it appears that we have two distinct words for each of these pronouns to express the different states in which they may be represented, exactly analogous to the nominative and accusative cases of the Romans. Whether these are to be admitted as cases of our pronouns, or whether they may not rather be considered as distinct words formed for that particular purpose, is of little consequence for us to inquire; as, in whatever light they be considered, this variation cannot be looked upon as an essential part of language, but only as a particular refinement, invented to prevent the disagreeable repetition of the pronoun, which behaved frequently to have happened without this contrivance. This seems to be the only reason why pronouns have been endowed with this variety, and not nouns. For as nouns are in themselves greatly diversified, the sameness of sounds does not here so often occur as it

would have done in the pronouns, where the same *I, THOU, HE, SHE, or IT*, answers for the name of every object which occurs in nature; but, by this diversity in the form of the words, this circumstance is in some measure obviated. And it is probably for the same reason, that the plural of each of these pronouns is so very different from the singular. Thus, from *I* of the first person is formed *we* in the plural, and from *ME* the plural *us*; from *THOU* and *THEE* the plurals *YE* and *YOU*; from *HE, SHE, HIM, HER, and IT*, the plurals *THEY* and *THEM*. In all of which there is not the least resemblance between the singular and plural of any one word; and, except in *HE* and *HIM, THEY* and *THEM*, there is not any similarity between what may by some be thought to be the different cases of the same word.

25. We have seen that the same object may sometimes be the cause of an action, and sometimes the object which suffers by it. We now observe, that the same object may sometimes be, with regard to the same action, both the active cause and passive subject: as when we say, *Brutus killed himself*. In which case it is evident, that Brutus was both the cause that produced, and the object that suffered by the action; the pronoun *himself* being put for his name: for, were it not for the sameness of the sound, and the ambiguity which would be occasioned by it, we might surely say, *Brutus killed Brutus*. It was therefore necessary to have a particular pronoun for the passive subject, in all those cases where the same object was the agent; and on this account the word *SELF* has been invented, having the plural *SELVES*. This pronoun therefore, which serves on all occasions to represent the action as returning upon the agent that produced it, may be called the *reciprocal pronoun*; which has this peculiarity, that it can never stand by itself, but must always have the assistance of the pronoun in whose place it is substituted; as, *MYSELF, THYSELF, HIMSELF, HERSELF, ITSELF*, with their plurals. But although this seems to have been the original use of this pronoun; yet, in the English language, its use has been extended further; and from its always having a reference to the agent of any action, it has been employed to denote that agent by way of emphasis, as performing the action without the aid or assistance of any other; as, *he himself went*. And from this circumstance it has been further extended to denote any object as performing or suffering any thing which we would not naturally have expected from its known character or nature; as in this sentence: "The most daring of mankind are sometimes startled before they venture upon the commission of any extraordinary crime; even Cæsar himself felt the utmost perturbation of mind before he dared to pass the Rubicon."

26. These are all that can be properly called *personal pronouns*; but there are others which are derived from them, called *possessive pronouns*, as, *MY, THY, MINE, HIS, HER'S, ITS, &c.* the nature of which it will be necessary here to explain. We have already shewn how nouns, when they came to denote possession, were no longer to be considered as nouns, but rather as definitives or articles; so the pronouns which we here consider, being the real substitutes of *nominal* articles, ought also to be considered as a distinct class of *pronominal* articles; for as these never, in any case, can be

sub-

PRONOUNS. substituted for a noun, they cannot be considered as pronouns. Grammarians have been led into the mistake of placing them under this head, because they are the substitutes of these words, which, although they assume the appearance of nouns, only perform the part of definitives. Thus we have seen, that when we say, *Alexander's house*; the word *Alexander's* can only be considered as a definitive: and, in the same manner, if Alexander was the speaker, he might say, *my house*; if the party addressed, it would be, *thy house*; or if any third person, *his*, and in the same manner *hers* or *its*, *house*. In all which cases this possessive pronoun is substituted for that word which only serves to define and ascertain the identity of the noun; and not for the noun itself, which must always be either exprest or understood. Hence the reason why one pronoun becomes the substitute of this noun and its proper definitive, whether that definitive appears in the form of a noun or pronoun: for I can say, "*Alexander's house* is more elegant than *Mary's*," or *his house* is more elegant than *hers*, although *IT* neither is so commodious nor agreeable to live in." In which example it is plain, that the words *his* and *hers* are strictly the substitutes only of *Alexander's* and *Mary's*, and nothing more; whereas the pronoun *IT* is the substitute of the whole noun with its definitive *Alexander's house*. The other class of pronouns possessive, *MINE*, *THINE*, &c. as they do not so much serve to distinguish individuals, as to ascertain the property of the thing spoken of, which may, in a certain sense, be considered as an attribute thereof, are more nearly allied to attributives, and have therefore by some been called *adjectives*. And it must be acknowledged, that these two classes of words are so nearly allied to one another, that it is difficult to ascertain, in all cases, the precise boundary between them.

27. Besides these, there are other words which sometimes assume the province of pronouns, and are generally considered as belonging to this class, although in many cases improperly; such as, *THIS*, *THAT*, *ANY*, *SOME*, *THESE*, *THOSE*, *ALL*, and some others, which may be called *improper pronouns*. To distinguish when they may be considered as pronouns, we may observe, that when they stand by themselves, and supply the place of a noun, as when we say, *this is virtue*, give me *that*, then are they pronouns. But when they are associated to some noun, as when we say, *this habit is virtue*, or *that man defrauded me*; then, as they do not supply the place of a noun, but only serve to ascertain one, they fall rather under the species of *definitives*, or *articles*. And indeed it must be confessed, that these, as well as the possessive pronouns, are more properly adapted to define and ascertain individuals among nouns, than to supply their place; and therefore are oftener to be considered as articles than as pronouns. The best rule to distinguish when they are to be considered as the one or the other, is this. The genuine pronoun always stands by itself; assuming the power of a noun, and supplying its place. The genuine article never stands by itself; but appears at all times associated to something else, requiring a noun for its support, as much as attributives or adjectives.

28. The three orders of pronouns already mentioned, may be called *prepositive*; because they are capable of

introducing or lending a sentence, without having reference to any thing previous. But there is another order of pronouns which can never be employed but to connect sentences, and must therefore always have a reference to some sentence that precedes them; as, *who*, *which*, *what*. The nature of which may be explained as follows.

29. Suppose I say, *light is a body*; *light moves with great celerity*: these would apparently be two distinct sentences. But if, instead of the second *light*, I were to place the prepositive pronoun *it*; and say; *light is a body*, *it moves with great celerity*; the sentences would still be distinct, and two. But if I add a connective, (as for example, *and*) saying, *light is a body*, *and it moves with great celerity*; I then, by connection, make the two into one. Now it is in the united powers of a connective and another pronoun, that we may see the force and character of the pronoun here treated of. For if, instead of the words *and it*, we substitute *that* or *which*; saying, *light is a body which moves with great celerity*; the sentence still retains its unity, and becomes, if possible, more compact than before. We may therefore call this pronoun the *subjunctive*; because it cannot introduce an original sentence, but only serves to subjoin one to some other which is previous.

30. The application of this *subjunctive*, like the other pronouns, is universal. It may be the substitute of all kinds of substantives, natural, artificial, or abstract; general, special, or particular: for we may say; *The man who*, *the ship which*, *Alexander who*, *virtue which*, &c. Nay, it may even be the substitute of all the other pronouns, and is therefore of course expressive of all the three persons. Thus we say, *I who now write*, *thou who now readest*, *he who now heareth*, &c. And thus the *subjunctive* is truly a pronoun from its substitution; there being no substantive existing in whole place it may not stand. At the same time it is essentially distinguished from the other pronouns by this particular, that it is not only a *substitute*, but likewise a *connective*.

31. As to the accidents of this pronoun: From its performing the part of a connective, it of course follows, that neither *gender* nor *number* can be considered as essential to it; because these are always exprest in the preceding parts of the sentence to which it refers; nor do we in fact find, that this pronoun, at least in modern languages, admits of any distinction to denote *number*, although the English language admits of one variation for the *gender*; as we employ *who* for the *masculine* and *feminine*, and *which* for the *neuter gender*, thus: *The man*, or *the woman*, *who went to Rome*; *the tree which stands on yonder plain*, &c. It likewise admits of a variation similar to that of the accusative case; at least when applied to males or females. For when the object, which it represents is the efficient cause of action, it is *who*; as, *the man who fell*, &c.; but when it is the passive subject, it then, in certain circumstances, takes the form of *whom*; as, *the man of whom I speak*; although, this is not universal; as we likewise say, *the man who was beaten*. But the neuter admits of no such distinctions, as we equally say, *the tree which fell*, or *the tree of which I spoke*. But both of these admit of a variation to denote possession or qualities, which is the

Verbs.

word whose for all genders. Thus we say, *Socrates whose only study was virtue; Elizabeth, whose reign was glorious.*

32. To conclude: We have seen that substantives are either *primary* or *secondary*; or, in other words, **NOUNS**, or **PRONOUNS**. The **NOUNS** denote substances, either *natural, artificial, or abstract*; and these either *general, special, or particular*. The **PRONOUNS**, their substitutes, are either *prepositive* or *subjunctive*: the **PREPOSITIVE** is distinguished into three orders, called the *first*, the *second*, and the *third* persons; the **SUBJUNCTIVE** includes the powers of all the three, having *superadded*, as of its own, the peculiar force of a connective.

CHAPTER II. OF ATTRIBUTIVES.

33. As all attributives must either be expressive of the attributes of SUBSTANCES, or of other ATTRIBUTES, we divide this class into two kinds: calling those of the first kind, ATTRIBUTIVES of the FIRST ORDER; and those of the second kind, ATTRIBUTIVES of the SECOND ORDER.

SECT. I. Attributives of the First Order.

34. ATTRIBUTIVES are all those principal words that denote *attributes* considered as attributes. Such, for example, are the words, *black, white, great, little, wise, eloquent, to write, to walk, to speak, &c.* all of which are the *attributes of substances*. Thus *black* is an attribute of *jet*, *white* of *snow*;—*wise* and *eloquent*, as also, *to write* and *to speak*, are attributes of *men*.

In examining the different attributes of substances, we readily perceive that some of them have their essence in *motion*: such are, *to walk, to fly, to strike, to live, &c.* Others have it in the *privation of motion*; as, *to stop, to rest, to cease, to die, &c.* And others have it in subjects that have *nothing to do* with either *motion* or its *privation*; such are the attributes of *great and little, wise and foolish, white and black*, and, in a word, the several *quantities and qualities* of all things. This therefore furnishes a natural division of attributives of this order; and grammarians have called all those, whose essence consists in *motion* or its *privation*, **VERBS**; and all the others have been called **ADJECTIVES**; each of which we shall consider separately.

I. OF VERBS.

35. **VERBS** are all those principal words which denote *attributes*, whose essence consists in *motion, or energies*, (for we choose to make use of this last term, as it implies the exertions of the mind as well as those of the body), or their *privation*. This order of attributives differs from the order called *adjectives*; not only in the particular above-mentioned, but also because adjectives denote only qualities or quantities, which do not admit of any change of state; whereas the verbal attributives may be considered as in several different states, and therefore admit of several variations in the term employed to express these. It may, in the first place, be considered as a simple attribute or energy, without particularizing any circumstance relating to the state it may be in; as in the word *write*. Or, in the second place, as these are all attributives which denote motions or energies, they may

Verbs.

be represented as in the state of actual motion or exertion; as in the word *writing*. Or, lastly, the motion or energy may be finished, and its effect completed; as in the word *written*. Hence, therefore, every verb admits of a threefold variation in every language, in each of which languages they are distinguished by some particular names. Our grammarians have given the name of the INFINITIVE MODE to the original verb itself, and the other two variations of it are both distinguished by the name of PARTICIPLES; that variation which exhibits the verb in its state of energy being called the PARTICIPLE PRESENT OF ACTIVE, and the other variation is called the PARTICIPLE PERFECT OF PASSIVE.

36. These variations of the verb are founded in the nature of things, and therefore must be found in every language under some form or other. As to the other supposed variations of verbs relating to person, number, time, &c. the slightest reflection on this subject will shew, that a verb, considered as a simple attributive, can admit of none of these affections, but must for ever remain the same at all times and in all situations whatever; for who does not see, that the attribute *to write* is the same whether it is possessed by *you, by me, or by any number of different persons*? Nor does this attribute suffer any change, whether it is represented as having been exerted *a thousand years ago, or at this present moment, or at any other assignable period of duration*; but, like every other attribute, it must remain for ever the same. For however *substances* may vary with time, and be incessantly changing; yet *attributes* of every sort are altogether beyond its power. And we must easily perceive, that the attribute which is expressed by the word *goon*, is the same now as it was at the creation, or will be while the world exists. And in the same manner, *to walk, to write, to fly*, denote attributes, which must each of them preserve their own particular nature during all the successive ages of time. Hence therefore we see, that the verbal attribute must for ever remain in that state, or modification, in which it is at first represented. Nor can it suffer any change, however different the circumstances may be in which it can be applied in language. All, therefore, that can be said of these several variations with which grammarians have usually endowed verbs, is this, That, as an attributive, it hath such an intimate connection with a substantive, as necessarily to be united with one, before it can make a principal figure in language: and as that union may be represented as taking place at different times, and under different circumstances, the inventors of some languages have contrived to express these different connections by a single word, instead of doing it by different words, as the thing in itself would naturally require; in the same manner as those who use the short-hand method of writing, make a single character express a whole word or sentence: And as it was most natural for the contrivers of these words to derive them from the verb itself of which they are compounded, they have each of them become a *real* variation of the original word which expresses the verbal attribute; and, from this being a variation of the verbal word, they have at last come to be considered as an *essential* variation of the verb itself, which has occasioned those contradictory definitions, and that confusion of ideas, which we meet with

with among all writers on this subject. But as we here consider language as in itself, without regarding the particular forms under which it may appear, we must reject all these variations of *persons*, *numbers*, *modes*, and *tenses*, which the verb itself has usually been supposed to undergo; and consider them, not as essential variations of the verb itself, but as variations produced in language by the combination of the verb with other parts of speech; and, therefore, relating to *syntax*, and of course belonging to those grammatical disquisitions alone which treat of the peculiarities of any particular language. But as these variations have been so universally considered as essential parts of the verb itself, and as the terms which this division of the verb have introduced into grammar are so frequently to be met with, it will be necessary to explain, in some measure, the meaning of these several terms.

37. In the natural world, no attribute can possibly exist without a substance to which it belongs, nor any substance without possessing certain attributes. So necessary and intimate is the connection between these, that it is as impossible to separate them, as to create or annihilate the several substances that possess these attributes. But although we are thus circumscribed as to our bodily powers, the mind admits not of such limitation; but can, with the utmost facility, separate every quality from every object whatever, and consider them apart; as, *colour* without *superficies*, *superficies* without *solidity*, or *weight* without *matter*, &c. and, when thus separated, apply them to what objects, and in what manner, it pleases. In this manner the mind abstracts those attributes which denote *motions* or *energies* from their *agents* or *energizers*, in the same way as it abstracts *qualities* from their *substances*. And it is these energies thus abstracted, which form that species of words called *verbs*; in the same manner as those attributes which denote *quantities* and *qualities* abstracted from their necessary substances, form *adjectives*. Thus, the term *to walk*, denotes a particular *energy* as considered perfectly apart from every *energizer*, in the same manner as the word *good* denotes a certain *quality* without regard to any particular *substance*.

38. Here then we discover a most essential difference between the order of nature, and that representation of it which man makes by means of words. For in *nature*, every quality must at all times be united with some substance, nor can ever be exhibited separate from it; but in *language*, every attributive, if it be considered at all, must be separated from the object to which it naturally belongs. Hence we see the reason why, in language, every *energy* and *energizer*, not only may be considered separately, but *must* for ever remain separate, unless they be united by some other power than what is necessarily their own. For the attribute *to write*, can no more be united to *man* its proper *energizer*, than a motion could commence without a cause; and till this attribute is united to its proper *energizer*, it must remain in a great measure dead and inefficacious in language.—To communicate life and energy, therefore, to this inert attribute, it must be united to its proper *energizer*; which can only be effected by the help of an assertion of the speaker himself; which may be considered as the same with regard to language, as life is in the natural world.

39. It is evident, that, by the assistance of an assertion, the speaker is enabled to unite any energy to any particular *energizer*, and thus, without making any change upon the attribute itself, represent a variety of changes produced upon other bodies by its means.—Thus, if I say, *I write*, what do I more than assert that I myself am possessed of that particular attribute denoted by the verb *to write*? If I say, *You write*, or *He writes*, what do I more than assert that another person is possessed of that particular attribute or energy?—If I say, *He did write*, I only assert that the same attribute was possessed at another time, by the same person, as before. Hence, therefore, by the help of this assertion of the speaker, we are enabled to join this particular attribute to many different *energizers*, as well as to represent these different combinations as occurring at many different times; so that the same attribute may thus be made to appear under a great many different circumstances, and exhibit a great variety of changes upon other objects, although itself remains unchanged; the several variations which we perceive, only relating to the objects with which it is combined, or the means by which that union is effected.—In the same manner it often happens, that any object in nature, a house, for example, may appear extremely different when viewed from different situations.

40. From the intimate connection that takes place between the energy, the *energizer*, the assertion, and time, these several accessories have been considered as essential parts of the verb; and therefore some grammarians have defined a verb to be *A word denoting an energy, with time, and an assertion*. But if we were thus to confound things with those which may necessarily accompany them, we could never arrive at a clear perception of any subject whatever. But not to enter into the arguments that might be produced to shew the impropriety of this definition, we shall only observe, that by the universal acknowledgment of all grammarians this cannot be just. For they unanimously agree, that the *infinitive mode* is not only a part of every verb, but the *most essential part*; as it forms the root from which all the other parts are derived. But as this mode neither denotes either time or an assertion, it is evident that these, even by their own acknowledgment, can be at best but accessories, and not essential parts of the verb.

41. From these arguments, therefore, we must conclude, that the verb itself admits of no other variations but those already taken notice of;—that before it can produce any active effect in language, like every other attribute, it must be united to some proper *energizer*;—that this union in language can never be effected but by means of an exertion of the vital powers of the speaker, whereby he either publishes his perception thereof, or his will that it should be;—and that this union may be represented as taking place at all the different times that can be assigned. These, therefore, are each of them necessary accompaniments of a verb, but each of them separate and distinct in their own nature, not only from this verb, but from one another; and it becomes an essential part of the syntax of every language, to consider the various ways in which these can be combined and affect one another.—Nay, so intimate has this connection been thought to be by some, that the contrivers of certain languages have arranged

Verbs.

Verbs.

them under particular classes, for the sake of distinctness and precision.—The form which a verb assumed, when thus varied in all the ways that their particular language would admit of, was called the CONJUGATION of the verb; the several parts of which may be understood from the following sketch.

42. When the verb is considered under the compound form of which we now speak, it can admit of variations chiefly in three respects. For, first, supposing the *attribute*, the *energizer*, and the *time* when that attribute was exerted by the energizer, to be the same; a variation may be occasioned by a change being produced in the *perception* or *volition* of the speaker, (which, for brevity, we will call the *assertion*), as in these examples: *I write*, SCRIBO; *I may write*, SCRIBAM; *do you write*, SCRIBE. The variations produced by this means have been called *MODES*. Secondly, Supposing the *attribute*, the *energizer*, and the *assertion*, to be the same; a change may be produced in the *time*, as in these examples: *I do write*, SCRIBO; *I have written*, SCRIPSI; *I shall write*, SCRIBAM, &c. The variations produced from this cause have been called *TENSES*. And thirdly, Supposing the *attribute*, the *time*, and the *assertion*, to remain unchanged, there may be a difference in the *energizer*; and this likewise admits of a division: for as the energizer may be only one or more persons, it must have a variation into *singular* and *plural* on these accounts; as in these examples: *I write*, SCRIBO; *thou writest*, SCRIBIS; *he writes*, SCRIBIT; and in the plural, *we write*, SCRIBIMUS; *ye write*, SCRIBITIS; *they write*, SCRIBUNT. The variations produced from this cause have been called *PERSON* and *NUMBER*.—These are all the variations which have been made in the Latin or Greek languages; and therefore our grammarians, who have adopted every idea they have of grammar from these languages, mention no more: but it was not necessary that they should have kept here; for an attribute is surely as susceptible of the distinction of sex as of person, so that they might have had a variation for *Gender* also; and instead of having one word SCRIBIT to answer for all the three genders, *he, she, or it writes*, they might have had three different words.—The composers of the Hebrew language have adopted this plan, and admit of two variations on this account. And the Russian language admits of a like variation in their verb for these genders; as in this example: ON ZOHELAL, *he has done*; ONA ZOHELALA, *she has done*, &c. But as the two languages above-mentioned do not admit of this distinction, therefore all the variations that our verbs are said to admit of are *MODES*, which include within them *TENSES*, which include under them *PERSONS*, under which head is included *NUMBER*; and these are all the parts into which a CONJUGATION has been divided.—As to what concerns the nature and lesser distinctions of each of these, the following general remarks may be sufficient.

43. With regard to *MODES*; as this relates solely to the *perception* or *volition* of the speaker, it necessarily follows, that there ought to be a distinct and particular *MODE* for each diversity that there can be in his manner of perceiving or willing any thing whatever, the principal of which are the following.

If we simply declare that we perceive any object, or that such a thing is or will be, without any limitation

or contingency, it forms what has been called the *DECLARATIVE* or *INDICATIVE MODE*; as, *I write*.—Again, if we simply represent it to be within our power, or to depend upon our choice, it forms two other modes, which may be called the *POTENTIAL*, as, *I can write*; or the *ELECTIVE*, as, *I may write*.—In the same manner, if the speaker represents himself, or any other object, as *determined* to perform any action, or as *compelled* to it, or as it is his *duty* to perform it; these form so many distinct modes, which may be called the *DETERMINATIVE*, as, *I will write*; the *COMPULSIVE*, as, *I must write*; and *OBLIGATIVE*, as, *I should write*. But although each of these represents the speaker as perceiving the agent under a different light with respect to the action; yet as all of them, except the *indicative*, agree in this, that however much they may represent it as the *duty* or *inclination*, &c. of the agent to perform any action with which they are associated, yet as they are all of the nature of contingents which may never take effect, they are frequently subjoined to any other verb; therefore the Latins have comprehended all of these under one mode, which they have called the *SUBJUNCTIVE*. We only take notice of this circumstance here, to shew, that however naturally sentences may be distinguished into modes, according to the different situation of the speaker; yet as the whole order of the variation of words in the conjugation of a verb is merely arbitrary, those who invent them may arrange them into what order they please, and call them by what names they may think most proper. But, however they may vary the names or external arrangement, this does not affect the things themselves. For, by whatever name the *mode* may be known which comprehends the words expressive of these several meanings, the sentences formed by these will be either *potential*, *obligative*, *compulsive*, &c. as above explained.

All these modes above-mentioned only relate to the different *perceptions* of the speaker. But as man is not only endowed with the powers of *perception*, but those of *volition* also, he must have words to express these; which forms another order of modes. As he is not only dependent himself, but has others depending upon him, he may *command*, *intreat*, *beg*, *pray*, *wish*, *inquire*.—Hence, therefore, so many different orders of modes, the *IMPERATIVE*, *REQUISITIVE*, *PRECATIVE*, *OPTATIVE*, *INTERROGATIVE*, &c. to which may be added the *VOCATIVE*. But although each of these displays a distinct affection of the speaker, yet grammarians have allotted only one variation of the verb for all of these purposes, called the *IMPERATIVE MODE*; all the other volitions being expressed by this, or some other modes, by the help of particular contrivances, which are different in different languages.

44. With regard to that variation of the verb which relates to *time*, called *TENSES*: As an action or event may be represented as happening at any assignable period of time, it is necessary to divide that duration into certain parts, that we may be able to represent the different relations which events bear to one another with respect to this particular. The first and most obvious division of time is into *present*, *past*, and *future*. But we may go farther still in our divisions of time. For as time past and future may be infinitely extended, we may in *universal time past* assume many particu-

lar

Verbs.

Verbs.

lar times past, and in universal time future many particular times future, some more, some less remote, and corresponding to each other under different relations. Even present time, however, in strict physical truth, it may be incapable of it, is by the power of the imagination brought to admit of these differences, and as necessarily implies some degree of extension, as every given line however minute: And hence it is not sufficient for language to denote INDEFINITELY mere *past, present, or future* times; but on many occasions to DEFINE with more precision what *kind of past, present, or future*, is meant.

45. Tenses, therefore, or those variations of a verb which denote a difference of time only, may be all divided into PRESENT, PAST, and FUTURE; each of which may be subdivided into DEFINITE and INDEFINITE. The *definite tenses* are those where the particular instant of time, whether present, past, or future, is pointed out. The *indefinite* are those where past, present, or future time is indicated in general, without confining it to a particular instant in either of these cases. These have been distinguished among grammarians by the name of AORISTS.—Thus when Milton makes Adam say,

*Millions of spiritual creatures walk the earth,
Unseen, both when we wake and when we sleep,*

the verb WALK means not that they were walking at that instant only when Adam spoke, but *indefinitely* in any instant whatever. So likewise, when the same author calls hypocrisy

*— the only evil which WALKS
Invisible except to God alone,*

the verb WALKS has the like aoristical signification. He WENT, he FELL, are *aorists* of the past, as they do not specify any particular instant, but refer to past time in general. So likewise in the legislative sentences, *thou shalt not kill, thou shalt not steal, &c.* the same aoristical meaning is perceived, as the prohibition does not relate to any particular time future, but is extended indefinitely to every time future.

46. But it is not sufficient for a language to denote time in this indefinite manner: it is necessary likewise that it should be capable of specifying any particular instant of time in an exact and definite manner. Thus, if, instead of the word WALK in the first sentence above quoted, we were to put ARE WALKING, it brings down the verb to denote a particular time, and specifies that these *spiritual creatures* are, at that very instant in which Adam speaks, walking upon the earth unseen. In like manner, in the second sentence, if the word WALKS were changed to IS WALKING, it denotes, that hypocrisy, at that particular instant in which the sentence was pronounced, was walking invisible upon the earth. And in the same manner, WAS WALKING, OR WILL BE WALKING, each of them denote, that these energies *were* or *will be* exerted at a particular specified time. These, therefore, form so many distinct definite tenses, under whatever technical name these may be known.

47. Here then we may see the use of that distinction of the different states of the verb, into the *verb properly so called, and participles*. For as the verb itself exhibits the word as altogether *indefinite*; when this is

joined to its proper energizer, it forms all these INDEFINITE TENSES which our language requires. Thus, *I write, I did write, I will write, I may write, I can write, &c.* each of them, although they represent the attribute as united to the energizer in *some past, present, or future* time, do not specify any particular instant, and are therefore so many aorists or indefinite tenses. Whereas in the *participle* the attribute is represented as in a state of exertion, it necessarily follows, that if it be ever united to its energizer, it must point out the particular instant when that union took effect, and of consequence form as great a variety of DEFINITE TENSES as the verb forms of indefinite. Thus, *I am writing*, necessarily implies that I am actually exerting this particular energy at the very instant that I declare it. So likewise, if I say, *I was writing*, it indicates, that at one particular instant of past duration, to which this has a reference, I was actually employed in that particular occupation. This instant is generally fixed by some collateral circumstance; as, “upon the twentieth day of August last, at twelve o’clock, *I was writing*;” or, “when the thunder broke upon the tower in my neighbourhood, *I was writing*,” &c. And the same may be said of future time; as, “to-morrow at ten o’clock *I shall be writing*,” &c. In all of which cases it is obvious, that a particular *now* or *instant* is pointed out, in which the attribute is represented as united to its proper energizer. We might here proceed to shew the various times that each of these different states of the verb might be made to indicate; the number of *tenses* that each mode admitted of; the several changes that might be produced by joining the *participle perfect* with any object; which cannot be here called the *energizer*, but the *subject*; for as the energy is by this participle represented as completed, if it has any connection with any person, as the attribute cannot be affected by any energizer after it is completed, it must of necessity affect the person, instead of being affected by it; and hence it is that the several variations produced by this participle perfect have been called the PASSIVE VOICE of the verb. But as all these particulars only relate to the construction of one particular language, it would lead us a great deal too far from the particular subject of which this article treats. We shall therefore only observe, that besides the above variations of the verb, which the Greeks and Romans have thought proper to make, the terms of which we have adopted; there are many others that they might with equal propriety have made, but which they rather chose to express by the help of other words called *adverbs*. But some other languages have gone further in this respect, and endowed their verbal word with several variations to express several other circumstances than they do. This is particularly the case with the Hebrew language, which, besides the variation for gender above-mentioned, has allotted certain other variations of its verb to express several other circumstances. Thus, *PAKAD* in that language signifies *he visited*; *PAKEDA, she visited, &c.*; *PIKKED, he visited diligently*; *HEPHKED, he made him visit*; and *HETHEPKED, he visited himself*. In this manner is every verb in that language varied; and each of these different conjugations of their verb admits of a particular variation for the passive of each.—Hence, there-

fore,

fore, the conjugation of a verb in that language admits of a great many variations which neither the Greeks nor Romans were acquainted with: for besides the distinctions of *modes, tenses, persons*, and *number*, they have divided their verb into so many distinct divisions to answer for these distinctions above mentioned, which they have denominated *KAL, PIHEL, HIPHIL, and HITHPAHEL*. with their passives *NIPHAL, RUHAL, and HOPHAL*; each of which admit of variations through all the *modes, tenses, persons, numbers, and genders* which any of their verbs admit of.

48. The only use which we meant to make of these observations on the Hebrew verbs, is this: That as the authors, who have formed their idea of grammar from the forms which the several parts of speech admit of in the Greek and Latin languages, have supposed that every variation which these languages admitted of was a natural and necessary part of language; and that therefore every language which did not admit of the same number of variations, with theirs, in every part of speech, was in so far defective and incomplete; so, for the same reason, an author who had formed his idea of grammar upon the model of the Hebrew tongue, would as naturally suppose, that the several variations which the verb admitted of in his own favourite language were essential and necessary; and that, of consequence, every language which did not admit of as many variations was imperfect and incomplete. But to any one who considers this matter with attention, it will appear, that there could be no end to these unnecessary discussions and groundless claims of fancied superiority: for if compound words have such an advantage over simple, the Chinese language, in which we are told almost every sentence has a particular compound character to express it, must be by far the most perfect in the world; but so far is this from being the case, that every one allows it to be the most imperfect and incomplete. The only method, therefore, which remains for us to consider this subject is, to disregard every particular form of language, and consider the words in themselves, as divested of every extraneous circumstance, and observe what variations they necessarily require, allowing every particular language to compound these with one another in what manner it shall think proper. It is in this manner we have considered the verbal attributives, and endeavoured to disentangle them from those unnecessary fetters with which they have been loaded, and restore them to their own original freedom.

49. Besides the variations above-mentioned, verbs have been distinguished from one another in a different manner; the names and nature of which may be thus explained.

We have already seen, that all verbs, as they denote *energies*, necessarily have reference to certain *energizing substances*. For, how could there be such energies as to *love, to fly, to wound?* &c. were there not such beings as *men, birds, swords*, &c. Farther, every energy not only requires an energizer, but is necessarily conversant about some subject. For example, if we say, *Brutus loves*, we must needs supply — *loves Cats, Cassius*, or some one. And thus it is, that every energy is necessarily situated between two substantives, an energizer which is *active* and a subject which is *passive*. If the energizer leads the

sentence, the energy has been said to follow its character, and becomes what we call a *VERB ACTIVE*: thus we say, *BRUTUS AMAT, Brutus loves*. On the contrary, if the passive subject be principal, it is said to follow the character of this too, and becomes what we call a *VERB PASSIVE*: thus we say, *PORTIA AMATUR, Portia is loved*. But in some verbs it happens, that the energy *always keeps within the energizer*, and never passes out to any extraneous subject. Thus, when we say, *Cæsar walketh, Cæsar sitteth*, it is impossible that the energy *should pass out*, because both the *energizer* and the *passive subject* are united in the *same person*. For what is the cause of this walking or sitting? it is the *will and vital powers* belonging to *Cæsar*: And what is the subject made so to move or sit? it is the *body and limbs* belonging also to the same *Cæsar*. This species of verbs have been by grammarians distinguished by the name of *VERBS NEUTER*, as if they were void both of *action* and *passion*, when perhaps they may be rather said to imply both. It is in this manner, that verbs have been distinguished into the three classes of *active, passive, and neuter*. These, however, might with more propriety be divided into two classes, which might be called verbs *TRANSITIVE*, and *NOT TRANSITIVE*; the first class including all those verbs which are usually called *active*, with the *passives* belonging to them; for it is evident, that these passives are not verbs themselves, but a variation only of a verb; and the second class including those verbs commonly called *neuter*.

Some languages, as the Greek and French, have another class of verbs, which are called by the first *VERBS MIDDLE*, and by the last *RECIPROCAL VERBS*; which are employed to denote that state of any transitive verb, when the energizer himself becomes the subject; as thus, *Brutus killed himself*, &c. But as these only express a slight variation of an accompaniment of a verb, they have no claim to be considered as a distinct species.

II. OF ADJECTIVES.

50. *ADJECTIVES* are all those words which denote attributes whose essence does not consist in motion or its privation: or, in other words, they are those words which denote the attributes of quantity, quality, and relation; such as, *many, few, great and little, black and white, good and bad, double, treble, quadruple*, &c.

As these attributes admit of no change of state, nor can be effected by the variations of time, or any other accident, but are in their own nature perfectly fixed and invariable, the words which express them ought to be in all situations and on all occasions the same. For as the qualities *good or bad, black or white*, admit of no change in their own nature, whether they be applied to a *man*, to a *woman*, to *many* or to *few*; neither ought the word which expresses any one of these attributes in strictness to admit of any alteration, whether it be joined to one or other of these substantives. So that although, in some languages, from the particular construction of the other parts of speech, it has been found necessary to endow their adjectives with the threefold distinction of *gender, number, and case*; yet this must only be considered as an accidental variation occasioned by particular circumstances, and not

adverbs.

Adverbs.

in the least essential to language, but rather a deviation from the order of nature, which would require them to be kept invariably the same in all cases. This order, the English language (which in this and almost every other case is most strictly conformable to the nature of things than any other language we are acquainted with) most strictly observes; as we say equally, *a good man, or a good woman, a good house; or good men, good houses, &c.*

It has probably been from observing that the adjectives in some particular languages are endowed with variations conformable to the gender, number, and case of their substantives, that grammarians have been led into the strange absurdity of ranging them with nouns, and separating them from verbs; though with respect to verbs they are perfectly homogeneous, and with respect to nouns they are quite the contrary. Adjectives are homogeneous with respect to verbs, as both sorts denote *attributes*; they are heterogeneous with respect to nouns, as *never properly denoting substances*.

31. Besides original adjectives, there is another class which are formed from substantives. Thus when we say, *the party of Pompey, the style of Cicero, the philosophy of Socrates*; in these cases, the party, the style, and philosophy spoken of, receive a stamp and character from the persons they respect, and actually pass into attributives, and as such assume the form of *adjectives*. And hence we say, *the Pompeian party, the Ciceronian style, and the Socratic philosophy*. In like manner, for a trumpet of brass, we say, *a brazen trumpet*; for a crown of gold, *a golden crown, &c.* Even pronominal substantives admit the like mutation; as, instead of saying the book of *me, of thee, or of him*, we say, *my book, thy book, his book, &c.* Yet it must be acknowledged, that these, as they often serve rather to define a noun than to denote any quality appertaining to it; they partake more of the nature of *articles* than *adjectives*; so that it is in many cases difficult to ascertain exactly to which class they are to be referred. But of this we have already taken particular notice.

The nature of these variations of adjectives, which have been called *degrees of comparison*, will be more properly explained under the following section.

SECT. II. Of Attributives of the Second Order, called ADVERBS.

52. As the Attributives hitherto mentioned denote the *attributes of substances*, so there is an inferior class of them which denote the *attributes only of attributes*. To explain these by examples of either kind: When we say, "*Cicero and Pliny were both of them eloquent; Statius and Virgil both of them wrote*;" in these instances, the attributes *eloquent* and *wrote*, are immediately referable to the substantives *Cicero, Virgil, &c.*: As, therefore, denoting the *attributes of substances*, we call them *ATTRIBUTIVES OF THE FIRST ORDER*. But when we say, "*Pliny was moderately eloquent, but Cicero exceedingly eloquent; Statius wrote indifferently, but Virgil wrote admirably*;" in these instances, the attributives *moderately, exceedingly, indifferently, and admirably*, are not referable to substantives, but to *other attributes*; that is, to the words *eloquent* and *wrote*: As, therefore, denoting *attri-*

butes of attributes, we call them *ATTRIBUTIVES OF THE SECOND ORDER*. These have been by grammarians, called *ADVERBS*. And indeed, if we take the word *verb* in its most comprehensive signification, as including all the words which denote the *attributes of substances*, (which was the sense in which Aristotle and many of the most ancient grammarians employed it), we shall find the name *adverb* to be a very just appellation, as denoting *a part of speech the natural appendage of verbs*. So great is this dependence in grammatical syntax, that an *adverb* can no more subsist without its *verb*, than a *verb* can subsist without its *substantive*.

53. Among the attributes of substances are reckoned quantities and qualities. Thus we say, *a white garment, a high mountain, &c.* Now some of these quantities and qualities are capable of *intension* and *remission*. Thus we say, *a garment exceedingly white, a mountain tolerably or moderately high*. Hence, then, one copious source of secondary attributives, or adverbs, to denote these two, that is, *intension* and *remission*; such as, *greatly, vastly, extremely, sufficiently, moderately, tolerably, indifferently, &c.*

But where there are different intentions of the same attribute, they may be compared together: thus, if the garment A be *exceedingly white*, and the garment B be *moderately white*, we may say, the garment A is *more white* than the garment B. In these instances, the adverb *more* not only denotes *intension*, but *relative intension*. Nay, we stop not here, as we not only denote *intension merely relative, but relative intension* *than which there is none greater*. Thus we not only say, *the mountain A is more high than the mountain B*, but that it is *the most high of all mountains*. Even verbs properly so called, as they admit of *simple intensions*, so they admit also of these *comparative ones*. Thus, in the following example, *Same he loveth more than riches, but virtue of all things he loveth most*; the words *more* and *most* denote the different *comparative intensions* of the verbal attribute *loveth*.

54. Hence the rise of *COMPARISON* of adjectives, and of its different *degrees*, which cannot well be more than the two species above-mentioned; one to denote *simple excess*, and one to denote *superlative*. Were we indeed to introduce more degrees than these, we ought perhaps to introduce *infinity*, which is absurd. For why stop at a limited number, when in all subjects susceptible of intension the intermediate excesses are in a manner infinite? There are infinite degrees of *more white*, between the first *simple white*, and the superlative *whitest*; and the same may be said of *more great, more strong, more minute, &c.* The doctrine of grammarians about three such degrees of comparison, which they call the *positive, the comparative, and the superlative*, must be absurd; both because in their positive there is no comparison at all, and because their superlative is a comparative as much as their comparative itself. Examples to evince this may be met with every where; *Socrates was the most wise of all the Athenians; Homer was the most sublime of all poets, &c.*

55. The authors of language have in some instances contrived a way to retrench these comparative adverbs, by expressing their force by an inflection of the primary

primary attributive. Thus, instead of *more fair*, they say FAIRER; instead of *most fair*, FAIREST: and the same method of composition takes place both in the Greek and Latin languages; with this difference, however, between the genius of these languages and ours, that we are at liberty to form the comparison either in the one method or the other; but, in these languages, the comparison is almost never formed by the assistance of the adverb, but always by the inflection of the adjective; and hence this inflection is always considered by them as a necessary accident of the adjective. But this method of expressing the power of the adverb has reached no farther than to adjectives, or to their participles, which are so nearly allied to adjectives. Verbs were perhaps thought to be too much diversified, to admit of more variations without perplexity.

56. Some qualities admit of comparison, others admit of none: such, for example, are those which denote that quality of bodies arising from their figure; as when we say, a circular table, a quadrangular court, a conical piece of metal, &c. The reason is, that a million of things participating the same figure, participate it equally if they do it all. To say, therefore, that while A and B are both quadrangular, that A is more or less quadrangular than B, is absurd. The same holds in all attributives denoting definite quantities, of whatever nature. For as there can be no comparison without intension or remission, and as there can be no intension or remission in things always definite, therefore these attributives can admit of no comparison. By the same method of reasoning, we discover the cause why *why no substantive is susceptible of these degrees of comparison*. A mountain cannot be said MORE TO BE or TO EXIST than a mole-hill; nor the lion A cannot be more a lion than the lion B: but the more or less must be sought for in their quantities and qualities; a mountain is more bulky than a mole-hill, and the lion A is more fierce than the lion B; the excess being always derived from their attributes.

57. Of the adverbs or secondary qualities already mentioned, those denoting intension and remission may be called adverbs of QUANTITY CONTINUOUS; *once, twice, thrice*, &c. are adverbs of QUANTITY DISCRETE; *more and most, less and least*, to which may be added *equally, proportionally*, &c. are adverbs of RELATION. There are others of QUALITY; as when we say, *HONESTLY industrious, PRUDENTLY brave; they fought BRAVELY, he painted FINELY*, &c.

58. The adverbs hitherto mentioned, are common to verbs of every species; but there are some which are confined to verbs properly so called, that is to say, to such as denote motions or energies with their privations. All motion and rest imply time and place as a kind of necessary coincidence. Hence, if we would express the place or time of either, we must needs have recourse to adverbs formed for this purpose; of PLACE, as when we say, *he stood THERE, he went HENCE, he travelled FAR*, &c.; or of TIME, as when we say, *he stood THEN, he went AFTERWARD, he travelled FORMERLY*, &c. Should it be asked, Why adverbs of time, when verbs have tenses? The answer is, though tenses may be sufficient to denote the greater distinctions of time, yet to denote them all by tenses would be a perplexity without end. What a variety of forms

would be necessary to denote yesterday, to-day, to-morrow, formerly, just now, now, immediately, presently, soon, hereafter? &c.

59. To these adverbs just mentioned may be added those which denote the intensions and remissions peculiar to MOTION, such as *speedily, hastily, swiftly, slowly*, &c.; as also adverbs of place made out of prepositions, such as *upward and downward, from up and down*. In some instances the preposition suffers no change, but becomes an adverb by nothing more than its application; as when we say, *he rides ABOUT, he was NEAR falling*, &c.

60. There are likewise adverbs of INTERROGATION: such as, *where, whence, whither, how*, &c. of which there is this remarkable, that when they lose their interrogative power, they assume that of a relative, so as to represent the relative or substantive pronoun; as in this doggerel translation of a line from Virgil,

And corn doth grow WHERE Troy town stood;
that is to say, *corn groweth in that place in WHICH Troy stood*, the power of the relative being implied in the adverb. It is in like manner that the relative pronoun becomes an interrogative; as in this line from Milton,

Who first seduc'd them to that soul revolt?
The reason of this is as follows: the pronoun and adverbs here mentioned are all, in their original character, RELATIVES. Even when they become interrogatives, they lose not this character, but are still relatives as much as ever: the difference is, that, without an interrogation, they have reference to a subject which is antecedent, definite, and known; with an interrogation, to a subject which is subsequent, indefinite, and unknown, and which it is expected the answer should express and ascertain. *Who first seduc'd them?* The question itself supposes a seducer, to which, though unknown, the pronoun *who* has a reference—*Th' infernal serpent*. Here, in the answer, we have the subject, which was indefinite, ascertained; so that we see *who*, in the interrogation, is as much a relative as if it had been said originally, without any interrogation at all, *It was the infernal serpent who first seduced them*: and thus interrogatives and relatives mutually pass into one another.

Having thus considered all those parts of speech which ARE SIGNIFICANT OF THEMSELVES, we proceed to those AUXILIARY PARTS which are ONLY SIGNIFICANT WHEN ASSOCIATED WITH OTHERS, which we have already said are either DEFINITIVES or CONNECTIVES. Of which in their order.

CHAPTER III.

Concerning DEFINITIVES commonly called ARTICLES.

61. The knowledge of man is at best but limited and confined. Although we have invented words to denominate almost all the substances which exist, yet as it is impossible for any person to be acquainted with all of these, it was necessary to fall upon some contrivance in language to obviate the difficulties which would arise from this cause. With this view, we have already seen, that substances have been divided into general classes, each of which includes under it several lesser in

A.D.

Articles.

Articles.

subdivisions; the names of which general classes, being but few, may be more easily retained, as *animal, edifice, motion*, &c. for by referring the several objects that we may accidentally see, and with which we are unacquainted, to the several classes to which they may belong, we are in some measure enabled to communicate our ideas without the knowledge of the particular names. But as this particular object must in some manner be distinguished from others of the same class to which it belongs, a particular class of words was found necessary to define and ascertain these individuals; which has given rise to this order of words of which we now treat, and which we have called *definitives*, because they serve to *define and ascertain any particular object, so as to separate it from the general class to which it does belong, and of course denote its individuality*. The principal of these definitives have been usually called *ARTICLES*, the nature of which may be explained as follows.

62. Supposing I see an object with which I am totally unacquainted, having a head and limbs, and appearing to possess the powers of self-motion and sensation. If I know it not as an individual, I refer it to its proper species, and call it *a dog, a horse, a lion*, or the like; and if none of the names of any species with which I am acquainted fit it, I refer it to the genus, and call it *an animal*.

But this is not enough. The object to which we are looking, and want to distinguish, is perhaps an individual. — Of what kind? *Known or unknown?* Seen now for the first time, or seen before and now remembered? It is here we shall discover the use of the two articles *A* and *THE*; for the article *A* respects our *primary* perception, and denotes individuals as *unknown*; whereas *THE* respects our *secondary* perception, and denotes individuals as *known*. To explain this by an example, I see an object pass by which I never saw till then: What do I say? *There goes a beggar with a long beard*. The man departs, and returns a week after: What do I then say? *There goes THE beggar with THE long beard*. Here the article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual once *vague* is now recognised as *something known*, and that merely by the efficacy of this latter article, which tacitly insinuates a kind of *previous* acquaintance, by referring a present perception to a like perception already past. Hence therefore we see, that although the articles *A* and *THE* are both of them *definitives*, as they circumscribe the latitude of genera and species, by reducing them, for the most part, to denote individuals; yet they differ in this respect, that the article *A* leaves the individual itself *unascertained*, but the article *THE* *ascertains the individual also*, and is for that reason the more accurate definitive of the two. They differ likewise in this respect, that as the article *A* serves only to separate one particular object from the general class to which it belongs, it cannot be applied to plurals. But as the article *THE* serves to define objects, or refer to them as already known, without relation to number, or any other circumstances, it is applicable to both numbers indiscriminately, as well as nouns of every gender, without suffering any sort of change; for it is evident, that no variation of the nature of the noun can make any difference in those words which

serve to define or denote a certain reference to them. So that although we find some modern languages which admit of a variation of their article, which relates to the gender of the noun with which it is associated, yet this cannot be considered as essential to this species of words: and so far is this from being an improvement to the language, that it only serves to perplex and confuse, as it always presents a particular idea of sex, where in many cases it is not in the least necessary.

63. Of all the parts of speech which may be considered as essential to language, there is none in which we find so many languages defective as in this. For we know of no language, except our own, which has the particular article *A*; and the Latin language has no word of the same import with the word *THE*. The reason of which deficiency is, that as other parts of speech may be so easily converted from their original meaning, and be made to assume the character of definitives, they have made some of these perform both of these offices: and as the article *A* only separates a particular object, and is therefore so nearly allied to a *numeral*, many languages, as the *French, Italian, Spanish, and German*, have made the numeral word *ONE* supply its office; while others, as the *Greek*, have denoted this particular object by a mere negation of the other article; and as the article *THE* agrees with pronouns in this respect, that they both *denote reference*, the Latins made their pronoun, by a forced periphrasis, supply the place of this. But all of these methods of supplying the want of the genuine article are defective, as will appear more particularly by and by.

64. As articles are by their nature definitives, it follows of course, that they cannot be united with such words as are in their own nature *as definitive as they may be*; nor with such words as, *being indefinite, cannot properly be made otherwise*; but only with those words which, though indefinite, are yet capable, through the article, of becoming definite. Hence we see the reason why it is absurd to say *THE I*, or *THE THOU*, because nothing can make these pronouns more definite than they are; and the same may be said of proper names. Neither can we say *THE BOTH*, because these words are in their own nature each of them perfectly defined. Thus, if it be said, “I have read *BOTH* poets,” this plainly indicates a *definite pair*, of whom some mention has been made already. On the contrary, if it be said, “I have read *TWO* poets,” this may mean *any pair*, out of all that ever existed. And hence this numeral, being in this sense *indefinite*, (as indeed are all others as well as itself,) is forced to *assume the article* whenever it would become definite. Hence also it is, that as *two*, when taken alone, has reference to some *primary and indefinite* perception, while the article *THE* has reference to some perception *secondary and definite*, it is bad language to say *TWO THE MEN*, as this would be *blending of incompatibles*, that is to say, of a *defined substantive with an undefined attributive*. On the contrary, to say *BOTH THE MEN*, is good and allowable; because the substantive cannot possibly be less apt, by being defined, to coalesce with an attributive which is defined as well as itself. So likewise it is correct to say, *THE TWO MEN*; because here the article, being placed at the beginning, *extends*

its power as well through substantive as attributive, and equally tends to define them both.

65. As some of the above words admit of no article, because they are by nature as definite as may be; so there are others which admit it not, because they are not to be defined at all. Of this sort are all INTERROGATIVES. If we question about substantives, we cannot say THE WHO IS THIS; but WHO IS THIS? And the same as to QUALITIES, and both kinds of QUANTITIES: for we say without an article, WHAT SORT OF, HOW MANY, NOW GREAT? The reason is, the article THE respects beings already known, and interrogatives respect beings about which we are ignorant; for as to what we know, interrogation is superfluous. In a word, the natural associates with articles are ALL THOSE COMMON APPELLATIVES WHICH DENOTE THE SEVERAL GENERA AND SPECIES OF BEINGS. It is these, which, by assuming a different article, serve either to explain an individual upon its first being perceived, or else to indicate, upon its return, a recognition or repeated knowledge.

66. But although proper names do not admit of the article, being in their own nature definite; yet as these often fall into homonymy, that is, different persons often go by the same name, it is necessary to distinguish these from one another, to prevent the ambiguity that this would occasion. For this purpose we are obliged to have recourse to adjectives or epithets. For example, there were two Grecian chiefs who bore the name of Ajax; and it was not without reason that Mnestheus uses epithets, when his intention was to distinguish the one from the other: "If both Ajaxes cannot be spared, (says he), at least let mighty Te-lawonian Ajax come." But as epithets are in their own nature perfectly indefinite, seeing the same adjective may be applied to infinite subjects, it is necessary to define these when we want to apply them to any particular object; so that it is necessary to endow these with an article, that they may have a reference to some single person only. And thus it is we say, Trypho the grammarian, Apollodorus the Cyrenian, &c. It is with reason, therefore, that the article is here also added, as it brings the adjective to an individuality as precise as the proper name. Even common appellatives, by the help of an article, come to have the force of proper names, without the assistance of any epithet whatever. Thus, in English, city is a name common to many places, and speaker a name common to many men. Yet if we prefix the article, THE CITY means our metropolis; and the THE SPEAKER, a high officer in the British parliament. And hence, by an easy transition, the article, from denoting reference, comes to denote eminence also; that is to say, from implying an ordinary pre-acquaintance, to presume a kind of general and universal notoriety. Thus, among the Greeks, the poet meant Homer, and the stagirite meant Aristotle; not but that there were many poets besides Homer, and many stagirites besides Aristotle, but none equally illustrious.

67. The articles already mentioned are those strictly so called; but, beside these, there are the PRONOMINAL ARTICLES, such as this, that, any, some, all, other, none, &c. Of these we have already spoken in the chapter upon Pronouns, where we have shewn when they may be taken as pronouns, and when as articles. Yet, in truth, if the essence of an article be to define

and ascertain, they are much more strictly articles than any thing else, and ought to be considered as such in universal grammar. Thus, when we say, "this picture I approve, but THAT I dislike," what do we perform by the help of these definitives, but bring down the common appellatives to denote individuals? So when we say, "some men are virtuous, but ALL men are mortal;" what is the natural effect of this ALL and SOME, but to define that universality and particularity which would remain indefinite were we to take them away? The same is evident in such sentences as these: "some substances have sensation, OTHERS want it; choose ANY way of acting, and SOME men will find fault, &c." For here, SOME, OTHER, and ANY, serve all of them to define different parts of a given whole; SOME, to denote a definite part; ANY, to denote an indefinite; and OTHER, to denote the remaining part, when a part has been already assumed. Even the attributive pronouns, my, thy, his, her's, &c. are, in strictness, more properly articles than any thing else, seeing each of them serves only to define and ascertain the individual object to which it is applied. As when we say, "my house is less commodious than YOUR'S; HER form is more elegant than HIS, &c." For, in these examples, what do the words MY and YOUR'S do, but ascertain two individual houses? or the words HIS and HER'S, but ascertain two individual forms, which are compared with one another? In the same manner, we have already seen nouns sometimes lay aside their own proper character, and become definitives, as in the words ALEXANDER'S, CESAR'S, POMPEY'S, &c. which may be said to form so many NOMINAL ARTICLES. But of these we have spoken so fully in the chapter of Nouns, that it is unnecessary to say more of them in this place.

68. Before we leave this subject, we shall produce one example to shew the utility of this species of words; which, although of themselves insignificant and seemingly of small importance, yet, when properly applied, serve to make a few general terms be sufficient for the accurate expression of a great variety of particulars, and thus makes language capable of expressing things infinite, without wandering into infinitude itself.—To explain this: Let the general term be MAN, which I have occasion to employ for the denoting of some particular. Let it be required to express this particular, as unknown; I say, a man:—Known; I say, the man:—Definite; A CERTAIN man:—Indefinite; ANY man:—Present, and near; THIS man:—Present, and distant; THAT man:—Like to some other; SUCH a man:—Different from some other; ANOTHER man:—An indefinite multitude; MANY men:—A definite multitude; A THOUSAND men:—The ones of a multitude, taken throughout; EVERY man:—The same ones, taken with distinction; EACH man:—Taken in order; FIRST man, SECOND man, &c.—The whole multitude of particulars taken collectively; ALL men:—The negation of that multitude; NO man:—A number of particulars present, and at some distance; THESE men:—At a greater distance, or opposed to others; THOSE men:—A number present and near; THESE men:—A number of individuals from another number; OTHER men:—A great number of individuals taken collectively; MANY men:—A small number; FEW men:—A proportionally greater number;

Conjunctions.

Conjunctions.

MORE men :--Smaller number; FEWER men :--And so on we might go almost to infinitude. But not to dwell longer upon this article, we shall only remark, "that minute changes in PRINCIPLES, lead to mighty changes in EFFECTS; so that PRINCIPLES are well intitled to regard, however trivial they may appear."

CHAPTER IV. OF CONNECTIVES.

69. CONNECTIVES, according as they connect either sentences or words, are called by the different names of CONJUNCTIONS or PREPOSITIONS. Of these names, that of the *preposition* is taken from a mere accident, as it commonly stands in connection before the part which it connects. The *conjunction*, as is evident, has reference to its *essential character*. We shall treat of these two separately.

SECT. I. OF CONJUNCTIONS.

70. A CONJUNCTION is a part of speech void of signification itself, but so formed as to help signification, by making two or more significant sentences to be one significant sentence. As, therefore, it is the essence of conjunctions to connect sentences; at the same time that they do this, they must either connect their meaning or not. For example, let us take these two sentences, *Rome was enslaved*—*Cæsar was ambitious*, and connect them together by the conjunction *BECAUSE*; *Rome was enslaved, BECAUSE Cæsar was ambitious*. Here the meanings, as well as the sentences, appear to be connected. But if I say, *manners must be reformed, or liberty will be lost*; here the conjunction *OR*, though it join the sentences, yet, as to their respective meanings, is a perfect *disjunctive*. And thus it appears, that though all conjunctions *conjoin sentences*, yet, with respect to the *sense*, some are *CONJUNCTIVE*, and others are *DISJUNCTIVE*.

Those conjunctions which conjoin both sentences and their meanings are either *COPULATIVES* or *CONTINUATIVES*. The principal copulative in *English* is *AND*. The continuatives are much more numerous; *IF, BECAUSE, THEREFORE, WHEREFORE, HENCE, THAT, &c.* The difference between these is this: The *copulative* does no more than barely couple sentences, and is therefore applicable to all subjects whose natures are not incompatible: *Continuatives*, on the contrary, by a more intimate connection, consolidate sentences into one continuous whole; and are therefore applicable only to subjects which have an *essential coincidence*: For example, it is noway improper to say, *Lyfippus was a statuary, and Priscian a grammarian*; the *sun shineth, and the sky is clear*; because these are things that may co-exist, and yet imply no absurdity. But it would be absurd to say, *Lyfippus was a statuary, BECAUSE Priscian was a grammarian*; though not to say, *the sun shineth BECAUSE the sky is clear*. The reason is, with respect to the first, the coincidence is merely *accidental*: with respect to the last, it is *essential*, and founded in nature.

As to the *continuatives*, they are *SUPPOSITIVES*, such as *if*; or *POSITIVE*, such as *because, therefore, as, &c.* Take examples of each:—*You will live happily if you live honestly*: *You live happily BECAUSE you live honestly*:—*You live honestly, THEREFORE you live happily*. The difference between these *continuatives* is this: The *suppositives* denote *connection*, but do not

assert actual existence; the *positives* imply both the one and the other.

These *positives* above mentioned are either *CASUAL*, such as *because, since, as, &c.* or *COLLECTIVE*, such as *therefore, wherefore, &c.* The difference between which is this: The *casuals* subjoin causes to effects; "the sun is in eclipse, BECAUSE the moon intervenes"; The *collectives* subjoin effects to causes; "the moon intervenes, THEREFORE the sun is in eclipse." We therefore use *casuals* in those instances where the effect being conspicuous we seek for its cause; and *collectives*, in demonstrations and science, properly so called, where the cause being first known, by its help we discern effects.

All these *continuatives* are resolvable into *copulatives*: For, instead of saying, *BECAUSE it is day, it is light*; we may say, *It is day, AND it is light*. Instead of *IF it is day, it is light*; we may say, *It is at the same time necessary to be day, AND to be light*. The reason is, That the power of the *copulative* extends to all connections, as well to the *essential* as to the *casual*. Hence the *continuative* may be resolved into a *copulative* and something more; that is to say, into a *copulative* implying an *essential* coincidence in the subjects conjoined.

As to *casual conjunctions*, we may further observe, that there is no one of the four species of causes which they are not capable of denoting. For example, the *MATERIAL cause*; *The trumpet sounds, BECAUSE it is made of metal*. The *FORMAL*; *The trumpet sounds, BECAUSE it is long and hollow*. The *EFFICIENT*; *The trumpet sounds, BECAUSE an artist blows it*. The *FINAL*; *The trumpet sounds, THAT it may raise our courage*. It is worth observing, that the three first causes are expressed by the strongest affirmation; because, if the effect actually be, that must be also. But this is not the case with respect to the last, which is only affirmed as a thing that may happen. The reason is, That however this may be the end which set the artist first to work, it may still be beyond his power to obtain, and which, like all other contingents, may either happen or not. Hence also it is connected by a particular conjunction, *THAT*, absolutely confined to this cause.

We now come to the *DISJUNCTIVE CONJUNCTIONS*; a species of words which bear this contradictory name, because, while they disjoin the *sense*, they conjoin the sentences.

With respect to these, we may observe, that as there is a principle of *union* diffused through all things by which this whole is kept together and preserved from dissipation; so there is, in like manner, a principle of *diversity* diffused through all, the source of *distinction*, of number, and of order. Now, it is to express in some degree the modifications of this diversity, that *DISJUNCTIVE CONJUNCTIONS* seem at first to have been invented.

Of these *disjunctives*, some are *SIMPLE*, some *ADVERSATIVE*. *Simple*; as when we say, *EITHER it is day, or it is night*:—*Adversative*; as when we say, *It is not day, BUT it is night*. The difference between these is, that the *simple* do no more than merely disjoin; the *adversative* disjoin with a concomitant opposition. Add to this, that the *adversative* are definite; the *simple* indefinite. Thus, when we say, the number

three is not an even number, BUT an odd; we not only disjoin two opposite attributes, but we definitely affirm one, and deny the other. But, when we say, *the number of the stars is EITHER even OR odd*; though we assert one attribute to be, and the other not to be, yet the alternative is, notwithstanding, left indefinite.

As to *adversative disjunctives*, it has been already said, that they imply OPPOSITION. Now, there can be no opposition of the same attribute in the same subject; as when we say, *Nereus was beautiful*. But the opposition must be either of the same attribute in different subjects; as when we say, "*Brutus was a patriot, BUT Cesar was not*;" Or of different attributes in the same subject; as when we say, "*Gorgius was a sophist, BUT not a philosopher*;" Or of different attributes in different subjects; as when we say, "*Plato was a philosopher, BUT Hippias was a sophist*." The conjunctions used for all these purposes may be called *absolute adjectives*.

But there are other adjectives besides these: as when we say, "*Nereus was more beautiful THAN Achilles*,"—*Virgil* was as great a poet as *Cicero* was an orator." The character of these latter is, that they go farther than the former, by marking not only opposition, but that equality or excess which arises from the comparison of subjects; and therefore they may be called *adjectives of comparison*.

Besides the adjectives here mentioned, there are two other species, of which the most eminent are UNLESS and ALTHOUGH: For example, "*Troy will be taken, UNLESS the Palladium be preserved*;" *Troy will be taken, ALTHOUGH Hector defend it*." The nature of these adjectives may be thus explained. As every event is naturally allied to its cause, so, by parity of reason, it is opposed to its preventive; and as every cause is either adequate or inadequate, (inadequate, when it endeavours, without being effectual), so in like manner is every preventive. Now, adequate preventives are expressed by such adjectives—as UNLESS: "*Troy will be taken, UNLESS the Palladium be preserved*;" that is, that this alone is sufficient to prevent it. The inadequate are expressed by such adjectives as ALTHOUGH: "*Troy will be taken, ALTHOUGH Hector defend it*;" that is, *Hector's* defence will prove ineffectual. These may be called adjectives ADEQUATE and INADEQUATE.

Before we leave this subject, we may observe, that the words *when* and *where*, and all others of the same nature, such as *whence*, *whether*, *whenever*, *where-ever*, &c. may be called ADVERBIAL conjunctions; because they participate the nature both of adverbs and conjunctions; of conjunctions, as they conjoin sentences; of adverbs, as they denote the attributes either of time or place. And these adverbial conjunctions (contrary to the character of accessory words, which have strictly no signification but when associated with other words), have a kind of obscure signification when taken alone, by denoting these attributes of time and place. And hence it is, that they appear in grammar like *xyrophytes* in nature, a kind of middle beings, of ambiguous character, which, by sharing the attributes of the higher and the lower, conduce to link the whole together.

SECT. II. Of those Connectives, called PREPOSITIONS.

A PREPOSITION is a part of speech devoid itself of signification, but so formed as to unite two words that are significant, and that refuse to coalesce of themselves. This connective power (which relates to words only, and not to sentences) will be better understood by the following observations.

Some things naturally coalesce and unite of themselves, while others refuse to do so without help, and as it were by compulsion. For example, all quantities and qualities coalesce immediately with their substances: thus it is we say, *a fierce lion, a vast mountain*, &c. In like manner actions coalesce with their agents, and passions with their patients: thus it is we say, *Alexander conquers, Darius is conquered*. Nay, as every energy is a kind of medium between its agent and patient, the whole three, agent, energy, and patient, coalesce with the same facility; as when we say, *Alexander conquers Darius*. Farther than this, as the greatest part of attributives themselves may be characterised, as when we say of such attributives as *ran, beautiful, learned*, &c. "*he ran swiftly, she was very beautiful, he was moderately learned*," &c. these must readily coalesce with the attributes which they thus characterise. From all which it appears, that *those parts of speech unite of themselves in grammar, whose original archetypes unite of themselves in nature*. Hence, therefore, it is, that although substances naturally coincide with their attributes, yet they absolutely refuse doing so one with another: and hence those known maxims in physics, that *body is impenetrable, that two bodies cannot possess the same place*, &c.

From these principles it follows, that when we form a sentence, the substance without difficulty coincides with the verb, from the natural coincidence of substance with energy; *the sun warmeth*: so likewise the energy with the subject on which it operates; *warmeth the earth*: so likewise both substance and energy with their proper attributes; *the splendid sun genially warmeth the fertile earth*. But suppose we are to add other substantives, as, for instance, *air, or beams*; how could these coincide, or under what character be introduced? Not either as the energizer of the verb, nor as the subject on which it operates; for both of these places are already filled up, the first by the word *sun*, and the last by the substance *earth*: not as attributes to these last, or to any other thing; for attributes by nature they neither are nor can be made. Here, then, we perceive the rise and use of prepositions: by these we connect those substantives to sentences, which at the time are unable to coalesce of themselves. Let us assume, for instance, a pair of these connectives, *through* and *with*, and mark their effect upon the substances here mentioned; *the splendid sun with his beams genially warmeth through the air the fertile earth*: the sentence, as before, remains entire and one; the substantives required are both introduced, and not a word which was there before is displaced from its proper station.

It must be here observed, that *most* if not all prepositions seem originally formed to denote the relations of place; because this is that grand relation which ba-

dies or natural substances maintain at all times to one another, whether they are contiguous or remote, whether in motion or at rest. Thus we have prepositions to denote the *contiguous relation of body*; as when we say, *Caius walked with a staff; the statue stood upon a pedestal; the river ran over a precipice*. Others, for the *detached relation*; as when we say, *he is going to Italy; the sun is risen above the hills; these figs came from Turkey*. So, as to *motion and rest*: only with this difference, that here the preposition varies its character with the verb: thus if we say, *that lamp hangs from the ceiling*, the preposition *from* assumes the character of *quiescence*; but if we say, *that lamp is falling from the ceiling*, the preposition assumes a character of *motion*. So in Milton;

— To support uneasy steps
Over the burning marble—

Again,

— He with looks of cordial love
Hung over her enamour'd.—

In the first of these examples, *over* denotes *motion*, and in the last it denotes *rest*.

But though the original use of prepositions was to denote the relations of *place*, they could not be confined to this office only; but by degrees extended themselves to subjects *incorporeal*, and came to denote relations as well *intellectual* as *local*. Thus because, in *place*, he who is *above* has commonly the advantage of him who is *below*, we transfer *over* and *under* to *dominion and obedience*: of a king we say, *he ruled over his people*; of a common soldier, *he served under such a general*: so too we say, *with thought; without attention; thinking over a subject; under anxiety; from fear; out of love; through jealousy, &c.* All which instances, with many of the like kind, shew, that the *first words* of men, like their *first ideas*, had an immediate reference to *sensible objects*; and that, in after days, when they began to discern with their *intellect*, they took these words which they found already made, and transferred them, by *metaphor*, to *intellectual conceptions*. There is indeed no method to express new ideas, but either by *metaphor*, or by *coining new words*; both which have been practised by philosophers, according to the nature and exigence of the occasion.

In the foregoing use of prepositions, we have seen how they are employed by way of *justa-position*; that is to say, where they are prefixed to a word without becoming a part of it: But they may be also used by

way of *composition*; that is, they may be prefixed to a word so as to become a part of it: thus, to *understand*, to *forget*, to *overact*, to *undervalue*, to *outgo*, &c. are so many distinct words formed by prepositions joined intimately with some other word: in all which cases, the prepositions commonly transfuse something of their own meaning into the word with which they are compounded; and this imparted meaning, in most instances, will be found resolvable into some of the relations of *place*, as used either in its *proper* or *metaphorical* acceptance.

BESIDES the above parts of speech, there is another, which cannot be comprehended under any of the foregoing classes, called *INTERJECTIONS*: of this kind are the words, *ah! alas! fie! &c.* This species of words coincide with no part of speech, but are either uttered alone, or else thrown into a sentence, without altering its form either in *syntax* or *signification*. It may be therefore objected, that as we say, that all language is divided into the several parts above enumerated, and this class cannot be comprehended in any of these divisions; of course, the analysis that we have made cannot be just, because it does not comprehend the whole. To this objection it may be answered, that the language of which we have been treating, is that which has been formed by mutual compact, for the purposes of reasoning and speculation; that, besides this artificial language, man, like every other sensitive animal, is endowed with a natural language, by which he can express any strong sensation. This language does not owe its characteristic expression to the arbitrary form of articulation; but derives its whole force from the tone of voice, and modification of countenance and gesture: and of consequence these tones and gestures express the same meaning without any relation to the articulation which they may assume, and are therefore universally understood by all mankind. Now, *interjection* is the name by which we distinguish these natural expressions: these cannot be properly called words, or parts of speech; but certain adventitious sounds, or voices of nature, expressing those passions and natural emotions which spontaneously arise in the mind upon the view or narrative of interesting events. We must, therefore, still conclude, that all language properly so called is composed of *words*, all of which may be arranged into the several classes above-mentioned; and as a recapitulation of the whole that we have said, we have annexed a *TABLE*, which presents at one view the several classes and subdivisions of words.

G R A

GRAMMARIAN, one that is skilled in, or teaches grammar.

Anciently the name *grammarian* was a title of honour, literature, and erudition, being given to persons accounted learned in any art or faculty whatever. But it is otherwise now, being frequently used as a term of reproach, to signify a dry plodding person, employed about words and phrases, but inattentive to the true beauties of expression and delicacy of sentiment. The ancient grammarians, called also *philologists*, must not be confounded with the grammatists, whose sole business was to teach children the first ele-

G R A

ments of language. Varro, Cicero, Meffala, and even Julius Caesar, thought it no dishonour to be ranked grammarians, who had many privileges granted to them by the Roman emperors.

GRAMMONT, a town of France, in the Limousin, remarkable for its abbey, which is the chief of the order. E. Lon. 133. N. Lat. 45. 56.

GRAMPOUND, a town of Cornwall in England, seated on the river Valle in W. Lon. 5. 25. N. Lat. 50. 20. The inhabitants have a considerable manufacture of gloves. It sends two members to parliament,

GRAM-

Grampus
||
Granada.

GRAMPUS, in ichthyology; a species of delphinus. See DELPHINUS.

GRANADA, a province of Spain, which for a long time was a kingdom distinct from the rest of that country, the history of which is given under the article of SPAIN. At present it is sometimes called Upper Andalusia. It is bounded to the south and east by the Mediterranean, to the west and north by Lower Andalusia, and to the north-east by Murcia. Its extent from west to east is two hundred and ten miles; but its greatest breadth exceeds not eighty. The air here is temperate and healthy; and though there are many mountains in the province, and some of them very high, yet they are almost every where covered with vines and fruit-trees, together with laurel, myrtle, sweet-basil, thyme, lavender, marjoram, and other aromatic herbs, which give an exquisite taste to the flesh of their sheep and cattle. A great deal of silk and sugar, flax and hemp, honey and wax, is also produced here; besides dates and acorns, superior to the finest nuts; good stone for building; several forts of gems; fumach, used in dressing goat-skins; and galls, of which a dye is made for leather. The valleys, with which the mountains are interperfed, are extremely beautiful and fertile. The inhabitants of some of the highest mountains are said to be descendants of the Moors; and, though they are become Roman-catholics, retain, in a great measure, their ancient customs, manners, and language. The principal rivers in the province are the Xenil and Guadaltan, besides which there are many lesser streams. Abundance of salt is made in this province; which, though neither so populous nor so well cultivated as when subject to the Moors, yet is as much so as any in Spain. It was the last of the kingdoms possessed by the Moors, and was not reduced and annexed to the crown of Castile until 1492.

GRANADA, the capital of the above province, stands at the conflux of the Xenil and Dario, in a wholesome air and fruitful country, an hundred and eighty miles south of Madrid, in W. Long. 2. 30. N. Lat. 36. 56. It is large and magnificent, containing a great number of very handsome public and private buildings. Its walls, which are adorned with many towers at equal distances, are said to be ten miles in compass. Here are two castles; the one built by the Moors, and the other by Charles V. and Philip II. They both command a very fine prospect; and the first is so large, that it looks like a city by itself, and, it is said, has room enough to accommodate forty thousand people, exclusive of the royal palace, and the convent of St. Francis. Here is also a court of inquisition; a royal tribunal; and an university, founded in 1531; with the see of an archbishop, who has a revenue of forty thousand ducats per annum. A great many noblemen, clergymen, and wealthy citizens, reside in this city, of which the silk trade and manufacture is very great, and the arsenal is said to be the best furnished of any in Spain. The inhabitants, who are partly descended of the Moors, are well supplied with water. There are several fine squares, particularly that called the Bivaramba or Plaza Mayor, where the bull-fights are held; and without the city is a large plain, full of towns and villages, called La Vega de Granada.

GRANADA, or GRENADA, one of the Caribbee islands. See GRENADA.

GRANADA, a town of America, in the province of Nicaragua, and in the audience of Guatemala, seated on the lake Nicaragua, 70 miles from the S. Sea. It was taken twice by the French buccaneers, and pillaged. The inhabitants carry on a great trade by means of the lake, which communicates with the N. Sea. W. Lon. 85. 10. N. Lat. 11. 8.

GRANADA, New, a province of South America, in Terra Firma, about 75 miles in length, and as much in breadth. It is bounded on the N. by Cartagena and St. Martha, on the E. by Venezuela, on the S. by Popayan, and on the W. by Darien. It contains mines of gold, copper, and iron; horses, mules, good pastures, corn, and fruits. It belongs to the Spaniards, and Santa-Fe-de-Bagota is the capital town.

GRANADILLOES, the name of some islands of the Caribbees, in America, having St. Vincent to the N. and Granada to the S. They are so inconsiderable that they are quite neglected; but were ceded to England by the treaty of peace in 1763.

GRANADIER, a soldier armed with a sword, a firelock, a bayonet, and a pouch full of hand-granadoes. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks.

Every battalion of foot has generally a company of grenadiers belonging to it; or else four or five grenadiers belong to each company of the battalion, which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

GRANADO or GRENADE, (in the art of war, a hollow ball or shell of iron or other metal, of about 2½ inches diameter, which being filled with fine powder, is set on fire by means of a small fuse, driven into the fuse-hole, made of well-seasoned beech-wood, and thrown by the grenadiers into those places where the men stand thick, particularly into the trenches and other lodgements made by the enemy. As soon as the composition within the fuse gets to the powder in the grenado, it bursts into many pieces, greatly to the damage of all who happen to be in its way. Granados were invented about the year 1594. The author of the Military Dictionary has the following remark on the use of granados. "Grenades have unaccountably sunk into disuse; but I am persuaded there is nothing more proper than to have grenades to throw among the enemy who have jumped into the ditch. During the siege of Cassel under the Count de La Lippe, in the campaign of 1762, a young engineer undertook to carry one of the outworks with a much smaller detachment than one which had been repulsed, and succeeded with ease from the use of grenades; which is a proof that they should not be neglected, either in the attack or defence of posts."—The word *granado* takes its rise from hence, that the shell is filled with grains, of powder as a pomegranate is with kernels.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time.

Sir Henry Wotton advises to make it look towards the north, because that quarter is the coolest and most temperate,

Granada
||
Granado.

Grandeur
and
sublimity.

temperate. Mr Worlidge observes, that the best granaries are built of brick, with quarters of timber wrought in the inside, to which the boards may be nailed, with which the inside of the granary must be lined so close to the bricks, that there may not be any room left for vermin to shelter themselves. There may be many stories one above another, which should be near the one to the other; because the shallower the corn lies, it is the better, and more easily turned.

GRANDEE, a designation given to a nobleman of Spain or Portugal.

The grandees are allowed to be covered before the king, who treats them like princes, styling them illustrious, in his letters; and in speaking to them, or of them, they are styled Eminences.

Double fig-
uration.

GRANDEUR and SUBLIMITY. These terms have a double signification: they commonly signify the quality or circumstance in objects by which the emotions of grandeur and sublimity are produced; sometimes the emotions themselves.

In handling the present subject, it is necessary that the impression made on the mind by the magnitude of an object, abstracting from its other qualities, should be ascertained. And because abstraction is a mental operation of some difficulty, the safest method for judging is, to choose a plain object that is neither beautiful nor deformed, if such a one can be found. The plainest that occurs, is a huge mass of rubbish, the ruins perhaps of some extensive building; or a large heap of stones, such as are collected together for keeping in memory a battle or other remarkable event. Such an object, which in miniature would be perfectly indifferent, makes an impression by its magnitude, and appears agreeable. And supposing it so large, as to fill the eye, and to prevent the attention from wandering upon other objects, the impression it makes will be so much the deeper. See ATTENTION.

But though a plain object of that kind be agreeable, it is not termed *grand*: it is not entitled to that character, unless, together with its size, it be possessed of other qualities that contribute to beauty, such as regularity, proportion, order, or colour: and according to the number of such qualities combined with magnitude, it is more or less grand. Thus St Peter's church at Rome, the great pyramid of Egypt, the Alps towering above the clouds, a great arm of the sea, and above all a clear and serene sky, are grand; because, beside their size, they are beautiful in an eminent degree. On the other hand, an overgrown whale, having a disagreeable appearance, is not grand. A large building agreeable by its regularity and proportions, is grand; and yet a much larger building destitute of regularity, has not the least tincture of grandeur. A single regiment in battle-array, makes a grand appearance; which the surrounding crowd does not, though perhaps ten for one in number. And a regiment where the men are all in one livery and the horses of one colour, makes a grand appearance, and consequently strikes more terror, than where there is confusion of colour and dress. Thus greatness or magnitude is the circumstance that distinguishes grandeur from beauty: agreeableness is the genus, of which beauty and grandeur are species.

Grandeur
distinguish-
ed from
beauty.

The emotion of grandeur, duly examined, will be found an additional proof of the foregoing doctrine. That this emotion is pleasant in a high degree, requires

no other evidence but once to have seen a grand object: and if an emotion of grandeur be pleasant, its cause or object, as observed above, must infallibly be agreeable in proportion.

The qualities of grandeur and beauty are not more distinct, than the emotions are which these qualities produce in a spectator. It is observed in the article BEAUTY, that all the various emotions of beauty have one common character, that of sweetness and gaiety. The emotion of grandeur has a different character: a large object that is agreeable, occupies the whole attention, and swells the heart into a vivid emotion, which, though extremely pleasant, is rather serious than gay. And this affords a good reason for distinguishing in language these different emotions. The emotions raised by colour, by regularity, by proportion, and by order, have such a resemblance to each other, as readily to come under one general term, viz. *the emotion of beauty*; but the emotion of grandeur is so different from these mentioned, as to merit a peculiar name.

Though regularity, proportion, order, and colour, contribute to grandeur as well as to beauty, yet these qualities are not by far so essential to the former as to the latter. To make out that proposition, some preliminaries are requisite. In the first place, the mind, not being totally occupied with a small object, can give its attention at the same time to every minute part; but in a great or extensive object, the mind, being totally occupied with the capital and striking parts, has no attention left for those that are little or indifferent. In the next place, two similar objects appear not similar when viewed at different distances: the similar parts of a very large object, cannot be seen but at different distances; and for that reason, its regularity, and the proportion of its parts, are in some measure lost to the eye; neither are the irregularities of a very large object so conspicuous as of one that is small. Hence it is, that a large object is not so agreeable by its regularity, as a small object; nor so disagreeable by its irregularities.

3
Demands
not strict re-
gularity.

These considerations make it evident, that grandeur is satisfied with a less degree of regularity, and of the other qualities mentioned, than is requisite for beauty; which may be illustrated by the following experiment. Approaching to a small conical hill, we take an accurate survey of every part, and are sensible of the slightest deviation from regularity and proportion. Supposing the hill to be considerably enlarged, so as to make us less sensible of its regularity, it will upon that account appear less beautiful. It will not, however, appear less agreeable, because some slight emotion of grandeur comes in place of what is lost in beauty. And at last, when the hill is enlarged to a great mountain, the small degree of beauty that is left, is sunk in its grandeur. Hence it is, that a towering hill is delightful, if it have but the slightest resemblance of a cone; and a chain of mountains not less so, though deficient in the accuracy of order and proportion. We require a small surface to be smooth; but in an extensive plain, considerable inequalities are overlooked. In a word, regularity, proportion, order, and colour, contribute to grandeur as well as to beauty; but with a remarkable difference, that in passing from small to great, they are not required in the same degree,

4
Qualities
contributing
to grandeur.

Grandeur
and
Sublimity.

degree of perfection. This remark serves to explain the extreme delight we have in viewing the face of nature, when sufficiently enriched and diversified with objects. The bulk of the objects in a natural landscape are beautiful, and some of them grand: a flowing river, a spreading oak, a round hill, an extended plain, are delightful; and even a rugged rock, or barren heath, though in themselves disagreeable, contribute by contrast to the beauty of the whole; joining to these the verdure of the fields, the mixture of light and shade, and the sublime canopy spread over all; it will not appear wonderful, that so extensive a groupe of splendid objects should swell the heart to its utmost bounds, and raise the strongest emotion of grandeur. The spectator is conscious of an enthusiasm which cannot bear confinement, nor the strictness of regularity and order: he loves to range at large; and is so enchanted with magnificent objects, as to overlook slight beauties or deformities.

The same observation is applicable in some measure to works of art. In a small building, the slightest irregularity is disagreeable: but in a magnificent palace, or a large Gothic church, irregularities are less regarded. In an epic poem, we pardon many negligences that would not be permitted in a sonnet or epigram. Notwithstanding such exceptions, it may be justly laid down for a rule, That in works of art, order and regularity ought to be governing principles; and hence the observation of Longinus, "In works of art we have regard to exact proportion; in those of nature, to grandeur and magnificence."

Sublimity.

The same reflections are in a good measure applicable to sublimity: particularly, that, like grandeur, it is a species of agreeableness; that a beautiful object placed high, appearing more agreeable than formerly, produces in the spectator a new emotion, termed *the emotion of sublimity*; and that the perfection of order, regularity, and proportion, is less required in objects placed high, or at a distance, than at hand.

The pleasant emotion raised by large objects, has not escaped the poets;

He doth bestride the narrow world
Like a Colossus; and we petty men
Walk under his huge legs. *Julius Caesar, act 1. sc. 3.*

Cleopatra. I dreamt there was an emper'or Antony:
Oh such another sleep, that I might see
But such another man!
His face was as the heav'n's; and therein stuck
A sun and moon, which kept their course, and lighted
The little O o'th' earth.
His legs bestrid the ocean, his rear'd arm
Crested the world. *Antony and Cleopatra, act 5. sc. 3.*

Majesty
Dies not alone; but, like a gulph, doth draw
What's near it with it. It's a vast wheel
Fix'd on the summit of the highest mount;
To whose huge spokes ten thousand lesser things
Are mortis'd and adjoin'd; which when it falls
Each small annexment, petty consequence,
Attends the boist'rous ruin. *Hamlet, act 3. sc. 8.*

The poets have also made good use of the emotion produced by the elevated situation of an object:

Quod si me lyricis vatibus inferes,
Sublimi feram sidera vertice. *Horat. Carm. l. 2. ode 1.*

Oh thou! the earthly author of my blood,
Whole youthful spirit, in me regenerate,
Dost with a twofold vigour lift me up,
To reach at victory above my head.

Richard II. act 1. sc. 4.

Northumberland, thou ladder wherewithal
The mounting Iolimbroke ascends my throne.

Richard II. act 5. sc. 2.

Anthony. Why was I rais'd the meteor of the world,
Hung in the skies, and blazing as I travel'd,
Till all my fires were spent; and then cast downward
To be trod out by Cæsar? *Dryden, All for Love, act 1.*

The description of Paradise in the fourth book of *Paradise Lost*, is a fine illustration of the impression made by elevated objects:

So on he fares, and to the border comes
Of Eden, where delicious Paradise,
Now nearer, crowns with her inclose green,
As with a rural mound, the champion head
With a steep wilderness; whose hairy sides
Of thicket overgrown, grotesque and wild,
Access deny'd; and over head up grew
Insuperable height of loftiest shade,
Cedar, and pine, and fir, and branching palm,
A sylvan scene; and at the rarks ascend,
Shade above shade, a woody theatre
Of stateliest view. Yet higher than their tops
The verd'rous wall of Paradise up sprung;
Which to our general eye gave prospect large
Into his nether empire, neighbor'ing round.
And higher than that wall a circling row
Of goodliest trees, loaden with fairest fruit,
Blossoms and fruits at once of golden hue,
Appear'd, with gay enamell'd colours mix'd. *l. 131.*

Though a grand object is agreeable, we must not infer that a little object is disagreeable; which would be unhappy for man, considering that he is surrounded with so many objects of that kind. The same holds with respect to place: a body placed high is agreeable; but the same body placed low, is not by that circumstance rendered disagreeable. Littleness and lowness of place are precisely similar in the following particular, that they neither give pleasure nor pain. And in this may visibly be discovered peculiar attention in fitting the internal constitution of man to his external circumstances. Were littleness and lowness of place agreeable, greatness and elevation could not be so: were littleness and lowness of place disagreeable, they would occasion uninterrupted uneasiness.

The difference between great and little with respect to agreeableness, is remarkably felt in a series when we pass gradually from the one extreme to the other. A mental progress from the capital to the kingdom, from that to Europe—to the whole earth—to the planetary system—to the universe, is extremely pleasant: the heart swells, and the mind is dilated at every step. The returning in an opposite direction is not positively painful, though our pleasure lessens at every step, till it vanish into indifference: such a progress may sometimes produce pleasure of a different sort, which arises from taking a narrower and narrower inspection. The same observation holds in a progress upward and downward. Ascent is pleasant because it elevates us; but descent is never painful: it is for the most part pleasant from a different cause, that it is according to the order of nature. The fall of a stone from

Grandeur
and
Sublimity.

Grandeur
and
Sublimity.

from any height, is extremely agreeable by its accelerated motion. We feel it pleasant to descend from a mountain, because the descent is natural and easy. Neither is looking downward painful; on the contrary, to look down upon objects, makes part of the pleasure of elevation: looking down becomes then only painful when the object is so far below as to create dizziness; and even when that is the case, we feel a sort of pleasure mixed with the pain: witness Shakspeare's description of Dover cliffs:

How fearful
And dizzy 'tis, to cast one's eye so low!
The crows and choughs, that wing the midway air,
Shew scarce so gross as beetles. Half-way down
Hangs one that galleys hamphire; dreadful trade!
Methinks he scems no bigger than his head.
The fishermen that walk upon the beach,
Appear like mice; and yon tall anchoring bark
Diminish'd to her cock; her cock, a buoy
Almost too small for sight. The murrainous surge,
That on th' unnumber'd idle pebbles chafes,
Cannot be heard so high. I'll look no more,
Left my brain turn, and the deficient sight
Topple down headlong.

King Lear, act 4. sc. 6.

A remark is made above, that the emotions of grandeur and sublimity are nearly allied. And hence it is, that the one term is frequently put for the other: an increasing series of numbers, for example, producing an emotion similar to that of mounting upward, is commonly termed an *ascending series*: a series of numbers gradually decreasing, producing an emotion similar to that of going downward, is commonly termed a *descending series*: we talk familiarly of going up to the capital, and of going down to the country: from a lesser kingdom we talk of going up to a greater; whence the *anabasis* in the Greek language, when one travels from Greece to Persia. We discover the same way of speaking in the language even of Japan; and its universality proves it the offspring of a natural feeling.

Grandeur
and sublimity
in a
figurative
sense.

The foregoing observation leads us to consider grandeur and sublimity in a figurative sense, and as applicable to the fine arts. Hitherto these terms have been taken in their proper sense, as applicable to objects of sight only: and it was of importance to bestow some pains upon that article; because, generally speaking, the figurative sense of a word is derived from its proper sense, which holds remarkably at present. Beauty, in its original signification, is confined to objects of sight; but as many other objects, intellectual as well as moral, raise emotions resembling that of beauty, the resemblance of the effects prompts us to extend the term *beauty* to these objects. This equally accounts for the terms *grandeur* and *sublimity* taken in a figurative sense. Every emotion, from whatever cause proceeding, that resembles an emotion of grandeur or elevation, is called by the same name: thus generosity is said to be an *elevated* emotion, as well as great courage; and that firmness of soul which is superior to misfortunes, obtains the peculiar name of *magnanimity*. On the other hand, every emotion that contracts the mind, and fixeth it upon things trivial or of no importance, is termed *low*, by its resemblance to an emotion produced by a little or low object of sight: thus an appetite for trifling amusements, is called a *low taste*. The same terms are ap-

Vol. V.

plied to characters and actions: we talk familiarly of an *elevated* genius, of a *great* man, and equally so of *littleness* of mind: some actions are *great* and *elevated*, and others are *little* and *groveling*. Sentiments, and even expressions, are characterized in the same manner: an expression or sentiment that raises the mind, is denominated *great* or *elevated*; and hence the *SUBLIME* in poetry. In such figurative terms, we lose the distinction between *great* and *elevated* in their proper sense; for the resemblance is not so entire, as to preserve these terms distinct in their figurative application. We carry this figure still farther. Elevation, in its proper sense, imports superiority of place; and lowness, inferiority of place: and hence a man of *superior* talents, of *superior* rank; of *inferior* parts, of *inferior* taste, and such like. The veneration we have for our ancestors, and for the ancients in general, being similar to the emotion produced by an elevated object of sight, justifies the figurative expression, of the ancients being *raised* above us, or possessing a *superior* place. The notes of the gamut, proceeding regularly from the blunter or grosser sounds, to the more acute and piercing, produce in the hearer a feeling somewhat similar to what is produced by mounting upward; and this gives occasion to the figurative expressions, a *high note*, a *low note*.

Such is the resemblance in feeling between real and figurative grandeur, that among the nations on the east coast of Africa, who are directed purely by nature, the officers of state are, with respect to rank, distinguished by the length of the baton each carries in his hand; and in Japan, princes and great lords shew their rank by the length and size of their sedan-poles. Again, it is a rule in painting, that figures of a small size are proper for grotesque pieces; but that an historical subject, grand and important, requires figures as great as the life. The resemblance of these feelings is in reality so strong, that elevation in a figurative sense is observed to have the same effect, even externally, with real elevation:

Real and
figurative
grandeur
intimately
connected.

K. Henry. This day is call'd the feast of Crispian.
He that outlives this day, and comes life home,
Will stand a-tiptoe when this day is nam'd,
And rouse him at the name of Crispian.

Henry V. act 4. sc. 8.

The resemblance in feeling between real and figurative grandeur, is humorously illustrated by Addison in criticising upon English tragedy: "The ordinary method of making an hero, is to clasp a huge plume of feathers upon his head, which rises so high, that there is often a greater length from his chin to the top of his head, than to the sole of his foot. One would believe, that we thought a great man and a tall man the same thing. As these superfluous ornaments upon the head, make a great man; a princess generally receives her grandeur, from those additional incumbrances that fall into her tail: I mean the broad sweeping train, that follows her in all her motions; and finds constant employment for a boy, who stands behind her to open and spread it to advantage." The Scotchians, impressed with the fame of Alexander, were astonished when they found him a little man.

A gradual progress from small to great, is not less remarkable

* Spectator,
No 421.

Grandeur
and
Sublimity.

remarkable in figurative than in real grandeur or elevation. Every one must have observed the delightful effect of a number of thoughts or sentiments, artfully disposed like an ascending series, and making impressions deeper and deeper: such disposition of members in a period, is termed a *climax*.

Within certain limits grandeur and sublimity produce their strongest effects, which lessen by excess as well as by defect. This is remarkable in grandeur and sublimity taken in their proper sense: the grandest emotion that can be raised by a visible object is where the object can be taken in at one view; if so immense as not to be comprehended but in parts, it tends rather to distract than satisfy the mind*: in like manner, the strongest emotion produced by elevation, is where the object is seen distinctly; a greater elevation lessens in appearance the object, till it vanish out of sight with its pleasant emotions. The same is equally remarkable in figurative grandeur and elevation; which shall be handled together, because, as observed above, they are scarce distinguishable. Sentiments may be so strained, as to become obscure, or to exceed the capacity of the human mind: against such licence of imagination, every good writer will be upon his guard. And therefore it is of greater importance to observe, that even the true sublime may be carried beyond that pitch which produces the highest entertainment. We are undoubtedly susceptible of a greater elevation than can be inspired by human actions, the most heroic and magnanimous; witness what we feel from Milton's description of superior beings: yet every man must be sensible of a more constant and sweet elevation, when the history of his own species is the subject; he enjoys an elevation equal to that of the greatest hero, of an Alexander, or a Cæsar, of a Brutus, or an Epaminondas: he accompanies these heroes in their sublimest sentiments and most hazardous exploits, with a magnanimity equal to theirs; and finds it no stretch, to preserve the same tone of mind for hours together, without sinking. The case is not the same in describing the actions or qualities of superior beings: the reader's imagination cannot keep pace with that of the poet; the mind, unable to support itself in a strained elevation, falls as from a height; and the fall is immoderate like the elevation: where that effect is not felt, it must be prevented by some obscurity in the conception, which frequently attends the descriptions of unknown objects. Hence the St Francis, St Dominics, and other tutelary saints among the Roman Catholics. A mind unable to raise itself to the Supreme Being self-existent and eternal, or to support itself in a strained elevation, finds itself more at ease in using the intercession of some faint whose piety and penances while on earth are supposed to have made him a favourite in heaven.

A strained elevation is attended with another inconvenience, that the author is apt to fall suddenly as well as the reader; because it is not a little difficult, to descend, sweetly and easily, from such

elevation, to the ordinary tone of the subject. The following passage is a good illustration of that observation:

Sæpe etiam immensum cælo venit agmen aquarum,
Et sædam glomerant tempestatem imbribus atris
Conlectæ ex alto nubes. Ruit ardens æther,
Et pluvia ingentia fata læta bonumque labores
Diluit. Implentur fossæ, et cava flumina crescent
Cum sonitu, fervetque fretis spirantibus aequor.
Ipse Pater, media nimborum in nocte, corusca
Fulmina molitur dextra. Quo maxima motu
Terra tremit: fugere feræ! et mortalia corda
Per gentes humilis iteravit pavore. Ille flagrant
Aut Atho, aut Rhodopen, aut alta Ceraunia celo
Deiecit: ingeminant austris, et densissimus imber.

Virg. Georg. l. 1.

In the description of a storm, to figure Jupiter throwing down huge mountains with his thunderbolts, is hyperbolically sublime, if we may use the expression: the tone of mind produced by that image, is so distant from the tone produced by a thick shower of rain, that the sudden transition must be unpleasant.

Objects of sight that are not remarkably great nor high, scarce raise any emotion of grandeur or of sublimity: and the same holds in other objects; for we often find the mind roused and animated, without being carried to that height. This difference may be discerned in many sorts of music, as well as in some musical instruments: a kettle-drum rouses, and a hautboy is animating; but neither of them inspires an emotion of sublimity: revenge animates the mind in a considerable degree; but it never produceth an emotion that can be termed *grand* or *sublime*; and perhaps no disagreeable passion ever has that effect.

No desire is more universal than to be exalted and honoured; and upon that account, chiefly, are we ambitious of power, riches, titles, fame, which would suddenly lose their relish did they not raise us above others, and command submission and deference: and it may be thought, that our attachment to things grand and lofty, proceeds from their connection with our favourite passion. This connection has undoubtedly an effect; but that the preference given to things grand and lofty must have a deeper root in human nature, will appear from considering, that many below their time upon low and trifling amusements, without having the least tincture of this favourite passion: yet these very persons talk the same language with the rest of mankind; and prefer the more elevated pleasures: they acknowledge a more refined taste, and are ashamed of their own as low and grovelling. This sentiment, constant and universal, must be the work of nature; and it plainly indicates an original attachment in human nature to every object that elevates the mind: some men may have a greater relish for an object not of the highest rank; but they are conscious of the preference given by mankind in general to things grand and sublime; and they are sensible, that their peculiar taste ought to yield to the general taste.

What is said above suggests a capital rule for reaching

* It is justly observed by Addison, that perhaps a man would have been more astonished with the majestic air that appeared in one of Lysippus's statues of Alexander, though no bigger than the life, than he might have been with Mount Athos, had it been cut into the figure of the hero, according to the proposal of Phidias, with a river in one hand and a city in the other. *Spectator*, No 415.

* Chap. 8.

reaching the sublime in such works of art as are susceptible of it; and that is, to present those parts or circumstances only which make the greatest figure, keeping out of view every thing low or trivial; for the mind, elevated by an important object, cannot, without reluctance, be forced down to bestow any share of its attention upon trifles. Such judicious selection of capital circumstances, is by an eminent critic styled *grandeur of manner* *. In none of the fine arts is there so great scope for that rule as in poetry; which, by that means, enjoys a remarkable power of bestowing upon objects and events an air of grandeur: when we are spectators, every minute object presents itself in its order; but in describing at second hand, these are laid aside, and the capital objects are brought close together. A judicious taste in thus selecting the most interesting incidents, to give them an united force, accounts for a fact that may appear surprising; which is, that we are more moved by spirited narrative at second hand, than by being spectators of the event itself, in all its circumstances.

Longinus * exemplifies the foregoing rule by a comparison of two passages.

Ye pow'rs, what madness! how on hips so frail
(Tremendous thought!) can thoughtless mortals fall?
For stormy seas they quit the pleasing plain,
Plant woods in waves, and dwell amidst the main.
Far o'er the deep (a trackless path) they go,
And wander oceans in pursuit of wo,
No care their hearts, no rest their eyes can find,
On heaven their looks, and on the waves their mind,
Sunk are their spirits, while their arms they rear,
And gods are wearied with their fruitless prayer.

ARISTEUS.

Burst as a wave that from the cloud impends,
And swell'd with tempests on the ship descends.
White are the decks with foam: the winds aloud
Howl o'er the masts, and sing through every shroud.
Pale, trembling, tir'd, the sailors freeze with fears,
And instant death on every wave appears.

HOMER.

In the latter passage, the most striking circumstances are selected to fill the mind with terror and astonishment. The former is a collection of minute and low circumstances, which scatter the thought and make no impression: it is at the same time full of verbal antitheses and low conceit, extremely improper in a scene of distress.

The following description of a battle is remarkably sublime, by collecting together, in the fewest words, those circumstances which make the greatest figure.

"Like autumn's dark storms pouring from two echoing hills, toward each other approached the heroes; as two dark streams from high rocks meet and roar on the plain, loud, rough, and dark in battle, meet Lochlin and Inisfail. Chief mixes his strokes with chief, and man with man: steel founds on steel, and helmets are cleft on high: blood bursts and smokes around: strings murmur on the polish'd yew: darts rush along the sky: spears fall like sparks of flame that gild the stormy face of night.

"As the noise of the troubled ocean when roll the waves on high, as the last peal of thundering heaven, such is the noise of battle. Though Cormac's hundred bards were there, feeble were the voice of a hundred bards to fend the deaths to future times;

"for many were the deaths of the heroes, and wide poured the blood of the valiant."

FINGAL.

Grandeur
and
Sublimity.

The following passage in the 4th book of the Iliad is a description of a battle, wonderfully ardent. "When now gathered on either side, the hosts plunged together in fight; shield is hardly laid to shield; spears crash on the brazen corselets; bosky buckler with buckler meets; loud tumult rages over all: groans are mixed with boasts of men; the slain and slayer join in noise; the earth is floating round with blood. As when two rushing streams from two mountains come roaring down, and throw together their rapid waters below, they roar along the gulph vale. The startled shepherd hears the sound, as he stalks o'er the distant hills; so, as they mixed in fight, from both armies clamour with loud terror arose." But such general descriptions are not frequent in Homer. Even his single-combats are rare. The fifth book is the longest account of a battle that is in the Iliad; and yet contains nothing but a long catalogue of chiefs killing chiefs, not in single combat neither, but at a distance with an arrow or a javelin; and these chiefs named for the first time and the last. The same scene is continued through a great part of the sixth book. There is at the same time a minute description of every wound, which for accuracy may do honour to an anatomist, but in an epic poem is tiresome and fatiguing. There is no relief from horrid langoir but the beautiful Greek language and melody of Homer's verification.

In the twenty-first book of the Odyssey, there is a passage which deviates widely from the rule above laid down: it concerns that part of the history of Penelope and her suitors, in which she is made to declare in favour of him who should prove the most dextrous in shooting with the bow of Ulysses:

Now gently winding up the fair ascent,
By many an easy step, the matron went:
Then o'er the pavement glides with grace divine,
(With polish'd oak the level pavements shine);
The folding gates a dazzling light display'd,
With pomp of various architecture'erlay'd.
The bolt, obedient to the silken string,
Forakes the staple as she pulls the ring;
The wards respondent to the key turn'd round;
The bars fall back; the flying valves resound;
Loud as a bull makes hill and valley ring;
So roar'd the lock when it releas'd the spring.
She moves majestic through the wealthy room,
Where treasure'd garments cast a rich perfume;
There from the column where aloft it hung,
Reach'd, in its splendid case, the bow unsprung.

Virgil sometimes errs against this rule: in the following passages minute circumstances are brought into full view; and what is still worse, they are described with all the pomp of poetical diction, *Æneid*, L. 1. l. 214. to 219. L. 6. l. 176. to 182. L. 6. l. 212; to 231: and the last, which describes a funeral, is the less excusable, as the man whose funeral it is makes no figure in the poem.

The speech of Clytemnestra, descending from her chariot in the Iphigenia of Euripides *, is stuffed with a number of common and trivial circumstances.

But of all writers, Lucan in this article is the most injudicious: the sea-fight between the Romans and Massilians †, is described so much in detail, without

Grandeur
and
Sublimity.

exhibiting any grand or total view, that the reader is fatigued with endless circumstances, without ever feeling any degree of elevation; and yet there are some fine incidents, those, for example, of the two brothers, and of the old man and his son, which, taken separately, would affect us greatly. But Lucan, once engaged in a description, knows no end. See other passages of the same kind, *L. 4. l. 292, to 337. L. 4. l. 750, to 765.* The episode of the forerunners Ericho, end of book 6th, is intolerably minute and prolix.

This rule is also applicable to other fine arts. In painting it is established, that the principal figure must be put in the strongest light; that the beauty of attitude consists in placing the nobler parts most in view, and in suppressing the smaller parts as much as possible; that the folds of the drapery must be few and large; that foreshortenings are bad, because they make the parts appear little; and that the muscles ought to be kept as entire as possible, without being divided into small sections. Every one at present subscribes to that rule as applied to gardening, in opposition to parterres split into a thousand small parts in the stiffest regularity of figure. The most eminent architects have governed themselves by the same rule in all their works.

11
General
terms ought
to be avoid-
ed where
sublimity is
intended.

Another rule chiefly regards the sublime, though it is applicable to every sort of literary performance intended for amusement; and that is, to avoid as much as possible abstract and general terms. Such terms, similar to mathematical signs, are contrived to express our thoughts in a concise manner; but images, which are the life of poetry, cannot be raised in any perfection but by introducing particular objects. General terms that comprehend a number of individuals, must be excepted from that rule: our kindred, our clan, our country, and words of the like import, though they scarce raise any image, have, however, a wonderful power over our passions: the greatness of the complex object overbalances the obscurity of the image.

Grandeur, being an extreme vivid emotion, is not readily produced in perfection but by reiterated impressions. The effect of a single impression can be but momentary; and if one feel suddenly somewhat like a swelling or exaltation of mind, the emotion vanishes as soon as felt. Single thoughts or sentiments are often cited as examples of the sublime; but their effect is far inferior to that of a grand subject display'd in its capital parts. We shall give a few examples, that the reader may judge for himself. In the famous action of Thermopylæ, where Leonidas the Spartan king, with his chosen band, fighting for their country, were cut off to the last man, a saying is reported of Dienees, one of the band, which, expressing cheerful and undisturbed bravery, is well entitled to the first place in examples of that kind: talking of the number of their enemies, it was observed, that the arrows shot by such a multitude would intercept the light of the sun; "So much the better, says he, for we shall then fight in the shade."

Herodotus,
lib. 7.

Somerjit. Ah! Warwick, Warwick, wert thou as we are,
We might recover all our lost again.

The Queen from France hath brought a puissant power.
Ev'n now we heard the news. Ah! couldst thou fly!

Warwick. Why, then I would not fly.

Third part, Henry VI. act 5. sc. 3.

Grandeur
and
Sublimity.

Such a sentiment from a man expiring of his wounds, is truly heroic; and must elevate the mind to the greatest height that can be done, by a single expression: it will not suffer in a comparison with the famous sentiment *Qu'il mourut* of Corneille: the latter is a tickle of indignation merely, the former of firm and cheerful courage.

To cite in opposition many a sublime passage, enriched with the finest images, and dressed in the most nervous expressions, would scarce be fair. We shall produce but one instance, from Shakspeare, which sets a few objects before the eye, without much pomp of language: it operates its effect by representing these objects in a climax, raising the mind higher and higher till it feel the emotion of grandeur in perfection:

The cloud-capt tow'rs, the gorgeous palaces,
The solemn temples, the great globe itself,
Yea all which it inherit, shall dissolve, &c.

The cloud-capt tow'rs produce an elevating emotion, heightened by the gorgeous palaces; and the mind is carried still higher and higher by the images that follow. Successive images, making thus stronger and stronger impressions, must elevate more than any single image can do.

As, on the one hand, no means directly applied have more influence to raise the mind than grandeur and sublimity; so, on the other, no means indirectly applied have more influence to sink and depress it: for in a state of elevation, the artful introduction of an humbling object, makes the fall great in proportion to the elevation. Of this observation Shakspeare gives a beautiful example, in the passage last quoted:

The cloud-capt tow'rs, the gorgeous palaces,
The solemn temples, the great globe itself,
Yea all which it inherit, shall dissolve,
And like the baseless fabric of a vision
Leave not a rack behind. — *Tempest, act 4. sc. 4.*

12
grandeur
and subli-
mity em-
ployed in-
directly to
sink the
mind.

The elevation of the mind in the former part of this beautiful passage, makes the fall great in proportion, when the most humbling of all images is introduced, that of an utter dissolution of the earth and its inhabitants. The mind, when warmed, is more susceptible of impressions than in a cool state; and a depressing or melancholy object listened to, makes the strongest impression when it reaches the mind in its highest state of elevation or cheerfulness.

But a humbling image is not always necessary to produce that effect: a remark is made above, that in describing superior beings, the reader's imagination, unable to support itself in a strained elevation, falls often as from a height, and sinks even below its ordinary tone. The following instance comes luckily in view; for a better cannot be given: "God said, Let there be light, and there was light." Longinus quotes this passage from Moses as a shining example of the sublime; and it is scarce possible, in fewer words, to convey so clear an image of the infinite power of the Deity: but then it belongs to the present subject to remark, that the emotion of sublimity raised by this image is but momentary; and that the mind, unable to support itself in an elevation so much above nature, immediately sinks down into humility and veneration for a Being so far exalted above groveling mortals.

Grandeur
and
Sublimity.

• Boileau
and Huet.

mortals. Every one is acquainted with a dispute about that passage between two French critics, the one positively affirming it to be sublime, the other as positively denying. What has been remarked, shows, that both of them have reached the truth, but neither of them the whole truth: the primary effect of the passage is undoubtedly an emotion of grandeur; which so far justifies Boileau: but then every one must be sensible, that the emotion is merely a flash, which, vanishing instantaneously, gives way to humility and veneration. That indirect effect of sublimity justifies Huet, on the other hand, who being a man of true piety, and probably not much carried by imagination, felt the humbling passions more sensibly than his antagonist did. And laying aside difference of character, Huet's opinion may perhaps be defended as the more solid; because in such images, the depressing emotions are the more sensibly felt, and have the longer endurance.

¹³
False sub-
limity.

The straining an elevated subject beyond due bounds, and beyond the reach of an ordinary conception, is not a vice so frequent as to require the correction of criticism. But false sublimity is a rock that writers of more fire than judgement commonly split on; and therefore a collection of examples may be of use as a beacon to future adventurers. One species of false sublime, known by the name of *bombast*, is common among writers of a mean genius: it is a serious endeavour, by strained description, to raise a low or familiar subject above its rank; which, instead of being sublime, fails not to be ridiculous. The mind, indeed, is extremely prone, in some animating passions, to magnify its objects beyond natural bounds: but such hyperbolical description has its limits; and when carried beyond the impulse of the propensity, it degenerates into burlesque. Take the following examples:

Sejanus.——Great and high

The world knows only two, that's Rome and I.

My roof receives me not: 'tis air I tread,

And at each step I feel my advance'd head

Knock out a star in heav'n. *Sejanus, Ben Jonson, act 5.*

A writer who has no natural elevation of mind, deviates readily into bombast: he strains above his natural powers; and the violent effort carries him beyond the bounds of propriety.

Caifford. Give way, and let the gushing torrent come;

Behold the tears we bring to swell the deluge,

Till the flood rise upon the guilty world

And make the ruin common.

Lady Jane Gray, act 4. near the end.

Another species of false sublime, is still more faulty than bombast: and that is, to force elevation by introducing imaginary beings without preserving any propriety in their actions; as if it were lawful to ascribe every extravagance and inconsistency to beings of the poet's creation. No writers are more licentious in that article than Johnson and Dryden:

Metethinks I see Death and the Furies waiting

What we will do, and all the heaven at leisure

For the great spectacle. Draw then your swords:

And if our destiny envy our virtue

The honour of the day, yet let us care

To sell ourselves at such a price, as may

Undo the world to buy us, and make Fate,

While she tempts ours, so fear her own estate.

Cassius, act 5.

——The furious flood on hills

Circling the place, and trembled to see men

Do more than they: whilst Piety left the field,

Grief'd for that side, that in so bad a cause

They knew not what a crime their valour was.

The sun flood fill, and was, behind the cloud

The battle made, seen swelling to drive up

His frighted horse, whom fill the noise drove backward.

Id., act 5.

Ofmyn. While we indulge our common happiness,

He is forgot by whom we all possess,

The brave Almanzor, to whose arms we owe

All that we did, and all that we shall do;

Who like a tempest that outstrips the wind,

Made a just battle ere the bodies join'd.

Abdulla. His victories we scarce could keep in view,

Or publish 'em so fast as he rough drew.

Abimelech. Fate after him below with pain did move,

And Victory could scarce keep pace above.

Death did at length so many slain forget,

And left the tale, and took 'em by the great.

Conquest of Granada, act 2. at beginning.

An actor on the stage may be guilty of bombast as well as an author in his closet: a certain manner of acting, which is grand when supported by dignity in the sentiment and force in the expression, is ridiculous where the sentiment is mean and the expression flat.

GRANGE, a house or farm, not only furnished with necessary places for all manner of husbandry, as stables for horses, stalls for cattle, &c. but where there are granaries and barns for corn, hay-lofts, &c. And by the grant of a grange, such places will pass, without being particularly mentioned.——The word is formed of the Latin *granea* or *granum*, grain, corn, &c. Hence also *granger*, or *grangier*, a grange-keeper or farmer.

GRANICUS, a smaller river near the Hellespont in Lesser Asia, remarkable for the first victory gained by Alexander the Great over the armies of Darius.——Authors disagree very much about the number of the Persians, though all agree that they were vastly more numerous than the Greeks. Justin and Orosius tell us, that the Persian army consisted of 600,000 foot and 20,000 horse; Arrian makes the foot amount to 200,000; but Diodorus tells us, that they were not more than 100,000 foot, and 10,000 horse. The Macedonian army did not exceed 30,000 foot and 5000 horse. The Persian cavalry lined the banks of the Granicus, in order to oppose Alexander wherever he should attempt a passage; and the foot were posted behind the cavalry on an easy ascent. Parmenio would have had Alexander to allow his troops some time to refresh themselves; but he replied, that, after having crossed the Hellespont, it would be a disgrace to him and his troops to be stopped by a rivulet. Accordingly a proper place for crossing the river was no sooner found, than he commanded a strong detachment of horse to enter, he himself following with the right wing which he commanded in person; the trumpets in the mean time sounding, and loud shouts of joy being heard through the whole army. The Persians let fly such showers of arrows against the detachment of Macedonian horse, as caused some confusion; several of their horses being killed or wounded. As they drew near the bank a most bloody engagement ensued; the Macedonians attempting to land, and the Persians pushing them back into the river. Alexander, who observed the confusion they were in, took the command

Grandeur
||
Granicus.

Granicus,
Granite.

mand of them himself; and landing in spite of all opposition, obliged the Persian cavalry, after an obstinate resistance, to give ground. However, Spithrobatas, governor of Ionia, and son-in-law to Darius, still maintained his ground, and did all that lay in his power to bring them back to the charge. Alexander advanced full gallop to engage him; neither did he decline the combat, and both were slightly wounded at the first encounter. Spithrobatas having thrown his javelin without effect, advanced sword in hand to meet his antagonist, who ran him through with his pike as he raised his arm to discharge a blow with his scymitar. But Rosaces, brother to Spithrobatas, at the same time gave Alexander such a furious blow on the head with his battle-ax, that he beat off his plume, and slightly wounded him through the helmet. As he was ready to repeat the blow, Clitus with one stroke of his scymitar cut off Rosaces's head, and thus in all probability saved the life of his sovereign. The Macedonians then, animated by the example of their king, attacked the Persians with new vigour, who soon after betook themselves to flight. Alexander did not pursue them; but immediately charged the enemy's foot with all his forces, who had now passed the river. The Persians, disheartened at the defeat of their cavalry, made no great resistance. The Greek mercenaries retired in good order to a neighbouring hill, whence they sent deputies to Alexander desiring leave to march off unmolested. But he, instead of coming to a parley with them, rushed furiously into the middle of this small body; where his horse was killed under him, and he himself in great danger of being cut in pieces. The Greeks defended themselves with incredible valour for a long time, but were at last almost entirely cut off.—In this battle the Persians are said to have lost 20,000 foot and 2,500 horse, and the Macedonians only 55 foot and 60 horse.

GRANITE, in natural history, a distinct genus of stones, composed of separate and very large concretions rudely compacted together; of great hardness, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire.

Of this genus there are three species: 1. The hard white granite with black spots, commonly called moor-stone. This is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running into one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass. It is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required. 2. The hard red granite variegated with black and white, and common in Egypt and Arabia. 3. The pale whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

Some of these kinds of stones are found in almost every country, and in many places they are found of immense bigness. The largest mass of this kind in the known world, lying as an unconnected stone, is found near the Cape of Good Hope in Africa, and of which we have the following description in the Phi-

lop. Transact. vol. 68. p. 102, given by Mr Anderson in a letter to Sir John Pringle. "The stone is so remarkable, that it is called by the people here the *Tower of Babel*, and by some the *Pearl Diamond*. It either takes the last name from a place near which it is situated, or it gives name to the tract of cultivated land called the Pearl. It lies upon the top of a ridge of low hills, beyond a large plain, at the distance of about thirty miles from the Cape Town; beyond which, at a little distance, is a range of hills of a much greater height. It is of an oblong shape, and lies north and south. The fourth end is highest; the east and west sides are steep and high; but the top is rounded, and slopes away gradually to the north end, so that you can ascend it by that way, and enjoy a most extensive prospect of the whole country. I could not precisely determine its circumference, but it took us above half an hour to walk round it; and by making every allowance for the rugged way, and stopping a little, I think the most moderate computation must make it exceed half a mile. The same difficulty occurred with respect to knowing its height: but I think, that, at the fourth-end, it is nearly equal to half its length; or, were I to compare it to an object you are acquainted with, I should say it equalled the dome of St Paul's Church.

"I am uncertain whether it ought to be considered as the top of the hill, or a detached stone, because there is no positive proof of either, unless we were to dig about its base; but it would certainly impress every beholder, at first sight, with the idea of its being one stone, not only from its figure, but because it is really one solid uniform mass from top to bottom, without any interruption; which is contrary to the general character of the high hills of this country, they being commonly divided, or composed of different strata, at least if we may judge from the rows of plants or shrubs which grow on the sides of the steepest, and, as I suppose, are produced from the small quantity of earth interposed between them. It has indeed a few fissures, or rather impressions, which do not reach deeper than four or five feet; and near its north end a stratum of a more compact stone runs across, which is not above twelve or fourteen inches thick, with its surface divided into little squares, or oblongs, disposed obliquely. This stratum is perpendicular; but whether it cuts the other to its base, or is superficial, I cannot determine. Its surface is also so smooth, that it does not appear to have formerly been joined to, or separated from, any other part by violence, as is the case with many other large fragments; but enjoys the exact situation where it was originally placed, and has undergone little change from being exposed for so many successive ages to the calcining power of a very hot climate."—A part of this stone being examined by Sir William Hamilton, he determined it to be a granite, and of the same nature with the tops of some of the Alps; and supposes both of them to have been elevated by volcanic explosions.

GRANIVOROUS, an appellation given to animals which feed on corn or seeds. These are principally of the bird kind.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, &c.

GRANT

Granite,
Grant.

GRANT (Francis), Lord Cullen, an eminent lawyer and judge in Scotland, was descended from a younger branch of the family of the Grants of Grant in that kingdom, and was born about the year 1660. When he commenced advocate he made a distinguished figure at the revolution, by opposing the opinion of the old lawyers, who warmly argued on the inability of the convention of estates to make any disposition of the crown. The abilities he shewed in favour of the revolution recommended him to an extensive practice; in which he acquired so much honour, that when the union between the two kingdoms was in agitation, queen Anne unexpectedly, and without application, created him a baronet, with a view of securing his interest in that measure; and upon the same principle, the soon after created him a judge, or one of the lords of session. From this time, according to the custom of Scotland, he was styled, from the name of his estate, Lord Cullen; and the same good qualities that recommended him to this honourable office, were very conspicuous in the discharge of it; which he continued for 20 years with the highest reputation, when a period was put to his life by an illness which lasted but three days. He expired without any agony on March 16th 1726.

His character is drawn to great advantage in the *Biographia Britannica*; where it is observed, among other remarks to his honour, "That as an advocate he was indefatigable in the management of business; but at the same time that he spared no pains, he would use no craft. He had so high an idea of the dignity of his profession, that he held it equally criminal to neglect any honest means of coming at justice, or to make use of any arts to elude it.

"In respect to fortune, though he was modest and frugal, and had a large practice, yet he was far from being avaricious. His private charities were very considerable, and grew in the same proportion with his profits. He was, besides, very scrupulous in many points; he would not suffer a just cause to be lost through a client's want of money. He was such an enemy to oppression, that he never denied his assistance to such as laboured under it; and with respect to the clergy of all professions (in Scotland) his conscience obliged him to serve them without a fee. He saw their wrongs required assistance, and he knew their circumstances would not admit of expence. His additions, therefore, to his paternal estate were much inferior to what might have been expected, and a large accession of character was the principal produce of that activity and diligence by which he was distinguished at the bar.

"When his merit had raised him to the bench, he thought himself accountable to God and man for his conduct in that high office; and that deep sense of his duty, at the same time that it kept him strictly to it, encouraged and supported him in the performance. The pleadings in Scotland are carried on chiefly in writing, which renders them sometimes very prolix, so as to take up much of a judge's time, and to exercise alike his parts and his patience in going through and making himself master of them. In this the diligence and dexterity of lord Cullen were equally conspicuous: he went through every thing that came into his hands very carefully, and sifted it thoroughly; so that the lawyers at the bar never found themselves too strong

for the bench, but on the contrary were often told many things by his lordship, which had either escaped their notice, or which the interest of their client had engaged them to conceal. As his attention to the pleadings guided him to the real merits of the cause; so when he was once master of these, his second care was to dispatch it. He knew, that, in judicature, the next fault to denying, was delaying justice; by which families are always injured, and too often ruined. Whenever, therefore, he had provided against being mistaken, he was desirous of bringing the matter to a short decision; and as he was very solicitous about the former, so the parties themselves helped him not a little as to the latter. Whenever he sat as lord ordinary; the paper of causes was remarkably full, for his reputation being equally established for knowledge and integrity, there were none, who had a good opinion of their own pretensions, but were desirous of bringing them before him, and not many who did not fit down satisfied with his decision. This prevailed more especially after it was found that few of his sentences were reversed; and when they were, it was commonly owing to himself: for if, upon mature reflection, or upon new reasons offered at the re-hearing, he saw any just ground for altering his judgment, he made no scruple of declaring it; being persuaded, that it was more manly, as well as more just, to follow truth, than to support opinion; and his conduct in this respect had a right effect; for instead of lessening, it raised his reputation.

"He would not, however, with all this great stock of knowledge, experience, and probity, trust himself in matters of blood, or venture to decide in criminal cases on the lives of his fellow-creatures; which was the reason, that, though often solicited, he could never be prevailed upon to accept of a seat in the judicial court.

"He was so true a lover of learning, and was so much addicted to his studies, that, notwithstanding the multiplicity of his business while at the bar, and his great attention to his charge when a judge, he nevertheless found time to write various treatises, on very different and important subjects: Some political, which were remarkably well-timed, and highly serviceable to the government: others of a most extensive nature, such as his essays on law, religion, and education, which were dedicated to his present majesty when prince of Wales; by whose command, his then secretary, Mr. Samuel Molyneux, wrote him a letter of thanks, in which were many gracious expressions, as well in relation to the piece, as to its author. He composed, besides these, many discourses on literary subjects, for the exercise of his own thoughts, and for the better discovery of truth; which went no farther than his own closet, and from a principle of modesty were not communicated even to his most intimate friends.

"In his lordship's private character he was as amiable as he was respectable in his public. There were certain circumstances that determined him to part with an estate that was left him by his father; and it being foreseen that he would employ the produce of it, and the money he had acquired by his profession, in a new purchase, there were many decayed families who solicited him to take their lands upon his own terms, relying
entirely

Grant.
Granville.

entirely on that equity, which they conceived to be the rule of his actions. It appeared that their opinion of him was perfectly well grounded. For being at length prevailed upon to lay out his money on the estate of an unfortunate family, who had a debt upon it of more than it was worth; he first put their affairs into order, and by classing the different demands, and compromising a variety of claims, secured some thousand pounds to the heirs, without prejudice to any, and of which they had never been possessed but from his interposition and vigilance in their behalf: So far was he either from making any advantage to himself of their necessities, or of his own skill in his profession; a circumstance justly mentioned to his honour, and which is an equal proof of his candor, generosity, and compassion. He was charitable without ostentation, disinterested in his friendships, and beneficent to all who had any thing to do with him. He was not only strictly just; but so free from any species of avarice, that his lady, who was a woman of great prudence and discretion, finding him more intent on the business committed to him by others, than on his own, took upon herself the care of placing out his money; and to prevent his postponing, as he was apt to do, such kind of affairs, when securities offered, she caused the circumstances of them to be stated in the form of cases, and so procured his opinion upon his own concerns, as if they had been those of a client. These little circumstances are mentioned as more expressive of his temper, than actions of another kind could be; because, in matters of importance, men either act from habit, or from motives that the world cannot penetrate; but, in things of a trivial nature, are less upon their guard, shew their true disposition, and stand confessed for what they are."

GRANVILLE (George), lord Lansdowne, was descended from a very ancient family, derived from Rollo the first duke of Normandy. At eleven years of age he was sent to Trinity College in Cambridge, where he remained five years: but at the age of 13 was admitted to the degree of master of arts; having, before he was 12, spoken a copy of verses of his own composition to the duchess of York at his college, when she paid a visit to the University of Cambridge. In 1696, his comedy called the *She-galants* was acted at the theatre-royal in Lincoln's-inn-fields, as his tragedy called *Herbic Love* was in the year 1698. In 1702 he translated into English the *second Olynthian of Demosthenes*. He was member for the county of Cornwall in the parliament which met in 1710; was afterwards secretary of war, comptroller of the household, then treasurer, and sworn one of the privy-council. The year following, he was created baron Lansdowne. On the accession of king George I. in 1714, he was removed from his treasurer's place; and the next year entered his protest against the bills for attainting lord Bolingbroke and the duke of Ormond. He entered deeply into the scheme for raising an insurrection in the west of England; and being seized as a suspected person, was committed to the tower, where he continued two years. In 1719, he made a speech in the house of Lords, against the bill to prevent occasional conformity. In 1722, he withdrew to France, and continued abroad almost ten years. At his return in 1732, he published a fine

edition of his works in 2 vols quarto. He died in 1735, leaving no male issue.

GRANVILLE, a sea-port town of France, in Lower Normandy, partly seated on a rock and partly on a plain. It gives a title to an English earl. W. Long. 1. 32. N. Lat. 48. 58.

GRANULATED, something that has undergone granulation. See the next article.

GRANULATION, in chemistry, an operation by which metallic substances are reduced into small grains, or roundish particles; the use of which is, to facilitate their combination with other substances. This operation is very simple; it consists only in pouring a melted metal slowly into a vessel filled with water, which is in the mean time to be agitated with a broom. With melted copper, however, which is apt to explode with great violence on the contact of water, some precautions are to be observed, of which an account is given under the article CHEMISTRY, n^o 406. Lead or tin may be granulated by pouring them when melted into a box, the internal surface of which is to be rubbed with powdered chalk, and the box strongly shaken till the lead has become solid. Metals are granulated, because their ductility renders them incapable of being pounded, and because filing is long and tedious, and might render the metal impure by an admixture of iron from the file.

GRAPE, the fruit of the vine. See VINE.

GRAPE-Shot, in artillery, is a combination of small shot put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball which is adapted to the cannon.

To form grape-shot, a bag of coarse cloth is made just to hold the bottom which is put into it, then as many shot as the grape is to contain; and with a strong pack-thread they are quilted, to keep the shot from moving; and when finished they are put into boxes for carriage, to be transported wherever it is necessary.

—The number of shot in a grape varies according to the service or size of the guns. In sea-service the number is always nine; but by land it is increased to any number or size, from an ounce and a quarter in weight. It has not yet been determined with any accuracy, what number or size best answers in practice; for they often scatter so much, that only a small number take place.

Proper charges for grape-shot have never yet been effectually determined. From some experiments, however, it appears, that for heavy six-pounders one third of the weight of the shot appears to be the best charge of powder; for the light six-pounders, one fourth of the weight of the shot; and, for howitzers, one eighth or one tenth answers very well.

This kind of fire seems yet not to have been enough respected or depended on. However, if cannon and howitzers can be made to throw one third or one fourth of their charge into a space of 39×12 feet, at 200 and 300 yards distance, and those fired ten or twelve times in a minute, it surely forms the thickest fire that can be produced from the same space.

GRAPHOMETER, a mathematical instrument, otherwise called a *Semicircle*; the use of which is to observe any angle whose vertex is at the centre of the instrument in any plane, though it is most commonly hori-

Granville
Graphometer.

Grappling, horizontal, or nearly so), and to find how many degrees it contains. See GEOMETRY, p. [12.]

GRAPPLING, a sort of small anchor, fitted with four or five flukes or claws, and commonly used to ride a boat or other small vessel.

Fire-GRAPPLING, an instrument nearly resembling the former, but differing in the construction of its flukes, which are furnished with strong barbs on their points. These machines are usually fixed on the yard-arms of a ship, in order to grapple any adversary whom the intends to board. They are, however, more particularly useful in *fire-ships* for the purposes described in that article.

GRASS, in botany, &c. a name given to several distinct plants; as the agrostis or couch-grass, the briza or quaking-grass, &c. Under the term *grafs* also are comprehended all manner of herbaceous plants serving for the food of cattle, as clover, rye-grass, &c. See AGRICULTURE, and GRAMINA.

Grass-Sowing. See AGRICULTURE, n° 51—57. and 133—137.

Grass-Walks are made, for the most part, not by sowing grass-seed, but by laying turfs: and indeed the turfs from a fine common or down are much preferable to sown grass: but if walks or plats are to be made by sowing, the best way is to procure the seed from those pastures where the grass is naturally fine and clear; or else the trouble of keeping it from spiry or benty grass will be very great, and it will scarce ever look handsome.

In order to sow grass-walks, the ground must be first dug; and when it has been dressed and laid even, it must be very carefully raked over, and all the clods and stones taken off, and then covered over an inch thick with good mould.

This being done, the seed is to be sown pretty thick, that it may come up close and short; it must then be raked over again, to cover the seed, that if the weather should happen to be windy, it may not be blown away. It ought also to be observed, that where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil or dutch clover sown with it; for this will make a fine turf much sooner than any other sown grass, and will continue a better verdure than any other of the grass-tribe.

In order to keep grass-plats or walks handsome, and in good order, you may sow in autumn fresh seed over any places that are not well filled, or where the grass is dead: but nothing improves grass so much as mowing and constant rolling.

When turf is laid in gardens, it is a generally practice to cover the surface of the ground under the turf, either with sand or very poor earth: the design of this is to keep the grass fine, by preventing its growing too rank. This is proper enough for very rich ground: but it is not so for such land as is middling, or but poor; for when this is practised in such places, the grass will soon wear out and decay in patches.

When turf is taken from a common or down, such ought to be chosen as is free from weeds: and when it is designed to remain for years without renewing, a dressing should be laid upon it every other year, either of very rotten dung, ashes, or, where it can be easily procured, very rotten tan; but these dressings

should be laid on early in the winter, that the rain may wash them into the ground, otherwise they will occasion the grass to burn, when the warmth of the the summer begins.

When grass is so dressed, and well rolled and mowed, it may be kept very beautiful for many years; but where it is not dressed, or fed with sheep, it will rarely continue handsome more than eight or ten years.

GRASSHOPPER, in zoology, a species of GRYLLUS. This insect breeds in such plenty in our meadows, that it is known to every body. It is of the colour of green leaves, except a line of brown which streaks the back, and two pale lines under the belly and behind the legs. It may be divided into the head, the corslet, and the belly. The head is oblong, regarding the earth, and bearing some resemblance to that of a horse. Its mouth is covered by a kind of round buckler, jutting over it, and armed with teeth of a brown colour, hooked at the points. Within the mouth is perceivable a large reddish tongue, and fixed to the upper jaw. The antennæ are very long, tapering off to a point; and the eyes are like two black specks, a little prominent. The corslet is elevated, narrow, armed above and below by two serrated spines. The back is armed with a strong buckler, to which the muscles of the legs are firmly bound; and round these muscles are seen the vessels by which the animal breathes, as white as snow. The last pair of legs are much longer and stronger than the first two pair; fortified by thick muscles, and well formed for leaping. It has four wings; the anterior ones springing from the second pair of legs, the posterior from the third pair. The hinder wings are much finer and more expansive than the foremost, and are the principal instruments of its flight. The belly is considerably large, composed of eight rings, and terminated by a forky tail, covered with down, like the tail of a rat. When examined internally, besides the gullet, we discover a small stomach; and behind that, a very large one, wrinkled and furrowed within-side. Lower down, there is still a third: so that it is thought, and with some probability, that all the animals of this order chew the cud; as they so much resemble ruminant animals in their internal conformation.

A short time after the grasshopper assumes its wings, it fills the meadows with its noise; which, like that among birds, is a call to courtship. The male only of this tribe is vocal; and, upon examining at the base of the wings, there will be found a little hole in its body, covered with a fine transparent membrane. This is thought, by Linnæus, to be the instrument it employs in singing; but others are of opinion the sound is produced by rubbing its hinder legs against each other. But, however this may be, the note of one male is seldom heard, without being returned by another; and the whole little animals, after many mutual insults of this kind, are seen to meet and fight desperately. The female is generally the reward of the victory; for, after the combat, the victor seizes her with his teeth behind the neck, and thus keeps her for several hours, till the business of fecundation is accomplished. At this time they are so strongly united, that it is almost impossible to separate them, without tearing their bodies asunder. Towards the latter end of autumn,

Grass-hopper.

Grasshopper.

the female prepares to deposit her burthen; and her body is then seen greatly distended with eggs, which she carries to the number of 150. In order to make a proper lodgment in the earth for them, nature has furnished her with an instrument in her tail, somewhat resembling a two-edged sword, which she can sheath and unsheath at pleasure: with this she pierces the earth as deep as she is able; and into the hole which the instrument has made, she deposits her eggs one after the other.

Having thus provided for the continuation of her posterity, the animal herself does not long survive; but, as winter approaches, she dries up, seems to feel the effect of age, and dies from a total decay. Some, however, assert that she is killed by the cold; others, that she is eaten by worms; but certain it is, that neither male nor female are ever seen to survive the winter. In the mean time, the eggs which have been deposited, continue unaltered either by the severity of the season, or the retardation of the spring. They are of an oval figure, white, and of the consistence of horn: their size nearly equals that of a grain of anise: they are enveloped in the body within a covering branched all over with veins and arteries; and when excluded, they crack on being pressed between the fingers. Their substance within, is a whitish, viscous, and transparent fluid. In this manner they remain deposited within the surface of the earth during the whole winter, till the return of spring begins to hatch them. About the beginning of May, each egg produces an insect about the bigness of a flea. These are at first of a whitish colour; at the end of two or three days they turn black, and soon after they become of a reddish brown. They appear from the beginning like grasshoppers wanting wings, and hop among the grass, as soon as excluded, with great agility. Yet still they are by no means arrived at their full state of perfection; although they bear a strong resemblance to the animal in its perfect form. They want, or seem to want, the wings which they at last assume; and can only hop among the grass, without being able to fly. The wings, however, are not wanting, but are concealed within four little bunches that seem to deform the sides of the animal. There they lie rolled up in a most curious manner, and occupying a smaller space than one could conceive who saw them extended. These wings, however, it has never been destitute of; though they remain folded up for 20 days, so that they cannot be seen. When it is to undergo this change, the animal ceases from its grassy food, and seeks about for a convenient place beneath some thorn or thistle that may protect it from an accidental shower. It swells up its head and neck, and then draws them in again; and thus alternately for some time it endeavours to get free. At length, the skin covering the head and breast divides above the neck, and the head issues forth. The other parts follow successively; so that the little animal, with its long feelers, legs, &c. works its way from the old skin, which remains fixed to the thistle or thorn. It is indeed inconceivable how the insect can extricate itself from such an exact sheath as that which covered every part of its body.

The grasshopper, thus disengaged from its outer skin, appears in its perfect form; but is then so feeble,

and its body so soft and tender, that it may be moulded like wax. It is no longer of the obscure colour it had before; but is of a greenish white, which becomes more vivid, as the moisture on the surface is dried away. Still, however, the animal continues to shew no signs of life; but appears quite spent and fatigued with its labour for more than an hour together. During this time the body is drying, and the wings unfolding to their greatest expansion; and the curious observer will perceive them, fold after fold, opening to the sun, till at last they become longer than the two hinder legs. The insect's body also is lengthened during this operation, and it becomes much more beautiful than before.

These insects are generally vocal in the midst of summer; and they are heard at sunsetting much louder than during the heats of the day. They are fed upon grass; and if their belly be pressed, they will be seen to return to the juices of the plants they have last fed upon. Though unwilling to fly, and slow of flight, particularly when the weather is moist or cool, they are sometimes seen to fly to considerable distances. If they are caught by one of the hinder legs, they quickly disengage themselves from it, and leave the leg behind them. This, however, doth not grow again, as with crabs and spiders; for as they are animals of but a single year's continuance, they have not sufficient time for repairing these misfortunes. The loss of their leg also prevents them from flying; for being unable to lift themselves in the air, they have not room upon the ground for the proper expansion of their wings. If they be handled roughly, they will bite very fiercely; and, when they fly, they make a noise with their wings. They generally keep in the plain, where the grass is luxuriant, and the ground rich and fertile: there they deposit their eggs, particularly in those cracks which are formed by the heat of the sun.

These animals are sometimes very mischievous, by reason of their great numbers. Some time ago they appeared in Languedoc, and other places of France, in very formidable swarms, and eat up all the harvest of several years. They took their flight like birds, were about an inch long, of a grey colour, and exactly shaped like the common sort. They were found in many places covering the whole surface of the earth, four or five inches deep, and used to lie quiet towards noon; but when the sun then shone warmly upon them, they used to arise and take wing, and, setting on the corn-fields, they would in a few hours eat up the whole produce, ears, leaves, and even the more tender parts of the stalks.—When they had destroyed one field in this manner, they used to take wing and fly to another. They usually flew very high in the air, and directly against the wind; but as soon as they saw a new crop of corn, they dropped together in a swarm, and cleared it as they had done the first. This practice they continued the whole day; and towards evening they settled upon the ground, where they remained quiet till the heat of the following day raised them again. When they had destroyed all the corn in the country, they seized upon the vines, garden-herbs, and willows, and at last upon the hemp. Whole fields of this last they eat up, notwithstanding its great bitterness. Towards autumn,

they

Grasshopper.

Gratarolas
Gratian.

they left off feeding, and were then found in copulation; and soon after this, the females were every where seen laying their eggs, which they deposited in the ground, making a hole with their tail, large enough to receive a goose-quill.

In these holes every female would lay 40 or 50 eggs, each of the size of a millet-seed; and when they had finished the laying, they covered up the hole to keep out the water. After this they died apace; and the multitude of their carcases stunk intolerably, poisoning the air. The next year they hatched in April: and from this one swarm such prodigious numbers were hatched, that 15 tuns of them were destroyed while no bigger than flies, and nine tuns of their eggs before the hatching; and yet there remained enough of them to destroy, in a great measure, the succeeding harvest. After this, they gradually decreased for several years, till they were not more numerous than elsewhere. This was attributed to the industry of the farmers in killing them; but it is more probable that unfavourable seasons destroyed them.

GRATAROLUS (William), a learned physician in the 16th century, was born at Bergamo in Italy; and taught physic with reputation at Padua: but having embraced the Protestant religion, he retired to Switzerland, where he was made professor of physic. He died at Basil in 1568, aged 52. He wrote several curious works in Latin; amongst which are, 1. The manner of preserving and improving the memory. 2. Of preserving in health travellers, men of letters, magistrates, and studious persons, &c.

GRATES for FIRES, are composed of ribs of iron, placed at small distances from one another, so that the air may have sufficient access to the fuel, and the accumulation of the ashes, which would choke the fire, may be prevented.—Grates seem peculiarly adapted to the use of pit-coal, which requires a greater quantity of air to make it burn freely than other kinds of fuel. The hearths of the Britons seem to have been fixed in the centre of their halls, as is yet practised in some parts of Scotland, where the fire is nearly in the middle of the house, and the family sit all around it. Their fire place was perhaps nothing more than a large stone, depressed a little below the level of the ground, and thereby adapted to receive the ashes. About a century ago, it was only the floor of the room, with the addition of a back or hob of clay. But it was now changed among the gentlemen for a portable fire-pan, raised upon low supporters, and fitted with a circular grating of bars. Such were in use among the Gauls in the first century, and among the Welsh in the tenth.

GRATIAN, the son of Valentinian I. by his first wife, was declared Augustus by his father at the city of Amiens in 365, and succeeded him in 376; a prince equally extolled for his wit, eloquence, modesty, charity, and zeal against heretics. He associated Theodosius with him in the empire, and advanced the poet Ausonius to the consulate. He made a great slaughter of the Germans at Strasburg *, and hence was surnamed *Alemannicus*. He was the first emperor who refused the title of *Pontifex Maximus*, upon the score of its being a Pagan dignity. He was assassinated by Andragathius in 375, in the 24th year of his age.

GRATIAN, a famous Benedictine monk, in the 12th

century, was born at Chiuffi, and employed near twenty-four years in composing a work, entitled, *Decretum*, or *Concordantia Discordantium Canonum*, because he there endeavoured to reconcile the canons, which seemed contradictory to each other. This work he published in 1151. As he is frequently mistaken, in taking one canon of one council, or one passage of one father, for another, and has often cited false decretals, several authors have endeavoured to correct his faults; and chiefly Anthony Augustine, in his excellent work, entitled, *De emendatione Gratiani*. To the decretals of Gratian, the popes principally owed the great authority they exercised in the thirteenth and following centuries.

GRATIUS, a Latin poet, cotemporary with Ovid, the author of a poem intitled *Cynegeticon*, or the *Manner of hunting with dogs*; the best edition of which is that of Leyden, 12mo, with the learned notes of Janus Ulitius.

GRATIOLA, HEDGE-HYSSOP; a genus of the monogynia order, belonging to the diandria class of plants. There are four species; the most remarkable of which is the officinalis, or common hedge-hyssop. This grows naturally on the Alps and other mountainous parts of Europe. It hath a thick, fleshy, fibrous, creeping root, which propagates very much, when planted in a proper soil and situation. From this arise several upright square stalks, garnished with narrow spear-shaped leaves, placed opposite. The flowers are produced on the side of the stalks at each joint; they are shaped like those of the fox-glove, but are small, and of a pale yellowish colour.—This herb has an emetic and purgative virtue; to answer which intentions, it was formerly used by the common people in England, but was never much prescribed by the physicians, and at last fell totally into disuse. Of late, however, it has been the subject of a dissertation by Dr James Kofczewski of Warsaw, in Poland; who gives some remarkable accounts of its effects in mania and obstinate venereal cases. It was given in powder, or in extract, to the quantity of half a drachm of the first, and a whole drachm of the second, at each dose. From the cases related in his dissertation, the author draws the following conclusions: 1. The gratiola may be given with safety both to male and female patients. 2. In all disorders proceeding from a superabundance of serum in the fluids, it appears to be a most effectual remedy. 3. In consequence of this, it is had recourse to with very great advantage in melancholy and mania arising from that state of the system. 4. It powerfully promotes purging, vomiting, sweat, and urine; and is therefore much superior to any of the usual evacuating medicines, most of which prove only active in promoting one of these discharges at once. 5. The most obstinate cases of gonorrhœa, fluor albus, and venereal ulcers, are cured by the powder.—In some instances it has induced salivation; but whether or not it can always be made to produce that effect, is not as yet altogether certain. 6. The powder of gratiola prepared from the extract, and exhibited with sugar, does not induce vomiting; and, on the contrary, the powder of the root always promotes that evacuation.

GRATZ, a handsome strong town of Germany, and capital of Styria, with a castle seated on a rock,
19 L 2 and

Grave
Gravelines.

and an university. The Jesuits have a college here; and there are a great number of handsome palaces, and a fine arsenal. The castle stands on a very lofty hill, and communicates with the river by means of a deep well. The empress-dowager was obliged to retire hither during the war of 1741 and 1742. It is seated on the river Muer, in E. Lon. 16. 25. N. Lat. 47. 4.

GRAVE, in music, is applied to a sound which is of a low or deep tone.

GRAVE. The names of places ending with this syllable come from the Saxon *graf*, a wood, thicket, den, or cave.

GRAVE, a very strong town of the Netherlands, in Dutch Brabant, seated on the river Maese, beyond which there is a fort. E. Lon. 5. 41. N. Lat. 51. 46.

GRAVEL, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant gravel-walks; an ornament peculiar to our gardens, and which gives them an advantage over those of other nations.

GRAVEL, in medicine. See the Index subjoined to that article.

GRAVEL-Walks. To make these properly, the bottom should be laid with lime-rubbish, large flint-stones, or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the gravel is to be laid six or eight inches thick. This should be laid rounding up in the middle, by which means the larger stones will run off to the sides, and may be raked away; for the gravel should never be screened before it is laid on. It is a common mistake to lay these walks too round, which not only makes them uneasy to walk upon, but takes off from their apparent breadth. One inch in five feet is a sufficient proportion for the rise in the middle; so that a walk of 20 feet wide should be four inches higher at the middle than at the edges, and so in proportion. As soon as the gravel is laid, it should be raked, and the large stones thrown back again: then the whole should be rolled both lengthwise and crosswise; and the person who draws the roller should wear shoes with flat heels, that he may make no holes; because holes made in a new walk are not easily remedied. The walks should always be rolled three or four times in very hard showers, after which they will bind more firmly than otherwise they could ever be made to do.

Gravel, with some loam among it, binds more firmly than the rarer kinds; and when gravel is naturally very harsh and sharp, it is proper to add a mixture of loam to it. The best gravel for walks is such as abounds with smooth round pebbles, which, being mixed with a little loam, are bound so firmly together, that they are never afterwards injured either by wet or dry weather. These are not so liable to be turned up by the feet in walking, as the more irregularly shaped pebbles, and remain much more firmly in their places after rolling.

GRAVELINES, a very strong sea-port town of the Netherlands in French Flanders, with a castle and harbour. It was ceded to France by the treaty of the Pyrenees, and is seated in a marshy country on the river Aa, near the sea, in E. Lon. 2. 13. N. Lat. 50. 59.

GRAVELLY LAND, or SOIL, that abounding with gravel or sand, which easily admits of heat and moisture; and the more stony such lands are, the more barren they prove.

GRAVENAC, a town of Germany, in the circle of Suabia, and capital of a county of the same name. E. Lon. 8. 15. N. Lat. 48. 22.

GRAVER, in the art of engraving, a tool by which all the lines, scratches, and shades, are cut in copper, &c. See ENGRAVING.

GRAVESANDE (William James), was born of an ancient and honourable family at Delft in Holland, in 1688. He studied the civil law at Leyden, but mathematical learning was his favourite amusement. When he had taken his doctor's degree in 1707, he settled at the Hague, and practised at the bar, in which situation he cultivated an acquaintance with learned men; with a society of whom, he published a periodical review entitled *Le Journal Littéraire*, which was continued without interruption from the year 1713 to the year 1722, when he died. The most considerable of his works are, *A treatise on perspective; An introduction to the Newtonian philosophy, or a treatise on the elements of physics confirmed by experiments; A treatise on the elements of algebra, for the use of young students; and A course of logic and metaphysics*. He had intended to have presented the public with a system of morality, but his death prevented the execution. The ministers of the republic consulted him on all occasions wherein his talents were requisite; and his skill in calculation was often of service to them; as was his address in decyphering, for detecting the secret correspondence of their enemies. As professor of mathematics and astronomy at Leyden, none ever applied the powers of nature with more success, or to more useful purposes.

GRAVESEND, a town of Kent in England, situated on the banks of the Thames. It is a place of great resort, being the common landing-place for seamen and passengers in their journey to London. All outward-bound ships are obliged to come to an anchor here, till they have been visited and examined by the custom-house officers, and here they generally take in provisions. Here is a blockhouse well mounted with cannon, to command the ships and river, directly opposite to Tilbury fort in Essex. Both at Billingsgate and Gravesend a bell is rung for 15 minutes at high water by night and day, to give notice to the tilt-boats and wherries to put off. The town is commonly called the *corporation of Gravesend and Milton*, these two places being united under the government of a mayor, 12 aldermen, 24 common-council, a town-clerk, &c. Here is a very handsome charitable foundation; Mr Henry Pinnock having in 1624 given two dwelling-houses, and a house for a master-weaver, to employ the poor; and a good estate is also settled for the repairs. The town was plundered and burnt by the French and Spaniards in the reign of Richard II. after which the king, at the request of the abbot of St Mary-le-Grace of Tower-hill, to whom he had granted a manor there, called *Parracks*, vested it with the sole privilege of carrying passengers thence by water. Great part of it was destroyed by fire in 1727, together with the church. The latter has since been rebuilt as one of the 50 new churches, and the houses

Gravelly
Gravelend.

are

Gravina
Graunt.

are much handfomer than before. The streets are narrow, but paved with flints. The chief employment of the labouring people is spinning of hemp to make ropes and nets for fishing. The town is also famous for gardening; the best asparagus in the kingdom being produced here.

GRAVINA, a town of Italy, in the kingdom of Naples, and Terra di Bori, with a bishop's see, and the title of a duchy. E. Lon. 17°. N. Lat. 41°.

GRAVINA (John Vincent), an eminent scholar, and illustrious lawyer of Italy, born at Roggiana in 1664. He was professor of the canon law in the college of Sapienzy at Rome; and though many foreign universities made proposals to draw him to them, he never quitted that city, but died there in 1718. His works are both curious and useful; the greatest of them is *De ortu et progressu Juris Civilis*. A collection of his notes was printed in 4to. at Leipzig in 1737, with the notes of Malcovinus.

GRAVINA (Peter), an Italian poet, much esteemed by the great general Gonzalvo, and Prosper Colonna. He wrote, in a pure Roman style, discourses on matters relating to the law and to the belles lettres, as well as poems. He died in 1527.

GRAVITATION, in natural philosophy, is sometimes distinguished from *gravity*. Thus M. Maupertuis takes gravity for that force whereby a body would fall to the earth; but gravitation for the same diminished by the centrifugal force. See NEWTONIAN *Philosophy*.

GRAVITY, or GRAVITATION, (for the words are most commonly used synonymously,) signifies either the force by which bodies are pressed towards the surface of the earth, or the manifest effect of that force; in which last sense the word has the same signification with *weight*, or *heaviness*.

Concerning gravity in the first sense of the word, or that active power by which all bodies are impelled towards the earth, there have been great disputes. Many eminent philosophers, and among the rest Sir Isaac Newton himself, have considered it as the first of all second causes; an incorporeal or spiritual substance, which never can be perceived any other way than by its effects; an universal property of matter, &c. Others have attempted to explain the phenomena of gravitation by the action of a very subtle ethereal fluid; and to this explanation Sir Isaac, in the latter part of his life, seems not to have been averse. He hath even given a conjecture concerning the manner in which this fluid might occasion these phenomena. But for a full account of the discoveries of this great philosopher concerning the laws of gravitation, the conjectures made by him and others concerning its cause, the various objections that have been made to his doctrine, and the state of the dispute at present, see the articles *Newtonian Philosophy*, *ASTRONOMY*, *ATMOSPHERE*, *EARTH*, *ELECTRICITY*, *FIRE*, *LIGHT*, *ATTRACTION*, *REPULSION*, *PLENUM*, *VACUUM*, &c.

Specific Gravity, denotes the weight belonging to an equal bulk of every different substance. Thus the exact weight of a cubic inch of gold, compared with a cubic inch of water, tin, lead, &c. is called its *specific gravity*. See *HYDROSTATICS*.

GRAUNT (John), author of a curious and celebrated book, entitled, *Natural and political observa-*

tions made upon the bills of mortality. He was a haberdasher of small wares; but laid down his trade, and all public employments, on account of his religion. He was educated a Puritan; afterwards professed himself a Socinian; yet, in the latter part of his life, declared himself of the Roman Catholic religion. He was a member of the royal society, and died in 1674.

GRAY, a town of France, in the Franch Compté, and capital of the bailiwick of Amont. It is a trading place, and seated on the river Saone, in E. Lon. 5. 41. N. Lat. 47. 30.

GRAY (Thomas), an admired English poet, was the youngest and only surviving son of a reputable citizen of London, and was born in Cornhill in 1716. He was educated at Eton, where he contracted a friendship with Mr Horace Walpole, and with Mr Richard West son of the third chancellor of Ireland. Mr West and Mr Gray were both intended for the bar; but the former died early in life, and the latter was diverted from that pursuit by an invitation to accompany Mr Walpole in his travels; which he accepted without any determined plan for his future life. During Mr Gray's travels, he wrote a variety of letters to Mr West and to his parents, which are printed with his poems; and when he returned, finding himself in narrow circumstances, yet with a mind indisposed for active employment, he retired to Cambridge, and devoted himself to study. Soon after his return, his friend West died: and the melancholy impressed on him by this event may be traced in his admired "Elegy wrote a country church-yard;" which is thought to have been begun, if not finished, at this time: tho' the conclusion, as it stands at present, is certainly different from what it was in the first manuscript copy.

The first impulse of his sorrow for the death of his friend gave birth to a very tender sonnet in English, on the Petrarchian model; and also to a sublime apostrophe in hexameters, written in the genuine strain of classical majesty, with which he intended to begin one of his books *De Principiis cogitandi*.

From the winter of the year 1742, to the day of his death, his principal residence was at Cambridge: from which he was seldom absent any considerable time, except between the years 1759 and 1762; when, on the opening of the British Museum, he took lodgings in Southampton-row, in order to have recourse to the Harleian and other manuscripts there deposited, from which he made several curious extracts, amounting in all to a tolerably-sized folio, at present in the hands of Mr Walpole.

About the year 1747, Mr Mason, the editor of Mr Gray's poems, was introduced to him. The former had written, a year or two before, some imitations of Milton's juvenile poems, viz. A Monody on the death of Mr Pope, and two pieces, entitled, *Il Bellisoso*, and *Il Pacifico*, on the peace of Aix-la-Chapelle; and the latter revised them, at the request of a friend. This laid the foundation of an intimacy, which continued without interruption to the death of Mr Gray.

About the year 1750, Mr Gray had put his last hand to his celebrated Elegy written in a country church-yard, and had communicated it to his friend Mr Walpole, whose good taste was too much charmed with it to suffer him to withhold the sight of it from his acquaintance. Accordingly it was shown about for some

Gray.

Gray.

some time in manuscript, and received with all the applause it so justly merited.

At last the publisher of one of the magazines having obtained a surreptitious copy of it, Mr Gray wrote to Mr Walpole, desiring that he would put his own manuscript into the hands of Mr. Doddley, and order him to print it immediately. This was the most popular of all our author's publications. It ran through eleven editions in a very short space of time; was finely translated into Latin by Messrs Antly and Roberts; and, in the same year, by Mr Lloyd.

From July 1759, to the year 1762, he generally resided in London, with a view, as we have already observed, of having recourse to the British Museum. In July 1768, his grace the duke of Grafton wrote him a polite letter, informing him, that his majesty had been pleased to offer to him the professorship of Modern History in the university of Cambridge, then vacant by the death of Mr Laurence Brockett. This place was valuable in itself, the salary being 400*l.* a-year; but what rendered it particularly acceptable to Mr Gray was its being given him without any solicitation. He was indeed remarkably disinterested in all his pursuits. Though his income, before this addition, was very small, he never read or wrote with a view of making his labours useful to himself. He may be said to have been one of those few personages in the annals of literature, especially in the poetical class, who are devoid of self-interest, and at the same time attentive to economy; and also was, among mankind in general, one of those very few economists, who possess that talent, untinged with the slightest stain of avarice. When his circumstances were at the lowest, he gave away such sums in private charity, as would have done credit to an ampler purse. But what chiefly deterred him from seeking any advantage by his literary pursuits, was a certain degree of pride, which led him to despise the idea of being thought an author by profession.

However, it is probable, that early in life he had an intention of publishing an edition of Strabo; for his papers contain a great number of notes and geographical disquisitions on that author, particularly with respect to that part of Asia which comprehends Persia and India. The insupportable pains which he took with the writings of Plato, and the quantity of critical as well as explanatory observations which he has left upon almost every part of his works, plainly indicate, that no man in Europe was better prepared to republish and illustrate that philosopher, than Mr Gray. Another work, on which he bestowed uncommon labour, was the *Anthologia*. In an interleaved copy of that collection of Greek epigrams, he has transcribed several additional ones, which he selected in his extensive reading; has inserted a great number of critical notes and emendations, and subjoined a copious index. But, whether he intended this performance for the press or not, is uncertain. The only work, which he meditated upon, with this direct view from the beginning, was a history of English poetry, upon a plan sketched out by Mr Pope. He has mentioned this himself in an advertisement to those three fine imitations of Norse and Welch poetry, which he gave the world in the last edition of his Poems. But, after he had made some considerable preparations for the execution of this design, and Mr Mason had offered him

Gray.

his assistance, he was informed, that Mr Warton, of Trinity College, Oxford, was engaged in a work of the same kind. The undertaking was therefore relinquished, by mutual consent; and, soon after, on that gentleman's desiring a sight of the plan, our author readily sent him a copy of it.

Among other sciences, Mr Gray had acquired a great knowledge of Gothic architecture. He had seen and accurately studied in his youth, while abroad, the Roman proportions on the spot, both in ancient times, and in the works of Palladio. In his later years he applied himself to consider those stupendous structures of more modern date that adorn our own country; which, if they have not the same grace, have undoubtedly equal dignity. He endeavoured to trace this mode of building, from the time it commenced, thro' its various changes, till it arrived at its perfection in the reign of Henry VIII. and ended in that of Elizabeth. For this purpose, he did not so much depend upon written accounts, as that internal evidence which the buildings themselves give of their respective antiquity; since they constantly furnish to the well informed eye, arms, ornaments, and other marks, by which their several ages may be ascertained. On this account he applied himself to the study of heraldry, as a preparatory science; and has left behind him a number of genealogical papers, more than sufficient to prove him a complete master of it. By these means he arrived at so very extraordinary a pitch of sagacity, as to be enabled to pronounce, at first sight, on the precise time when every particular part of any of our cathedrals was erected.

But the favourite study of Mr Gray, for the last ten years of his life, was natural history, which he then rather resumed than began; as, by the instructions of his uncle Antrobus, he was a considerable botanist at fifteen. The marginal notes, which he has left on Linnaeus, and other writers on the vegetable, animal, and fossil kingdoms, are very numerous: but the most considerable are on Hudson's *Flora Anglica*, and the tenth edition of the *Systema Nature*; which latter he interleaved and filled almost entirely. While employed on zoology, he read Aristotle's treatise on that subject with great care, and explained many difficult passages of that obscure ancient by the lights he had received from modern naturalists. In a word, excepting pure mathematics, and the studies dependent on that science, there was hardly any part of human learning, in which he had not acquired a competent skill, and in most of them a consummate mastery.

To this account of his literary character we may add, that he had a fine taste in painting, prints, gardening, and music; and was moreover a man of good-breeding, virtue, and humanity.

He died in 1771; and an edition of his poems, with memoirs of his life and writings, were published in 4to, in 1775, by Mr Mason. This gentleman, however, instead of employing his own pen in drawing Mr Gray's character, has adopted one drawn by the Rev. Mr Temple, rector of Mamhead in Devonshire, in a letter to Mr Boswell; to whom the public are indebted for communicating it.

"Perhaps (says Mr Temple) he was the most learned man in Europe. He was equally acquainted with the elegant and profound parts of science, and that

Gray.
Greaves.

that not superficially but thoroughly. He knew every branch of history, both natural and civil; had read all the original historians of England, France, and Italy; and was a great antiquarian. Criticism, metaphysics, morals, politics, made a principal part of his plan of study; voyages and travels of all sorts were his favourite amusement; and he had a fine taste in painting, prints, architecture, and gardening. With such a fund of knowledge, his conversation must have been equally instructing and entertaining; but he was also a good man, a well-bred man, a man of virtue and humanity. There is no character without some speck, some imperfection; and I think the greatest defect in his was an affectation in delicacy, or rather effeminacy, and a visible fastidiousness, or contempt and disdain of his inferiors in science. He also had, in some degree, that weakness which disgusted Voltaire so much in Mr Congreve: though he seemed to value others chiefly according to the progress they had made in knowledge, yet he could not bear to be considered himself merely as a man of letters; and though without birth, or fortune, or station, his desire was to be looked upon as a private independent gentleman, who read for his amusement. Perhaps it may be said, What signifies so much knowledge, when it produces so little? Is it worth taking so much pains to leave no memorial but a few poems? But let it be considered, that Mr Gray was, to others, at least innocently employed; to himself, certainly beneficially. His time passed agreeably; he was every day making some new acquisition in science; his mind was enlarged, his heart softened, and his virtue strengthened; the world and mankind were shewn to him without a mask; and he was taught to consider every thing as trifling, and unworthy the attention of a wise man, except the pursuit of knowledge, and the practice of virtue in that state wherein God hath placed us."

GRAYLING, in ornithology, a species of SALMO.

In angling for this fish your hook must be armed upon the shanks with a very narrow plate of lead, which should be slenderest at the bent of the hook, that the bait (which is to be a large grasshopper, the uppermost wing of which must be pulled off) may come over to it the more easily. At the point let there be a cad-bait in a continual motion. The jag-tail, which is a worm of a pale flesh-colour, with a yellow tag on its tail, is an excellent bait for the grayling in March and April.

GREASE, a swelling and gourdfiness of the legs of a horse. See FARRIERY, § XXXV.

GREATER TONE, in music. See TONE.

GREAVES (John), an eminent physician and antiquary, was the eldest son of John Greaves rector of Colemore near Alresford in Hampshire, and born in 1602. He was educated at Balliol college in Oxford, from which he removed to Merton. He was afterwards, on the foot of his great merit, chosen geometry professor of Gresham college. His ardent thirst of knowledge soon carried him into several parts of Europe, where he eagerly seized every opportunity of improving it. His next voyage was into the eastern countries; where nothing remarkable in the heavens, earth, or even subterraneous places, seems to have escaped his nice observation. He, with indefatigable

industry, and even at the peril of his life, collected a considerable number of Arabic, Persian, and Greek manuscripts for archbishop Laud. Of these he well knew the value, as he was a master of the languages in which they were written. He also collected for that prelate many oriental gems and coins. He took a more accurate survey of the pyramids than any traveller who went before him. On his return from the East, he visited several parts of Italy a second time. During his stay at Rome, he made a particular inquiry into the true state of the ancient weights and measures. Soon after he had finished his second voyage, he was chosen Savilian professor of astronomy at Oxford. He was eminently qualified for this professorship, as the works of ancient and modern astronomers were familiar to him. His books relating to oriental learning, his *Pyramidographia*, or a description of the pyramids in Egypt, his *Epocha Celestiorum*, and other curious and useful pieces, of which Mr Ward has given us a catalogue, shew him to have been a great man. Those which he intended to publish would have shewn him to be a greater; but he was stopped in his great career by death, in 1652.

GREBE, in ornithology. See COLYMBUS.

GREECE, the present Rumelia, and in many respects one of the most deservedly celebrated countries in the world, was anciently bounded on the north by Macedonia, and the river Strymon; on the west by the Ionian sea; on the south by the Mediterranean; and on the east by the Egean sea and Archipelago. It extended from the Strymon, by which it was parted from Thrace, to the promontory of Tenarus, the southmost point of the Peloponnesus, now the Morea, about 6° 20' of latitude, or nearly 440 English miles, and in breadth from east to west about 359 miles.

The general names by which the inhabitants of this country were known to the ancients, were those of *Graioi*, or *Graioi*, from whence the name of *Greece* is plainly derived. These names are thought come from *Græcus*, the father, or (according to some) the son, of Thessalus, who gave name to Thessaly; but some modern critics chuse to derive it from *Ragus*, the same with *Reu*, the son of Peleg, by the transposition of a letter to soften the sound.—These names were afterwards changed for *Achai* and *Hellenes*; the first, as is supposed, from *Acheus*, the son of Xuthus, the son of Hellen, and father of Ion; or, according to the fable, the son of Jupiter: the other from Hellen, above mentioned, the son of Deucalion, and father of Dorus, from whom came the *Dores*, afterwards a famous nation among the Greeks.—Another name by which the Greeks were known in some parts of the country, was that of *Pelagii*, which the Arcadians, the most ancient people in Greece, deduced from their pretended founder *Pelagius*; who is said to have got such footing in Peloponnesus, that the whole peninsula from him was called *Pelagisia*. But the most ancient name of all is universally allowed to have been that of *Iones*, which the Greeks themselves derived from Ion the son of Xuthus; or, as the fable hath it, of Apollo, by Crenusa the daughter of Erichtheus the grandson of Deucalion. Josephus, however, affirms, that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, was the first who peopled these countries; which Bochart hath also rendered

Grebe,
Greece.

Greece.

dered very probable. It is true, indeed, that among the Greeks themselves, only the Athenians, and such colonies as sprung from them, were called *Ionæ*; but it is also plain beyond exception, that other nations gave this name to all the inhabitants of Greece.

The inhabitants of Greece in the first ages, even by the confession of their own historians, appear to have been savages scarce a degree removed from brutes. They lived indifferently on every fruit, herb, or root that came in their way; and lay either in the open fields, or at best sheltered themselves in dens, caves, and hollow trees; the country itself in the mean time remaining one continued uncultivated desert. —The first improvement they made in their way of living, was the exchanging of their old food for the more wholesome acorns, building huts for themselves to sleep in, and covering their bodies with the skins of beasts. For all this, it seems, they were beholden to Pelægius above-mentioned, (supposed by some to be Peleg spoke of in Scripture), and who was highly revered by them on that account. —This reformation in their way of life, however, it seems wrought none in their manners. On the contrary, they who had nothing to fight for but a hole to sleep in, began now to envy and rob one another of these slender acquisitions. This, in process of time, put them under a necessity of joining themselves into companies under some head, that they might either more safely plunder their neighbours, or preserve what they had got. Laws they had none, except that of the sword: so that those only lived in safety who inhabited the most barren and craggy places; and hence Greece for a long time had no settled inhabitants, the weakest being always turned out by the strongest. Their gigantic size and strength, if we may believe Plutarch, added so much to their insolence and cruelty, that they seemed to glory in committing the greatest acts of violence and barbarity on those that unhappily fell into their hands.

The next advance towards civilization, was their forming themselves into regular societies, to cultivate the lands, and build themselves towns and cities for their safety. Their original barbarity and mutual violences against each other naturally prevented them from uniting as one nation, or even into any considerable community; and hence the great number of states into which Greece was originally divided. The most remarkable of these small principalities mentioned in history are the following: — In Peloponnesus were those of Sicyon, Argos, and Messenia, Achaia Propria, Arcadia, and Laconia. In Grecia Propria, (that part of Greece which lay without Peloponnesus), were those of Attica, Megara, Boeotia, Locris, Epichæmidia, Doris, Phocis, Locris, Ozolæ, and Ætolia. In Epirus were the Molossi, Amphiloichi, Cassiopæi, Dræopes, Chaoces, Threpsotii, Almeni, and Acarnani. In Thessaly were those of the Thessaliois, Estiotis, Pelasgiotis, Magnesia, and Phthia. —All these have at one time or other been severally governed by kings of their own, though we only find the names of many of them mentioned in the histories of the more considerable kingdoms of Sparta, Attica, Thebes, &c. —The erection of these kingdoms, however, for some time, did not much alter the case; the inhabitants of the new kingdoms plundered and destroyed one another without mercy. Attica was the only place

Greece.

in any degree free from these incursions, because it was naturally destitute of every thing that could invite a plundering enemy; but those cities fared much worse which were situated in the sea-coasts; because they were in continual danger of being plundered either by sea or land: for pirates at that time did not less infect all those seas, than robbers did the land. And this was one main cause why most of the ancient cities of Greece were situated at some considerable distance from the shore; but even in these, as all their safety consisted in the resistance they could make against an invader, their inhabitants were under a necessity of going constantly armed, and being ever on their guard.

Another mischief arising from these continual piracies and robberies was, that they occasioned the far greater part of the lands to lie uncultivated, so that the people only planted and sowed as much as was barely necessary for their present support; and where there was such an universal neglect of agriculture, there could be as little room for any discoveries in other useful arts and trades. Hence, when other nations, as the Jews, Egyptians, Midianites, Phœnicians, &c. had improved themselves to a very high degree, the Greeks seem to have been utter strangers to every useful art.

During this period of savage barbarity, the most renowned Grecian heroes, as Hercules, Theseus, &c. performed their exploits; which, however exaggerated by poetic fiction, no doubt had a foundation in truth. Some indeed are of opinion that the Grecian heroes are entirely fictitious, and their exploits derived from those of the Hebrew worthies, such as Samson, Gideon, &c. Yet, considering the extreme degree of barbarity which at that time prevailed throughout Greece, it seems not at all improbable that some persons of extraordinary strength and courage might undertake the cause of the oppressed, and travel about like the more modern knights-errant in quest of adventures.

The first expedition in which we find the Greeks united, was that against Troy, the particulars of which are recited under the article *Troy*. Their success here (which happened about 1184 B. C.) cost them very dear; vast numbers of their bravest warriors being slain; great numbers of the survivors being cast away in their return; and many of those who had the good luck to get back again, being soon after murdered, or driven out of their country. It is probable, however, that their having staid for such a long time in Asia, might contribute to civilize the Greeks somewhat sooner than what they otherwise would have been; and accordingly from this time, we find their history somewhat less obscure, and as it were begun to emerge out of darkness. The continual wars, indeed, in which they were engaged among themselves, no doubt, for a long time, prevented them from making any considerable progress in those arts in which they afterwards made so great progress. These wars, which indeed never ceased as long as the Greeks preserved their liberty, rendered them brave, and skilled in the military art, above all other nations; but at the same time they effectually prevented them from making permanent conquests, and confined them within the bounds of their own country; while the different states were one way or other so equally balanced, that scarce

one

Greece.

one of them was able perfectly to subdue another. The Spartans, however, having, with great difficulty, reduced the kingdom of Messene, and added its territories to their own, became the leading people in Greece. Their superiority was long disputed by Athens; but the Peloponnesian war at last determined that point in favour of the Spartans, when the city of Athens was taken, and its walls demolished by Lyfander the Spartan general. See *ATLANTA*, n° 164. —By the battle of Leuctra, the Spartans lost that superiority which they had maintained for 500 years, and which now devolved on the Thebans. After the death of Epaminondas, the celebrated Theban general, however, as no person was found possessed of his abilities, the Thebans were again obliged to yield the superiority to the Spartans. But by this time the Greeks had become acquainted with the luxuries and elegancies of life; and all the rigour of their original laws could not prevent them from valuing these as highly as other people. This did not indeed abate their valour, but it heightened their mutual animosities; at the same time that, for the sake of a more easy and comfortable life, they became more disposed to submit to a master. The Persians, whose power they had long dreaded, and who were unable to resist them by force of arms, at last found out (by the advice of Alcibiades) the proper method of reducing the Grecian power; namely, by assisting them by turns, and supplying one state with money to fight against another, till they should all be so much reduced, that they might become an easy prey. Thus the Greeks were weakened, though the Persians did not reap any benefit from their weakness. Philip of Macedon entered into the same political views; and partly by intrigue, partly by force, got himself declared Generalissimo of Greece. His successor Alexander the Great completed their subjection; and by destroying the city of Thebes, and exterminating its inhabitants, struck such a terror throughout Greece, that he was as fully obeyed by all the states, as by any of the rest of his subjects. During his absence in Persia, however, they attempted to shake off the Macedonian yoke, but were quelled by his general Antipater. The news of Alexander's death was to them a matter of the utmost joy; but their mutual animosities prevented them from joining in any solid plan for the recovery of their liberties, and hence they continued to be oppressed by Alexander's successors, or other tyrants, till Aratus, an Achæan, about 268 B. C. formed a design of setting his country free from these oppressors. He persuaded a number of the small republics to enter into a league for their own defence, which was called the *Achæan league*; and notwithstanding that the republics, taken singly, had very little strength, they not only maintained their independency, but soon became formidable when united. This association continued to become daily more and more powerful; but received a severe check from Cleomenes, king of Sparta, which obliged them to call in Antigonus to their assistance. This prince overcame Cleomenes at the battle of Sellasia, and afterwards made himself master of Sparta. Thus he became a more formidable enemy than the one he had conquered, and the recovery of the Grecian liberties was incomplete.

Soon after this, the Greeks began to feel the weight
Vol. V.

Greece.

of a power more formidable than any which they had yet experienced; namely, that of the Romans. That insidious and haughty republic first intermeddled with the Grecian affairs, under pretence of setting them at liberty from the oppression of Philip of Macedon. This, by a proper union among themselves, they might have accomplished: but in this they acted as though they had been infatuated; receiving with the utmost joy the decree of the Roman consul, who declared them free; without considering, that he who had thus given them liberty, might take it away at his pleasure. This lesson, however, they were soon taught, by the total reduction of their country to a Roman province; yet this can scarce be called a misfortune, when we look back to their history, and consider their outrages upon one another: nor can we sympathize with them for the loss of that liberty which they only made use of to fill their country with slaughter and bloodshed. After their conquest by the Romans, they made no united effort to recover their liberty. They continued in quiet subjection till the beginning of the 15th century. About that time, they began to suffer under the tyranny of the Turks, and their sufferings were completed by the taking of Constantinople in 1453. Since that time, they have groaned under the yoke of a most despotic government; so that all traces of their former valour, ingenuity, and learning, are now in a manner totally extinct.

Modern Greece comprehends Macedonia; Albania, now called Arnaut; Epirus; Thessaly, now Jana; Achaia, now Livadia; the Peloponnesus, now Morea; together with the islands on its coast, and in the Archipelago. The continent of Greece is seated betwixt the 36th and 43d degrees of north latitude; and between the 19th and 27th degrees of longitude, east of London. To the north it is bounded, by Bulgaria and Servia, from which it is divided by a ridge of mountains; to the south, by the Mediterranean sea; to the east, by Romania and the Archipelago; and to the west, by the Adriatic, or gulph of Venice. Its length is said to be about four hundred miles, and its utmost breadth about three hundred and fifty. The air is extremely temperate and healthy; and the soil fruitful, though badly cultivated, yielding corn; wine, delicious fruits, and abounding with cattle, fowls, and venison. As to religion, Christianity was planted in Greece soon after the death of our Saviour, and flourished there for many ages in great purity; but since the Greeks became subject to the Turkish yoke, they have sunk into the most deplorable ignorance, in consequence of the slavery and thraldom under which they groan, and their religion is now greatly corrupted. It is indeed little better than a heap of ridiculous ceremonies and absurdities. The head of the Greek church is the patriarch of Constantinople; who is chosen by the neighbouring archbishops and metropolitans, and confirmed by the emperor or grand vizir. He is a person of great dignity, being the head and director of the eastern church. The other patriarchs are those of Jerusalem, Antioch, and Alexandria, Mr. Tournefort tells us, that the patriarchates are now generally set to sale, and bestowed upon those who are the highest bidders. The patriarchs, metropolitans, archbishops, and bishops, are always chosen from among the Caloyers or Greek monks. Ba-
fore

Greece.

fore the patriarchs receive their patents and the caftan, which is a veft of linley-woolsey, or fome other ftuff, prefented by the grand fignior to ambaffadors and other perfons newly invefted with fome confiderable dignity, they are obliged to make large prefents to the vizir, &c. The income of the patriarch of Conftantinople is faid to amount to no lefs than one hundred and twenty thoufand guilders, of which he pays the one half by way of annual tribute to the Ottoman Porte, adding fix thoufand guilders befides as a prefent at the feaft of Bairam. The next perfon to a bifhop among the clergy is an archimandrite, who is the director of one or more convents, which are called mandren; then come the abbot, the arch-prieft, the prieft, the deacon, the under-deacon, the chanter, and the lecturer. The feccular clergy are fubjected to no rules, and never rife higher than high-prieft. They are allowed to marry once; but it muft be with a virgin, and before they are ordained. They have neither glebe nor tythes, but depend on the perquifites that arife from their office; and they feldom preach but in Lent. The Greeks have few nunneries; but a great many convents of monks, who are all priefts, and, ftudents excepted, obliged to follow fome handicraft employment, and lead a very auftere life. The Greeks deny the fupremacy of the pope, and abhor the worfhip of images; but have a multitude of pictures of faints in their churches, whom they pray to as mediators. Their fafts are very fevere. They believe alfo in the doctrine of tranfubftantiation, and that the Holy Ghoft does not proceed from the Son. They admit not of purgatory, fays Mr. Thevenot: but yet they allow a third place, where they fay the bleffed remain, in expectation of the day of judgment. At mafs they confecrate with leavened bread; and communicate under both kinds, as well laics as priefts, and as well women and children as men. When they carry the facrament to the fick, they do not proftitate themfelves before it, nor expose it to be adored: neither do they carry it in proceffion, or have any particular feaft in honour of it. Baptifm is performed among them by plunging the whole body of the child thrice into water. Immediately after baptifm, they give it confirmation and the communion; and feven days after that, it undergoes the ceremony of abfolution. When a prieft is married, among other ceremonies, the bridegroom and bride drink each two glaffes of wine; then the glafs is given to the prieft, who merrily drinks off the reft of the wine, and breaking the glafs, fays, So may the bridegroom break the virginity of the bride. As to the character of the modern Greeks, they are faid to be very covetous, hypocritical, treacherous, great pederaffs, and at the fame time revengeful to the higheft degree; but very fuperftitious. They are fo much defpifed by the Turks, that thefe do not value even a Greek who turns Mahometan. The Turks are remarkable for their taciturnity; they never ufe any unneceffary words: but the Greeks, on the contrary, are very talkative and lively. The Turks generally praftife what their religion enjoins, but the Greeks do not; and their mifery puts them upon a thoufand mean shifts and fcandalous praftices, authorized by bad example, and perpetuated from father to fon. The Greek women have fine features and beautiful complexions: their

countenances ftill very much refemble thofe of the ancient Greek ftatues.

GREEK, or GRECIAN, any thing belonging to ancient Greece.

The Greek language, as preferved in the writings of the celebrated authors of antiquity, as Homer, Hefiod, Demofthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expreffions, fuitable to the genius and occafions of a polite and learned people, who had a tafte for arts and fciences. In it, proper names are fignificative; which is the reafon that the modern languages borrow fo many terms from it. When any new invention, inftrument, machine, or the like, is difcovered, recourfe is generally had to the Greek for a name to it; the facility wherewith words are there compounded, affording fuch as will be expreffive of its ufe: fuch are, barometer, hygrometer, microfcope, telescope, thermometer, &c. But of all fciences, medicine moft abounds with fuch terms; as diaphoretic, diagnosis, diarrhoea, hæmorrhage, hydrophobia, phthifis, atrophy, &c. Befides the copioufnefs and fignificancy of the Greek, wherein it excels moft, if not all, other languages, it has alfo three numbers, *viz.* a fingular, dual, and plural: alfo abundance of tenfes in its verbs, which makes a variety in difcourfe, prevents a certain drynefs that always accompanies too great a uniformity, and renders that language peculiarly proper for all kinds of verfe. The ufe of the participles, of the aorift and preterite, together with the compound words already mentioned, give it a peculiar force and brevity without taking any thing from their perfpicuity.

It is no eafy matter to affign the precise difference between the modern and ancient Greek; which confifts in the terminations of the nouns, pronouns, verbs, &c. not unlike what obtains between fome of the dialects of the Italian or Spanifh. There are alfo in the modern Greek many new words, not to be met with in the ancient. We may therefore diftinguifh three ages of the Greek tongue: the firft of which ends at the time when Conftantinople became the capital of the Roman empire; the fecond lafted from that period to the taking of Conftantinople by the Turks; and the third, from that time to this.

GREEK Bible. See BIBLE.

GREEK Church. See GREECE.

GREEK Monks and Nuns, of whatever order, confider St. Bafil as their founder and common father, and efteem it the higheft crime to deviate in the leaft from his conftitutions. There are feveral beautiful convents with churches, in which the monks perform divine fervice day and night. Some of the monks are cœnobites, or live together, wear the fame habit, eat at the fame table, and perform the fame exercifes and employments.

GREEN, one of the original prismatic colours, exhibited by the refraction of the rays of light. See OPTICS.

GREEN, among painters. See COLOUR-Making, n° 26.

GREEN Cloth, a board or court of juftice held in the compting-house of the kings houfehold, compofed of the Lord Steward and officers under him, who fit daily. To this court is committed the charge and oversight of the king's houfehold in matters of juftice

Greek,
Green.

Green,
Greenland.

justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court-royal; which is every way about 200 yards from the last gate of the palace where his majesty resides.

It takes its name, *board of green cloth*, from a green cloth spread over the board where they sit.

Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

Clerks of the GREEN Cloth are two officers of the board of green cloth, who appoint the diet of the king and his household; and keep all records, ledgers, and papers relating thereto; made up bills, parcels, and debentures for salaries, and provisions and necessaries for the officers of the buttery, pantry, cellar, &c.

They also wait upon foreign princes when entertained by his majesty.

GREEN-Finch in ornithology, the English name of the greenish fringilla, with the wings and tail variegated with yellow. See FRINGILLA.

GREEN-House, or *Conservatory*, a house in a garden, contrived for sheltering and preserving the most curious and tender exotic plants, which in our climate will not bear to be exposed to the open air, especially during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

GREEN-Silver, the name of an ancient custom within the manor of Writtel in the county of Essex in England; which is, that every tenant whose fore-door opens to Greenbury, shall pay an half-penny yearly to the lord, by the name of *green-silver*.

GREEN Wax, is used where estates are delivered to the sheriffs out of the exchequer, under the seal of that court, made in green wax, to be levied in the several counties. This word is mentioned the 43d stat. Ed. III. c. 9. and 7 Hen. IV. c. 4.

GREENLAND, a general name by which are denoted the most easterly parts of America, stretching towards the north pole, and likewise some islands to the northward of the continent of Europe, lying in very high latitudes.

This country is divided into West and East Greenland.—West Greenland is now determined by our latest maps to be a part of the continent of America, though upon what authority is not very clear. That part of it which the Europeans have any knowledge of is bounded on the west by Baffin's bay, on the south by Davis's straits, and on the east by the northern part of the Atlantic Ocean. It is a very mountainous country, and some parts of it so high that they may be discerned thirty leagues off at sea. The inland mountains, hills, and rocks, are covered with perpetual snow; but the low lands on the sea-side are clothed with verdure in the summer season. The coast abounds with inlets, bays, and large rivers; and is surrounded with a vast number of islands of different dimensions. In a great many places however, on the eastern coast especially, the shore is inaccessible by reason of the floating mountains of ice. The principal river, called *Baal*, falls into the sea in the 64th degree of latitude, where the first Danish lodge was built in 1721; and has been navigated above 40 miles up the country.

West Greenland was first peopled by Europeans in

the eighth century. At that time a company of Greenlanders, headed by one Ericke Rande, were by accident driven on the coast. On his return he represented the country in such a favourable light, that some families again followed him thither, where they soon became a thriving colony, and bestowed on their new habitation the name of *Greenland*, or *Greenland*, on account of its verdant appearance. This colony was converted to Christianity by a missionary from Norway, sent thither by the celebrated Olaf, the first Norwegian monarch who embraced the true religion. The Greenland settlement continued to increase and thrive under his protection; and, in a little time, the country was provided with many towns, churches, convents, bishops, &c. under the jurisdiction of the archbishop of Drontheim. A considerable commerce was carried on between Greenland and Norway; and a regular intercourse maintained between the two countries till the year 1406, when the last bishop was sent over. From that time all correspondence was cut off, and all knowledge of Greenland has been buried in oblivion.

This strange and abrupt cessation of all trade and intercourse has been attributed to various causes; but the most probable is the following. The colony, from its first settlement, had been harassed by the natives, a barbarous and savage people, agreeing in customs, garb, and appearance, with the Esquimaux found about Hudson's Bay. This nation, called *Schrellings*, at length prevailed against the Iceland settlers who inhabited the western district, and exterminated them in the 14th century; inasmuch, that when their brethren of the eastern district came to their assistance, they found nothing alive but some cattle and flocks of sheep running wild about the country. Perhaps they themselves afterwards experienced the same fate, and were totally destroyed by these Schrellings, whose descendants still inhabit the western parts of Greenland, and from tradition confirm this conjecture. They affirm that the houses and villages whose ruins still appear, were inhabited by a nation of strangers, whom their ancestors destroyed. There are reasons, however, for believing that there may be still some descendants of the ancient Iceland colony remaining in the eastern district, though they cannot be visited by land, on account of the stupendous mountains, perpetually covered with snow, which divide the two parts of Greenland; while they have been rendered inaccessible by sea, by the vast quantity of ice driven from Spitzbergen, or East Greenland. One would imagine that there must have been some considerable alteration in the northern parts of the world since the 15th century, so that the coast of Greenland is now become almost totally inaccessible, though formerly visited with very little difficulty. It is also natural to ask, By what means the people of the eastern colony surmounted the above-mentioned obstacles when they went to the assistance of their western friends, how they returned to their own country, and in what manner historians learned the success of their expedition? Concerning all this we have very little satisfactory information. All that can be learned from the most authentic records is, that Greenland was divided into two districts, called *West Bygd*, and *East Bygd*: that the western division contained four parishes, and 100 villages: that

Peopled by a colony from Iceland.

All correspondence with it suddenly cut

Colony supposed to be exterminated.

6
Attempts to redi-
ver the
country.

the eastern district was still more flourishing, as being nearer to Iceland, sooner settled, and more frequented by shipping from Norway. There are also many accounts, though most of them romantic and slightly attested, which render it probable that part of the eastern colony still subsists, who, at some time or other, may have given the imperfect relation above-mentioned. This colony, in ancient times, certainly comprehended twelve extensive parishes, one hundred and ninety villages, a bishop's see, and two monasteries. The present inhabitants of the western district are entirely ignorant of this part, from which they are divided by rocks, mountains, and deserts, and still more effectually by their apprehension : for they believe the eastern Greenlanders to be a cruel, barbarous nation, that destroy and eat all strangers who fall into their hands. About a century after all intercourse between Norway and Greenland had ceased, several ships were sent successively by the kings of Denmark, in order to discover the eastern district ; but all of them miscarried. Among these adventurers, Mogens Heinsön, after having surmounted many difficulties and dangers, got sight of the land, which, however, he could not approach. At his return, he pretended that the ship was arrested in the middle of her course, by certain rocks of loadstone at the bottom of the sea. The same year, 1576, in which this attempt was made, has been rendered remarkable by the voyage of Captain Martin Frobisher, sent upon the same errand by Queen Elizabeth. He likewise desired the land ; but could not reach it, and therefore returned to England ; yet not before he had sailed sixty leagues in the strait which still retains his name, and landed on several islands, where he had some communication with the natives. He had likewise taken possession of the country in the name of Queen Elizabeth ; and brought away some pieces of heavy black stone, from which the refiners of London extracted a certain proportion of gold. In the ensuing spring, he undertook a second voyage, at the head of a small squadron, equipped at the expense of the public ; entered the straits a second time ; discovered upon an island a gold and silver mine ; bestowed names upon different bays, islands, and headlands ; and brought away a lading of ore, together with two natives, a male and a female, whom the English kidnapped.

Such was the success of this voyage, that another armament was fitted out under the auspices of Admiral Frobisher, consisting of fifteen sail, including a considerable number of soldiers, miners, smelters, carpenters, and bakers, to remain all the winter near the mines in a wooden fort, the different pieces of which they carried out in

the transports. They met with boisterous weather, impenetrable fogs, and violent currents upon the coast of Greenland, which retarded their operations until the season was far advanced. Part of their wooden fort was lost at sea ; and they had neither provision nor fuel sufficient for the winter. The admiral therefore determined to return with as much ore as he could procure : of this they obtained large quantities out of a new mine, to which they gave the name of the Countess of Suffex. They likewise built an house of stone and lime, provided with ovens ; and here, with a view to conciliate the affection of the natives, they left a quantity of small morrice-bells, knives, beads, looking-glasses, leaden pictures, and other toys, together with several loaves of bread. They buried the timber of the fort where it could be easily found next year ; and sowed corn, pease, and other grain, by way of experiment, to know what the country would produce. Having taken these precautions, they sailed from thence in the beginning of September ; and after a month's stormy passage, arrived in England : but this noble design was never prosecuted.

Christian IV. king of Denmark, being desirous of discovering the old Greenland settlement, sent three ships thither, under the command of Captain Godtke Lindenow ; who is said to have reached the east coast of Greenland, where he traded with the savage inhabitants, such as they are still found in the western district, but saw no signs of a civilized people. Had he actually landed in the eastern division, he must have perceived some remains of the ancient colony, even in the ruins of their convents and villages. Lindenow kidnapped two of the natives, who were conveyed to Copenhagen ; and the same cruel fraud * was practised by other two ships which sailed into Davis's Straits, where they discovered divers fine harbours, and delightful meadows covered with verdure. In some places they are said to have found a considerable quantity of ore, every hundred pounds of which yielded twenty-six ounces of silver. The same Admiral Lindenow made another voyage to the coast of Greenland in the year 1606, directing his course to the westward of Cape Farewell. He coasted along the Straits of Davis ; and having made some observations on the face of the country, the harbours and islands, returned to Denmark. Carsten Richards, being detached with two ships on the same discovery, desired the high land on the eastern side of Greenland ; but was hindered by the ice from approaching the shore.

Other expeditions of the same nature have been planned and executed with the same bad success, under the auspices of a Danish company of merchants. Two ships

* Nothing can be more inhuman and repugnant to the dictates of common justice, than this practice of tearing away poor creatures from their country, their families, and connections : unless we suppose them altogether destitute of natural affection ; and that this was not the case with those poor Greenlanders, some of whom were brought alive to Copenhagen, appears from the whole tenor of their conduct, upon their first capture, and during their confinement in Denmark. When first captivated, they rent the air with their cries and lamentations : they even leaped into the sea, and, when taken on board, for some time refused all sustenance. Their eyes were continually turned towards their dear country, and their faces always bathed in tears. Even the countenance of his Danish majesty, and the caresses of the court and people, could not alleviate their grief. One of them was perceived to shed tears always when he saw an infant in the mother's arms ; a circumstance from whence it was naturally concluded, that he had left his wife with a young child in Greenland. Two of them went to sea in their little canoes, in hope of reaching Greenland : but one of them was retaken. Other two made the same attempt : but were driven by a storm on the coast of Schonen, where they were apprehended by the peasants, and reconveyed to Copenhagen. One of them afterwards died of a fever, caught in fishing pearl, during the winter, for the governor of Kolding. The rest lived some years in Denmark : but at length, seeing no prospect of being able to revisit their native country, they sunk into a kind of melancholy disorder, and expired.

ships returned from the western part of Greenland loaded with a kind of yellow sand, supposed to contain a large proportion of gold. This being assayed by the goldsmiths of Copenhagen, was condemned as useless, and thrown overboard : but from a small quantity of this sand, which was reserved as a curiosity, an expert chemist afterwards extracted a quantity of pure gold. The captain, who brought home this adventure, was so chagrined at his disappointment, that he died of grief, without having left any directions concerning the place where the sand had been discovered. In the year 1654, Henry Muller, a rich Dane, equipped a vessel under the command of David de Nelles, who failed to the west coast of Greenland, from which he carried off three women of the country. Other efforts have been made, under the encouragement of the Danish king, for the discovery and recovery of the old Iceland colony in Greenland : but all of them miscarried, and people began to look upon such expeditions as wild and chimerical. At length the Greenland company at Bergen in Norway, transported a colony to the western coast, about the 64th degree of latitude ; and these Norwegians failed in the year 1712, accompanied by the Reverend Hans Egede, to whose care, ability, and precision, we owe the best and most authentic account of modern Greenland. This gentleman endeavoured to reach the eastern district, by coasting southwards, and advanced as far as the States Promontory : but the season of the year, and continual storms, obliged him to return ; and as he could not even find the Strait of Frobisher, he concluded that no such place ever existed. In the year 1724, a ship, being equipped by the company, failed on this discovery, with a view to land on the east side opposite to Iceland ; but the vast shoals of ice, which barricaded that part of the coast, rendered this scheme impracticable. His Danish majesty, in the year 1728, caused horses to be transported to Greenland, in hope that the settlers might by their means travel over land to the eastern district ; but the icy mountains were found impassable. Finally, lieutenant Richards, in a ship which had wintered near the new Danish colony, attempted, in his return to Denmark, to land on the eastern shore ; but all his endeavours proved abortive.

Mr Egede is of opinion, that the only practicable method of reaching that part of the country, will be to coast north-about in small vessels, between the great flakes of ice and the shore ; as the Greenlanders have declared, that the currents continually rushing from the bays and inlets, and running south-westwards along the shore, hinder the ice from adhering to the land ; so that there is always a channel open, through which vessels of small burden might pass, especially if lodges were built at convenient distances on the shore, for the convenience and direction of the adventurers.

That part of the country which is now visited and settled by the Danes and Norwegians, lies between the 64th and 68th degrees of north latitude ; and thus far it is said the climate is temperate. In the summer, which continues from the end of May to the middle of September, the weather is warm and comfortable, while the wind blows easterly ; though even at this time storms frequently happen, which rage with incredible violence ; and the sea-coasts are infested with

fogs that are equally disagreeable and unhealthy. Near the shore, and in the bays and inlets, the low land is clothed with the most charming verdure ; but the inland mountains are perpetually covered with ice and snow. To the northward of the 68th degree of latitude the cold is prodigiously intense ; and towards the end of August all the coast is covered with ice, which never thaws till April or May, and sometimes not till the latter end of June. Nothing can exhibit a more dreadful, and at the same time a more dazzling appearance, than those prodigious masses of ice that surround the whole coast in various forms, reflecting a multitude of colours from the sun-beams, and calling to mind the enchanted scenes of romance. Such prospects they yield in calm weather ; but when the wind begins to blow, and the waves to rise in vast billows, the violent shocks of those pieces of ice dashing against one another, fill the mind with horror.—Greenland is seldom visited with thunder and lightning, but the *Aurora Borealis* is very frequent and bright. At the time of new and full moon, the tide rises and falls upon this coast about three fathoms ; and it is remarkable, that the springs and fountains on shore rise and fall with the flux and reflux of the ocean.

The soil of Greenland varies like that of all other mountainous countries. The hills are very barren, being indeed frozen throughout the whole year ; but the valleys and low grounds, especially near the sea, are rich and fruitful. The ancient Norwegian chronicles inform us, that Greenland formerly produced a great number of cattle ; and that considerable quantities of butter and cheese were exported to Norway ; and, on account of their peculiar excellency, set apart for the king's use. The same histories inform us, that some parts of the country yielded excellent wheat ; and that large oaks were found here, which carried acorns as big as apples. Some of these oaks still remain in the southern parts, and in many places the marks of ploughed land are easily perceived. At present, however, the country is destitute of corn and cattle, though in many places it produces excellent pasture ; and, if properly cultivated, would probably yield grain also. Mr Egede sowed some barley in a bay adjoining to the Danish colony. It sprang up so fast, that, by the latter end of July it was in the full ear ; but being nipped by a night-frost, it never arrived at maturity. This seed was brought from Bergen, where the summer is of greater heat and duration than in Greenland ; but in all probability the corn which grows in the northern parts of Norway would also thrive here. Turnips and coleworts of an excellent taste and flavour are also produced here. The sides of the mountains near the bays are clothed with wild thyme, which diffuses its fragrance to a great distance. The herb tormentil is very common in this country, and likewise many others not described by the botanists. Among the fruits of Greenland we number juniper-berries, blue-berries, bil-berries, and bramble-berries.

Greenland is thought to contain many mines of metal, though none of them are wrought. To the southward of the Danish colony are some appearances of a mine of copper. Mr Egede once received a lump of ore from one of the natives ; and here he found calamine of a yellow colour. He once sent a considerable quantity

Greenland. quantity of sand of a yellow colour, intermixed with streaks of vermilion, to the Bergen company. They probably found their account in this present; for they desired him by a letter to procure as much of that sand as possible: but he was never able to find the place where he saw the first specimen. It was one of the smallest among a great number of islands; and the mark he had set up was blown down by a violent storm. Possibly this might be the same mineral of which Capt. Frobiher brought so much to England. This country produces rock-crystals both red and white, and whole mountains of the asbestos or incombustible flax. Around the colony, which is known by the name of *Good Hope*, they find a kind of ballard marble of various colours, which the natives form into bowls, lamps, pots, &c. All that has been said of the fertility of Greenland, however, must be understood only of that part which lies between the 60th and 65th degrees of latitude. The most northern parts are totally destitute of herbs and plants. The wretched inhabitants cannot find grafs in sufficient quantities to stuff into their shoes to keep their feet warm, but are obliged to buy it from those who inhabit the more southern parts.

The animals which abound most in Greenland are rein-deer, foxes, hares, dogs, and white bears. The hares are of a white colour, and very fat; the foxes are of different colours, white, greyish, and bluish; and smaller than those of Denmark and Norway. The natives keep a great number of dogs, which are large, white, or speckled, and rough, with ears standing upright, as is the case with all the dogs peculiar to cold climates. They are timorous and stupid; and neither bay nor bark, but sometimes howl dismally. In the northern parts the natives yoke them in sledges; which, though heavy laden, they will draw on the ice at the rate of 70 miles in a short winter's day. These poor animals are very ill rewarded for their service; being left to provide for themselves, except when their masters happen to catch a great number of seals. On these occasions the dogs are regaled with the blood and entrails; at other times, they subsist, like wild beads, upon muscles and berries. Here also are found great numbers of ravens, eagles of a prodigious size, falcons, and other birds of prey; and likewise a kind of linnet, which warbles very melodiously. Whales, sword-fish, porpoises, &c. abound on the coasts; also hollybut, turbot, cod, haddock, &c. The more dubious animals also, called *mermaids*, *sea serpents*, and *kraken*, said to be found on the coast of Norway, are said likewise to dwell in these seas. Mr Eggede assures us, that, in the year 1734, the sea-serpent was seen off the new Danish colony, and raised its head mast-high above the surface of the water. See *KRAKEN*, *MERMAID*, and *SEA-SERPENT*.

9 Account of the inhabi-
tants. The people who now inhabit the western coast of Greenland, and who, without doubt, are the descendants of the ancient *Schrellings*, who exterminated the first Iceland colony, bear a near resemblance to the Samoides and Laplanders in their persons, complexions, and way of life. They are short, brawny, and inclined to corpulency; with broad faces, flat noses, thick lips, black hair and eyes, and a yellowish tawney complexion. They are for the most part vigorous and healthy, but remarkably short-lived; few of them

reaching the grand climacteric; and many dying in their infancy, and in the prime of youth. They are subject to a weakness in the eyes, occasioned by the piercing winds and the glare of the snow in the winter-time. The leprosy is known among them, but is not contagious. Those that dwell in the northern parts are miserably tormented with dysenteries, rheums, and pulmonary disorders, boils, and epilepsy. The small-pox being imported among them from Copenhagen in the year 1734, made terrible havoc among these poor people, who are utterly destitute of any knowledge of the medicinal art, and depend entirely for assistance upon their *angekuts* or conjurers. In their dispositions the Greenlanders are cold, phlegmatic, indolent, and slow of apprehension; but very quiet, orderly, and good-natured. They live peaceably together; and have every thing in common, without strife, envying, or animosity. They are civil and hospitable, but slovenly to a degree almost beyond the Hottentots themselves. They never wash themselves with water; but lick their paws like the cat, and then rub their faces with them. They eat after their dogs without washing their dishes; devour the lice which devour them; and even lick the sweat, which they scrape off from their faces with their knives. The women wash themselves with their own urine, which they imagine makes the hair grow; and in the winter-time go out immediately after, to let the liquor freeze upon their skin. They will often eat their victuals off the dirty ground, with out any vessel to hold them in; and devour rotten flesh with the greatest avidity. In times of scarcity they will subsist on pieces of old skin, reeds, sea-weed, and a root called *tugbronet*, dressed with train-oil and fat. The dung of rein-deer taken from the intestines, the entrails of partridges, and all sorts of offals, are counted dainties among these savages; and of the scrapings of seals skins they make delicate pan-cakes. At first they could not taste the Danish provisions without abhorrence; but now they are become extremely fond of bread and butter, though they still retain an aversion to tobacco and spirituous liquors, in which particular they differ from almost all savages on the face of the earth.

The Greenlanders commonly content themselves with one wife; who is condemned, as among other savage nations, to do all the drudgery, and may be corrected, or even divorced, by the husband at pleasure. Heroes, however, and extraordinary personages, are indulged with a plurality of wives. Their young women are generally chaste and bashful; but at some of their feasts, in the midst of their jollity, a man retires with his neighbour's wife behind a curtain made of skins; and all the guests, thus coupled, retire in their turns. The women think themselves happy if an *angekut* or prophet will thus honour them with his caresses. These people never marry within the prohibited degrees of consanguinity, nor is it counted decent in a couple to marry who have been educated in the same family.—They have a number of ridiculous and superstitious customs, among which the two following are the most remarkable. While a woman is in labour, the gossips hold a chamber-pot over her head, as a charm to hasten the delivery. When the child is a year old, the mother licks and flatters it all over, to render it, as she imagines, more strong and hardy.

Greenland.

to
language,
igion,
c.

All the Greenlanders hitherto known speak the same language, though different dialects prevail in different parts of the country. It abounds with double consonants; and is so guttural, that the pronunciation of many words is not to be learned except by those who have been accustomed to it from their infancy. The letters C, D, F, Q, and X, are not known in their alphabet. Like the North Americans, and inhabitants of Kamchatka, they have a great number of long polysyllables. Their words, nouns as well as verbs, are inflected at the end by varying the terminations without the help of articles; but their language being found defective, they have adopted a good many words from the Norwegian dialect. Notwithstanding the endeavours of the Danish missionaries, they have no great reason to boast of the profelytes they have made of the natives of Greenland. These savages pay great deference and respect to the Danes, whom indeed they obey as their masters, and hear the truths of the Christian religion expounded without doubting the veracity of their teachers; but at the same time they listen with the most mortifying indifference, without being in the least influenced by what they have heard. They believe in the immortality of the soul, and the existence of a spirit whom they call *Torngarfuk*; but of whom they have formed the most ridiculous notions. The Angekuts, who are supposed to be his immediate ministers, differ concerning the principles of his existence; some affirming that he is without form or shape; others, that he has the shape of a bear; others, that he has a large human body with only one arm; while others affirm that that he is no larger than a man's finger, with many other absurdities of a similar kind. They have also a peculiar kind of mythology, by which they believe all the elements to be full of spirits, from among which every one of their prophets is supplied with a familiar which they name *Torgack*, and who is always ready when summoned to his assistance.

The Greenlanders are employed all the year round either in fishing or hunting. At sea they pursue whales, morse, seals, fish for eating, and sea-fowl. On shore they hunt the rein-deer in different parts of the country. They drive these animals, which feed in large herds, into a narrower circle or deile, where they are easily slain with arrows. Their bow is made of fir-tree, wound about with the twisted sinews of animals: the string is composed of the same stuff, or of seal skin: the arrow is a good fathom in length, pointed with a bearded iron, or a sharp bone; but those with which they kill birds are blunt, that they may not tear the flesh. Sea-fowls they kill with lances, which they throw to a great distance with surprising dexterity. Their manner of catching whales is quite different from that practised by the Europeans. About 50 persons, men and women, set out in one long boat, which is called a *kone-boat*, from *kone* a "woman," because it is rowed by females only. When they find a whale, they strike him with harpoons, to which are fastened with long lines some seals skins blown up like bladders. These, by floating on the surface, not only discover the back of the whale, but hinder him from diving under water for any length of time. They continue to pursue him until he loses strength, when they pierce him with spears and lan-

ces till he expires. On this occasion they are clad in their spring-coats consisting of one piece, with gloves, boots, caps made of seal-skin so closely laced and sewed that they keep out water. Thus accoutred, they leap into the sea; and begin to slice off the fat, even under water, before the whale is dead.—They have many different ways of killing seals; namely, by striking them with a small harpoon equipped also with an air-bag; by watching them when they come to breathe at the air-holes in the ice, and striking them with spears; by approaching them in the disguise of their own species, that is, covered with a seal-skin, creeping upon the ice, and moving the head from side to side as the seals are accustomed to do. By this stratagem the Greenlanders move towards the unsuspecting seal, and kills him with a spear. The Greenlanders angle with lines made of whale-bone cut very small, by means of which they succeed wonderfully. The Greenland canoe, like that used in Nova Zembla and Hudson's bay, is about three fathoms in length, pointed at both ends, and three quarters of a yard in breadth. It is composed of thin rafts fastened together with the sinews of animals. It is covered with dressed seal-skins both below and above, in such a manner, that only a circular hole is left in the middle, large enough to admit the body of one man. Into this the Greenlander thrusts himself up to the waist, and fastens the skin so tight about him that no water can enter. Thus secured, and armed with a paddle broad at both ends, he will venture out to sea in the most stormy weather to catch seals and sea-fowl; and if he is overset, he can easily raise himself by means of his paddle. A Greenlanders in one of these canoes, which was brought with him to Copenhagen, outstripped a pinnace of 16 oars, manned with choice mariners.—The *kone-boat* is made of the same materials, but more durable; and so large, that it will contain 50 persons with all their tackle, baggage, and provisions. She is fitted with a mast, which carries a triangular sail made of the membranes and entrails of seals, and is managed without the help of braces and bowlines. These *kones* are flat-bottomed, and sometimes 60 feet in length. The men think it beneath them to take charge of them; and therefore they are left to the conduct of the women, who indeed are obliged to do all the drudgery, including even the building and repairing their houses, while the men employ themselves wholly in preparing their hunting implements and fishing tackle.

This country is but thinly inhabited. In the winter the people dwell in huts built of stone or turf: on the one side are the windows, covered with the skins of seals or rein-deer. Several families live in one of these houses, possessing each a separate apartment, before which is a hearth with a great lamp placed on a trevi, over which hangs their kettle: above is a rack or shelf on which their wet clothes are dried. They burn train-oil in their lamps; and instead of wick, they use a kind of moss, which fully answers the purpose. These fires are not only sufficient to boil their victuals; but likewise produce such a heat, that the whole house is like a bagnio. The door is very low, that as little cold air as possible may be admitted. The house within is lined with old skins, and

Greenland. and surrounded with benches for the convenience of strangers. In the summer-time they dwell in tents made of long poles fixed in a conical form, covered in the inside with deers skins, and on the outside with seals skins, dressed so that the rain cannot pierce them.

¹¹
East Greenland. East Greenland was for a long time considered as a part of the continent of West Greenland, but is now discovered to be an assemblage of islands lying between $76^{\circ} 46'$ and $80^{\circ} 30'$ of north latitude, and between 9° and 20° of east longitude. It was discovered by Sir Hugh Willoughby in the 1553, who called it *Greenland*; supposing it to be a part of the western continent. In 1595, it was again visited by William Barentz and John Cornelius, two Dutchmen, who pretended to be the original discoverers, and called the country *Spitzbergen*, or Sharp Mountains, from the many sharp-pointed and rocky mountains with which it abounds. They alleged that the coast discovered by Sir Hugh Willoughby was some other country; which accordingly the Hollanders delineated on their maps and charts by the name of *Willoughby Land*; whereas in fact no such land ever existed; and long before the voyage of these Dutchmen, Stephen Barrows, an English shipmaster, had coasted along a desolate country from N. Lat. 78° to $80^{\circ} 11'$, which was undoubtedly *Spitzbergen*. The sea in the neighbourhood of the islands of *Spitzbergen* abounds very much with whales, and is the common resort of the whale-fishing ships from different countries, and the country itself is frequently visited by these ships; but till the late voyage of the Hon. Capt. Phipps, by order of his Majesty, the situation of it was erroneously laid down. It was imagined that the land stretched to the northward as far as 82° of north latitude; but Capt. Phipps found the most northerly point of land, called *Seven Islands*, not to exceed $80^{\circ} 30'$ of latitude. Towards the east he saw other lands lying at a distance, so that *Spitzbergen* plainly appeared to be surrounded by water on that side, and not joined to the continent of Asia, as former navigators had supposed. The north and west coasts also he explored, but was prevented by the ice from failing so far to the northward as he wished. The coast appeared neither habitable nor accessible. It is formed of high, barren, black rocks, without the least marks of vegetation; in many places bare and pointed; in others covered with snow, appearing even above the clouds. The valleys between the high cliffs were filled with snow and ice. "This prospect," says Capt. Phipps, "would have suggested the idea of perpetual winter, had not the mildness of the weather, the smooth water, bright sun-shine, and constant day-light, given a cheerfulness and novelty to the whole of this romantic scene." The current ran along this coast half a knot an hour, north. The height of one mountain seen here was found by geometrical mensuration to be at one time $1503\frac{1}{2}$ feet, at another $1503\frac{8}{10}$ feet. By a barometer constructed after Dr. Luc's method, the height was found to be $1588\frac{1}{2}$ feet. On this occasion Capt. Phipps has the following remarks. "I cannot account for the great difference between the geometrical measure and the barometrical according to M. de Luc's calculation, which amounts to 84.7 feet. I have no reason to doubt the accuracy of Dr Irving's

observations, which were made with great care. As to the geometrical measure, the agreement of so many triangles, each of which must have discovered even the smallest error, is the most satisfactory proof of its correctness. Since my return I have tried both the theodolite and barometer, to discover whether there was any fault in either; and find them, upon trial, as I had always done before, very accurate."

There is good anchorage in *Schmeerenburg* harbour, lying in N. Lat. $74^{\circ} 44'$ E. Long. $9^{\circ} 50' 45''$, in 13 fathom, sandy bottom, not far from the shore, and well sheltered from all winds. Close to this harbour is an island called *Amsterdam Island*, where the Dutch used formerly to boil their whale-oil; and the remains of some convenience erected by them for that purpose are still visible. The Dutch ships still resort to this place for the latter season of the whale-fishery. —The stone about this place is chiefly a kind of marble, which dissolves easily in the marine acid. There were no appearances of minerals of any kind, nor any signs of ancient or modern volcanoes. No insects, or any species of reptiles, were seen, not even the common earth-worm. There were no springs or rivers; but great plenty of water was produced from the snow which melted on the mountains.

The most remarkable views which these dreary regions present are those called *Icebergs*. They are large bodies of ice filling the valleys between the high mountains. Their face towards the sea is nearly perpendicular, and of a very lively light-green colour. One was about 300 foot high, with a cascade of water issuing from it. The black mountains on each side, the white snow, and greenish coloured ice, composed a very beautiful and romantic picture. Large pieces frequently broke off from the icebergs, and fell with great noise into the water. One piece was observed to have floated out into the bay, and grounded in 24 fathom; it was 50 feet high above the surface of the water, and of the same beautiful colour with the iceberg from which it had separated.

These islands are totally uninhabited, though it doth not appear but that human creatures could subsist on them, notwithstanding their vicinity to the pole. Eight English sailors, who were accidentally left here by a whale-fishing ship, survived the winter, and were brought home next season. The Dutch then attempted to settle a colony on *Amsterdam* island above-mentioned; but all the people perished, not through the severity of the climate, but of the scurvy, owing to the want of those remedies which are now happily discovered, and which are found to be so effectual in preventing and curing that dreadful disease. —The late account also of six Russian sailors who staid four years in this inhospitable country, affords a decisive proof, that a colony might be settled on East Greenland, provided the doing so could answer any good purpose.

GREENOCK, a sea-port town of Scotland, and one of the ports of the city of Glasgow. It is situated 22 miles from that city; and was formerly called the *Bay of St. Lawrence*. The Frith of Clyde here expands into a fine basin four miles wide, and is landlocked on all sides.

GREENWICH, a town of the county of Kent, in England, pleasantly situated on the bank of the Thames,

Greenwich. Thames, about five miles east from London. Here was formerly a royal palace, built by Humphry Duke of Gloucester, enlarged by Henry VII. and completed by Henry VIII. The latter often chose this town for his place of residence; as did also the Queens Mary and Elizabeth, who were born in it. This palace, however, is now pulled down; and what goes by the name of *palace* at present, serves for apartments for the governor of the hospital, and the ranger of the park. This park was walled and planted by Charles II. and hath a hill in the middle, whence there is a noble prospect of London, the Thames, and shipping; also a Royal Observatory, furnished with a complete set of astronomical observations. This observatory in the latest English maps is accounted the place of the first meridian; and the degrees of longitude, either east or west, are accounted from it. But the most remarkable building about Greenwich, is the hospital for superannuated and disabled seamen, and likewise for their widows and children. It is a very noble structure; the wing next London being part of the palace which King Charles II. intended to have erected for himself, and which cost him 36,000 pounds; being finely adorned with all the decorations of painting, sculpture, and architecture. About 2000 old disabled seamen are maintained in it. The nurses, who must be seamens widows, have ten pounds a-year, and such as attend the infirmary, two shillings a-week more. Besides private benefactions, to the amount of about L. 60,000, the parliament, in the year 1732, settled upon this hospital the earl of Derwentwater's estate, to the value of L. 6000 *per annum*. The hall of the hospital is finely painted by Sir James Thornhill. All strangers who see it, pay twopence each; and this income is applied to the support of the mathematical school for the sons of sailors. For the better support of this hospital, every seaman in the royal navy, and in the merchant service, pays sixpence a-month, topped out of their pay, and delivered in at the six-penny receiver's office in Tower-hill.—On this account, a seaman, who can produce an authentic certificate of his being disabled, and rendered unfit for service, by defending any ship belonging to his Majesty's British subjects, or in taking any ship from the enemy, may be admitted into this hospital, and receive the same benefit from it as if he had been in his Majesty's immediate service. Besides the seamen and widows above-mentioned, about 100 boys, the sons of seamen, are bred up for the service of the royal navy; but there are no out-pensioners as at Chelsea. Each of the mariners has a weekly allowance of bread, beef, mutton, pease, cheese, butter, and beer, and one shilling a-week tobacco-money. The tobacco-money of the boatwains is two shillings and sixpence a-week each, that of their mates one shilling and sixpence, and that of the other officers in proportion to their rank. Each common pensioner also, once in two years, has a suit of blue clothes, a hat, three pair of stockings, two pair of shoes, five neck-cloths, three shirts, and two night-caps. The principal officers of the house, are a governor, lieutenant-governor, treasurer, three captains, six lieutenants, two chaplains, a physician, and surgeon, a clerk of the cheque, and an auditor, who have handsome salaries. The profits of the market belong to this hospital,

whose governors have the direction of it. The first hospital founded by an English Protestant, was at Greenwich, in 1560, by one Mr Lambard, (author of a book called the *Perambulation of Kent*), for twenty poor.

Gregarious
Gregory.

GREGARIOUS, among zoologists, a term applied to such animals as do not live solitary, but associate in herds or flocks.

GREGORIAN CALENDAR, that which shews the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epochs disposed through the several months of the Gregorian year. See ASTRONOMY, n^o 295.

GREGORIAN Year. See ASTRONOMY, n^o 295.

GREGORY the Great, was born at Rome, of a patrician family. He discovered such abilities in the exercise of the senatorial employments, that the emperor Justin the younger appointed him prefect of Rome. Pope Pelagius II. sent him nuncio to Constantinople, to demand succours against the Lombards. When he thought of enjoying a solitary life, he was elected Pope by the clergy, the senate, and the people of Rome. Besides his learning and diligence in instructing the church, both by writing and preaching, he had a very happy talent in winning over princes in favour of the temporal as well as spiritual interest of religion. He undertook the conversion of the English, and sent over some monks of his order, under the direction of Augustine their abbot. His morality with respect to the chastity of churchmen was very rigid, asserting that a man who had ever known a woman ought not to be admitted to the priesthood; and he always caused the candidates for it to be examined upon that point. He likewise vigorously exerted himself against such as were found guilty of calumny. However, he flattered the emperor Phocas, while his hands were yet reeking with the blood of Mauritius, and of his three children, who had been butchered in his fight. He likewise flattered Brunehaut, a very wicked queen of France. He is accused of destroying the noble monuments of ancient Roman magnificence, that those who visited the city might not attend more to the triumphal arches, than to holy things; and burnt a multitude of heathen books, Livy in particular. He died in 604.

GREGORY of Nazianzen, surnamed the *Divine*, was one of the most illustrious ornaments of the Greek church in the fourth age. He was made bishop of Constantinople in 397; but finding his election contested by Timotheus, archbishop of Alexandria, he voluntarily resigned his dignity about 382, in the general council of Constantinople. His works are extant, in two volumes, printed at Paris in 1609. His style is said to be equal to that of the most celebrated orators of ancient Greece.

GREGORY (Theodorus), surnamed *Thaumaturgus* on account of his miracles, was the scholar of Origen; and was elected bishop of Neocesarea, the place of his birth, about the year 240, during his absence. He assisted at the council of Antioch, in 255, against Paulus Samocetanus; and died in 270. He had the satisfaction of leaving only seventeen idolaters in his diocese, where there were but seventeen Christians when he was ordained. There is still extant of his, A gratulatory oration to Origen, A canonical epistle, and some other works.

Gregory.

GREGORY, bishop of Nyssa, one of the fathers of the church, and author of the Nicene creed, was born in Cappadocia, about the year 331. He was chosen bishop of Nyssa in 372, and banished by the emperor Valens for adhering to the council of Nice. He was nevertheless afterwards employed by the bishops in several important affairs, and died in 396. He wrote, Commentaries on the Scriptures; Sermons on the mysteries; Moral discourses; Dogmatical treatises; Panegyrics on the saints; some letters on church discipline; and other works. His style is very allegorical and affected.

GREGORY of Tours, or *Georgius Florentius Gregorius*, one of the most illustrious bishops, and celebrated writers of the sixth century, was descended from a noble family in Auvergne. He was educated by his uncle Gallus, bishop of Clermont; and distinguished himself so much by his learning and virtue, that in 573 he was chosen bishop of Tours. He afterwards went to Rome to visit the tomb of the apostles, where he contracted a friendship with Gregory the Great, and died in 595. This author was extremely credulous with regard to miracles. He wrote, 1. The history of France. 2. The lives of the saints; and other works. The best edition is that published by Father Rumart, 1699.

GREGORY (James), an eminent mathematical genius of Scotland, was born at Aberdeen in 1639, and educated at that university. He made a good progress in classical learning; but being more delighted with philosophical researches, the works of Des Cartes and Kepler were his principal study; and he began early to make improvements on their discoveries in optics. The first of these improvements was the invention of the reflecting telescope, which still bears his name; and which was so happy a thought, that that has given occasion to the most considerable improvements made in optics since the invention of the telescope.

He published the construction of this instrument in 1663, at the age of 24; and coming next year or the year after that to London, he became acquainted with Mr John Collins, who recommended him to the best optic glass grinders there, in order to have it executed. But as this could not be done for want of skill in the artists to grind a plate of metal for the object speculum into a true parabolic concave, which the design required, he was much discouraged thereby; and after a few imperfect trials made with an ill polished spherical one, which did not succeed to his wish, he dropped the pursuit, and resolved to make the tour of Italy, then the mart of mathematical learning, in the view of prosecuting his favourite study with greater advantage.

He had not been long abroad, when the same inventive genius which had before shewed itself in practical mathematics, carried him to some new improvements in the speculative part. The sublime geometry on the doctrine of curves was then hardly past its infant state; and the famed problem of squaring the circle still continued a reproach to it, when our author discovered a new analytical method of summing up an infinite converging series, whereby the area of the hyperbola, as well as of the circle, may be computed to any degree of exactness. He was then at

Padua; and getting a few copies of his invention printed there in 1667, he sent one to his friend Mr Collins, who communicated it to the Royal Society, where it met with the commendations of lord Brouncker and Dr Wallis. Our author printed it at Venice, and published it the following year 1668; together with another piece, wherein he first of any one entertained the public with an account of the transformation of curves. An account of this piece was also read by Mr Collins before the Royal Society, of which Mr Gregory, being returned from his travels, was chosen a member, and communicated to them an account of the controversy in Italy about the motion of the earth, which was denied by the famous astronomer Riccioli and his followers.

The same year his quadrature of the circle being attacked by the celebrated Mr Huygens, a controversy arose between these two eminent mathematicians, in which our author produced some improvements of his series.

In 1672, Sir Isaac Newton, in his wonderful discoveries on the nature of light, having contrived a new reflecting telescope, made several objections to Mr Gregory's. This gave occasion to a controversy betwixt these two philosophers, which was carried on this and the following year in the most amicable manner on each side. Mr Gregory defended his own construction, but gave his antagonist the whole honour of having made the catoptric telescopes preferable to the dioptric ones; shewing that the imperfections in these instruments were not so much owing to a defect in the object speculum, as to the different refrangibility of the rays of light. In the course of this dispute our author described a burning concave mirror, which was approved by Sir Isaac, and is still in good esteem.

All this while he attended the proper business of his professorship with great diligence; which, taking up the greatest part of his time, especially in the winter season, hindered him in the pursuit of his proper studies. These, however, led him to farther improvements in the invention of infinite series, which he occasionally communicated to his friend and correspondent Mr Collins, who might have had the pleasure of receiving many more, had not our professor's life been cut short by a fever in December 1675, at the age of 36 years.

Besides the inventions already mentioned, he was the first who gave a geometrical demonstration of lord Brouncker's series for squaring the hyperbola, as it had been explained by Mercator in his *Logarithmotechnia*. He was likewise the first who demonstrated the meridian line to be analogous to a scale of logarithmic tangents of the half complement of latitude. He also invented, and demonstrated geometrically, by the help of the hyperbola, a very swift converging series for making the logarithms, and therefore recommended by Dr Halley as very proper for practice. He also sent to Mr Collins the solution of the famous Keplerian problem by an infinite series. He found out a method of drawing tangents to curves geometrically, without any previous calculations. He gave a rule for the direct and inverse method of tangents, which stands upon the same principle (of exhaustions) with the fluxions, and differs not much from it in the method

Gregory.

Gregory.

of application. He likewise gave a series for the length of the area of a circle from the tangent, and *vice versa*; as also for the secant and logarithmic tangent and secant, and *vice versa*. These, with others for certifying or measuring the length of the elliptic and hyperbolic curves, were sent to Mr Collins in return for some received from him of Sir Isaac Newton's; and their elegance being admirable, above whatever he had produced before, and after the manner of Sir Isaac Newton, gave room to think that he had improved himself greatly by that matter, whose example he followed in giving his series in simple terms, independent of each other. These several inventions are contained, 1. In his *Optica promota*, &c. 4to. edit. 1663. 2. *Vera circuli & hyperbole quadratura*, Padua 1667. 3. *Geometrie pars universalis*, &c. 1667, 4to. 4. Several letters and papers printed in the *Philosophical Transactions*; the *Journal des Sçavans*; the *Commerc. epistol. Jo. Collins & alior.* 1715, 8vo. and in the Appendix to the English edition of Dr David Gregory's *Elements of Optics*, 1735, 8vo. by Dr De-faguliers.

GREGORY (David), nephew of the preceding, was born June 24th, 1661, at the same place, where he also received the first grounds of his learning; but was afterwards removed to Edinburgh, and took the degree of master of arts in that university. The great advantage of his uncle's papers induced his friends to recommend the mathematics to him; and he had a natural subtilty of genius, which particularly fitted him for that study, to which he applied with insatiable industry; and succeeded so well, that he was advanced to the mathematical chair at Edinburgh, at the age of 25: and the same year he published a treatise entitled, *Exercitatio geometrica de dimensione figurarum*, Edinb. 1684, 4to.

He had already seen some hints in his uncle's papers concerning Sir Isaac Newton's method, of which he made the best use he could, and the advantage he found thereby raised an ardent desire in him to see that method published. Under this impatient expectation, the *Principia* was no sooner out in 1687, but our author took it in hand, and presently made himself so much master of it as to be able to read his professorial lectures upon the philosophy contained in it; and causing his scholars to perform their exercises for their degrees upon several branches of it, became its first introducer into the schools.

He continued at Edinburgh till the year 1691; when hearing the news of Dr Bernard's intention to resign the Savilian professorship at Oxford, he left Scotland, and, coming to London, was admitted a member of the Royal Society. Proceeding to Oxford, he was elected astronomical professor there, having been first admitted of Balliol-college, incorporated master of arts, and created doctor of physic. He had no relish for the technical part of his profession, and was seldom seen in the observatory. His genius lay more to geometry, in which he distinguished himself both by his *Elements of Optics*, and of *Physical and geometrical astronomy*. This last is reckoned his masterpiece; and having finished it in 1702, he immediately engaged in carrying on the noble design of his predecessor, Dr Bernard, to print all the works of the ancient mathematicians; the first fruits of which appeared in an

edition of Euclid's works in Greek and Latin, in folio, the following year; and, in the same design, he afterwards joined with his colleague Dr Halley, in preparing an edition of *Apollonius's Conics*. Dr Bernard had the materials for the first four books, which our author undertook to complete, but was prevented by his death, which happened Oct. 16. 1710.

GREGORY (Dr John), professor of medicine in the university of Edinburgh, was born in May 1725. His father was professor of medicine in the King's-college, Aberdeen; and his grandfather was professor of mathematics, first at St Andrews, and afterwards at Edinburgh. Thus Dr Gregory was the third professor of his family in a lineal descent. But it deserves to be remarked, that from his great-grandfather David Gregory, esq; of Kinnaird in Aberdeenshire, he was the 15th descendant who had held a professorship in a British university.

Dr Gregory began the study of medicine at Aberdeen; which he afterwards prosecuted, first at Edinburgh, next at Leyden, and then at Paris. In the 20th year of his age he was elected professor of philosophy in king's-college, Aberdeen; and had, at the same time, the degree of doctor of medicine conferred upon him. In the year 1756, upon the death of his brother Dr James Gregory, who had succeeded his father as professor of medicine, he was elected to that chair. But about the beginning of the year 1765, he left Aberdeen, and came to Edinburgh. Soon after this he was appointed professor of the practice of medicine in the university there, in the room of Dr Rutherford, who resigned in his favour. The year following, upon the death of Dr White, he was nominated first physician to his majesty for Scotland. Thus, at the time of his death, besides very extensive practice, he enjoyed the highest and most important offices in the way of his profession, which could be obtained in his native country.

These distinguishing honours were universally allowed to be the just reward of singular merit. Of this the writings which he published will bear ample testimony to future ages. His first publication, which is entitled, *A comparative view of the faculties of man with those of the animal world*, made its appearance in 1765. This production, while it demonstrates the author to have been a philosopher whose reflections were just and original, at the same time displays a liberality of sentiment seldom to be equalled. Such was the avidity with which it was read, that in the space of two years it went through four editions; and, while it was perused by all with peculiar pleasure, it was honoured by those distinguished for taste and literature with high approbation.

In the year 1770, a second work of Dr Gregory's made its appearance; but without his consent, and even contrary to his inclination. His preliminary lectures on the practice of physic were heard by his pupils with universal satisfaction. From a copy of these lectures taken down in short-hand, there was published a book entitled, "Observations on the duties and office of a physician, and on the method of prosecuting inquiries in philosophy." Although these lectures were not intended for the press, and did not pass through the finishing hand of the author before they were presented to the public; yet such was

Gregory.

the matter they contained, that, had they appeared in a much worse dress, they could have done him no discredit. In these lectures, by the most forcible arguments, he laboured to convince his pupils, that a physician who studies the principles of his profession, who has an extensive acquaintance with every branch of natural knowledge, and who properly applies his knowledge, must have an infinite advantage, as a practitioner, over one who is ignorant of the theory of medicine, and of every science connected with it. He endeavoured to persuade them, that genius and sense, which indeed are the peculiar gifts of heaven, are yet capable of high improvement; and that, without improvement, they can be but of little account either to the public, or to an individual. In short, no argument was omitted which could prompt them to study medicine with attention and ardour, and afterwards to practise it with prudence and humanity.—Dr Gregory, however, was dissatisfied with the dress in which this work appeared. Soon after, therefore, he published an edition of it himself, in which his former sentiments are set off with all the advantages which can be derived from a correct and elegant style. His last publication, *Elements of the practice of physic*, was intended as a syllabus to his lectures; and in it he meant to have comprehended all the diseases of which he usually treated. But not having leisure to finish the whole, he was obliged to stop at those diseases which are usually reckoned febrile. Although this work appears with all those disadvantages, under which every text must labour; yet it sufficiently shews how the author thought and acted in the exercise of his profession. The world was deprived of this excellent person in February 1774. He left behind him a small, but inestimable production, under the title of *A father's legacy to his daughters*, designed for their private instructions; but rendered a common bequest by the benevolence of his eldest son, who gave it to the public after his death. The maxims and advices it contains, which are classed under the general topics—of religion, of conduct and behaviour, of amusements, of friendship, love, and marriage,—are as just as they are important; and appear to be the dictates of a mind which had long been inviolably attached to the interests of virtue; the results of an observation equally interesting, extensive, and mature. They are delivered in a style which is simple and unadorned; yet chastised with that elegance and correctness which result from the operations of a mind habitually governed by a refined taste, and the clearest judgement.

Had Dr Gregory lived to a more advanced age, the world would probably have been favoured with other works no less honourable to the author than beneficial to mankind. But his extensive practice, and his zeal in his duty as a professor, occupied the greater part of his time.

To pretend to enumerate the many advantages which his pupils derived from him in the capacity of a teacher, would exceed our limits. Let it suffice to say, that, from the extent of his views, from the justice and importance of his observations, and from the force and accuracy of his reasoning, every hearer obtained the most thorough conviction of his abilities, and retired from academical labours both pleased and

instructed.

To conclude: Dr Gregory was not more eminent as a physician, than he was amiable and respectable as a man. With the mathematical genius of his family he united a correct taste for the fine arts, and a high relish for every social virtue. He possessed a clear and vigorous understanding; a chaste and lively imagination; and an affectionate and feeling heart: and while he was distinguished for paternal and conjugal attachment, he was a constant friend to poverty and distress, and an unwearied patron of science and virtue.

GRE-HOUND. See CANIS.—Among a litter of gre-hound puppies, the best are always those which are lightest. These will make the nimblest dogs as they grow up. The gre-hound is best for open countries where there is little covert. In these places there will sometimes be a course after a hare of two or three miles or more, and both the dogs and the game in sight all the while. It is generally supposed that the gre-hound bitch will beat the dog in running: but this seems to be an error; for the dog is both longer-made, and considerably stronger, than the bitch of the same kind. In the breeding these dogs the bitch is principally to be regarded; for it is found by experience, that the best dog and a bad bitch will not get so good puppies as an indifferent dog with a good bitch. The dog and bitch should be as nearly as may be of the same age; and for the breeding of fine and perfect dogs, they should not be more than four years old. An old bitch may be used with a young dog, but the puppies of a young bitch and an old dog will never be good for any thing.

The general food for a gre-hound, ought to be chippings or raspings of bread, with soft bones and gristles; and those chippings ought always to be soaked in beef or mutton broth.

The proper exercise for a gre-hound is coursing him three times a-week, and rewarding him with blood; which will animate him in the highest degree, and encourage him to prosecute his game. But the hare also should ever have fair play. She should have the law, as it is called; that is, have leave to run about twelve score yards before the dog is slipped at her, that he may have some difficulty in the course, and not pick up the game too early. If he kills the hare, he must never be suffered to tear her; but she must be taken from him, his mouth cleaned of the wool, and the liver and lights given him by way of encouragement. Then he is to be led home, and his feet washed with butter and beer, and about an hour after he is to be fed.

When the dog is to be taken out to course, he should have nothing in the morning but a toast and butter, and then he is to be kennelled till taken out to the field. The kennelling these dogs is of great use, always giving them spirit and nimbleness when they are let loose; and the best way of managing a fine gre-hound is, never to let him stir out of the kennel, except at the times of feeding, walking, or coursing.

GRENADE, one of the Caribbee islands, lying in W. Long. 61. 40. N. Lat. 12. 0. It is the last of the Windward Caribbees; and lies 30 leagues north of New Andalusia, on the continent. According to some, it is 24 leagues in compass; according to others, only

only 22; and it is said to be 30 miles in length, and in some places 15 in breadth. The chief port is called *Lesoir*; and stands on the west side of the island, in the middle of a large bay, with a sandy bottom. It is pretended that 1000 barks, from 300 to 400 tons, may ride secure from storms; and that 100 ships, of 1000 tons each, may be moored in the harbour. A large round basin, which is parted from it by a bank of sand, would contain a considerable number of ships, if the bank was cut through: but by reason of it, the large ships are obliged to pass within 80 paces of one of the mountains lying at the mouth of the harbour; the other mountain lying about half a mile distant. The island abounds with wild game and fish; it produces also very fine timber, but the cocoa-tree is observed not to thrive here so well as in the other islands. A lake on a high mountain, about the middle of the island, supplies it with fresh-water streams. Several bays and harbours lie round the island, some of which might be fortified to great advantage; so that it is very convenient for shipping, not being subject to hurricanes. The soil is capable of producing tobacco, sugar, indigo, pease, and millet.

In 1638, M. Poincy, a Frenchman, attempted to make a settlement in Grenada; but was driven off by the Caribbeans, who resorted to this island in greater numbers than to the neighbouring ones, probably on account of the game with which it abounded. In 1650, Mons. Parquet, governor of Martinico, carried over from that island 200 men, furnished with presents to reconcile the savages to them; but with arms to subdue them, in case they should prove intractable. The savages are said to have been frightened into submission by the number of the Frenchmen: but, according to some French writers, the chief not only welcomed the new-comers; but in consideration of some knives, hatchets, scissars, and other toys, yielded to Parquet the sovereignty of the island, reserving to themselves their own habitations. The Abbe Raynal informs us, that these first French colonists, *imagining* they had purchased the island by these trifles, assumed the sovereignty, and soon acted as tyrants. The Caribs, unable to contend with them by force, took their usual method of murdering all those whom they found in a defenceless state. This produced a war; and the French settlers having received a reinforcement of 300 men from Martinico, forced the savages to retire to a mountain; from whence, after exhausting all their arrows, they rolled down great logs of wood on their enemies. Here they were joined by other savages from the neighbouring islands, and again attacked the French, but were defeated anew; and were at last driven to such desperation, that 40 of them, who had escaped from the slaughter, jumped from a precipice into the sea, where they all perished, rather than fall into the hands of their implacable enemies. From thence the rock was called *le morne des sauteurs*, or "the hill of the leapers;" which name it still retains. The French then destroyed the habitations and all the provisions of the savages; but fresh supplies of Caribbeans arriving, the war was renewed with great vigour, and great numbers of the French were killed. Upon this they resolved totally to exterminate the natives: and having accordingly attacked the savages unawares,

they inhumanly put to death the women and children, as well as the men; burning also their boats and canoes, to cut off all communication between the few survivors and the neighbouring islands. Notwithstanding all these barbarous precautions, however, the Caribbees proved the irreconcilable enemies of the French, and their frequent insurrections at last obliged Parquet to sell all his property in the island to the Count de Cerillac in 1657. The new proprietor, who purchased Parquet's property for 30,000 crowns, sent thither a person of brutal manners to govern the island. He behaved with such insupportable tyranny, that most of the colonists retired to Martinico; and the few who remained condemned him to death, after a formal trial. In the whole court of justice that tried this miscreant, there was only one man (called *Archangel*) who could write. A farrier was the person who impeached: and he, instead of the signatures, sealed with a horse-shoe; and Archangel, who performed the office of clerk, wrote round it these words in French, "Mark of Mr de la Brie, council for the court."

It was apprehended that the court of France would not ratify a sentence passed with such unusual formalities; and therefore most of the judges of the governor's crimes, and witnesses of his execution, disappeared. Only those remained whose obscurity screened them from the pursuit of the laws. By an estimate, taken in 1700, there were at Grenada no more than 251 white people, 53 free savages or mulattoes, and 525 slaves. The useful animals were reduced to 64 horses, and 569 head of horned cattle. The whole culture consisted of three plantations of sugar, and 52 of indigo.—The island had been sold in 1664 to the French West India company for 100,000 livres.

This unfavourable state of the affairs of Grenada was changed in 1714. The change was owing to the flourishing condition of Martinico. The richest of the ships from that island were sent to the Spanish coasts, and in their way touched at Grenada to take in refreshments. The trading privateers, who undertook this navigation, taught the people of that island the value of their soil, which only required cultivation. Some traders furnished the inhabitants with staves and utensils to erect sugar-plantations. An open account was established between the two colonies. Grenada was clearing its debts gradually by its rich produce; and the balance was on the point of being closed, when the war, in 1744, interrupted the communication between the two islands, and at the same time stopped the progress of the sugar-plantations. This loss was supplied by the culture of coffee, which was pursued during the hostilities with all the activity and eagerness that industry could inspire.—The peace of 1748 revived all the labours, and opened all the former sources of wealth. In 1753 the population of Grenada consisted of 1262 white people, 175 free negroes, and 11,991 slaves. The cattle amounted to 2298 horses or mules, 2456 head of horned cattle, 3278 sheep, 902 goats, and 331 hogs. The cultivation rose to 83 sugar-plantations; 2,725,600, coffee-trees; 150,300 cocoa-trees, and 800 cotton-plants. The provisions consisted of 5,740,450 trenches of cassia; 933,596 banana trees; and 143 squares of potatoes and

Grénada.

and yams. The colony made a rapid progress, in proportion to the excellence of its soil; but in the course of last war, the island was taken by the British. At this time one of the mountains at the side of *Lewis* harbour was strongly fortified, and might have made a good defence, but surrendered without firing a gun; and, by the treaty concluded in 1763, the island was ceded to Britain. On this cession, and the management of the colony after that event, the Abbe Raynal has the following remarks:—"This long train of evils [the ambition and mismanagement of his countrymen] has thrown Grenada into the hands of the English, who are in possession of this conquest by the treaty of 1763. But how long will they keep this colony? Or, will it never again be restored to France?—England has not made a fortunate beginning. In the first enthusiasm raised by an acquisition, of which the highest opinion had been previously formed, every one was eager to purchase estates there. They sold for much more than their real value. This caprice, by expelling old colonists, who were inured to the climate, has sent about L. 1,553,000 out of the mother-country. This imprudence has been followed by another. The new proprietors, misled, no doubt, by national pride, have substituted new methods to those of their predecessors. They have attempted to alter the mode of living among their slaves. The negroes, who from their very ignorance are more attached to their customs than other men, have revolted. It hath been found necessary to send out troops, and to shed blood. The whole colony was filled with suspicions. The masters who had laid themselves under a necessity of using violent methods, were afraid of being burnt or massacred in their own plantations. The labours have declined, or been totally interrupted. Tranquillity has at length been restored. The number of slaves has been increased as far as 40,000, and the produce has been raised to the treble of what it was under the French government.

"The plantations will still be improved by the neighbourhood of a dozen of islands, called the *Grenadines* or *Grenadilles*, that are dependent on the colony. They are from three to eight leagues in circumference, but do not afford a single spring of water. The air is wholesome. The ground, covered only with thin bushes, has not been screened from the sun. It exhales none of those noxious vapours which are fatal to the husbandman.

"*Cariacou*, the only one of the Grenadines which the French have occupied, was at first frequented by turtle fishermen; who, in the leisure afforded them by so easy an occupation, employed themselves in clearing the ground. In process of time, their small number was increased by the accession of some of the inhabitants of *Guadalupe*; who, finding that their plantations were destroyed by a particular sort of ants, removed to *Cariacou*. The island flourished from the liberty that was enjoyed there. The inhabitants collected about 1200 slaves, by whose labours they made themselves a revenue of near L. 20,000 a year in cotton.—The other Grenadines do not afford a prospect of the same advantages, though the plantation of sugar is begun there. It has succeeded remarkably well at *Beconya*, the largest and most fertile of these is-

lands, which is no more than two leagues distant from *St. Vincent*."

All these islands have lately been reduced again under the power of France, and the inhabitants treated with inhumanity and injustice.

GRENADINES, or **GRENADILLOS**. See the preceding article.

GRENOBLE, a large, populous, and ancient town of Dauphiny in France, with a bishop's see. It contains a great number of handsome structures, particularly the churches and convents. The leather and gloves that are made here are highly esteemed. It is seated on the river *Isere*, over which there are two bridges to pass into that part called *Perriere*, a large tract on the other side of the river. E. Lon. 5. 49. N. Lat. 45. 12.

GRESHAM (Sir Thomas), an opulent merchant of London, descended from an ancient and honourable family of Norfolk, was born in 1519. He was, as his father had been before him, appointed king's agent at Antwerp, for taking up money of the merchants; and, in 1551, he removed to that city with his family. This employment was suspended on the accession of queen Mary; but, on proper representations, was restored to him again. Queen Elizabeth conferred the honour of knighthood upon him, and made him her agent in foreign parts. It was at this time he thought proper to provide himself with a mansion-house in the city, suitable to his station and dignity; with which intention he built that large house on the west side of Bishopgate-street, afterwards known by the name of *Gresham-college*. His father had proposed building a house or exchange for the merchants to meet in, instead of walking in the open street; but this design remained for the son to accomplish. Sir Thomas went beyond his father: he offered, if the citizens would provide a proper piece of ground, to build a house at his own expence; which being accepted, he fulfilled his promise after the plan of the exchange at Antwerp. When the new edifice was opened, the queen (Jan. 29, 1570,) came and dined with the founder; and caused a herald with a trumpet to proclaim it by the name of the *Royal Exchange*. In pursuance also of a promise to endow a college for the profession of the seven liberal sciences, he made a testamentary disposition of his house in London for that purpose; leaving one moiety of the royal exchange to the corporation of London, and the other to the mercer's company, for the salaries of seven lecturers in divinity, law, physic, astronomy, geometry, music, and rhetoric, at 50*l.* each *per ann.* He left several other considerable benefactions, and died in 1579.—Those who have drawn Sir Thomas's character observe, that he had the happiness of a mind every way suited to his fortune, generous and benign; ready to perform any good actions, and encourage them in others. He was a great friend and patron of our celebrated martyrologist John Fox. He was well acquainted with the ancient and several modern languages; he had a very comprehensive knowledge of all affairs relating to commerce, whether foreign or domestic; and his success was not less, being in his time esteemed the highest commoner in England. He transacted queen Elizabeth's mercantile affairs so constantly, that he was called *the royal merchant*; and his

reville. his house was sometimes appointed for the reception of foreign princes upon their first arrival at London.

GREVILLE (Fulke) lord Brook, of Beauchamp's Court in Warwickshire, a poet and miscellaneous writer, was born in the year 1554, and descended from the noble families of Beauchamps of Powick and Willoughby de Brook. In company with his cousin Sir Philip Sidney, he began his education at a school in Shrewsbury: thence he went to Oxford, where he remained for some time a gentleman commoner, and then removed to Trinity-college in Cambridge. Having left the university: he visited foreign courts, and thus added to his knowledge of the ancient languages a perfect knowledge of the modern. On his return to England he was introduced to queen Elizabeth by his uncle Robert Greville, at that time in her majesty's service; and by means of Sir Henry Sidney, lord president of Wales, was nominated to some lucrative employments in that principality.

In the year 1581, when the French commissioners who came to treat about the queen's marriage with the duke of Anjou were sumptuously entertained with tilts and tournaments, Mr Greville, who was one of the challengers, so signalized himself, as to "win the reputation of a most valiant knight." He continued a constant attendant at court, and a favourite with the queen to the end of her reign, during which he obtained the office of treasurer of marine causes, also a grant of the manor of Wedgnoek, and likewise the honour of knighthood. In this reign he was several times elected member for the county of Warwick; and from the journals of the house seems to have been a man of business, as his name frequently appears in committees.

On the accession of king James I. he was installed knight of the Bath; and soon after obtained a grant of the ruinous castles of Warwick, which he repaired at a considerable expence, and where he probably resided during the former part of this reign: but in the year 1614, the twelfth of James I. he was made under-treasurer and chancellor of the exchequer, one of the privy-council, and gentleman of the bed-chamber; and, in the 1620, was raised to the dignity of a baron, by the title of lord Brook of Beauchamp's Court. He was also privy-counsellor to king Charles I. in the beginning of whose reign he founded a history-lecture in Cambridge.

Having thus attained the age of 74, through a life of continued prosperity, universally admired as a gentleman and a scholar, he fell by the hand of an assassin, one of his own domestics, who immediately stabbed himself with the same weapon with which he had murdered his master. This fellow's name was Haywood; and the cause is said to have been a severe reprimand for his presumption in upbraiding his master for not providing for him after his death. It seems he had been witness to lord Brook's will, and knew the contents. Some say he stabbed him with a knife in the back; others, with a sword. This affair happened at Brook-house in Holborn.—Lord Brook was buried with great pomp, in St Mary's church at Warwick, in his own vault, over which he had erected a monument of black and white marble, ordering at his death the following inscription to be engraven upon the tomb. "Fulke Greville, servant to

queen Elizabeth, counsellor to king James, and friend to Sir Philip Sidney. *Trophæum peccati*." He wrote several works, both in verse and prose; among which are, 1. Two tragedies, Alaham and Multapha. 2. A treatise of human learning, &c. in verse, folio. 3. The life of Sir Philip Sidney. 4. An inquisition upon fame and honour, in 86 stanzas. 6. *Calica*, a collection of 109 songs. 7. His remains, consisting of political and philosophical poems.

GREW (Nehemiah), a learned English writer in the 17th century, had a considerable practice as a physician in London, and succeeded Mr Oldenburgh in the office of secretary to the royal society. In this capacity, pursuant to an order of council, he drew up a catalogue of the natural and artificial rarities belonging to the society, under the title of *Museum Regalis Societatis*, &c. 1681. He also wrote, besides several pieces in the Philosophical Transactions. 1. The comparative anatomy of the stomach and guts, folio. 2. The anatomy of plants, folio. 3. *Tractatus de saltu cathartici natura et usu*. 4. *Cosmologia sacra*, or a discourse of the universe as it is the creature and kingdom of God; folio. He died suddenly in 1721.

GREWIA, in botany; a genus of the polyandria order, belonging to the gynandria class of plants.

Species. 1. The occidentalis, with oval created leaves, has long been preserved in many curious gardens both in England and Holland. It is a native of the Cape of Good Hope, and grows to the height of ten or twelve feet. The stem and branches greatly resemble those of the small-leaved elm, the bark being smooth, and of the same colour with that when young. The leaves are also very like those of the elm, and fall off in autumn. The flowers are produced singly along the young branches from the wings of the leaves, and are of a bright purple colour. 2. The Africana, with oval spear-shaped serrated leaves, is a native of Senegal in Africa, from whence its seeds were brought by Mr Adanson. In this country it rises with a shrubby stalk five or six feet high, sending out many lateral branches, with a brown hairy bark, and garnished with spear-shaped, serrated leaves; but the plants have not flowered in Britain.

Culture and uses. The first sort, though a native of a warm climate, will bear the open air in this country; only requiring to be sheltered in a green-house during the winter-time. It may be propagated by cuttings or layers planted in pots filled with soft loamy earth. The second sort is tender, and must be kept constantly in a warm bark-house. In summer, they require a large share of the free air to be admitted to them, and should have water three or four times a week in warm weather; but in the winter they must be sparingly watered. — The negroes of Senegal highly value a decoction of the bark of this last species, and use it as a never-failing remedy against venereal complaints.

GREY or GRAY, a mixed colour, partaking of the two extremes black and white. See BLACK, n^o 8, 9, 10.

GREY (Lady Jane), a most illustrious and unfortunate lady, descended of the blood-royal of England by both parents, was the eldest daughter of Henry Grey marquis of Dorset and Francis the daughter of Charles Brandon lord Suffolk, by Mary dowager

dowager of Lewis XII. king of France, who was the youngest daughter of Henry VII. king of England. She was born in the year 1537, at Broadgate, her father's seat in Leicestershire. She discovered an early propensity to all kinds of good literature; and having a fine genius, improved under the tuition of Mr Elmer, she made a most surprising progress in the languages, arts, and sciences. She understood perfectly both kinds of philosophy, and could express herself very properly at least in the Latin and Greek tongues; and we are informed by Sir Thomas Chaloner (in Strype's memorials, vol. iii. p. 93.) that she was well versed in Hebrew, Chaldee, Arabic, French, and Italian; "and (he adds), she played well on instrumental music, writ a curious hand, and was excellent at the needle." Chaloner also tells us, that she accompanied her musical instruments with a voice exquisitely sweet in itself, assisted by all the graces that art could bestow.

In the year 1553, the dukes of Suffolk and Northumberland, who were now, after the fall of Somerset, arrived at the height of power, began, on the decline of the king's health, to think how to prevent that reverse of fortune which, as things then stood, they foresaw must happen upon Edward's death. To obtain this end, no other remedy was judged sufficient but a change in the succession of the crown, and transferring it into their own families, by rendering Lady Jane queen. Those most excellent and amiable qualities which had rendered her dear to all who had the happiness to know her, joined to her near affinity to the king, subjected her to become the chief tool of an ambition so notoriously not her own. Upon this very account she was married to lord Guilford Dudley, fourth son of the duke of Northumberland, without discovering to her the real design of the match; which was celebrated with great pomp in the latter end of May, so much to the king's satisfaction, that he contributed bounteously to the expence of it from the royal wardrobe. The young king Edward VI. died in July following; and our fair scholar, with infinite reluctance, overpowered by the solicitations of her ambitious friends, allowed herself to be proclaimed queen of England, on the strength of a deed of settlement extorted from that prince by her father-in-law the duke of Northumberland, which set aside the succession of queen Mary, queen Elizabeth, and Mary queen of Scots. Her regal pageantry continued but a few days. Queen Mary's undoubted right prevailed; and the unfortunate lady Jane Grey and her husband were committed to the tower, and on the 13th of November arraigned and found guilty of high treason. On the 12th of February following they were both beheaded on Tower-hill. Her magnanimity in this dreadful catastrophe was astonishing. Immediately before her execution, she addressed herself to the weeping multitude with amazing composure and coherency: she acknowledged the justice of the law, and died in charity with that wretched world which she had so much reason to execrate. Thus did the pious Mary begin her reign with the murder of an innocent young creature of 18; who for simplicity of manners, purity of heart, and extensive learning, was hardly ever equalled in any age or country. But alas! Jane was an obstinate heretic.—A few

days before her execution, Fleckenham, the queen's chaplain, with a pious intention to rescue her poor soul from eternal misery, paid her frequent visits in the tower, and used every argument in his power to convert her to the popish religion: but he found her so much his superior in argument, that he gave up the contest; resigning her body to the block, and her soul to the devil.

Her writings are, 1. Four Latin epistles; three to Bullenger, and one to her sister lady Catharine. The last was written, the night before her execution, in a blank leaf of a Greek Testament. Printed in a book entitled *Epistolæ Helveticæ Reformatioribus, vel ad eos scriptæ*, &c. Tiguri, 1742, 8vo. 2. Her conference with Fleckenham. (Ballard). 3. A letter to Dr Harding, her father's chaplain. Printed in the Phoenix, vol. ii. p. 28. 4. A prayer for her own use during her confinement. In Fox's acts and monuments. 5. Four Latin verses; written in prison with a pin. They are as follow.

Non aliena putes, homini, quæ obtingere possint:
Sors hodierna mihi, tunc cito illa tibi.

Jane Dudley.

Deo juvante, nil nocet livor malus:
Et non juvante, nil juvat labor gravis.

Post tenebras spero lucem.

6. Her speech on the scaffold. (Ballard). It began thus: "My Lords, and you good Christian People who come to see me die; I am under a law, and by that law, as a never-ending judge, I am condemned to die: not for any thing I have offended the queen's majesty; for I will wash my hands guiltless thereof, and deliver to my God a soul as pure from such trespass as innocence from injustice; but only for that I consented to the thing I was enforced unto, constraint making the law believe I did that which I never understood," &c.—Hollinshed, Sir Richard Baker, Bale, and Fox, tell us that she wrote several other things, but do not mention where they are to be found.

GREY-Hound. See GRAY-Hound.

GRIBALDUS (Matthew), a learned civilian of Padua, left Italy in the 16th century, in order to make a public profession of the Protestant religion. After having been for some time professor of the civil law at Tübingen, he was obliged to make his escape to avoid the punishment he would have incurred had he been convicted of differing from Calvin with respect to the doctrine of the Trinity: but he was seized at Berne, where he would have met with very severe treatment had he not pretended to renounce his opinions; but as he relapsed again, he would certainly have been put to death, had he not died of the plague in 1664. He wrote *De methodo ac ratione studendi in jure civili*; and several other works which are esteemed.

GRIBNER (Michael Henry,) a learned civilian of Germany, was born at Leipzig in 1682. After writing some time in the journal of Leipzig, he was made professor of law at Wittemberg; whence he passed to Dresden, and was at last recalled to Leipzig to succeed M. Mencke. He died in 1734. Besides several academical dissertations, he wrote, 1. *Principia processus judicarii*; 2. *Principia jurisprudentiæ naturalis*, a small work much esteemed; 3. *Opuscula juris*

Grief *ris publici et privati.*

Grifgris.

GRIEF, or **SORROW**. The influence of this passion on the human mind is very great. It relaxes the solids, slackens the motion of the fluids, and destroys the health; it particularly weakens the stomach and intestines, destroying all appetite and desire for food. Opiates, if not given in large doses, are good cordials in this case.

GRIERSON (Constantia), born of poor parents in the county of Kilkenny in Ireland, was one of the most learned women on record, though she died at the age of 27, in 1733. She was an excellent Greek and Latin scholar; and understood history, divinity, philosophy, and mathematics. She proved her skill in Latin by her dedication of the Dublin edition of Tacitus to lord Carteret, and by that of Terence to his son; to whom she also addressed a Greek epigram. She wrote many elegant English poems, several of which were inserted by Mrs Barber among her own. When lord Carteret was lord lieutenant of Ireland, he obtained a patent for Mr Griereson to be the king's printer; and to reward the uncommon merit of his wife, caused her life to be included in it.

GRIFFON, in heraldry, an imaginary animal, feigned by the ancients to be half eagle and half lion. By this form they intended to give an idea of strength and swiftness joined, together with an extraordinary vigilance in guarding the things intrusted to its care. Thus the heathen naturalists persuaded the ignorant, that gold mines were guarded by these creatures with incredible watchfulness and resolution.

GRIMSBY, a large sea-port town of Lincolnshire in England, which had formerly a castle, and two parish-churches, with a commodious harbour, now almost choaked up. At present it has only one church, which is a large handsome structure like a cathedral. The town consists of several streets, whose houses are well built; and is a corporation, and sends two members to parliament. E. Long. o. 4. N. Lat. 53. 34.

GRINDING, the reducing hard substances to powder.

GRINDING Optic Glasses. See **OPTICS**, the *Mechanical Part*.

GRIPSWALD, a strong and considerable town of Pomerania in Germany; formerly imperial, but now subject to the Swedes, with a good harbour and university. E. long. 13. 53. N. lat. 54. 12.

GRISGRIS, a superstition greatly in vogue among the negroes in the interior parts of Africa. The grifgris, according to Le Maire, are certain Arabic characters mixed with magical figures drawn by the Marabuts or priests upon paper. Labat affirms, that they are nothing else than scraps of the alcoran in Arabic; but this is denied by Barbot, who brought over one of these grifgris to Europe, and shewed it to a number of persons deeply skilled in oriental learning. None of these could find the least trace of any character they understood. Yet, after all, this might be owing to the badness of the hand-writing; and the words are probably of the Mandingo language, though the characters are an attempt to imitate the Arabic. The poorest negro never goes to war without his Grifgris, as a charm against wounds; and if it proves ineffectual, the priest transfers the blame on the immorality

Grifgris.
Grifsons.

of his conduct. These priests invent grifgris against all kinds of dangers, and in favour of all desires and appetites; by virtue of which the possessors may obtain or avoid whatever they like or dislike. They defend them from storms, enemies, diseases, pains, and misfortunes; and preserve health, long life, wealth, honour, and merit, according to the Marabuts. No clergy in the world are more honoured and revered by the people, than these impostors are by the negroes; nor are any people in the world more impoverished by their priests than these negroes are, a grifgris being frequently fold at three slaves and four or five oxen. The grifgris intended for the head is made in the form of a cross, reaching from the forehead to the neck behind, and from ear to ear; nor are the arms and shoulders neglected. Sometimes they are planted in their bonnets in the form of horns; at other times, they are made like serpents, lizards, or some other animals, cut out of a kind of pasteboard, &c. There are not wanting Europeans, and otherwise intelligent seamen and merchants, who are in some degree infected with this weakness of the country, and believe that the negro forcerers have an actual communication with the devil, and that they are filled with the malignant influence of that evil spirit, when they see them distort their features and muscles, make horrid grimaces, and at last imitate all the appearance of epileptics.

GRISONS, a people situated among the Alps, and allies of the Swiss. Their country is bounded on the north by the counties of Surgans and Bludenz, the canton of Glaris, and the principality of Lichtenstein; on the south by the canton's Italian bailiwicks, the county of Chavanne, and the Valteline; on the east by the territories of Venice and Milan; and on the west by some of the Italian bailiwicks, and the canton of Uri. It is divided into three leagues, viz. the *Grifon* or *grey league*, the *league of the house of God*, and that of the *ten jurisdictions*. The two first lie towards the south, and the third towards the north. The length of the whole is above 70 miles, and the breadth about 60. The inhabitants are said to have had the name of *Grifons* from the grey coats they wore in former times. This country, lying among the Alps, is very mountainous; but the mountains yield good pasture for cattle, sheep, and goats, with some rye and barley: in the valleys there is plenty of grain, pulse, fruits, and wine. This country also abounds with hogs and wild-fowl; but there is a scarcity of fish and salt, and their horses are mostly purchased of foreigners. The principal rivers are the Rhine, the Inn, and the Adda. Here are also several lakes, most of which lie on the tops of the hills. The language of the Grifons is either a corrupt Italian, or the German. About two-thirds of the inhabitants are Calvinists, and the rest Papists; the latter of whom, in spirituals, are under the bishop of Coire, except a few that are in the diocese of Como. Each of the leagues is subdivided into several lesser communities, which are so many democracies; every male above 16 having a share in the government of the community, and a vote in the election of magistrates. Deputies from the several communities constitute the general diet of the Grifon leagues, which meets annually, and alternately at the capital of each league; but they can conclude nothing without the consent of their constituents.

Grifons
||
Groat.

constituents. This country was anciently a part of Rhetia. After the extinction of the Roman empire in the west, it was some time subject to its own dukes, or those of Swabia. Then the bishop of Coire, and other petty princes, dependent on the emperors of Germany, became masters of great part of it: at last, by the extinction of some, purchase, voluntary grants, and force, it got rid of all its lords, and erected itself into three distinct republics, each of which, as we observed already, is subdivided into a certain number of communities, which are a sort of republics, exercising every branch of sovereignty, except that of making peace or war, sending embassies, concluding alliances, and enacting laws relating to the whole country, which belong to the provincial diets of the several leagues. The communities may be compared to the cities of Holland, and the diets of the several leagues to the provincial states. The particular diets are composed of a deputy from each community; and both in them and the communities every thing is determined by a majority of votes. In the communities, every male above 16 has a vote. Besides the annual provincial diets for choosing the chiefs and other officers, and deliberating on the affairs of the respective leagues, there are general diets for what concerns all the three leagues, or whole body. In both these, the representatives can do nothing of themselves, but are tied down to the instructions of their principals: however, as all resolutions are decided by the plurality of votes, and as the Protestants are at least two-thirds of the people, this republic may be deemed a Protestant state. There is a general seal for all the three leagues; and each particular league has a separate seal. Besides the stated times of meeting, extraordinary diets are sometimes summoned, when either the domestic affairs of the state or any foreign minister require it. In the general diets, the Grey League has 28 votes; that of the House of God, 23; and that of the Ten Jurisdctions, 15. These leagues, at different times, have entered into close alliances with the neighbouring cantons, and their associates. The bailiwics belonging in common to the three leagues are those of the Val-teline, Chiavegne, Bormio, Meyenfeld, Malans, and Jennins; the officers of which are nominated successively by the several communities, every two years. The yearly revenue arising to the Grifons from their bailiwics is said to amount to about 13,500 florins. The public revenues all together are but small, though there are many private persons in the country that are rich. However, in case of any extraordinary emergency, they tax themselves in proportion to the necessity of the service, and the people's abilities. They have no regular troops, but a well-disciplined militia; and upon occasion, it is said, can bring a body of 30,000 fighting men into the field: but their chief security arises from the narrow passes and high mountains by which they are surrounded.

GRIST, in country affairs, denotes corn ground, or ready for grinding.

GROAT, an English money of account, equal to four pence. Other nations, as the Dutch, Poles, Saxons, Bohemians, French, &c. have likewise their groats, groots, grôches, gros, &c. In the Saxon times, no silver coin bigger than a penny was struck in England, nor after the conquest, till Edward III.

who, about the year 1351, coined groffes, i. e. *groats*, or great pieces, which went for 4d. a-piece; and so the matter stood till the reign of Henry VIII. who, in 1504, first coined shillings.

GROATS, in country affairs, oats for the hulls are off, or great oat-meal.

GROCERS, anciently were such persons as engrossed all merchandize that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

GROENLAND, or SPITZBERGEN. See GREENLAND.

GROGRAM, a kind of stuff made of silk and mohair.

GROIN, that part of the belly next the thigh.—In the Philosophical Transactions we have an account of a remarkable case, where a peg of wood was extracted from the groin of a young woman of 21, after it had remained 16 years in the stomach and intestines, having been accidentally swallowed when she was about five years of age. *Vide Vol. LXVII. p. 459.*

GRONINGEN, the most northerly of the Seven United Provinces, is bounded on the north by the German ocean; on the south, by the county of Drenthe; on the east by the bishopric of Munster, and the principality of East-Friesland; and on the west by the province of Friesland, from which it is parted by the river Lauwers. Its greatest length from south-east to north-west is about 47 miles; but its breadth is very unequal, the greatest being about 33 miles. Here also are rich pastures, large herds of great and small cattle, plenty of sea and river fish, and of turf, with some forests and corn-land. There are several rivers in the province, of which the principal is the Hunte; and a great number of canals and dykes. The states consist of the deputies of the town of Groningen, and the Ommeland, or circumjacent country; and hold their assemblies always in the town of Groningen. The province had anciently governors, under the title of *burggraves*; but their power being limited, the people enjoyed great privileges. Afterwards, it became subject to the bishop of Utrecht; but shook off his yoke at last, and recovered its liberty. In 1536 it submitted to Charles V. and in 1579 acceded to the union of Utrecht. The colleges are much the same here as in the other provinces, viz. the provincial states, council of state, provincial tribunal, and chamber of accounts. Six deputies are sent from hence to the states-general. Of the established clergy there are 160 ministers, which form seven classes, whose annual synod is held, by turns, at Groningen and Appingedam.

GRONINGEN, the capital of the province of that name, is situated about 12 miles from the nearest shore of the German ocean, at the conflux of several rivulets, which form the Hunte and Fivel. Ships of considerable burthen can come up to the city, in consequence of which it enjoys a pretty good trade. It was formerly very strong, but its fortifications are now much neglected. The university here was founded in 1615, and is well endowed out of the revenues of the ancient monasteries. The town, which was formerly one of the Hanse, and has still great privileges, is large and populous, being the seat of the high colleges, and con-

Groats

Gronovius
Grotius.

taining three spacious market-places, and 27 streets, in which are many fine houses, besides churches and other public structures. By the river Fivel, and the Eems, it has a communication with Westphalia. In 1672 it made such a gallant resistance against the bishop of Munster, that he is said to have lost ten thousand men before it. Rodolphus Agricola and Velsius, two of the most learned men of the age in which they lived, were born here. Under the jurisdiction of this city is a considerable district, called the *Corecht*. E. Lon. 6. 25. N. Lat. 53. 10.

GRONOVIVS (John Frederic), a very learned critic, was born at Hamburgh in 1613; and having travelled through Germany, Italy, and France, was made professor of polite learning at Deventer, and afterwards at Leyden, where he died in 1671. He published, 1. *Diatrise in Statii*, &c. 2. *De sefertitiis*. 3. Correct editions of Seneca, Statius, T. Livy, Pliny's Natural History, Tacitus, Aulus Gellius, Phædrus's Fables, &c. with notes; and other works.

GRONOVIVS (James), son of the preceding, and a very learned man, was educated first at Leyden, then went over to England, where he visited the universities, consulted the curious MSS. and formed an acquaintance with several learned men. He was chosen by the grand duke to be professor at Pisa, with a considerable stipend. He returned into Holland, after he had resided two years in Tuscany, and consulted the MSS. in the Medicean library. In 1679, he was invited by the curators of the university to a professorship; and his inaugural dissertation was so highly approved of, that the curators added 400 florins to his stipend, and this augmentation continued to his death in 1716. He refused several honourable and advantageous offers. His principal works are, *The treasure of Greek antiquities*, in 13 vols. folio; and a great number of dissertations, and editions of ancient authors. He was compared to Schioppus for the virulence of his style; and the severity with which he treated other great men who differed from him, exposed him to just censure.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole. See *STOLE*, and *WARDROBE*.

GROOM is more particularly used for a servant appointed to attend on horses in the stable.—The word is formed from the Flemish *grom*, a boy.

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding, style, or rail, to put their panels in, in wainscoting.

GROSS-BEAK, in ornithology; a species of *LOxia*. *GROSSULARIA*. See *RIPES*.

GROTESQUE, or GROTESK, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprise and ridicule.

GROTIUS (Hugo), or more properly *HUGO DE GROOT*, one of the greatest men in Europe, was born at Delft in 1583. He made so rapid a progress in his studies, that at the age of 15 he had attained a great know-

ledge in philosophy, divinity, and civil law; and a yet greater proficiency in polite literature, as appeared by the commentary he had made at that age on Martinius Capella. In 1598, he accompanied the Dutch ambassador into France, and was honoured with several marks of esteem by Henry IV. He took his degree of doctor of laws in that kingdom; and at his return to his native country, devoted himself to the bar, and pleaded before he was 17 years of age. He was not 24 when he was appointed attorney-general. In 1613 he settled in Rotterdam, and was nominated syndic of that city; but did not accept of the office, till a promise was made him, that he should not be removed from it. This prudent precaution he took from his foreseeing, that the quarrels of the divines on the doctrine of grace, which had already given rise to many factions in the state, would occasion revolutions in the chief cities. The same year he was sent into England, on account of the divisions that reigned between the traders of the two nations, on the right of fishing in the northern seas; but he could obtain no satisfaction. He was afterwards sent to England, as is it thought, to persuade the king and the principal divines to favour the Arminians; and he had several conferences with king James on that subject. On his return to Holland, his attachment to Barneveldt involved him in great trouble; for he was seized, and sentenced to perpetual imprisonment in 1619, and to forfeit all his goods and chattels. But after having been treated with great rigour for above a year and a half in his confinement, he was delivered by the advice and artifice of his wife, who having observed that his keepers had often fatigued themselves with searching and examining a great trunk-full of soul linen which used to be washed at Gorkum, but now let it pass without opening it, the advised him to bore holes in it to prevent his being stifled, and then to get into it. He complied with this advice, and was carried to a friend's house in Gorkum; where dressing himself like a mason, and taking a rule and trowel, he passed through the market-place, and stepping into a boat went to Valvec in Brabant. Here he made himself known to some Arminians, and hired a carriage to Antwerp. At first there was a design of prosecuting his wife, who staid in the prison; and some judges were of opinion that she ought to be kept there in her husband's stead: however, she was released by a plurality of voices, and universally applauded for her behaviour. He now retired into France, where he met with a gracious reception from that court, and Lewis XIII. settled a pension upon him. Having resided there eleven years, he returned to Holland, on his receiving a very kind letter from Frederic Henry, prince of Orange: but his enemies renewing their persecution, he went to Hamburgh; where, in 1634, queen Christina of Sweden made him her counsellor, and sent him ambassador into France. After having discharged the duties of this office above eleven years, he returned, in order to give an account to queen Christina of his embassy; when he took Holland in his way, and received many honours at Amsterdam. He was introduced to her Swedish majesty at Stockholm; and there begged that she would grant his dismissal, in order that he might return to Holland. This he obtained with difficulty; and the queen gave him many

Grotto
Grotto.

marks of her esteem, though he had many enemies at this court. As he was returning, the ship in which he embarked was cast away on the coast of Pomerania; and being now sick, he continued his journey by land; but was forced to stop at Rostock, where he died, on the 28th of August 1645. His body was carried to Delft, to be interred in the sepulchre of his ancestors. Notwithstanding the embassies in which he was employed, he composed a great number of excellent works; the principal of which are, 1. A treatise *De jure belli et pacis*, which is esteemed a master-piece. 2. A treatise on the truth of the Christian religion. 3. Commentaries on the holy scriptures. 4. The history and annals of Holland. 5. A great number of letters. All which are written in Latin.

GROTSCHAW, a town of Turkey in Europe, in the province of Servia, where a battle was fought between the Germans and Turks, in the year 1739, in which the Germans were forced to retreat with loss. E. Lon. 21. O. N. Lat. 45. o.

GROTSKAU, a strong town of Germany, capital of a province of the same name in Silesia. It is very agreeably seated, in a fruitful plain. E. Lon. 17. 35. N. Lat. 50. 42.

GROTTO, a large deep cavern or den in a mountain or rock.

Of these there are several remarkable ones in different parts of the world†. The most celebrated one of our own country, is that called *Oakley-hole*, on the fourth side of Mendip hills. Its length is about two hundred yards, and its height various; being in some places very low, and in others eight fathoms.

Grotto is also used for a small artificial edifice made in a garden, in imitation of a natural grotto.

The outides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, coral, &c. and also furnished with various fountains and other ornaments.

GROTTA del Cani, a little cavern near Pozzuoli, four leagues from Naples, the steams whereof are of a mephitic or noxious quality; whence also it is called *bocca venenosa*, the poisonous mouth.

"Two miles from Naples, says Dr Mead, just by the Lago de Agnano, is a celebrated mofeta, commonly called the *Grotta del Cani*, equally destructive to all within the reach of its vapours.

"It is a small grotto about eight feet high, twelve long, and six broad; from the ground arises a thin, subtle, warm fume, visible enough to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave: having this remarkable difference from common vapours, that it does not, like smoke, disperse itself into the air, but quickly after its rise falls back again, and returns to the earth, the colour of the sides of the grotto being the measure of its ascent; for so far it is of a darkish green, but higher only common earth. And as I myself found no inconvenience by standing in it, so no animal, if its head be above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it, or by reason of its smallness cannot hold its head above it, it presently loses all motion, falls down as dead or in

a swoon, the limbs convulsed and trembling, till at last no more signs of life appear, than a very weak and almost insensible beating of the head and arteries; which, if the animal be left a little longer, quickly ceases too, and then the case is irrecoverable; but if snatched out, and laid in the open air, soon comes to life again, and sooner if thrown into the adjacent lake."

"The fumes of the grotto, the same author argues, are no real poison, but act chiefly by their gravity; else the creatures could not recover so soon; or if they did, some symptoms, as faintness, &c. would be the consequence of it. He adds, that in creatures killed therewith, when dissected, no marks of infection appear; and that the attack proceeds from a want of air, by which the circulation tends to an entire stoppage, and this so much the more, as the animal inspires a fluid of a quite different nature from the air, and so nowise fit to supply its place.

"Taking the animal out while alive, and throwing it into the neighbouring lake, it recovers. This is owing to the coldness of the water, which promotes the contraction of the fibres, and so assists the retarded circulation. The small portion of the air which remains in the vesiculae, after every expiration, may be sufficient to drive out the noxious fluid. After the same manner, cold water acts in a deliquium animi: the lake of Agnano has no other virtue in it more than others."

The steam arising in this grotto was for a long time reckoned to be of a poisonous nature, and thought to suffocate the animals which breathed it. Dr Hales imagined that it destroyed the elasticity of the air, caused the vesicles of the lungs to collapse, and thus occasioned sudden death.—It is now, however, found that this steam is nothing else than fixed air, which from time immemorial hath issued out of the earth in that place in very great quantity, the causes of which cannot yet be investigated from any of the modern discoveries concerning that species of air. It proves pernicious when breathed in too great quantity, by rarefying the blood too much; and hence the best method of recovering persons apparently killed by fixed air, is to apply a great degree of cold all over their bodies, in order to condense the blood as much as possible. This is the reason why the dogs recover when thrown into the lake Agnano, as above-mentioned. See the articles BLOOD, DAMPS, and (the Index subjoined to) MEDICINE.

GROTTA del Serpi, is a subterraneous cavern near the village of Sassa, eight miles from the city of Bracciano in Italy, described by Kircher thus:

"The grotto del serpi is big enough to hold two persons. It is perforated with several stiltular apertures, somewhat in manner of a sieve; out of which, at the beginning of the spring season, issues a numerous brood of young snakes of divers colours, but all free from any particularly poisonous quality.

"In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where, the warmth of the subterraneous steams resolving them into a sweat, and the serpents clinging variously all around, licking and sucking them, they become so thoroughly freed of all their vicious humours, that, upon repeating the operation for some time,

Grotto.

† See
Antiperiod.

time, they become perfectly restored."

This cave Kircher visited himself; and found it warm, and every way agreeable to the description given of it. He saw the holes, and heard a murmuring hissing noise in them. Though he missed seeing the serpents, it not being the season of their creeping out; yet he saw a great number of their exuviae, or sloughs, and an elm growing hard by laden with them.

Museum
Worm.

The discovery of this cave, was by the cure of a leper going from Rome to some baths near this place. Losing his way, and being benighted, he happened upon this cave. Finding it very warm, he pulled off his clothes; and being weary and sleepy, had the good fortune not to feel the serpents about him till they had wrought his cure.

GROVE, in gardening, a small wood impervious to the rays of the sun.

Groves are not only great ornaments to gardens; but are also the greatest relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the garden are useless; so that every garden is defective which has not shade.

Groves are of two sorts, viz. either open or close. Open groves are such as have large shady trees, which stand at such distances, as that their branches approach so near to each other as to prevent the rays of the sun from penetrating through them.

Close groves have frequently large trees standing in them; but the ground under these are filled with shrubs or underwood; so that the walks which are in them are private, and screened from winds; by which means they are rendered agreeable for walking, at those times when the air is either too hot or too cold in the more exposed parts of the garden. These are often contrived for as to bound the open groves, and frequently to hide the walls or other inclosures of the garden: and when they are properly laid out, with dry walks winding through them, and on the sides of these sweet-smelling shrubs and flowers irregularly planted, they have a charming effect.

GROVE (Henry), a learned and ingenious Presbyterian divine, was born at Taunton in Somersetshire, in 1683. Having obtained a sufficient stock of classical literature, he went through a course of academical learning, under the reverend Mr Warren of Taunton, who had a flourishing academy. He then removed to London, and studied some time under the Reverend Mr Rowe, to whom he was nearly related. Here he contracted a friendship with several persons of merit, and particularly with Dr Watts, which continued till his death, though they were of different opinions in several points warmly controverted among divines. After two years spent under Mr Rowe, he returned into the country, and began to preach with great reputation; when an exact judgment, a lively imagination, and a rational and amiable representation of Christianity, delivered in a sweet and well-governed voice, rendered him generally admired; and the spirit of devotion, which prevailed in his sermons, procured him the esteem and friendship of Mrs Singer, afterwards Mrs Rowe, which she expressed in a fine ode on death, addressed to Mr Grove. Soon after his beginning to preach, he married; and on the death of Mr Warren,

was chosen to succeed him in the academy at Taunton.

This obliging him to reside there, he preached for eighteen years to two small congregations in the neighbourhood; and though his salary from both was less than twenty pounds a-year, and he had a growing family, he went through it cheerfully. In 1708, he published a piece, intitled *The regulation of diversions*, drawn up for the use of his pupils. About the same time, he entered into a private dispute by letter with Dr Samuel Clarke: but they not being able to convince each other, the debate was dropped with expressions of great mutual esteem. He next wrote several papers printed in the *Spectator*, viz. Numb. 588. 601. 626. 635. The last was republished, by the direction of Dr Gibson bishop of London, in the *Evidence of the Christian Religion*, by Joseph Addison, Esq. In 1725, Mr James, his partner in the academy, dying, he succeeded him in his pastoral charge at Fulwood, near Taunton, and engaged his nephew to undertake the other parts of Mr James's work as tutor; and in this situation Mr Grove continued till his death, which happened in 1738. His great concern with his pupils, was to inspire and cherish in them a prevailing love of truth, virtue, liberty, and genuine religion, without violent attachments or prejudices in favour of any party of Christians. He represented truth and virtue in a most engaging light; and though his income, both as a tutor and a minister, was insufficient to support his family, without breaking into his paternal estate, he knew not how to refuse the call of charity. Besides the above pieces, he wrote, 1. An essay towards a demonstration of the soul's immortality. 2. An essay on the terms of Christian communion. 3. The evidence of our Saviour's resurrection considered. 4. Some thoughts concerning the proof of a future state from reason. 5. A discourse concerning the nature and design of the Lord's supper. 6. Wisdom the first spring of action in the Deity. 7. A discourse on saving faith. 8. Miscellanies in prose and verse. 9. Many sermons, &c. After his decease, his posthumous works were published by subscription, in four volumes octavo, with the names of near 700 subscribers, among whom were some of the best judges of merit in the established church.

GROUND, in painting, the surface upon which the figures and other objects are represented.

The ground is properly understood of such parts of the piece, as have nothing painted on them, but retain the original colour upon which the other colours are applied to make the representations.

A building is said to serve as a ground to a figure, when the figure is painted on the building.

The ground behind a picture in miniature, is commonly blue or crimson, imitating a curtain of satin or velvet.

GROUND, in etching, denotes a guminous composition smeared over the surface of the metal to be etched, to prevent the aquafortis from eating, except in such places where this ground is cut through with the point of a needle. See the article *ETCHING*.

GROUND-*Angling*, fishing under water without a float, only with a plumb of lead, or a bullet, placed about nine inches from the hook; which is better, because it will roll on the ground. This method of fishing.

Ground || ing is most proper in cold weather, when the fish swim very low. Growth.

The morning and evening are the chief seasons for the ground-line in fishing for trout; but if the day prove cloudy, or the water muddy, you may fish at ground all day.

GROUND-TACKLE, a ship's anchors, cables, &c. and in general whatever is necessary to make her ride safe at anchor.

GROUND-IVY, in botany. See **GLECHOMA**.

GROUND-PINE, in botany. See **TEUCRIUM**.

GROUNDSEL. See **SENECIO**.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other. See **PAINTING**.—The word is formed of the Italian *gruppo*, a knot.

The Groups, a cluster of islands lately discovered in the south sea. They lie in about S. Lat. 18. 12. and W. Lon. 142. 42. They are long narrow slips of land, ranging in all directions, some of them ten miles or upwards in length, but not more than a quarter of a mile broad. They abound in trees, particularly those of the cocoa-nut. They are inhabited by well-made people, of a brown complexion. Most of them carried in their hands a slender pole about 14 feet in length, pointed like a spear; they had likewise something shaped like a paddle, about four feet long. Their canoes were of different sizes, carrying from three to six or seven people, and some of them hoisted a sail.

GROUSE, or **GROUSE**. See **TETRAO**.

GROWTH, the gradual increase of bulk and stature that takes place, in animals or vegetables, to a certain period.—The increase of bulk in such bodies as have no life, owing to fermentations excited in their substance, or to other causes, is called **EXPANSION**, **SWELLING**, &c.

The growth of animals, nay even of the human species, is subject to great variations. A remarkable instance in the last was observed in France in the year 1729. At this time the Academy of Sciences examined a boy who was then only seven years old, and who measured four feet eight inches and four lines high, without his shoes. His mother observed the signs of puberty on him at two years old, which continued to increase very quick, and soon arrived at the usual standard. At four years old he was able to lift and toss the common bundles of hay in stables into the horses racks; and at six years old could lift as much as a sturdy fellow of twenty. But though he thus increased in bodily strength, his understanding was no greater than is usual with children of his age, and their playthings were also his favourite amusements.

Another boy, a native of the hamlet of Bouzanquet, in the diocese of Alais, though of a strong constitution, appeared to be knit and stiff in his joints till he was about four years and a half old. During this time nothing farther was remarkable of him than an extraordinary appetite, which was satisfied no otherwise than by giving him plenty of the common aliments of the inhabitants of the country, consisting of rye-bread, chefnuts, bacon, and water; but his limbs soon becoming supple and pliable, and his body beginning to expand itself, he grew up in so extraor-

dinary a manner, that at the age of five years he measured four feet three inches; some months after, he was four feet eleven inches; and at six, five feet, and bulky in proportion. His growth was so rapid, that one might fancy he saw him grow: every month his cloaths required to be made longer and wider; and what was still very extraordinary in his growth, it was not preceded by any tickle, nor accompanied with any pain in the groin or elsewhere. At the age of five years his voice changed, his beard began to appear, and at six he had as much as a man of thirty; in short, all the unquestionable marks of puberty were visible in him. It was not doubted in the country but this child was, at five years old, or five and a half, in a condition of begetting other children; which induced the rector of the parish to recommend to his mother that she would keep him from too familiar a conversation with children of the other sex. Tho' his wit was ripier than is commonly observable at the age of five or six years, yet its progress was not in proportion to that of his body. His air and manner still retained something childish, though by his bulk and stature he resembled a complete man, which at first sight produced a very singular contrast. His voice was strong and manly, and his great strength rendered him already fit for the labours of the country. At the age of five years, he could carry to a good distance, three measures of rye, weighing eighty-four pounds; when turned of six, he could lift up easily on his shoulders and carry loads of a hundred and fifty pounds weight a good way off; and these exercises were exhibited by him as often as the curious engaged him thereto by some liberality. Such beginnings made people think that he would soon shoot up into a giant. A mountebank was already soliciting his parents for him, and flattering them with hopes of putting him in a way of making a great fortune. But all these hopes suddenly vanished. His legs became crooked, his body shrank, his strength diminished, his voice grew sensibly weaker, and he at last sunk into a total imbecility.

In the Paris Memoirs also there is an account of a girl who had her menses at three months of age. When four years old, she was four feet six inches in height, and had her limbs well proportioned to that height, her breasts large and plump, and the parts of generation like those of a girl of eighteen; so that there is no doubt but that she was marriageable at that time, and capable of being a mother of children. These things are more singular and marvellous in the northern than in the southern climates, where the females come sooner to maturity. In some places of the East Indies, the girls have children at nine years of age.

Many other instances of extraordinary growth might be brought, but the particulars are not remarkably different from those already related.—It is at first sight astonishing that children of such early and prodigious growth do not become giants: but when we consider that the signs of puberty appear so much sooner than they ought, it seems evident that the whole is only a more than usually rapid expansion of the parts, as in hot climates; and accordingly it is observed that such children, instead of becoming giants, always decay and die apparently of old age, long before the natu-

ral term of human life.

GRUB, in zoology, the English name of the hexapode worms, produced from the eggs of beetles, and which at length are transformed into winged insects of the same species with their parents.

GRUBBING, in agriculture, the digging or pulling up of the stubs and roots of trees.

When the roots are large, this is a very troublesome and laborious task; but Mr Mortimer hath shewn how it may be accomplished in such a manner as to save great expence by a very simple and easy method. He proposes a strong iron hook to be made about two feet four inches long, with a large iron ring fastened to the upper part of it. This hook must be put into a hole in the side of the root, to which it must be fastened; and a lever being put into the ring, three men, by means of this lever, may wring out the root, and twist the sap-roots asunder. Stubs of trees may also be taken up with the same hook, in which work it will save a great deal of labour, though not so much as in the other; because the stubs must be first cleft with wedges, before the hook can enter the sides of them, to wrench them out by pieces.

GRUBENHAGEN, a town and castle of the duchy of Brunswick, in Lower Saxony, remarkable for its mines of silver, copper, iron, and lead. E. Lon. 9. 36. N. Lat. 51. 45.

GRUBS, in medicine, certain unctuous pimples arising in different parts of the face, but chiefly in the aleæ of the nose. The cure of these ought only to be attempted by evacuations and cleansers of the blood.

GRUINALES, (from *grus*, a crane); the name of the fourteenth order in Linnaeus's fragments of a natural method, consisting of geranium, and a few other genera which the author considers as allied to it in their habit and external structure.

GRUME, in medicine, denotes a concentered clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscosity and stagnating in the capillary vessels produces several disorders.

GRUPPO, or *Turned SHAKE*, a musical grace, defined by Playford to consist in the alternate prolation of two notes in juxtaposition to each other, with a clofe on the note immediately beneath the lower of them. See *SHAKE*.

GRUS, in ornithology. See *ARDEA*.

GRUTER (James), a learned philologist, and one of the most laborious writers of his time, was born at Antwerp in 1560. He was but a child, when his father and mother, being persecuted for the Protestant religion by the dukes of Parma governors of the Netherlands, carried him into England. He imbibed the elements of learning from his mother, who was one of the most learned women of the age, and besides French, Italian, and English, was a complete mistress of Latin, and well skilled in Greek. He spent some years in the university of Cambridge; after which he went to that of Leyden, to study the civil law; but at last applied himself wholly to polite literature. After travelling much, he became professor in the university of Heidelberg; near which city

he died, in 1627. He wrote many works; the most considerable of which are, 1. A large collection of ancient inscriptions. 2. *Thefaurus criticus*. 3. *Deliciae poetarum Gallorum, Italorum, et Belgarum, &c.*

GRUYERS, a town of Switzerland, in the canton of Friburgh, with a pretty good castle. It is famous for its cheese, which are all its riches. E. Lon. 7. 23. N. Lat. 46. 35.

GRYLLUS, in zoology, the name of the cricket and locust kind; which, together with the grasshoppers, make only one genus of insects, belonging to the order of hemiptera. The characters are these: The antennæ are setaceous and filiform; the exterior wings are membranaceous, narrow, and have much of the appearance of the wings of some of the fly-kind; the thorax is compressed and angulated; and the legs are formed for leaping. See Plate CXV. CXL. and the articles GRASSHOPPER, GRYLLOTALPA, LOCUST, (and CRICKET in Appendix.)

GRYLLOTALPA, the MOLE-CRICKET; an insect very destructive to gardens. Like the cricket, it makes a noise in the evening; and like the mole, is perpetually employed in digging below ground. It is an insect of a very unpleasant form. It is of the length and thickness of a man's little finger; and is of a brown colour, which is darker in the male than in the female. There are on each side of the anus two hairy processes, resembling the tails of mice; its belly is composed of eight joints, and is covered with as many scales, which are of a pale flesh-colour, and are covered with short hair. The back is covered by a pair of pointed wings, along each of which there runs a black streak or line. These wings fold any way at the creature's pleasure, and when fully expanded are very large. Over these lie the antennæ; which are variegated also with black, and reach about half the length of the wings. It has only four legs: the hinder pair are long and fit for hopping; the anterior pair are short, and furnished with a sort of hands for digging in the manner of the mole. The breast is covered with a crustaceous substance, which is blackish and hairy on the outside, and smooth and pale within. The eyes are very bright and black, and are very hard; and the mouth is wide, and has two tonsils, and teeth in both jaws. This creature lives under ground, and is principally found in damp and boggy places. They come out in the dusk of the evening, and make a very loud noise of the nature of that of the cricket.

The mole-cricket moves very slowly: and Goedartius is of opinion, that its wings were given it rather as an ornament, than as a thing of use; or if they have any real use, that it is the covering and defending the tender body of the creature, which is very soft, and easily liable to accidents; and Mousset says, that its flights are no more than long leaps. But we have a very different account of the use this creature makes of its wings, in the German Ephemerides. Mentzelius, in a paper there, declares this to be one of the most mischievous insects of the creation. He says it is a kind of amphibious creature; and that it lives equally well under ground, in the air, or under water: that while it is under ground, it does infinite mischief, by burrowing under the beds of a garden, and eating the roots of flowers; and that in the night

Gryllotalpa it comes out, and taking wing, settles upon the fruit-trees, where it does no little mischief: and all this the author affirms from his own experience, in the gardens which he observed.

This creature is very nice in the construction of its nest. This is always under ground, and it chooses a foetid clay for the purpose. All its precautions seem to be necessary to secure its eggs from becoming a prey to a kind of black fly, which conceals itself under ground. The noise of this animal is variously accounted for by naturalists; but it is most probably effected by the play of organs in their belly, of a singular construction. This is certain, that if the head of the animal be taken off, or if it be severed in the middle, it continues to live, and even to chirp, for some considerable time.

It is remarkable of this creature, that it can move backward as fast as forward, and often does so when frightened.

GRYNEUS (Simon), son to a peasant of Suabia, born in 1493, was Greek professor at Heidelberg, in 1523. He took a tour into England, and received great civility from the lord chancellor Sir Thomas More, to whom Erasmus had recommended him. He was a learned and laborious man, and did great service to the commonwealth of letters. He was the first who published the *Almagest* of Ptolemy in Greek. He also published a Greek Euclid, and Plato's works, with some commentaries of Proclus.

GRYPHIUS (Sebastian), an eminent Swiss printer, and accurate corrector; on which account his Hebrew and Latin Bibles are esteemed. He died in 1556.

GRYPHITES, in natural history, in English crow's stone, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward.

They are frequently found in our gravel or clays, in many counties. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so; and the plates of which they are composed, are in some smaller and thinner, in others thicker and larger, in specimens of the same bigness.

GUADALAJARA, or GUADALAXARA, a town of Spain, in New Castile, and district of Alcalá, seated on the river Herases, W. Lon. 2. 45. N. Lat. 40. 36.

GUADALAJARA, a considerable town of North America, and capital of a rich and fertile province of the same name, with a bishop's see. W. Lon. 114. 59. N. Lat. 20. 20.

GUADALAVIAR, a river of Spain, which rises on the confines of Arragon and New Castile, and, running by Turvel in Arragon, crosses the kingdom of Valencia, passes by the town of the same name, and soon after falls into the Mediterranean sea, a little below Valencia.

GUADALUPE, a handsome town in Spain, in Estramadura, with a celebrated convent, whose structure is magnificent, and is immensely rich. It is seated on a rivulet of the same name. E. Lon. 3. 50. N. Lat. 39. 15.

GUADALQUIVER, one of the most famous rivers of Spain, rises in Andalusia, near the confines of Granada, and running quite through Andalusia, by

the towns of Baiza, Andaxar, Cordova, Seville, and Guadalupe, St. Lucar, falls at last into the Bay of Cadiz.

GUADALUPE, one of the Caribbee islands, belonging to the French, the middle of which is seated in about 16. 30. N. Lat. and 61. 20. W. Lon.

This island, which is of an irregular figure, may be about 80 leagues in circumference. It is divided into two parts by a small arm of the sea, which is not above two leagues long, and from 15 to 40 fathom broad. This canal, known by the name of the Salt River, is navigable, but will only carry vessels of 50 tons burthen.

That part of the island which gives its name to the whole colony, is, towards the centre, full of craggy rocks, where the cold is so intense, that nothing will grow upon them but fern, and some useless shrubs covered with moss. On the top of these rocks, a mountain called *la Souphriere*, or the *Brimstone Mountain*, rises to an immense height. It exhales, through various openings, a thick black smoke, intermixed with sparks that are visible by night. From all these hills flow numberless springs, which fertilize the plains below, and moderate the burning heat of the climate by a refreshing stream, so celebrated, that the galleons which formerly used to touch at the Windward Islands, had orders to renew their provision with this pure and salubrious water. Such is that part of the island properly called *Guadalupe*. That which is commonly called *Grand Terre*, has not been so much favoured by nature. It is indeed less rugged; but it wants springs and rivers. The soil is not so fertile, or the climate so wholesome or so pleasant.

No European nation had yet taken possession of this island, when 550 Frenchmen, led on by two gentlemen named *Loline* and *Duplestis*, arrived there from Dieppe on the 28th of June 1635. They had been very imprudent in their preparations. Their provisions were so ill chosen, that they were spoilt in the passage; and they had shipped so few, that they were exhausted in two months. They were supplied with none from the mother-country. St. Christopher's, whether from scarcity or design, refused to spare them any; and the first attempts in husbandry they made in the country, could not as yet afford any thing. No resource was left for the colony but from the savages; but the superfluities of a people, who cultivate but little, and therefore had never laid up any stores, could not be very considerable. The new comers, not content with what the savages might freely and voluntarily bring, came to a resolution to plunder them; and hostilities commenced on the 16th of January 1636.

The Caribs, not thinking themselves in a condition openly to resist an enemy who had so much the advantage from the superiority of their arms, destroyed their own provisions and plantations, and retired to Grand Terre, or to the neighbouring islands. From thence the most desperate came over to the island from which they had been driven, and concealed themselves in the thickest parts of the forests. In the day-time, they shot with their poisoned arrows, or knocked down with their clubs, all the Frenchmen who were scattered about for hunting or fishing. In the night, they burned the houses and destroyed the plantations of their unjust spoilers.

A dreadful famine was the consequence of this kind of war. The colonists were reduced to graze in the fields,

Guadalupe. fields, to eat their own excrements, and to dig up dead bodies for their subsistence. Many who had been slaves at Algiers, held in abhorrence the hands that had broken their fetters; and all of them cursed their existence. It was in this manner that they atoned for the crime of their invasion, till the government of Aubert brought a peace with the savages at the end of the year 1640. The remembrance, however, of hardships endured in an invaded island, proved a powerful incitement to the cultivation of all articles of immediate necessity; which afterwards induced an attention to those of luxury consumed in the mother-country. The few inhabitants who had escaped the calamities they had drawn upon themselves, were soon joined by some discontented colonists from St Christopher's, by Europeans fond of novelty, by sailors tired of navigation, and by some sea-captains, who prudently chose to commit to the care of a grateful soil the treasures they had saved from the dangers of the sea. But still the prosperity of Guadalupe was stopped or impeded by obstacles arising from its situation.

The facility with which the pirates from the neighbouring islands could carry off their cattle, their slaves, their very crops, frequently brought them into a desperate situation. Intelline broils, arising from jealousies of authority, often disturbed the quiet of the planters. The adventurers who went over to the windward islands, disdaining a land that was fitter for agriculture than for naval expeditions, were easily drawn to Martinico, by the convenient roads it abounds with. The protection of those intrepid pirates, brought to that island all the traders who flattered themselves that they might buy up the spoils of the enemy at a low price, and all the planters who thought they might safely give themselves up to peaceful labours. This quick population could not fail of introducing the civil and military government of the Caribbee islands into Martinico. From that time, the French ministry attended more seriously to this than to the other colonies, which were not so immediately under their direction; and, hearing chiefly of this island, they turned all their encouragements that way.

It was in consequence of this preference, that in 1700 the number of inhabitants in Guadalupe amounted only to 3825 white people, 325 savages, free negroes, mulattoes, and 6725 slaves, many of whom were Caribs. Her cultures were reduced to 60 small plantations of sugar, 66 of indigo, a little cocoa, and a considerable quantity of cotton. The cattle amounted to 1620 horses and mules, and 3699 head of horned cattle. This was the fruit of sixty years labour. But her future progress was as rapid as her first attempts had been slow.

At the end of the year 1755, the colony was peopled with 9,643 whites, 41,140 slaves of all ages and of both sexes. Her saleable commodities were the produce of 334 sugar-plantations, 15 plots of indigo, 46840 items of cocoa, 11700 of tobacco, 2,257,725 of coffee, 12,748,447 of cotton. For her provisions she had 29 squares of rice or maize, and 1219 of potatoes or yams, 2,028,520 banana trees, and 32,577,950 trenches of cassava. The cattle of Guadalupe consisted of 4946 horses, 2924 mules, 125 asses, 13,716 head of horned cattle, 11,162 sheep or goats, 2444 hogs. Such was the state of Guadalupe

Vol. V.

when it was conquered by the British in the month of April 1759.

France lamented this loss; but the colony had reason to comfort themselves for this disgrace. During a siege of three months, they had seen their plantations destroyed, the buildings that served to carry on their works burnt down, and some of their slaves carried off. Had the enemy been forced to retreat after all these devastations, the island was ruined. Deprived of all assistance from the mother-country, which was not able to send her any succours; and expecting nothing from the Dutch, (who, on account of their neutrality, came into her roads), because she had nothing to offer them in exchange; she could never have subsisted till the ensuing harvest.

The conquerors delivered them from these apprehensions. The British, indeed, are no merchants in their colonies. The proprietors of lands, who mostly reside in Europe, send to their representatives whatever they want, and draw the whole produce of the estate by the return of their ship. An agent settled in some sea-port of Great Britain, is intrusted with the furnishing the plantation, and receiving the produce. This was impracticable at Guadalupe; and the conquerors in this respect were obliged to adopt the custom of the conquered. The British, informed of the advantage the French made of their trade with the colonies, hastened, in imitation of them, to send their ships to the conquered island; and so multiplied their expeditions, that they overstocked the market, and sunk the price of all European commodities. The colonists bought them at a very low price, and, in consequence of this plenty, obtained long delays for the payment.

To this credit, which was necessary, was soon added another arising from speculation, which enabled the colony to fulfil its engagements. A great number of negroes were carried thither, to hasten the growth and enhance the value of the plantations. It has been said in various memorials, all copied from each other, that the English had stocked Guadalupe with 30,000, during the four years and three months that they remained masters of the island. The registers of the custom-houses, which may be depended on, as there could be no inducement for an imposition, attest that the number was no more than 18,721. This was sufficient to give the nation well-grounded hopes of reaping great advantages from their new conquest. But their hopes were frustrated; and the colony, with its dependencies, was restored to its former possessors, by the treaty of peace in July 1763.

By the survey taken in 1767, this island, including the smaller islands, Defeada, St Bartholomew, Mari-galante, and the Saints, dependent upon it, contains 11,863 white people of all ages, and of both sexes; 752 free blacks and mulattos; 72,761 slaves; which makes in all a population of 85,376 souls. The cattle consists of 5060 horses, 4854 mules, 111 asses, 17,378 head of horned cattle, 14,895 sheep or goats, and 2669 hogs. The provision is 30,476,218 trenches of cassava, 2,819,262 banana trees, 2118 squares of land planted with yams and potatoes. The plantations contain 72 arnotto trees, 327 of cassia, 13,292 of cocoa, 5,881,176 of coffee, 12,156,769 of cotton, 21,474 squares of land planted with sugar-canes.

19 P.

The

Guadiana
||
Guañacum.

The woods occupy 22,097 squares of land. There are 20,247 in meadows, and 6405 are uncultivated or forsaken. Only 1582 plantations grow cotton, coffee, and provisions. Sugar is made but in 401. These sugar-works employ 140 water-mills, 263 turned by oxen, and 11 wind-mills.

The produce of Guadalupe, including what is poured in from the small islands under her dominion, ought to be very considerable. But in 1768, it yielded to the mother-country no more than 140,418 quintals of fine sugar, 23,603 quintals of raw sugar, 34,205 quintals of coffee, 11,955 quintals of cotton, 456 quintals of cocoa, 1884 quintals of ginger, 2529 quintals of logwood, 24 chests of sweetmeats, 165 chests of liquors, 34 casks of rum, and 1202 undressed skins. All these commodities were sold in the colony only for 310,792 l. 18 s. 3 d. and the merchandise it has received from France has cost but 197,919 l. 18 s. 6 d.

GUADIANA, a large river of Spain, having its source in New Castile, and, passing cross the high mountains, falls down to the lakes called *Ojas of Guadiana*; from whence it runs to Calatrava, Medellin, Merida, and Badajoz in Eltremaadura of Spain; and after having run for some time in Alentejo in Portugal, it passes on to separate the kingdom of Algarve from Andalusia, and falls into the bay or gulph of Cadiz between Castro Marino and Agramonte.

GUADIX, a town of Spain, in the kingdom of Granada, with a bishop's see. It was taken from the Moors in 1253, who afterwards retook it, but the Spaniards again got possession of it in 1489. It is seated in a fertile country, in W. Long. 2. 12. N. Lat. 37. 5.

GUAJACUM, *LIGNUM VITÆ*, or *Pockwood*; a genus of the monogynia order, belonging to the decandria class of plants.

Species. 1. The officinale, or common *lignum vitæ* used in medicine, is a native of the West India islands. There it becomes a large tree, having a hard, brittle, brownish bark, not very thick. The wood is firm, solid, ponderous, very resinous, of a blackish yellow colour in the middle, and of a hot aromatic taste. The smaller branches have an ash-coloured bark, and are garnished with leaves divided by pairs of a bright green colour. The flowers are produced in clusters at the end of the branches, and are composed of oval concave petals of a fine blue colour. 2. The sanctum, with many pairs of obtuse lobes, hath many small lobes placed along the mid-rib by pairs of a darker green colour than those of the foregoing sort. The flowers are produced in loose bunches towards the end of the branches, and are of a fine blue colour, with petals fringed on the edges. This species is also a native of the West India islands, where it is called *bastard lignum vitæ*. 3. The *Alpum* with many blunt-pointed leaves, is a native of the Cape of Good Hope. The plants retain their leaves all the year, but have never yet flowered in this country.

Culture. The first species can only be propagated by seeds, which must be procured from the countries where it naturally grows. They must be sown fresh in pots, and plunged into a good hot-bed, where they will come up in six or eight weeks. While young, they may be kept in a hot-bed of tan-bark under a

frame during the summer; but in autumn, they must be removed into the bark-stove, where they should constantly remain. The second sort may be propagated the same way; but the third is to be propagated by layers, and will live all the winter in a good greenhouse.

Uses. The wood of the first species is of very considerable use both in medicine and in the mechanical arts. Ulric Hutten says this wood was introduced into Europe in 1517; but Braslavous says, not until 1525. It is brought from the West Indies, in large pieces, each weighing from four to five hundred weight: it is hard, compact, and so heavy as to sink in water: the outer part is often of a pale yellowish colour; but the heart is blacker, or of a deep brown. Sometimes it is marbled with different colours. It has little or no smell, except when heated, and then a slight aromatic one is perceived. When chewed, it impresses a mild acrimony, biting the palate and fauces. Its pungency resides in its resinous matter, which it gives it out in some degree to water by boiling, but spirit extracts it wholly.

Of the bark of guaiac, there are two kinds, one smooth, the other unequal on the surface; they are both of them weaker than the wood.

The gum, or rather resin, exudes from the tree; and is of a brown colour, partly reddish, and often greenish, brittle, having a glossy surface when broke, of a pungent taste, affecting the tongue and palate in the same manner as is said of the wood. The chief of what is brought to us is in irregular masses, of a dusky green colour. There is a sort in drops, which is the best, but is very rarely met with.

In the choice of the wood, that which is the freshest, most ponderous, and of the darkest colour, is the best; the largest pieces are to be preferred too; and the best method is to rasp them as wanted, for the finer parts are apt to exhale when the raspings or chips are kept a while. In choosing the gum, prefer those pieces which have flaps of the bark adhering to them, and that easily separate therefrom by a quick blow.

Neumann assures us, that a composition of colophony and balsam of sulphur is imposed on the unwary for true gum guaiacum; but the cheat is easily detected by exposing it to a due degree of heat, by which the odour of the false is perceived to be quite different from that of the true.

The guaiac wood was first introduced into Europe as a remedy for the venereal disease. It is a good assistant to mercury, as it warms and stimulates, and so promotes perspiration and urine; it also proves gently purgative in a somewhat increased dose: and these seem to be its primary virtues. When the excretory glands are obstructed, the vessels lax and flaccid, the habit replete with ferous humours, in many cutaneous and catarrhus disorders, some female weaknesses, in gouty complaints, and rheumatic disorders, it produces good effects. The hectic fever which sometimes follows a salivation, gives way to a decoction of the woods.

A long use of this medicine hath been observed to produce a yellowness in the skin. In this emaciated habits and an acrimonious state of the fluids, it often does harm. It is also improper in hot bilious habits, and where the fibres are very tense.

Three ounces of the wood, or four ounces of the bark, may be boiled in 4lb. of water to 2lb. and if a little liquorice is added at the latter end of the boiling, or when the decoction is taken from the fire, it will abate the disagreeable pungency of this medicine, which affects the throat very much in swallowing it. Of this decoction, at least half a pint should be taken in a day. Of the gum, or extract, the dose may be from gr. v. to ℥ i. which last purges pretty much. These should be dissolved by the mediation of egg, or the mucilage of gum arabic; for otherwise they do not easily mix the juices in the stomach.

A pound of guaiacum wood, distilled over an open fire, gave 3 iiii of acid, which is called spirit, and 3 iis. of empyreumatic oil.—An hard extract of guaiacum is accounted an excellent erubine.

The wood of this tree is so hard, that it breaks the tools which are employed in felling it; and is therefore seldom used as firewood, but is of great use to the sugar-planters for making wheels and cogs to the sugar-mill. It is also frequently wrought into bowls, mortars, and other utensils.

GALEOR, a large town of Indostan in Asia, and capital of a province of the same name, with a strong fort. E. Long. 69. 5. N. Lat. 25. 45.

GUAM, the largest of the Ladrones islands in the South Sea, being about 100 miles in circumference. The inhabitants are almost all natives, but the Spaniards have a garrison which keeps them in awe. The island abounds with excellent fruits, and the air is wholesome; notwithstanding which, the people are subject to the leprosy. E. Long. 139. 25. N. Lat. 13. 25.

GUAMANGA, a considerable town of South America, and capital of a province of the same name in Peru, and in the audience of Lima, with a bishop's see. It is remarkable for its sweetmeats, manufactures, and mines of gold, silver, leadstone, and quicksilver. W. Long. 7. 50. S. Lat. 13. 0.

GUANUCO, a rich and handsome town of S. America, and capital of a district of the same name in the audience of Lima. W. Long. 72. 55. S. Lat. 9. 55.

GUANZAVELCA, a town of South America, in Peru, and in the audience of Lima. It abounds in mines of quicksilver. W. Lon. 71. 59. S. Lat. 12. 40.

GUARANTY, in matters of polity, the engagement of mediatorial or neutral states, whereby they plight their faith that certain treaties shall be inviolably observed, or that they will make war against the aggressor.

GUARD, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprize; or, the care, precaution, and attention, we make use of to prevent any thing from happening contrary to our intention or inclinations.

GUARD, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy. In garrison the guards are relieved every day; hence it comes that every soldier mounts guard once every three or four days in time of peace, and much oftener in time of war. See

Honours.

Advanced GUARD, is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger. These guards are either made stronger or weaker, according to situation, the danger to be apprehended from the enemy, or the nature of the country.

Van GUARD. See *Advanced GUARD*.

Artillery GUARD, is a detachment from the army to secure the artillery when in the field. Their *corps de garde* is in the front of the artillery park, and their centres dispersed round the same. This is generally a 48-hours guard; and upon a march, this guard marches in the front and rear of the artillery, and must be sure to leave nothing behind; if a gun or or wagon breaks down, the officer that commands the guard is to leave a sufficient number of men to assist the gunners and matrosses in getting it up again.

Artillery Quarter-GUARD, is frequently a non-commissioned officer's guard from the royal regiment of artillery, whose *corps de garde* is always in the front of their incampment.

Artillery Rear-GUARD, consists in a corporal and six men, posted in the rear of the park.

Corps de GARDE, are soldiers entrusted with the guard of a post, under the command of one or more officers. This word also signifies the place where the guard mounts.

Grand GUARD; three or four squadrons of horse, commanded by a field-officer, posted at about a mile or a mile and a half from the camp, on the right and left wings, towards the enemy, for the better security of the camp.

Forage GUARD, a detachment sent out to secure the foragers, and who are posted at all places, where either the enemy's party may come to disturb the foragers, or where they may be spread too near the enemy, so as to be in danger of being taken. This guard consists both of horse and foot, and must remain on their posts till the foragers are all come off the ground.

Main GUARD, is that from which all other guards are detached. Those who are for mounting guard assemble at their respective captain's quarters, and march from thence to the parade in good order; where, after the whole guard is drawn up, the small guards are detached to their respective posts: then the subalterns throw lots for their guards, who are all under the command of the captain of the main guard. This guard mounts in garrison at different hours, according as the governor pleases.

Piquet GUARD, a good number of horse and foot, always in readiness in case of an alarm: the horses are generally saddled all the time, and the riders booted.

The foot draw up at the head of the battalion, frequently at the beating of the tat-too; but afterwards return to their tents, where they hold themselves in readiness to march upon any sudden alarm. This guard is to make resistance in case of an attack, until the army can get ready.

Baggage GUARD, is always an officer's guard, who has the care of the baggage on a march. The waggoners should be numbered by companies, and follow

Guard.

Guard.

one another regularly: vigilance and attention in the passage of hollow ways, woods, and thickets, must be strictly observed by this guard.

Quarter GUARD, is a small guard commanded by a subaltern officer, posted in the front of each battalion, at 222 feet before the front of the regiment.

Rear GUARD, that part of the army which brings up the rear on a march, generally composed of all the old grand guards of the camp. The rear-guard of a party is frequently eight or ten horse, about 500 paces behind the party. Hence the advance-guard going out upon a party, form the rear-guard in their retreat.

Rear GUARD, is also a corporal's guard placed in the rear of a regiment, to keep good order in that part of the camp.

Standard GUARD, a small guard under a corporal, out of each regiment of horse, who mount on foot in the front of each regiment, at the distance of 20 feet from the freets, opposite the main street.

Trench GUARD, only mounts in the time of a siege, and sometimes consists of three, four, or six battalions, according to the importance of the siege. This guard must oppose the besieged when they fall out, protect the workmen, &c.

Provost GUARD, is always an officer's guard that attends the provost in his rounds, either to prevent desertion, marauding, rioting, &c. See PROVOST.

GUARD, in fencing, implies a posture proper to defend the body from the sword of the antagonist.

Ordinary GUARDS, such as are fixed during the campaign, and relieved daily.

Extraordinary GUARDS, or detachments, which are only commanded on particular occasions; either for the further security of the camp, to cover the foragers, or for convoys, escorts, or expeditions.

GUARDS, also imply the troops kept to guard the king's person, and consist both of horse and foot.

Horse GUARDS, in England, are gentlemen chosen for their bravery, to be entrusted with the guard of the king's person; and are divided into four troops, called the *1st*, *2d*, *3d*, and *4th troop of horse-guards*. The first troop was raised in the year 1660, and the command given to lord Gerard; the second in 1659, and the command given to Sir Philip Howard; the third in 1665, and the command given to earl Feverham; the fourth in 1660, and the command given to earl Newburgh. Each troop has one colonel, two lieutenant-colonels, one cornet and major, one guidon and major, four exempts and captains, four brigadiers and lieutenants, one adjutant, four sub-brigadiers and cornets, and 60 private men.

Horse-Grenadier GUARDS, are divided into two troops, called the *1st* and *2d troops of horse-grenadier guards*. The first troop was raised in 1693, and the command given to lieutenant-general Cholmondeley; the second in 1702, and the command given to lord Forbes. Each troop has one colonel, lieutenant-colonel, one guidon or major, three exempts and captains, three lieutenants, one adjutant, three cornets, and 60 private men.

Women of the GUARD, first raised by Henry VII. in the year 1485. They are a kind of pompous foot-guards to the king's person; and are generally called by a nickname, the *bee-eaters*. They were anciently

250 men of the first rank under gentry; and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 in constant duty, and 70 more not on duty; and when any one of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of king Henry VIII's time. Their first commander or captain was the earl of Oxford, and their pay is 2s. 6d. per day.

Foot-GUARDS, are regiments of foot appointed for the guard of his majesty, and his palace. There are three regiments of them, called the *1st*, *2d*, and *3d regiments of foot-guards*. They were raised in the year 1660; and the command of the first given to colonel Ruffel, that of the second to general Monk, and the third to the earl of Linlithgow. The first regiment is at present commanded by one colonel, one lieutenant-colonel, three majors, 23 captains, one captain-lieutenant, 31 lieutenants, and 24 ensigns; and contains three battalions. The second regiment has one colonel, one lieutenant-colonel, two majors, 14 captains, one captain-lieutenant, 18 lieutenants, 16 ensigns; and contains only two battalions. The third regiment is the same as the second.

The *French GUARDS* are divided into those within, and those without, the palace.—The first are the *gardes du corps*, or body-guards; which consist of four companies, the first of which companies was anciently Scots. See *SCOTS GUARDS*, *infra*.

The guards without are the *Gens d'Armes*, light horse, musqueteers, and two other regiments, the one of which is French, and the other Swiss.

SCOTS GUARDS; a celebrated band, which formed the first company of the ancient *gardes du corps* of France.

It happened from the ancient intercourse between France and Scotland, that the natives of the latter kingdom had often distinguished themselves in the service of the former. On this foundation the company of *Scots guards*, and the company of *Scots gendarmes*, were instituted.—Both of them owed their institution to Charles VII. of France, by whom the first standing army in Europe was formed, anno 1454; and their fates cannot but be interesting to Scotsmen. See *GENDARMES*.

Valour, honour, and fidelity, must have been very conspicuous features of the national character of the Scots, when so great and civilized a people as the French could be induced to choose a body of them, foreigners as they were, for guarding the persons of their sovereigns.—Of the particular occasion and reasons of this predilection, we have a recital by Lewis XII. a succeeding monarch. After setting forth the services which the Scots had performed for Charles VII. in expelling the English out of France, and reducing the kingdom to his obedience, he adds—"Since which reduction, and for the service of the Scots upon that occasion, and for the great loyalty and virtue which he found in them, he selected 200 of them for the guard of his person, of whom he made an hundred men at arms, and an hundred life-guards: And hundred men at arms are the hundred lances of our the ancient ordinances; and the life-guard men are those of our guard, who still are near and about our person."—As to their fidelity in this honourable station; the historian, speaking of Scotland, says, "The French have for ancient a friendship

History of Lewis XII. by Claud Seyll, master of request to that prince, and

Guard. and alliance with the Scots, that of 400 men appointed for the king's life-guard, there are an hundred of the said nation who are the nearest to his person, and in the night keep the keys of the apartment where he sleeps. There are, moreover, an hundred complete lances and two hundred yeomen of the said nation, besides several that are dispersed through the companies: And for so long a time as they have served in France, never hath there been one of them found, that hath committed or done any fault against the kings or their state; and they make use of them as of their own subjects."

The ancient rights and privileges of the Scottish life-guards were very honourable; especially of the twenty-four first. The author of the *Ancient Alliance* says, "On high holidays, at the ceremony of the *royal touch*, the erection of knights of the king's order, the reception of extraordinary ambassadors, and the public entries of cities, there must be six of their number next to the king's person, three on each side; and the body of the king must be carried by these only, wheresoever ceremony requires. They have the keeping of the keys of the king's lodging at night, the keeping of the choir of the chapel, the keeping the boats where the king passes the rivers; and they have the honour of bearing the *white silk fringe* in their arms, which in France is the *coron colour*. The keys of all the cities where the king makes his entry are given to their captain in waiting or out of waiting. He has the privilege, in waiting or out of waiting, at ceremonies, such as coronations, marriages, and funerals of the kings, and at the baptism and marriage of their children, to take duty upon him. The coronation-robe belongs to him: and this company, by the death or change of a captain, never changes its rank, as do the three others."

This company's first commander, who is recorded as a person of great valour and military accomplishments, was Robert Patillock, a native of Dundee; and the band, ever ardent to distinguish itself, continued in great reputation till the year 1578. From that period, the Scots guards were less attended to, and their privileges came to be invaded. In the year 1612, they remonstrated to Lewis XIII. on the subject of the injustice they had suffered, and set before him the services they had rendered to the crown of France. Attempts were made to re-establish them on their ancient foundation; but no negotiation for this purpose was effectual. The troops of France grew jealous of the honours paid them: the death of Francis II. and the return of Mary to Scotland, at a time when they had much to hope, were unfortunate circumstances to them: the change of religion in Scotland, was an additional blow: and the accession of James VI. to the throne of England, disunited altogether the interests of France and Scotland. The Scots guards of France have now, therefore, no connection with Scotland but the name.

GUARD-BOAT, a boat appointed to row the rounds amongst the ships of war which are laid up in any harbour, &c. to observe that their officers keep a good look-out, calling to the guard-boat as she passes, and not suffering her crew to come on board, without having previously communicated the watch-word of the night.

GUARD-SHIP, a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watchword kept duly, by sending her guard-boats around them every night. She is also to receive seamen who are imprisoned in the time of war.

GUARDIAN, in law, a person who has the charge of any thing; but more commonly it signifies one who has the custody and education of such persons as have not sufficient discretion to take care of themselves and their own affairs, as children and idiots.

Their business is to take the profits of the minor's lands to his use, and to account for the same: they ought to sell all moveables within a reasonable time, and to convert them into land or money, except the minor is near of age, and may want such things himself; and they are to pay interest for the money in their hands, that might have been so placed out; in which case it will be presumed that the guardians made use of it themselves. They are to sustain the lands of the heir, without making destruction of any thing thereon, and to keep it safely for him: if they commit waste on the lands, it is a forfeiture of the guardianship, 3 Edw. I. And where persons, as guardians, hold over any land, without the consent of the person who is next intitled, they shall be adjudged trespassers, and shall be accountable; 6 Ann. cap. xviii.

GUARDIAN, or Warden, of the Cinque-ports, is an officer who has the jurisdiction of the Cinque-ports, with all the power which the admiral of England has in other places.

GUARDIAN of the Spiritualities, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant. A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province; or by delegation, as he whom the archbishop or vicar-general for the time appoints. Any such guardian has power to hold courts, grant licences, dispensations, probates of wills, &c.

GUARINI (Battista), a celebrated Italian poet, born at Ferrara, in 1538. He was great-grandson to Guarino of Verona and was secretary to Alphonso; Duke of Ferrara, who entrusted him with several important commissions. After the death of that prince, he was successively secretary to Vincenzo de Gonzaga, to Ferdinand de Medicis grand duke of Tuscany, and to Francis Maria de Feltri duke of Urbino. But the only advantages he reaped under these various masters, were great encomiums on his wit and compositions. He was well acquainted with polite literature; and acquired immortal reputation by his Italian poems, especially by his *Pastor Fido*, the most known and admired of all his works, and of which there have been innumerable editions and translations. He died in 1612.

GUARDIA, or GUARDA, a town of Portugal, in the province of Beira, with a bishop's see. It contains about 2300 inhabitants, is fortified both by art and nature, and has a stately cathedral. W. Lon. 5. 17. N. Lat. 40. 20.

GUARDIA-Alferaz, a town of Italy, in the kingdom of Naples, and in the Contado-di-Molise, with a bishop's see. E. Lon. 15. 53. N. Lat. 51. 50.

GUARGALA, or GUERGUELA, a town of Africa,

Gustalla
||
Guber.

rica, and capital of a small kingdom of the same name, in Biedlergerid, to the S. of Mount Atlas. E. Lon. 9. 55. N. Lat. 28. 0.

GUASTALLA, a strong town of Italy, in the duchy of Mantua, with the title of a duchy, remarkable for a battle between the French and Imperialists in 1734. It was ceded to the duke of Parma in 1748, by the treaty of Aix-la-Chapelle. It is seated near the river Po, in E. Lon. 10. 33. N. Lat. 44. 55.

GUATIMALA, the Audience of, in North America, and in New Spain, is above 750 miles in length, and 450 in breadth. It abounds in chocolate, which they make use of instead of money. It has 12 provinces under it: and the native Americans, under the dominions of Spain, profess Christianity; but it is mixed with great many of their own superstitions. There is a great chain of high mountains, which run across it from E. to W. and it is subject to earthquakes and storms. It is however very fertile; and produces, besides chocolate, great quantities of cochineal and cotton.

GUATIMALA, a province of North America, in New Spain, and in the Audience of the same name; bounded on the W. by Soconusco, on the N. by Verapaz and Honduras, on the E. by Nicaragua, and on the S. by the fourth sea. St. Jago de Guatemala is the capital of the whole audience.

GUATIMALA, a large and rich town of North America, in New Spain; and capital of a government of the same name, with a bishop's see, and an university. It carries on a great trade, especially in chocolate. W. Lon. 91. 30. N. Lat. 14. 0.

GUATIMALA (the Volcano of), is a mountain, which throws out fire and smoke. St. Jago de Guatemala was almost ruined by it in 1541. It was afterwards rebuilt at a good distance from this dreadful mountain. A few years ago, however, it was again destroyed, with circumstances more terrible perhaps than any mentioned in history.

GUAXACA, a province of North America, in New Spain, which is very fertile in wheat, Indian corn, cochineal, and cassia. It is bounded by the gulph of Mexico on the N. and by the fourth sea on S. It contains mines of gold, silver, and crystal. Guaxaca is the capital town.

GUAXACA, a town of North America, in the Audience of Mexico, and capital of a province of the same name, with a bishop's see. It is without walls, and does not contain above 2000 inhabitants; but it is rich, and they make very fine sweet-meats and chocolate. It has several rich convents, both for men and women. W. Lon. 100. 0. N. Lat. 17. 45.

GUAYRA, a district of the province of La Plata, in South America, having Brasil on the E. and Paraguay on the W.

GUBEN, a handsome town of Germany, in Lower Lusatia, seated on the river Niesse, and belonging to the house of Sax-Merfenburg. E. 14. 59. N. Lat. 51. 55.

GUBER, a kingdom of Africa, in Negroland. It is surrounded with high mountains; and the villages, which are many, are inhabited by people who are employed in taking care of their cattle sheep. There are also abundance of artificers, and linen-weavers, who send their commodities to Tombuto. The whole country is overflowed every year by the inundations of

the Niger, and at that time the inhabitants sow their rice. There is one town, which contains almost 6000 families, among whom are many merchants.

GUBIO, a town of Italy, in the territory of the church, and in the duchy of Urbino, with a bishop's see. E. Lon. 12. 41. N. Lat. 43. 18.

GUDGEON, in ichthyology; a species of cyprinus. See CYPRINUS.

This fish, though small, is of so pleasant a taste, that it is very little inferior to smelt. They spawn twice in the summer-season; and their feeding is much like the barbel in streams and on gravel, dighting all manner of flies: but they are easily taken with a small red worm, fishing near the ground; and being a leather-mouthed fish, will not easily get off the hook when struck.—The gudgeon may be fished for with float, the hook being on the ground; or by hand, with a running line on the ground, without cork or float. But although the small red worm above-mentioned is the best bait for this fish, yet wasps, gentles, and cad-baits will do very well. You may also fish for gudgeons with two or three hooks at once, and find very pleasant sport, where they rise any thing large. When you angle for them, stir up the sand or gravel with a long pole; this will make them gather to that place, bite faster, and with more eagerness.

Sea-GUDGEON, Rock-fish, or Black Goby. See GOBIUS.

GUELPHS, or GUELFs, a celebrated faction in Italy, antagonists of the GIBELINS. See GIBELIN.

The Guelphs and Gibelins filled Italy with blood and carnage for many years. The Guelphs stood for the Pope, against the emperor. Their rise is referred by some to the time of Conrad III. in the twelfth century; by others, to that of Frederic I.; and by others, to that of his successor Frederic II. in the thirteenth century.

The name of Guefs is commonly said to have been formed from *Welfs*, or *Welfs*, on the following occasion: the emperor Conrad III. having taken the duchy of Bavaria from Welfe VI. brother of Henry duke of Bavaria, Welfe, assisted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the Guefs.

Others derive the name *Guefs* from the German *Wolfs*, on account of the grievous evils committed by that cruel faction: others deduce the denomination from that of a German called *Guefs*, who lived at Pi-sfoye; adding, that his brother, named *Gibel*, gave his name to the Gibelins. See (History of) ITALY.

GUELDERLAND, one of the united provinces, bounded on the W. by Utrecht and Holland, on the E. by the bishoprick of Munster and the duchy of Cleves, on the N. by the Zuyder sea and Overysse, and on the S. it is separated from Brabant by the Maas. Its greatest extent from N. to S. is about 47 miles, and from W. to E. near as much; but its figure is very irregular. The air here is much healthier and clearer than in the maritime provinces, the land lying higher. Excepting some part of what is called the *Veluwe*, the soil is fruitful. It is watered by the Rhine, and its three branches, the Wahal, the Yssel, and the Leck, besides lesser streams. In 1079, it was raised to a county by the emperor Henry IV. and in 1339 to a duchy by the emperor Lewis of Bavaria. It had dukes of its own till 1528, when it was yielded up to the

Gubio
||
Guelder-
land.

Guel-
dres
||
Guernsey.

the emperor Charles V. In 1579, it acceded to the union of Utrecht. It is divided into three districts, each of which has its states and diets. Those for the whole province are held twice a-year at the capital towns. The province sends 19 deputies to the states-general. Here are computed 285 Calvinist ministers, 14 Roman-Catholic congregations, 4 of the Lutheran persuasion, besides 3 others of Remonstrants and Anabaptists. The places of most note are Nimeguen, Zutphen, Arnheim, Harderwyk, Loo, &c.

GUELDRES, a strong town of the Netherlands, in the duchy of the same name. It was ceded to the king of Prussia by the peace of Utrecht, and is seated among marshes. E. Lon. 6. 21. N. Lat. 51. 30.

GUERICKE, or GUERICHE, (Otho), the most celebrated mathematician of his time, was born in 1602. He was the inventor of the air-pump; and author of several works in natural philosophy, the chief of which is *Experimenta Magdeburgica*. He died in 1686.

GUERNSEY, an island in the English channel, on the coast of Normandy, subject to Britain; but, (as well as the adjacent islands,) governed by its own laws. See JERSEY.—Of this island, Dr Campbell gives the following account. "It lies 20 leagues south-west from Weymouth in Dorsetshire, between eight and nine leagues west from the coast of Normandy, 13 south of Bretagne, seven north-west from Jersey, five south-west from Alderney, and two west from Sark. In length from north-east to south-west, about twelve miles; in breadth, from south to north, about nine; in circumference, upwards of 30; containing 50 square miles, or 32,000 acres. The climate is mild and temperate; not subject to excessive heats, much less to severe cold; somewhat windy; but, taking all things together, equally healthy and pleasant. The soil is, generally speaking, rich and fertile; the country, though sufficiently inclosed with stone fences, yet more open than in Jersey, and as capable of cultivation of every kind. On the north side, the coast is commonly low and flat, rising gradually, so that on the south side the cliffs are of a prodigious height. The face of the country is variegated with hills and little eminences, and tolerably well watered with springs and sharp gravelly streams. There was formerly a fine lake, about half a league in extent, now filled up, and turned into a meadow; but many gentlemen have still very beautiful and convenient fish-ponds.

"There are very few countries in the world more capable of improvement. Most of the rising grounds afford a short thick grass, equally beautiful to the eye, and succulent as pasture. Roots and herbs it produces of all kinds, esculent, medicinal, and aromatic; with a profusion of flowers that grow wild, and are exquisitely fragrant. All sorts of shrubs and fruit-trees flourish here: and there is some, though but little timber; not through any defect of soil or climate, but because they cannot conveniently afford it room. Grain they have of every species we cultivate in Britain, but more especially wheat; and though they have not either lime, chalk, or marl, yet the sea-wreck answers all the intention of manure, so well as to keep their ground in constant heart. They have large quantities of sheep, but small in size; and had formerly a very singular breed, of which the ewes had

four horns, and the rams six; but these are now become very scarce. Their black cattle are in such abundance, as not only to support their own uses, but to furnish also a considerable exportation; and their horses, though but little, are equally strong and hardy. The sea also furnishes a prodigious variety as well as plenty of fish, more especially red and grey mullet, excellent mackerel, and, above all, conger-eels. To these advantages we may add, the singular privilege of being free from all venomous creatures.

"There are in this island ten parishes, each of which is divided into several vintons, for the more easy management of affairs, civil, ecclesiastical, and military, and the choice of their respective officers and magistrates. Though the country is very fully peopled, yet the houses are scattered up and down, according to the humour or the convenience of the inhabitants: so that there is, properly speaking, but one town in the island, which is likewise the only haven of any resort; though there are some creeks on the north and west sides of the island, such as Bazon, L'Aucresse, Ferminer, St Sampson, and the West Passage. All these ports are in a state of nature; but might be certainly improved and fortified, which would be productive of many advantages to the island; as was long ago observed and proposed to government by captain Yarranton. In the reign of king Charles II. when the French formed an insidious design of making themselves masters of this isle by treachery, it left such an impression on his majesty's mind, that some years after he sent over the lord Dartmouth, accompanied by certain engineers, who discovered on the north-west side of the isle, a deep bay, which, by the help of a mole, might cover a numerous squadron, even of ships of the line, under the protection of what was also intended to be built, a strong castle: but his exchequer being exhausted, this necessary work was never carried into execution. As this port would look full into the channel, it deserves consideration, how far it might be useful to us in the time of a French war, and of what infinite detriment it might prove if this island should ever fall into the hands of our enemies.

"The inhabitants are very industrious in their respective employments; naturally sober, frugal in their manner of living, honest in their dealings, sincere in their religion, which is that of the church of England, and loyal to their princes, as well as steady to the British interest. They are, however, reserved to a degree that makes them sometimes thought morose; they are somewhat suspicious; and, which is their greatest error, they are, or at least were, very litigious. They are good husbandmen in their own way, and manage the sea-wreck (which first serves the poor people for fuel, and then its ashes are employed by those in better circumstances for manure) with great skill, and under very prudent regulations. The wreck is cut in summer, and about the vernal equinox, by the proclamation of the magistrates, and when dried, distributed by their order. As for the winter-wreck, which after storms is thrown in large quantities on the coast; this is also equitably divided, and being strewed wet, and so ploughed into the ground, renders it continually fertile. They have a stronger turn, however, to grazing, than to agriculture; and though they bring in annually some corn, yet in the same space they send out a few hundred cattle,

Guernsey.

Guernsey.

cattle. They are still more inclined to orchards, which enables them to make many thousand hogheads of cyder every year; of which, it being the common drink of the people, they export but little. The woollen is their principal manufacture, for the carrying on of which they are allowed to import 2000 tons from England, which they work up chiefly in stockings, waistcoats, and breeches. They might certainly make their fishery turn to profit, more especially as of late years they have set up salt-works; and yet, except lobsters, I never heard that any of their fish went to a foreign market. Our French and Portugal merchants have large flocks of wine here, which they import as they have occasion. As they are enabled, by this method, to keep it to a proper age before they are obliged to pay the duty, it seems to be a benefit to the mother-country, by putting it in their power both to buy and sell cheaper: as on the other hand, from the rent of warehouses, the subsisting factors and their servants, the resort of ships employed in this trade, it must be very advantageous to the inhabitants of this island. It is a point of justice to observe, that this manner of depositing wines, has nothing at all to do with smuggling; a practice equally injurious to the interests of this country and to the people of Guernsey, as it breeds few seamen, is carried on in very small vessels, and upon the whole is not only an infamous, but a very unprofitable kind of traffic. Heretofore, merchants of this isle traded to most parts of Europe, and had several stout ships of their own; and if this vile practice was abolished, as it might easily be, without any violation of the liberties of the people, they would soon find their account in it, by the revival of many lucrative branches of commerce. As they take from England some of the necessaries, and almost all the conveniences, of life, such as corn, malt-liquor, sugars, spices, coals, household-furniture, many species of the iron and leather manufactures, grocery, haberdashery, and hard-ware, the balance is greatly in our favour; and must continually increase, in proportion as they augment in number, and grow easier in circumstances. At present, upon a very moderate computation, there are in Guernsey upwards of 15,000 souls.

"The several islets and vast chains of rocks that surround this country on every side, and cause such a variety of tides and currents, add much to the security of the place, by rendering it equally difficult and dangerous for ships to approach it, unless they have pilots aboard extremely well acquainted with the coast. On the south side, the cliffs are prodigiously high; so that the old writers say, it looks like a park in the sea, impaled with rocks. On the west side lie the Hanoyas, or, as the French write them, *Hanovaux*, which cover that coast so effectually, that a descent there is little to be feared. At the north-west extremity lies a little island called the *Howe*; which would be a very convenient place for a salt-work, glass-house, or manufactory of soap. At the north-east extremity we meet with St Michael in the vale, a peninsula some miles in extent, connected with Guernsey by a very narrow isthmus, with bays that might be rendered useful on both sides. This peninsula is likewise guarded by rocks and islets, the most considerable of which are the Bryants, the Hummet, and the Hays. South-east from the vale, lies the island of Harnet, or Arne, about

a league in compass, formerly desart, but now cultivated. At a league south from thence lies Brichoe, of less extent; and between both, the little island of Gythau, or Jethau, which serves the governor for a kind of park, or rather paddock.

GUIANA, a large country of South America, is bounded on the east and north by the Atlantic ocean, and the river Oroonoko; on the south, by the river of the Amazons; and on the west, by the provinces of Grenada and New-Andalusia, in Terra-Firma, from which it is separated both on the west and north by the river Oroonoko. It extends above 1200 miles from the north-east to the south-west, that is, from the mouth of the river Oroonoko to the mouth of the river of Amazons, and near 600 in the contrary direction.

Most geographers divide it into two parts, calling the country along the coast *Caribbeana Proper*, and the interior country *Guiana Proper*: the last is also styled *El Dorado* by the Spaniards, on account of the immense quantity of gold it is supposed to contain.

The Portuguese, French, and Dutch, have all settlements along the coast. What lies south of Cape North belongs to the first of these nations; the coast between Cape North and Cape Orange is possessed by the natives; French Guiana, Old Cayenne, or Equinoctial France, extends from Cape Orange, about 240 miles along the coast, to the river Marani; where the Dutch territory begins, and extends to the mouth of the Oroonoko.

Along the coast, the land is low, marshy, and subject to inundations in the rainy season, from a multitude of rivers which descend from the inland mountains. Hence it is, that the atmosphere is suffocatingly hot, moist, and unhealthy, especially where the woods have not been cleared away. Indeed, the Europeans are forced to live in the most disagreeable situations, and fix their colonies at the mouths of the rivers, amidst stinking marshes, and the putrid ooze of salt morasses, for the convenience of exportation and importation.

"Dutch Guiana (according to an account lately published by a gentleman who resided several years at Surinam as a physician) was first discovered by Columbus in 1498. It lies between the 7° of north, and the 5° of south latitude, and between the 53° and 60° of longitude west from London. It is bounded on the north and east, by the Atlantic; on the west, by the rivers Oroonoko and Negroe; and on the south, by the river of Amazons.

"It is now divided between the Spaniards, Dutch, French, and Portuguese; but except its sea-coast, and lands adjacent to its rivers, it has hitherto remained unknown to all but its original natives; and even of these, it is only the Dutch territories that foreigners have any knowledge of; for those of the Spaniards, French, and Portuguese, are inaccessible to them.

"This country, on account of the diversity and fertility of its soil, and of its vicinity to the equator, which passes through it, affords almost all the productions of the different American countries between the tropics, besides a variety peculiar to itself.

"Dutch Guiana was formerly the property of the English, who made settlements at Surinam, where a kind

Guiana.

kind of corrupt English is still spoken by the negroes. The Dutch took it in the reign of Charles the Second; and it was ceded to them by a treaty in 1674, in exchange for what they had possessed in the province now called *New York*.

The land for 50 miles up the country from the sea-coast is flat; and, during the rainy seasons, covered two feet high with water. This renders it inconceivably fertile, the earth, for 12 inches deep, being a stratum of perfect manure: an attempt was once made to carry some of it to Barbadoes; but the wood-ants so much injured the vessel, that it was never repeated. The excessive richness of the soil is a disadvantage, for the canes are too luxuriant to make good sugar; and, therefore, during the first and second crop, are converted into rum.

There are some trees on this part; but they are small and low, consisting chiefly of a small species of palm, intermixed with a leaf near 30 feet long and three feet wide, which grows in clusters, called a *Troaslie*; and, at the edges of running-water, with mangroves.

Farther inward the country rises; and the soil, though still fertile, is less durable. It is covered with forests of valuable timber, that are always green; and there are some sandy hills, though no mountains; in the French territories, however, there are mountains, according to the report of the Indians, for they have never been visited by any other people.

In this country the heat is seldom disagreeable: the trade-winds by day, the land breezes in the evening, and the invariable length of the nights, with gentle dews, refresh the air, and render it temperate and salubrious. There are two wet seasons, and two dry, of three months each, in every year; and, during more than a month in each wet season, the rain is incessant. The dry seasons commence six weeks before the equinoxes, and continue six weeks after. The wet seasons are more wholesome than the dry, because the rains keep the waters that cover the low lands, next the sea, fresh and in motion; but during the dry season it stagnates, and, as it wastes, becomes putrid, sending up very unwholesome exhalations. Blossoms, green and ripe fruit, are to be found upon the same tree in every part of the year. There are some fine white and red agates in Guiana, which remain untouched; and mines of gold and silver, which the Dutch will not suffer to be wrought.

The inhabitants of Guiana are either natives, who are of a reddish brown; or negroes and Europeans; or a mixed progeny of these in various combinations. The natives are divided into different tribes, more or less enlightened, and polished, as they are more or less remote from the settlements of the Europeans. They allow polygamy, and have no division of lands. The men go to war, hunt, and fish; and the women look after domestic concerns, spin, weave, in their fashion, and manage the planting of cassava and manive, the only things which in this country are cultivated by the natives. Their arms are bows and arrows; short poisoned arrows, blown through a reed, which they use in hunting; and clubs made of a heavy wood called *iron-wood*. They eat the dead bodies of those that are slain in war, and sell for slaves those they take prisoners; their wars being chiefly undertaken to fur-

VOL. V.

nish the European plantations. All the different tribes go naked. On particular occasions they wear caps of feathers; but, as cold is wholly unknown, they cover no part but that which distinguishes the sex. They are cheerful, humane, and friendly; but timid, except when heated by liquor, and drunkenness is a very common vice among them.

Their houses consist of four stakes set up in a quadrangular form, with crofs poles, bound together by slit nibbees, and covered with the large leaves called *troaslies*. Their life is ambulatory; and their house, which is put up and taken down in a few hours, is all they have to carry with them. When they remove from place to place, which, as they inhabit the banks of rivers, they do by water in small canoes, a few vessels of clay made by the women, a flat stone on which they bake their bread, and a rough stone on which they grate the roots of the cassava, a hammock and a hatchet, are all their furniture and utensils; most of them, however, have a bit of looking-glass framed in paper, and a comb.

Their poisoned arrows are made of splinters of a hard heavy wood, called *cacario*; they are about 12 inches long, and somewhat thicker than a coarse knitting needle: one end is formed into a sharp point; round the other is wound some cotton, to make it fit the bore of the reed through which it is to be blown. They will blow these arrows 40 yards with absolute certainty of hitting the mark, and with force enough to draw blood, which is certain and immediate death. Against this poison no antidote is known. The Indians never use these poisoned arrows in war, but in hunting only, and chiefly against the monkeys; the flesh of an animal thus killed may be safely eaten, and even the poison itself swallowed with impunity.

GUIAQUIL, a town, bay, and harbour of South America, in Peru, and capital of an audience of the same name. W. Long. 76. 55. S. Lat. 2. o.

GUIARA, a sea-port town of South America, and on the Caracca coast. The English attempted to take it in 1749 and 1743; but they were repulsed both times. W. Long. 66. 5. N. Lat. 10. 35.

GUICCIARDINI (Francisco), a celebrated historian, born at Florence in 1482. He professed the civil law with reputation, and was employed in several embassies. Leo X. gave him the government of Modena and Reggio, and Clement VII. that of Romagna and Bologna. Guicciardini was also lieutenant-general of the pope's army, and distinguished himself by his bravery on several occasions; but Paul III. having taken from him the government of Bologna, he retired to Florence, where he was made counsellor of state, and was of great service to the house of Medicis. He at length retired into the country to write his History of Italy, which he composed in Italian, and which comprehends what passed from the year 1494 to 1532. This history is greatly esteemed; and was continued by John Baptist Adriani, his friend. He died in 1540.

GUICCIARDINI (Lewis), his nephew, composed a history of the Low Countries, and memoirs of the affairs of Europe, from 1530 to 1560. He wrote with great spirit, against the persecution of the duke d'Alva, for which he imprisoned him. Died in 1583.

GUIDI (Alexander), an eminent Italian poet,

born at Pavia in 1650. Having a desire to see Rome, he there attracted the notice of queen Christina of Sweden, who retained him at her court; he beside obtained a considerable benefice from pope Innocent XI. and a pension from the duke of Parma. For a good office he did the state of Milan with prince Eugene, he was enrolled among the nobles and decorations of that town; and died in 1712. Nature had been kinder to his intellects than to his exterior form; his body was small and crooked, his head was large, and he was blind of his right eye. A collection of his works was published at Verona in 1726.

GUIDO (Reni), an illustrious Italian painter, born at Bologna in 1575. In his early age he was the disciple of Denis Calvert, a Flemish master of good reputation; but afterwards entered himself in the school of the Caracci. He first imitated Ludovico Caracci; but fixed at last in a peculiar style of his own, that secured him the applause of his own time and the admiration of posterity. He was much honoured, and lived in splendor; but an unhappy attachment to gaming ruined his circumstances; the reflection on which brought on a languishing disorder, that put an end to his life in 1642. There are several designs of this great master in print, etched by himself.

GUIENNE, the largest province of France, bounded on the north by Saintonge, Angoumois, and Limousin; on the east by Limousin, Auvergne, and Languedoc; on the south by the Pyrenees, Lower Navarre, and Bearn; and on the west by the ocean. It is about 225 miles in length, and 200 in breadth. It is divided into the Upper and Lower. The Upper comprehends Querci, Rouergue, Armagnac, the territory of Comminges, and the county of Bigorre. The Lower contains Bourdelois, Perigord, Agenois, Condomois, Bazadois, the Lander, Proper Gascony, and the district of Labour. The principal rivers are the Garonne, the Adour, the Tarn, the Aveyron, and the Lot. Bourdeaux is the capital town.

GUILLANDINA, the NICKAR TREE; a genus of the monogynia order, belonging to the decandria class of plants.

Species. 1. The bonduc, or yellow nickar. 2. The bonducella, or gray nickar. These are climbing plants, natives of the West Indies, where they rise to the height of twelve or fourteen feet: the flowers come out at the wings of the stalks; and are composed of five concave yellow petals. They are succeeded by pods about three inches long and two broad, closely armed with slender spines, opening with two valves, each inclosing two hard seeds about the size of children's marbles, of a yellowish colour. 3. The moringa, or morunga nickar, is a native of the island of Ceylon, and some places on the Malabar coast. It rises to the height of 25 or 30 feet, having flowers produced in loose bunches from the side of the branches, and composed of an unequal number of petals.

Culture and Uses. These plants being natives of warm climates, require to be kept through the winter in a stove in this country. They are propagated by seeds; but those of the first sort are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they

will remain for years without vegetating.—The roots of the third sort are scraped when young, and used by the inhabitants of Ceylon and Malabar as those of horle-radish are in Europe. The wood dyes a beautiful blue colour.

GUILD, (from the Saxon *gildan*, to "pay"), signifies a fraternity or company, because every one was *gildare*, i. e. to pay something towards the charge and support of the company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed; upon which the neighbours entered into an association, and became bound for each other, either to produce him who committed any offence, or to make satisfaction to the injured party: in order to this, they raised a sum among themselves, which they put into a common stock; out of which they, upon occasion, made a pecuniary compensation according to the quality of the offence committed. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough. See *Borough*.

Every royal borough has a dean of *guild*, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, water-courses, and other nuisances; calls courts, at which his brethren of the *guild* are bound to attend; manages the common stock of the *guild*; and amerces and collects fines.

GUILD, *Gild*, or *Geld*, is also used among our ancient writers, for a compensation, or mulct, for a fault committed.

GUILD-HALL, the chief hall of the city of London, for holding of courts, and for the meeting of the lord-mayor and commonalty, in order to make laws and ordinances for the welfare and regulation of the city.

Dean of *Guild*, in Scots law, a magistrate of a royal borough, who is head of the merchant-company. See *Law*, N^o clviii. 11.

GULDFORD, or GULDEFORD, a borough-town of Surrey, situated on the river Wye, thirty-miles south-west of London. It sends two members to parliament. Long. 0. 40. N. Lat. 51. 16.

GUILLEMOT, in ornithology. See *Colymbus*.

GUILLIM, (John), of Welsh extraction, was born in Herefordshire, about the year 1565. Having completed his education at Brazen-nose college, Oxford, he became a member of the college of arms in London; and was made *rouge croix* purfuitant, in which post he died in 1621. He published, in 1610, a celebrated work, intitled *the Display of Heraldry*, folio, which has gone through many editions. To the fifth, which came out in 1679, was added *A treatise of honour civil and military*, by captain John Loggan.

GUINEA, a large tract of country lying along the west side of the continent of Africa. It is divided into the upper and lower, the latter of which is also called *Congo*. See *Congo*.—These two together, reckoning from Cape Tigrin, near the mouth of the river Sierra Leoni in N. Lat. 9° 18', to Cape Negro

Guinea.

Guinea.

gro in S. Lat. 16° 45', extend about 2500 miles along the sea-coast, and many more, if we reckon all the turnings, windings, and bays. As for its inland extent, it is not easy to ascertain it.

As all this country lies between the tropics, the air is excessively hot, especially from the beginning of September to the end of March, which, with the coolness of the nights, the frequent thick, stinking, sulphureous mists, and the periodical rains, when the flat country is overflowed, makes it very unhealthy, especially to Europeans, to whom it is generally fatal. The winds on the coast of Guinea Proper set from west to east, directly contrary to the trade-winds, except in the rainy season, between the vernal and autumnal equinox, when they have violent storms of wind, with terrible thunder and lightning: and these winds blowing from the south, the shipping on the coast at this time are in great danger of being wrecked; and, even in the calmest weather, there is always such a surf beating upon the shore, that it is very difficult and dangerous landing. As to the face of the country, a variety of hills, valleys, woods, and plains, are seen all along the coast, intermixed with bogs and morasses.

The animals of Guinea are the same as those of Caffraria; but their grain is different. Here is no wheat; but plenty of Guinea grain, rice, maize, or Indian corn. There are no grapes here; but the palm-tree affords them wine, and their cocoa-nuts a pleasant drink. Here are also oranges and lemons, plantains, pomegranates, tamarinds, pine-apples, and other tropical fruits.

Of forest-trees they have a great variety, which grow to a prodigious height and bulk; some of them being excellent timber, and having a very beautiful grain.

Their metals are gold, copper, and iron. The gold is found by the natives in the sands of their rivulets in dust; sometimes they meet with large pieces, but there are no gold mines open, and possibly there may be no mines of that metal. As it is found washed down into the brooks and rivulets in every place our people bring it from, it seems probable that it lies pretty near the surface. There is plenty of salt on the Guinea coast; which they make by letting the salt-water into shallow pans in the dry seasons, and the sun exhaling the water, the salt is left at bottom.

Besides gold, ivory, and slaves, this country affords indigo, wax, gum-fenega, gum-tragacanth, and a variety of other gums and drugs. These articles may be had in most parts of this extensive coast, but chiefly in Proper Guinea.

Of mountains in Guinea, the most remarkable are those of Sierra Leoni. The principal capes are those of Cape Blanco, Cape Verd, Cape Leon, Cape St. Ann's, Cape Palmas, and Cape Three-Points, Cape Formosa, Cape Monte, Cape St. John, Cape Lopes, Cape Ledé, and Cape Negro. The chief bays are the Cyprian or Cintra Bay, and the Bite of Guinea. Of the rivers, the most considerable are those of Coanzo and Ambrisi, the Zaara, the Lunde, the Cameron, the Formosa, the Volta, the Sierra Leon, and the Sherbro. All these run from east to west, (except the Volta, which runs from north to south),

and fall into the Atlantic.

The natives of Guinea, descended from the original inhabitants, are all negroes, well known by their flat noses, thick lips, and short woolly hair; though there are among them many camps or villages of Arabs, who are of a tawny complexion; and there is a mixed breed of Mulattoes, proceeding from the commerce of the Portuguese and natives, who are almost as dark as the negroes.

As to their habits, the common people have generally only a cloth about their middle; but people of condition have another over their shoulders, and are adorned with abundance of rings, and bracelets of gold, ivory, or copper: the arms, legs, and a great part of the bodies of the men are naked; but the women are veiled, when they go abroad.

The Europeans tell us, that the natives have generally more wit than honesty, frequently mixing their gold with base metal: but there is reason to suspect, that the little tricks and cheats they use in trade have been taught them by the Christians with whom they traffic; and if the women are lewd, they are not worse than those that accuse them, who first tempt them to incontinence, and then reproach them for it.

Every family almost in Guinea make their own tools and utensils: they are all smiths, carpenters, and masons; building their own houses or huts, which are, indeed, of very slight materials; and, till the Europeans brought them hammers, &c. one stone served them for an anvil, and another for a hammer. The women manage all the husbandry, as well as their domestic affairs: they dig, sow, plant, and bring in the harvest, while the husband looks on: so that the more wives a man has, the richer he is said to be in this country; and some negroes on the coast make money by letting out their wives; and, indeed, they make little difference between their wives and their slaves.

The small-pox is as fatal to the negroes as the plague, and worms are an epidemical distemper; not those in the stomach and bowels; but a species that are found between the skin and the flesh, and give the patient extreme pain, till they are drawn out: which is an operation that sometimes takes a month to perform; for, if they attempt to draw it out too hastily, the worm breaks, and rots in the flesh, or breaks out in another place. Some negroes have nine or ten of these worms in their skin at once, and the Europeans are not entirely free from them. A greedy ravenous appetite is also reckoned among the diseases of the Guinea negroes; and the venereal disease is often fatal to them, having no effectual methods of cure of their own: nor are the wounds they receive in the field of Mars less dangerous than the other, especially if the bones are shattered; for they can cure only ordinary flesh-wounds, which they do by applying poultices of herbs. The negroes are seldom long-lived, though they are generally healthful while they live.

The distempers the Europeans are subject to on this coast are fevers, fluxes, and colics, which are occasioned by indifferent water and bad air; their settlements lying near the coast, where the fogs and streams arising from the ooze and salt-marshes, and

Guinea.

the stinking fish the natives dry on the beach, corrupt the air, and render it fatal to the foreigners. The most temperate men find it difficult to preserve their health; but a great many hasten their death by their intemperance, or negligence, exposing themselves to the cold air in the evening, after a very hot day. This sudden change, from one extreme to the other, has often very bad effects in hot climates.

As to religion, the natives generally acknowledge one Supreme Being, that created the universe; and yet pay him no manner of worship or adoration, never praying to him, or giving him thanks for any thing they enjoy. They believe he is too far exalted above poor mortals to take notice of them; and therefore pray to a multitude of inferior deities, of which there are some common to whole nations, and yet every man has a god of his own choosing besides.

In Guinea there are some sovereign princes, whose dominions are very extensive, rich, powerful, and themselves arbitrary, limited by no laws, or any other restraint; and there are many others, to whom the Dutch and other Europeans have given the name of kings, whose dominions do not exceed the bounds of an ordinary parish, and whose power and revenues are proportionably mean.

The country of Guinea-*Proper* extends from Cape Palmas to the river Volta, about an hundred and fifty leagues along the sea-coast, which bounds it to the south. The Europeans divide it into two parts, the Tooth and the Gold Coast; the former extending from Cape Palmas to the river Sucria da Costa, 18 miles west of the river Mancha, by some called *Rio Cobre*, and Aukeber; and the latter from thence to the river Volta.

The Tooth, Ivory, or Quaqua Coast, is so called from the great plenty of elephants teeth found there. According to Dapper, the inhabitants of this coast, though they seem the most barbarous and savage people of all Guinea, are really the most civilized and the most reasonable, and pass for such among their neighbours. When they come to trade with any ship, they take some water into their hands, and let a few drops of it fall into their eyes; which is a kind of oath, by which they intimate, that they would rather lose their eye-sight than cheat those they trade with. They are no less averse to drunkenness than to fraud; and though their country produces numbers of palm-trees, yet they drink no palm-wine, but only a certain liquor, called *bordon*, or *tombo-wine*, which they mix with water. Their chief manufactures and trade consist in cotton habits, which are called *Quaqua gowns*, and are made of five or six breadths sewed together. One of the fundamental laws of this country is, that every one is obliged to continue all his life-time in the condition in which he was born; so that one whose father was a fisherman, for instance, can never become any thing else but a fisherman, and so of all other trades and professions.

The Gold-coast had its name given it by the Portuguese, from the immense quantity of that precious metal it produces: the same reason has made all the other nations of Europe retain the same appellation. According to the best charts, the situation of the Gold-coast is between 4° 30' and 8° north latitude, and 16° and 8° 4' of longitude, beginning at the river

Guinea.

Ankobar, and extending to the Rio Volta, that is, about 130 leagues from west to east. The beginning of the Gold-coast, however, is placed by many at Rio de Suero da Colla, near Iknui, that being the first place where gold is found; and the end at Lay, in the country of Lampi, three or four leagues from Akra, because there the gold is procured but accidentally, from a people called *Anaho*, inhabiting the more distant interior country.

This coast contains a variety of different kingdoms and states, viz. Adomir, called likewise *Saku*, and *Avina*: Axim, Ankobar, Adom, likewise called *Little Inkassan*, or *Warshe*; Jabi, or Jabs; Commendo, or Guaflo; Fetu, Sabo, Fantin, Ackron, Agonna, or Anguirra; Amra, or Aquambus, Lubbadé, and Ningó, or Lampi. Each of the above divisions, provinces, or kingdoms, have one, two, or more towns or villages on the sea-coast, between or under the European forts and settlements. Eight of them are real monarchies, having their own proper kings, who, before the arrival of the Europeans, were called *captains*; the rest are republics, governed by magistrates, who are subject to the laws, and periodical changes. Upon the river Cobre or Ankobar, and in the country of that name, which is properly the first country of the Gold-coast, there are a number of towns, in the three provinces of Ankobar, Aborrel or Abocro, and Eguira. The first is a monarchy; the two latter republics. For a number of years the Dutch had a fort at Eguira; and their gold trade, besides what they drew from the neighbouring countries, was very considerable, this canton having its own proper mines; but lost all their footing in the country by a quarrel with the negroes.

NEW GUINEA, a long and narrow island of the East Indies, very imperfectly known. It was supposed to be connected with New-Holland, until Captain Cook discovered the strait which separates them. New Guinea, including Papua, its north-western part, (which according to Bougainville's conjecture is separated from it by a strait) reaches from the equator to the twelfth degree of south latitude, and from 13° to 150 deg. east longitude; in one part it does not appear to be above fifty miles broad. It was first visited by an European ship in 1529. Saavedra, a Portuguese, who made the discovery of the north-west part of this country, called it *Terra de Papua*; or *Papua*. Van Schouten, a Dutch discoverer, afterwards gave the name of *New-Guinea* to its south-western part. Admiral Roggewain also touched here; and before him Dampier, 1st January 1700. Captain Cook made the coast of New-Guinea, in latitude 6 deg. 15 min. longitude 138. east, on the 3d of September, and landed in the pinnace, accompanied by Mr Banks, Doctor Solander, nine of the ship's crew; and servants well armed, and leaving two seamen to take care of the boat advanced some little way up the country; but coming to the skirts of a thick wood, they judged it prudent to proceed no further, lest they should fall into an ambuscade of the natives, and their retreat to the boat be cut off. Having advanced about a quarter of a mile from the boat, three Indians rushed out of the wood with a hideous shout; they threw their darts, and showed such a hostile disposition, that the party, to prevent the destruction of these

these people, returned to the boat, as they had no intention forcibly to invade their country, either to gratify their appetites or curiosity, and it was evident nothing could be done upon friendly terms. When they got on board the boat, they rowed along the shore, and the number of Indians assembled seemed to be between sixty and a hundred. They made much the same appearance as the New-Hollanders, being stark naked, and their hair cropped short. All the while they were shouting defiance, and throwing something out of their hand which burnt exactly like gun-powder, but made no report; what these fires were, or for what purpose intended, could not be guessed at; those who discharged them had in their hands a short piece of stick, possibly a hollow cane, which they swung sideway from them, and immediately fire and smoke issued, exactly resembling the discharge of a musket, and of no longer duration. This wonderful phenomenon was observed from the ship; and the deception was so great, that the people on board thought they had fire-arms, and even in the boat, if they had not been so near as that, they must have heard the report, if there had been any, they should have thought they had been firing volleys. After looking at them attentively some time, without making any notice of their flashing and vociferation, the sailors fired some muskets over their heads. Upon hearing the balls rattle among the trees, they walked leisurely away, and the boat returned to the ship. Upon examining some weapons which the natives had thrown, they were found to be light darts, about four feet long, very ill made, of a reed or bamboo cane, and pointed with hard wood, in which there were many barbs. They were discharged with great force, for at sixty yards distance they went beyond the party; but in what manner they were thrown could not be exactly seen. * But the general opinion was, that they were thrown with a flick in the manner practised by the New-Hollanders.

The land here is very low, as is every other part of the coast; but it is covered with a luxuriance of wood and herbage that can scarcely be conceived. Here the cocoa-nut, plantain, and bread-fruit, flourish in the highest perfection.

GUINEA is also the name of a British gold coin, value 1 l. 1 sh. Sterling.

GUINEA Hen, in ornithology. See NUMIDIA.

GUINEA-Pig, in zoology. See MUS.

GUIPUSCOA, the north-east division of the province of Biscay in Spain, situated on the confines of Navarre.

GUISE, small town of France, in Picardy, and in Tierache, with a very strong castle, and the title of a duchy. It is seated on the river Ouse, in E. Lon. 3. 42. N. Lat. 49. 54.

GUISE (Henry) of Lorraine, duke of Guise, (eldest son of Francois of Lorraine duke of Guise) memorable in the history of France as a gallant officer; but an imperious, turbulent, seditious subject, who placed himself at the head of an armed force, and called his rebel band, The League. The plan was formed by the cardinal, his younger brother; and under the pretext of defending the Roman Catholic religion, the king Henry III. and the freedom of the state, against the design of the Huguenots, or French

Protestants, they carried on a civil war, massacred the Huguenots, and governed the king, who forbid his appearance at Paris: but Guise now became an open rebel, entered the city against the king's express order, and put to the sword all who opposed him; the streets being barricaded to prevent his progress, this fatal day is called in the French history, The day of the barricades. Masters of Paris, the policy of the Guises failed them: for they suffered the king to escape to Blois, though he was defeated in his palace at Paris by his very guards. At Blois, Henry convened an assembly of the states of France; the duke of Guise had the boldness to appear to a summons sent him for that purpose; a forced reconciliation took place between him and the king, by the advice of this assembly; but it being accidentally discovered, that Guise had formed a plan to dethrone the king, that weak monarch, instead of resolutely bringing him to justice, had him privately assassinated, December 23, 1558, in the 38th year of his age. His brother the cardinal shared the same fate the next day.

GUITTAR, GUITARRA, a musical instrument of the stringed kind, with five double rows of strings; of which those that are bass are in the middle, except it be for the burthen, an octave lower than the fourth.—This instrument was first used in Spain, and by the Italians. In the former country it is still greatly in vogue. There are few of that nation who cannot play on the guitar; and with this instrument they serenade their mistresses at night. At Madrid, and other cities in that country, it is common to meet in the streets young men equipped with a guitar and a dark lantern, who, taking their station under the windows, sing, and accompany their voices with this instrument; and there is scarce an artificer or day-labourer in any of the cities or principal towns, who does not entertain himself with his guitar.

GULES, in heraldry, a corruption of the French word *gueules*, which in this science signifies *red*, and is represented in engraving by perpendicular lines. It may serve of itself to denote martial prowess, boldness, and hardiness: for the ancients used this colour to make themselves terrible to their enemies, to stir up magnanimity, and to prevent the seeing of blood, by the likeness of the colours; for which reason perhaps it is used by the English. But, according to G. Leigh, if this tincture is compounded with

Or.	} it signifies	Desire.
Arg.		Envy.
Azu.		Ardour.
Ver.		Strength.
Pur.		Justice.
Sab.		Weariness.

This colour is by the generality of the English heralds ranked before azure; but French heralds, N. Upton and his followers, prefer azure to it.

GULF, in ichthyology. See LARUS.

GULF, a broad and capacious bay comprehended between two promontories, and sometimes taking the name of a *sea* when it is very extensive; but particularly when it only communicates with the sea by means of a strait. Such are the Euxine or Black Sea, otherwise called the *Gulf of Constantinople*; the Adriatic Sea, called also the *Gulf of Venice*; the gulf of Sidra near Barbary; and the gulf of Lions near France. All these gulfs

Gum.

gulfs are in the Mediterranean. There are, besides the gulf of Mexico, the gulf of St Lawrence, and the gulf of California, which are in North America. There are also the gulf of Persia, otherwise called the *Red Sea*, between Persia and Arabia; the gulf of Bengal in India; and the gulfs of Cochinchina and Kamtschatka, near the countries of the same name. See 2d Plate CXVI.

The word comes from the French *golfé*, and that from the Italian *golfo*, which signify the same. Some deduce these further from the Greek γολφός; which Guishart again derives from the Hebrew גול, *gob*. Du Cange derives them from the barbarous Latin *gulfum*, or *gulfus*, which signify the same thing.

GUM (*Gumma*), in medicine, is a tumour arising out of the substance of a bone; it is so soft as to yield to the finger. When these tumours are harder they are called *tophi*; when harder still, they receive the name of *nodos*; but the hardest tumours in bones are *exostoses*. In venereal patients such tumours often happen on the head, and even in the middle of the most solid bones. They seem to be produced when the vessels running between the bony laminae, being either obstructed or inflamed, are dilated, and so raise the incumbent laminae. Perhaps the bone degenerates too into a morbid softness. A softness of the bones sometimes succeeds abscesses of the adjacent parts; and sometimes the origin of the disorder is lodged in the substance of the bone, especially in the lues venerea; gummata have, however, been discovered, when no such adequate cause could be observed.

GUM (*Gummi*), is a concrete vegetable juice, of no particular smell or taste, becoming viscous and tenacious when moistened with water; totally dissolving in water into a liquid, more or less glutinous in proportion to the quantity of the gum; not dissolving in vinous spirits or in oils; burning in the fire to a black coal, without melting or catching flame; suffering no dissipation in the heat of boiling water.

The true gums are gum arabic, gum tragacanth, gum fenega, the gum of cherry and plum trees, and such like. All else have more or less of resin in them.

The virtues of gums are similar to all mucilaginous substances in general, vegetable and animal; the more tenacious, glutinous, vegetable productions are called *gums*, those that are less so are *mucilages*. The first distil naturally from trees, the second are the produce of art.

Gum *Arabic*, called also *Gum Acanthinum*, *Gum Thebaicum*, *Gum Serapionis*, and the true *Gum Acacia*. It exudes from the Egyptian acacia, or thorn-tree, whose fruit affords the inspissated juice of that name. It is brought from Turkey in small irregular masses, of a clear whitish, or very pale yellow colour.

The gum fenega is generally sold for it; but they are thus distinguished: the gum arabic is in whitish transparent pieces, and is dry and brittle; but the gum fenega is clammy, tenacious, rougher, of a deeper colour, and in larger pieces.

The gum does not dissolve in spirit, nor in oil: yet when it is softened with water into a mucilage, it is easily miscible with both; also with resins, and renders them miscible with water. Dr Grew was used to mix essential oil with water by means of gum arabic; and in

the Lond. Med. Obs. and Inq. vol. i. a variety of experiments are inserted, by which it appears that oils both expressed and distilled, resins, balsams, &c. may by the same means be mixed uniformly with water or with spirit. Alkaline salts both fixed and volatile, though they render pure oil miscible with water, prevent the mixture of gum with oil. Acids do not in the least prevent the effect of the gum in this particular.

Animal glues have the general qualities of the vegetable gums; with this difference, that the former are more nutritive, and apt to run into a putrid state. Considered as the subjects of chemistry, their difference is very great: those of the animal kind are changed by fire into a volatile alkaline salt, and a fetid oil; the vegetable into an acid liquor, and a very minute portion of oily matter considerably less fetid than the former.

The medical character of gum arabic is its glutinous quality, in consequence of which it serves to incrassate and obtund thin acrid humours, so proves useful in tickling coughs, alvine fluxes, hoarsenesses, in fluxes of the belly with gripes, and where the mucus is abraded from the bowels or from the urethra. In a dysuria the true gum arabic is more cooling than the other simple gums, so should be preferred.

One ounce of gum arabic renders a pint of water considerably glutinous; four ounces gives it a thick syrupy consistence: but for mucilage, one part gum to two parts water is required; and for some purposes an equal proportion will be necessary.

In Dr Percival's Essays we have the following curious account, by Mr Henry, of the faculty which this gum hath of dissolving and keeping suspended in water not only resinous but also other substances, which should seem not likely to be at all affected by it. Vol. I. 319.

"One scruple of balsam of tolu, rubbed with half an ounce of distilled rain-water, added gradually to it, for 15 minutes, formed a mixture, which on standing about a minute subsided, but re-united by shaking: being set by a few days, the balsam became a concrete mass, not again miscible by shaking up the bottle. The same quantity required more trituration to mix it with common pump-water. One scruple of the same, rubbed with 15 grains of gum arabic, was nearly as long in perfectly uniting with half an ounce of distilled water, as that without the gum. This was perhaps owing to the latter piece being more resinous; however, though on long standing there was a small sediment, it immediately reunited a week after by agitation. Fifteen grains of balsam capivi united very smoothly with half an ounce of distilled water, by the medium of three grains of gum arabic. Five grains of the gum were not so effectual with pump-water. Balsam Peru ten drops, with gum arabic three grains, distilled water half an ounce, formed a neat white emulsion, but with common water a very unequal mixture. Gum myrrh powdered, that there might be no difference in the several quantities used, half a scruple, dissolved readily with gum arabic three grains, in both kinds of water, and even mixed with them by longer trituration without any medium, but more easily with distilled than common spring water. Olibanum, mastich, gum guaiacum, and galbanum, may likewise be mixed with water by rubbing, without any gum arabic

bic or egg. The spring-water made use of in these experiments was very aluminous.

"In the making of all the saline preparations, when any considerable quantities of water are used, distilled or pure rain or river water is greatly to be preferred: for the calcareous, aluminous, and selenitical matter, which so much abounds in moist spring water, will render any salt dissolved in it very impure."

"The solution of crude mercury with mucilage of gum arabic being so easily accomplished; and it being very disagreeable to many patients, and to some almost impossible, to swallow pills, boluses, or electuaries; I was induced to try whether calomel, cinnabar, and the other heavy and metalline bodies commonly administered only under these forms, might not by the same means be rendered miscible with water, so as to be given more agreeably in a liquid form. I accordingly rubbed ten grains of cinnabar of antimony and a scruple of gum arabic, with a sufficient quantity of distilled water to form a mucilage, and added a drachm of simple syrup, and three drachms more of water. This makes an agreeable little draught; and having stood about half an hour without depositing any sediment, I added three drachms more of water to it; and notwithstanding the mucilage was rendered so much more dilute, very little of the cinnabar subsided, even after it had stood some days.

"Steel simply prepared, and prepared tin, were both mixed with water by their own weight of gum arabic, and remained suspended, except a very small portion of each, which was not reduced to a sufficiently fine powder.

"Five grains of calomel were mixed with two drachms of distilled water, and half a drachm of simple syrup, by means of five grains of gum arabic, which kept it sufficiently suspended: a double quantity of the gum preserved the mixture uniform still longer. In this form it will be much more easily given to children, than in syrups, conserves, &c. as a great part of it is generally wasted, in forcing those viscid vehicles into them; and it may be joined with scammony and other resinous purgatives by the same method, and of these perhaps the gum arabic would be the best corrector.

"Gum arabic likewise greatly abates the disagreeable taste of the corrosive sublimate, mixed with water instead of brandy; and (from the few trials I have made) fits easier on the stomach, and will not be so apt to betray the patient by the smell of the brandy.

Mr Plenck, who first instructed us in the method of mixing quicksilver with mucilage, observes, (and experience confirms the truth of it), that this preparation is not so apt to bring on a spitting as the *argent. viv.* mixed by any other medium, or as the saline and other mercurial preparations.—How far the theory by which he accounts for it may be just, is not of much importance; but it may perhaps be worth while to inquire whether it would not be equally effectual in preventing calomel, and the other preparations of mercury, from affecting the mouth.—If so, is it not improper, where a salivation is intended, to give emulsions with gum arabic and other mucilaginous liquors for the patient's common drink, as by that means the spitting may be retarded? And on the contrary, may it not be a useful medicine to diminish the discharge when too copious?

"The following case may in some measure serve to confirm the above observation.—A gentleman, always easily affected by mercurials, having taken about 26 grains of calomel in doses from one to three grains, notwithstanding he was purged every third day, was suddenly seized with a salivation. He spat plentifully, his breath was very fetid, teeth loose, and his gums, fauces, and the margin of his tongue, greatly ulcerated and inflamed. He was directed to use the following gargle. *R. Gum. arab. semunc. solve in aqua font. bullient. scilicet. & adde mel. rosac. unc. unam. M. st. gargar.* And to drink freely of a ptisan prepared with *aq. hord. lib. ij. gum. arabic. unc. ij. nitr. pur. drachm. ij. sacchar. alb. unc. j.*

"His purgative was repeated the succeeding morning. The next day his gums were less inflamed; but the sloughs on his tongue, &c. were still as foul: his spitting was much the same: he had drank about a pint of the ptisan.—Some *spt. vitrioli* was added to the gargle.—From this day to the fourth, he was purged every day without effect—his salivation still continued,—his mouth was no better—he had neglected the mucilaginous drink—This evening he was persuaded to drink about a pint of it which remained, and he had it repeated, and drank very freely of it that night.—On the fifth morning, the purgative was again repeated. Though it operated very little, yet the change was very surprising; his mouth was nearly well, and his pytalism greatly decreased.—The ptisan was repeated; and on the sixth day, being quite well, he was permitted to go abroad."

In Mr Hasselquist's travels we have an instance of the extraordinary nutritive virtues of this gum. "The Abyssinians, (says he), make a journey every year to Cairo, to sell the products of their country. They must travel over terrible deserts, and their journey depends as much on the weather as a voyage at sea: consequently they know as little as a seaman how long they must be on their journey; and the necessities of life may chance to fail them when the journey lasts too long. This happened to the Abyssinian caravan in the year 1740, their provisions being consumed when they had still two months to travel. They were then obliged to search for something among their merchandise, wherewith they might support nature; and found nothing more proper than gum Arabic, of which they had carried a considerable quantity along with them. This served to support above 1000 persons for two months; and the caravan at last arrived at Cairo without any great loss of people, either by hunger or diseases."

Gum Seneca, is a gum extremely resembling gum Arabic. It is brought to us from the country through which the river Seneca runs, in loose or single drops; but these are much larger than those of the gum arabic usually are; sometimes it is of the bigness of an egg, and sometimes much larger: the surface is very rough, or wrinkled; and appears much less bright than the inner substance, where the masses are broken. It has no smell, and scarce any taste. We are not acquainted with the tree which produces it. The virtues of it are the same with the gum arabic; but it is rarely used in medicine, unless as mixed with the gum arabic: the dyers and other artificers consume the great quantities of it that are annually imported hither. The negroes

negroes dissolve it in milk, and in that state make it a principal ingredient in many of their dishes, and often feed on it thus alone.

GUM Tragacanth, the gum of the tragacanth, a thorny bush growing in Crete, Asia, and Greece. This gum is of a much stronger body than either of the foregoing, and does not so perfectly dissolve in water. A dram of it will give the consistence of a syrup to a whole pint of water, which an ounce of gum arabic will scarce do. Hence it is used for forming troches and the like purposes, in preference to the other gums. In its general medicinal virtues, it agrees with gum arabic.

Other substances known by the name of *gums*, are as follow:

GUM Aloes, a preparation of aloes. See PHARMACY, n° 613.

GUM Ammoniac. See AMMONIAC.

GUM Elemi. See ELEMI.

GUM Guaiacum. See GUAIACUM.

GUM Lacca. See LACCA.

GUM, among gardeners, a kind of gangrene incident to fruit-trees of the stone-kind, arising from a corruption of the sap, which, by its viscidness, not being able to make its way through the fibres of the tree, is, by the protrusion of other juice, made to extravasate and ooze out upon the bark.

When the distemper surrounds the branch, it admits of no remedy; but when only on one part of a bough, it should be taken off to the quick, and some cowdung clapped on the wound, covered over with a linen cloth, and tied down. M. Quintinie directs to cut off the morbid branch two or three inches below the part affected.

GUMS in anatomy, the hard fleshy substance in either jaw, through which the teeth spring from the jawbone. See ANATOMY, n° 26. g.

The gums are apt to become spongy, and to separate from the teeth; but the cause is frequently a stony kind of crust, which forms itself therein, which when separated, the gums soon return to their former state, especially if rubbed with a mixture of the infusion of roses four parts, and the tincture of myrrh one part.—The scurvy is another disorder which affects the gums. This disorder, when not manifest in any other part, sometimes appears in this: indeed when a scorbutic disorder invades the whole habit, its first symptom is a putrid state of the gums.

GUN, in the military art, a fire-arm, or weapon of offence, which forcibly discharges a ball or other hard and solid matter through a cylindric tube, by means of inflamed gun-powder. See *Gun-Powder*.

The word *gun* now includes most of the species of fire-arms; pistols and mortars being almost the only ones excepted from this denomination. They are divided into great and small guns; the former including all that we also call cannon, ordnance, or artillery; the latter includes musquets, carabines, musketoons, blunderbusses, fowling-pieces, &c.

It is not known at what time these weapons were first invented. Though, comparatively speaking, the introduction of guns into the western part of the world is but of a modern date; yet it is certain that in some parts of Asia they have been used, though in a very rude and imperfect manner, for many ages.—Philo-

stratus speaks of a city near the river Hyphasis in the Indies, which was said to be impregnable, and that its inhabitants were relations of the gods, because they threw thunder and lightning upon their enemies. Hence some imagine that guns were used by the eastern nations even in the time of Alexander the Great; but however this may be, many of our modern travellers assert that they were used in China as far back as the year of Christ 85, and have continued in use ever since.

The first hint of the invention of guns in Europe, is in the works of Roger Bacon, who flourished in the 13th century. In a treatise wrote by him about the year 1280, he proposes to apply the violent explosive force of gun-powder, for the destruction of armies. In 1320, Bartholomew Schwartz, a German monk, is commonly said to have invented gun-powder; tho' it is certainly known that this composition is described by Bacon in some of his treatises long before the time of Schwartz. The following is said to have been the manner in which Schwartz invented gun-powder. Having pounded the materials for it in a mortar, which he afterwards covered with a stone; a spark of fire accidentally fell into the mortar, and set the mixture on fire: upon which the explosion blew the stone to a considerable distance. Hence it is probable that Schwartz might be taught the simplest method of applying it in war; for Bacon seems rather to have conceived the manner of using it to be by the violent effort of the flame unconfined, and which is indeed capable of producing astonishing effects*. The figure and name of mortars given to a species of old artillery, and their employment (which was throwing great stone-bullets at an elevation) very much corroborates this conjecture.

Soon after the time of Schwartz, we find guns commonly made use of as instruments of war. Great guns were first used. They were originally made of iron bars soldered together, and fortified with strong iron-hoops; some of which are still to be seen, viz. one in the tower of London, two at Woolwich, and one in the royal arsenal at Lisbon. Others were made of thin sheets of iron rolled up together, and hooped; and on emergencies they were made of leather, with plates of iron or copper. These pieces were made in a rude and imperfect manner, like the first essays of many new inventions. Stone balls were thrown out of them, and a small quantity of powder used on account of their weakness. These pieces had no ornaments, were placed on their carriages by rings, and were of a cylindric form. When or by whom they were made, is uncertain: the Venetians, however, used cannon at the siege of Claudia Jessa, now called *Chioggia*, in 1366, which were brought thither by two Germans, with some powder and leaden balls; as likewise in their wars with the Genoese in 1379. King Edward III. made use of cannon at the battle of Cressy in 1346, and at the siege of Calais in 1347. Cannon were made use of by the Turks at the siege of Constantinople, then in possession of the Christians, in 1394, and in that of 1452, that threw a weight of 100 lb. but they generally burst, either the first, second, or third shot. Louis XII. had one cast at Tours, of the same size, which threw a ball from the Bastile to Charenton. One of those famous cannon

* See *Gun-Powder*.

was taken at the siege of Dieu in 1546, by Don John de Castro; and is in the castle of St Juliao da Barra, 10 miles from Lisbon: its length is 20 feet 7 inches, diameter at the centre 6 feet 3 inches, and it discharges a ball of 100 lb. It has neither dolphins, rings, nor button; is of a curious kind of metal; and has a large Indian inscription upon it, which says it was cast in 1400.

Formerly the cannon were disguised with uncommon names; for, in 1503, Louis XII. had 12 brass cannon cast, of an extraordinary size, called after the names of the 12 peers of France. The Spanish and Portuguese called them after their saints. The emperor Charles V. when he marched before Tunis, founded the 12 Apostles. At Milan there is a 70 pounder, called the *Pimontelle*; and one at Bois-le-duc, called the *Devil*. A 60 pounder at Dover castle, called *Queen Elizabeth's pocket-pistol*. An 80 pounder in the tower of London, (formerly in Stirling castle), called *Mounts-meg*. An 80 pounder in the royal arsenal at Berlin, called the *Thunderer*. An 80 pounder at Malaga, called the *Terrible*. Two curious 60 pounders in the arsenal at Bremen, called the *Messengers of bad news*. And lastly, an uncommon 70 pounder in the castle of St Angelo at Rome, made of the nails that fastened the copper-plates which covered the ancient Pantheon, with this inscription upon it: *Ex clavis trabalibus porticus Aegrippæ*.

In the beginning of the 15th century these uncommon names were generally abolished, and the following more universal ones took place, viz.

	Pounders.	Cwt.
Cannon royal, or carthoun	= 48	about 90
Bastard cannon, or $\frac{1}{2}$ carthoun	= 36	79
$\frac{1}{2}$ carthoun	= 24	60
Whole culverins	= 18	50
Demi culverins	= 9	30
Falcon	= 6	25
Sacker	lowest fort =	5
	ordinary =	6
	largest size =	8
Basilisk	= 48	85
Serpentine	= 4	8
Aspic	= 2	7
Dragon	= 6	12
Syren	= 60	81
Falconet	= 3, 2, & 1	15, 10, 5.

Moyens, which carried a ball of 10 or 12 ounces, &c.

Rabinet, which carried a ball of 16 ounces.

These curious names of beasts and birds of prey were adopted, on account of their swiftness in motion, or of their cruelty; as the falconet, falcon, facker, and culverin, &c. for their swiftness in flying; the basilisk, serpentine, aspique, dragon, syren, &c. for their cruelty.

At present cannon take their names from the weight of the ball they discharge. Thus a piece that discharges a ball of 24 pounds, is called a 24 pounder; one that carries a ball of 12 pounds, is called a 12 pounder; and so of the rest, divided into the following forts, viz.

VOL. V.

Ship-guns, confiding in 42, 36, 32, 24, 18, 12, 9, 6, and 3 pounders.

Garrison-guns, in 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering-guns, in 24, 18, and 12 pounders.

Field-pieces, in 12, 9, 6, 3, 2, $1\frac{1}{2}$, 1, and $\frac{1}{2}$ pounders.

Mortars are thought to have been fully as ancient as cannon. They were employed in the wars of Italy, to throw balls of red-hot iron, stones, &c. long before the invention of shells. These last are thought to be of German invention, and the use of them in war to have been taught by the following accident. A citizen of Venlo, at a certain festival celebrated in honour of the duke of Cleves, threw a number of shells, one of which fell on a house and set fire to it, by which misfortune the greatest part of the town was reduced to ashes. The first account of shells used for military purposes is in 1435, when Naples was besieged by Charles VIII. History informs us with more certainty, that shells were thrown out of mortars at the siege of Wachtendonk, in Guelderland, in 1588, by the Earl of Mansfield. Mr Malter, an English engineer, first taught the French the art of throwing shells, which they practised at the siege of Motte in 1634. The method of throwing red-hot balls out of mortars was first certainly put in practice at the siege of Stralsund in 1675 by the elector of Brandenburg; though some say in 1653 at the siege of Bremen. For the proper dimensions of guns, their weight, the metal of which they are formed, &c. see the article GUNNERY.

Muskets were first used at the siege of Rhege in the year 1521. The Spaniards were the first who armed part of their foot with these weapons. At first they were very heavy, and could not be used without a rest. They had match-locks, and did execution at a great distance. On their march, the soldiers carried only the rests and ammunition, and had boys to bear their muskets after them. They were very slow in loading; not only by reason of the unwieldiness of their pieces, and because they carried the powder and ball separate, but from the time it took to prepare and adjust the match; so that their fire was not near so brisk as ours is now. Afterwards a lighter matchlock-musquet came in use: and they carried their ammunition in bandeliers, to which were hung several little casks of wood, covered with leather, each containing a charge of powder. The balls were carried loose in a pouch, and a priming horn hanging by their side. The muskets with rests were used as late as the beginning of the civil wars in the time of Charles I. The lighter kind succeeded them, and continued till the beginning of the present century, when they also were disused, and the troops throughout Europe armed with fire-locks.

GUNELLUS, in ichthyology. See BLENNIUS.

GUNNER, an officer appointed for the service of the cannon; or one skilled to fire the guns.

In the tower of London, and other garrisons, as well as in the field, this officer carries a field staff, and a large powder-horn in a string over his left shoulder: he marches by the guns; and when there is any apprehension of danger, his field-staff is armed with match: his business is to lay the gun to paws, and to help to load and traverse her.

19 R

Master-

Gunnery.

Master GUNNER, a patent-officer of the ordinance, who is appointed to teach all such as learn the art of gunnery, and to certify to the master-general the ability of any person recommended to be one of the king's

gunners. To every scholar he administers an oath, *Gunnery.* not to serve, without leave, any other prince or state; or teach any one the art of gunnery, but such as have taken the said oath.

G U N N E R Y,

IS the art of charging, directing, and exploding fire arms, as cannons, mortars, muskets, &c. to the best advantage.—As this art depends greatly on having the guns and shot of a proper size and figure, and well adapted to each other, it hence follows that the proper dimensions, &c. of cannon and small arms come properly to be considered under the present article.

SECT. I. *History of Gunnery.*

History.

THE ancients, who knew not the use of gun-powder and fire-arms, had, notwithstanding, machines which were capable of discharging stones, darts, and arrows, with great force. These were actuated chiefly by the elastic force of ropes, or of strong springs, and required a great number of men to work them; for which reason, the explosion of gun-powder, as acting instantaneously, and seemingly with irresistible force, seemed to be a most proper succedaneum for all the powers by which the military engines in former times were actuated. It soon appeared, however, that this force was not very easily applied. Though the experiment of Bartholomew Schwartz, mentioned under the article Gun, had given a good hint towards this application in a successful manner, yet the violent reaction of the inflated powder on the containing vessels rendered them very apt to burst, to the great danger of those who stood near them. The gun-powder in those days, therefore, was much weaker than it is now made; tho' this proved a very insufficient remedy for the inconvenience above-mentioned. It was also soon discovered, that iron bullets of much less weight than stone ones would be more efficacious if impelled by greater quantities of stronger powder. This occasioned an alteration in the matter and form of the cannon, which were now cast of brass. These were lighter and more manageable than the former, at the same time that they were stronger in proportion to their bore. Thus they were capable of enduring greater charges of a better powder than what had been formerly used; and their iron bullets, (which were from 40 to 60 pounds weight, being impelled with greater velocities, were more effectual than the heaviest stones could ever prove. This change took place about the latter end of the 15th century.

By this means powder compounded in the manner now practised over all Europe came first in use. But the change of the proportion of materials was not the only improvement it received. The method of graining it is undoubtedly a considerable advantage. At first the powder was always in the form of fine meal, such as it was reduced to by grinding the materials together. It is doubtful whether the first graining of powder was intended to increase its strength, or only to render it more convenient for filling into small charges and the charging of small arms, to which alone it was applied for many years, whilst meal-pow-

der was still made use of for cannon. But at last the additional strength which the grained powder was found to acquire from the free passage of the air between the grains, occasioned the meal-powder to be entirely laid aside.

For the last two hundred years, the formation of cannon hath been very little improved; the best pieces of modern artillery differing little in their proportions from those used in the time of Charles V. Indeed lighter and shorter pieces have been often proposed and essayed; but though they have their advantages in particular cases, yet it seems now to be agreed that they are altogether insufficient for general service. But though the proportions of the pieces have not been much varied within that period, yet their use and application have undergone considerable alterations; the same ends being now accomplished by smaller pieces than what were formerly thought necessary. Thus the battering cannon now universally approved of are those formerly called *semi-cannons*, carrying a ball of 24 pounds weight; it being found by experience, that their stroke, though less violent than that of larger pieces, is yet sufficiently adapted to the strength of the usual profiles of fortification; and that the facility of their carriage and management, and the ammunition they spare, give them great advantages beyond the whole cannons formerly employed in making breaches. The method also of making a breach, by first cutting off the whole wall as low as possible before its upper part is attempted to be beat down, seems also to be a considerable modern improvement in the practical part of gunnery. But the most considerable improvement in the practice is the method of firing with small quantities of powder, and elevating the piece so that the bullet may just go clear of the parapet of the enemy, and drop into their works. By this means the bullet, coming to the ground at a small angle and with a small velocity, does not bury itself, but bounds or rolls along in the direction in which it was fired: and therefore, if the piece be placed in a line with the battery it is intended to silence, or the front it is to sweep, each shot rakes the whole length of that battery or front; and has thereby a much greater chance of disabling the defendants, and dismounting their cannon, than it would have if fired in the common manner. This method was invented by Vauban, and was by him styled *Batterie à Ricochet*. It was first put in practice in the year 1692 at the siege of Aeth.—Something similar to this was put in practice by the king of Prussia at the battle of Rossbach in 1757. He had several six-inch mortars, made with trunnions and mounted on travelling carriages, which fired obliquely on the enemy's lines and amongst their horse. They were charged with eight ounces of powder, and elevated at an angle of one degree fifteen minutes, and did great execution; for the shells rolling along the lines with

burn-

THEORY. burning fuses made the stoutest of the enemy not wait for their burling.

SECT. II. *Theory of Gunnery.*

² THE use of fire-arms had been known for a long time before any theory concerning them was attempted. The first author who wrote professedly on the right of cannon-shot was Tartalea. In 1537 he published a book, at Venice, entitled *Nova Scientia*; and afterwards another, entitled *Questiti et Inventioni diversi*, printed at the same place in 1546, in which he treats professedly on these motions. His discoveries were but few, on account of the imperfect state of mechanical knowledge at that time. However, he determined, that the greatest range of cannon was with an elevation of 45 degrees. He likewise determined, (contrary to the opinion of practitioners), that no part of the track described by a bullet was a right line; although the curvature was in some cases so little, that it was not attended to. He compared it to the surface of the sea; which, though it appears to be a plane, is yet undoubtedly incurved round the centre of the earth. He also assumes to himself the invention of the gunner's quadrant, and often gave shrewd guesses at the event of some untried methods. But as he had not opportunities of being conversant in the practice, and founded his opinions only on speculation, he was condemned by most of the succeeding writers, though often without any sufficient reason. The philosophers of those times also intermeddled in the questions hence arising; and many disputes on motion were set on foot (especially in Italy), which continued till the time of Galileo, and probably gave rise to his celebrated *Dialogues on motion*. These were published in the year 1638; but in this interval, and before Galileo's doctrine was thoroughly established, many theories of the motion of military projectiles, and many tables of their comparative ranges at different elevations, were published; all of them egregiously fallacious, and utterly irreconcilable with the motions of these bodies. Very few of the ancients indeed refrained from indulging themselves in speculations concerning the difference betwixt natural, violent, and mixed motions; although scarce any two of them could agree in their theories.

³ It is strange, however, that, during all these contests, so few of those who were intrusted with the charge of artillery thought it worth while to bring these theories to the test of experiment. Mr Robins informs us, in his Preface to the *New Principles of Gunnery*, that he had met with no more than four authors who had treated on this subject. The first of these is Collado, who has given the ranges of a falconet carrying a three-pound shot to each point of the gunner's quadrant. But from his numbers it is manifest, that the piece was not charged with its customary allotment of gun-powder. The results of his trials were, that the point-blank shot, or that in which the path of the ball did not sensibly deviate from a right line, extended 268 paces. At an elevation of one point (or $7\frac{1}{2}$ of the gunner's quadrant) the range was 594 paces; at an elevation of two points, 794 paces; at three points, 954 paces; at four, 1010; at five, 1040; and at six, 1053 paces. At the seventh point, the range fell between those of the third

and fourth; at the eighth point, it fell between the ranges of the second and third; at the ninth point, it fell between the ranges of the first and second; at the tenth point, it fell between the point-blank distance and that of the first point; and at the eleventh point, it fell very near the piece.—The paces spoke of by this author are not geometrical ones, but common steps.

The year after Collado's treatise, another appeared on the same subject by one Bourne an Englishman. His elevations were not regulated by the points of the gunner's quadrant, but by degrees; and he ascertains the proportions between the ranges at different elevations and the extent of point-blank shot. According to him, if the extent of the point-blank shot be represented by 1, the range at 5° elevation will be $2\frac{1}{2}$, at 10° it will be $3\frac{1}{2}$, at 15° it will be $4\frac{1}{2}$, at 20° it will be $4\frac{1}{2}$, and the greatest random will be $5\frac{1}{2}$. This last, he tells us, is in a calm day when the piece is elevated to 42°; but according to the strength of the wind, and as it favours or opposes the flight of the shot, it may be from 45° to 36°.—He hath not informed us with what piece he made his trials; tho' by his proportions it seems to have been a small one. This however ought to have been attended to, as the relation between the extent of different ranges varies extremely according to the velocity and density of the bullet.

After him Eldred and Anderson, both Englishmen, published treatises on this subject. The first published his treatise in 1646, and has given the actual ranges of different pieces of artillery at small elevations all under ten degrees. His principles were not rigorously true, though not liable to very considerable errors; yet, in consequence of their deviation from the truth, he found it impossible to make some of his experiments agree with his principles.

⁴ In 1638, Galileo printed his dialogues on motion. In these he pointed out the general laws observed by nature in the production and composition of motion; and was the first who described the action and effects of gravity on falling bodies. On these principles he determined, that the flight of a cannon shot, or any other projectile, would be in the curve of a parabola, except in as far as it was diverted from that track by the resistance of the air. He has also proposed the means of examining the inequalities which arise from thence, and of discovering what sensible effects that resistance would produce in the motion of a bullet at some given distance from the piece.

Though Galileo had thus shewn, that, independent of the resistance of the air, all projectiles would, in their flight, describe the curve of a parabola; yet those who came after him, seem never to have imagined that it was necessary to consider how far the operations of gunnery were affected by this resistance. The subsequent writers indeed boldly asserted, without making the experiment, that no considerable variation could arise from the resistance of the air in the flight of shells or cannon-shot. In this persuasion they supported themselves chiefly by considering the extreme rarity of the air, compared with those dense and ponderous bodies; and at last it became an almost generally established maxim, that the flight of these bodies was nearly in the curve of a parabola.

EXPLANATION.

By this plan events are referred to the year of the world; and, within the proper periods, to the aeras of the Olympiads, of Nabonassar, and of Rome: but the principal reference is to the birth of Christ, marked as above by a deep black line.

The plan extends only to the Flood; the preceding period of 1056 years is left blank as above.

There being 2348 years from the Flood to the birth of Christ, the space between them is divided into 23 parts, each representing an hundred years or centuries; and all these parts, together with some centuries preceding the birth of Christ, are subdivided into tens.
