NEREIDS, in the Pagan theology, ſea-nymphs, daughters of Nereus and Doris.—The Nereids were eſteemed very handſome; inſomuch that Caſſiope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the Nereids, they were ſo enraged that they ſent a prodigious ſea-monſter into the country; and, to appeaſe them, ſhe was commanded by the oracle to expoſe her daughter Andromeda, bound to a rock, to be devoured by the monſter. In ancient monuments, the Nereids are repreſented riding upon ſea-horſes; ſometimes with an entire human form, and at other times with the tail of a fiſh.

NEREIS, in zoology, a genus of animals belonging to the order of vermes molluſca. The body is oblong, linear, and fitted for creeping; it is furniſhed with lateral pencilled tentacula. There are 11 ſpecies; of which the moſt remarkable is the noctiluca, being one of the cauſes of the luminouſneſs of the ſea. They are inhabitants of almoſt every ſea; and illuminate the water like glow-worms, but with a brighter ſplendour, ſo as at night to make the element appear as if on fire all around. Their bodies are ſo minute as to elude examination by the naked eye.

NEREUS, in fabulous hiſtory, a marine deity, was the ſon of Oceanus and Thetis. He ſettled in the Ægean Sea, was conſidered as a prophet, and had the power of aſſuming what form he pleaſed. He married his ſiſter Doris, by whom he had 50 daughters called the *Nereids*, who conſtantly attended on Neptune, and when he went abroad ſurrounded his chariot.

NERO (Domitius) emperor, ſon of Caius Domitius Ænobarbus, and of Agrippina, who married Claudius, whom Nero ſucceeded, A. D. 54, aged 18. He proteſted he would follow the example of Auguſtus, and at firſt he did; and as they once preſented him the ſentence of a perſon condemned to death, "I wiſh," ſaid he, "that I could not write." But after five years reign he fell into the moſt extravagant crimes that ever entered the imagination of man. He would appear upon the ſtage in wonan's dreſs. He commited ſodomy with the greateſt debauchees, and particularly Sporus, whom he kept in quality of his wife, and cauſed to be dreſſed like a woman; which gave occaſion to that pleaſant ſaying, "That the world had been happy if his father Domitius had had ſuch a wife." He cauſed his mother to be murdered, his wife to be put to death, and his maſter Seneca to loſe his life, &c. and wiſhed that mankind had but one head, that he might have the pleaſure of cutting it off. To have the glory of rebuilding Rome, he ſet it on fire, laid the blame upon the Chriſtians, and began the firſt perſecution againſt them.

them. Being exhaufted by his immenfe profufion, and become the common deteftation of mankind, his armies in Gaul declared againft him, and Galba revolted in Spain. This caft him into defpair, and in a rage he cried out, "Have I neither friend nor enemy?" So he was forced to turn his own executioner, A. D. 68, in the 32d year of his age and 14th of his reign.

NERVA (Cocceius), emperor after Domitian. He recalled thofe who had been banifhed for their religion, and forgot nothing that might contribute to the reftoring of the empire to its former luftre; but finding his age would not fuffer him to finifh it, he adopted Trajan, and died A. C. 98.

NERVES, in anatomy; certain white gliftening cords, proceeding from the brain and fpinal marrow, and dividing into very fmall branches, which are fent off throughout all parts of the body; and which are found to be the organs of fenfation and motion. See ANATOMY, n° 400.

NERVOUS FLUID. See ANATOMY, n° 400, l.

NEST. See NIDUS.

Eatable Birds-NESTS. See BIRDS-*Nefts*.

NESTOR, in fabulous hiftory, king of Pylos, and the fon of Neleus and Chloris. He fubdued the Eleans, and conquered the Centaurs, who would have carried off Hippodamia. He afterwards went to the fiege of Troy with Agamemnon, who had a particular efteem for him on account of his wifdom and eloquence. He was then, according to Homer, fo old, that he had feen three generations of men.

NESTORIANS, a Chriftian fect, the followers of Neftorius bifhop and patriarch of Conftantinople; who, about the year 520, taught that there were two perfons in Jefus Chrift, the divine and the human, which are united not hypoftatically or fubftantially, but in a myftical manner; whence he concluded, that Mary was the mother of Chrift, and not the mother of God. For this opinion Neftorius was condemned and depofed by the council of Ephefus; and the decree of this council was confirmed by the emperor Theodofius, who banifhed the bifhop to a monaftery.

NET, a device for catching fifh and fowl. See the article FISHERY.

The taking fowls by nets is the readieft and moft advantageous of all others, where numbers are to be taken. The making the nets is very eafy, and what every true fportfman ought to be able to do for himfelf. All the neceffary tools are wooden needles, of which there fhould be feveral of different fizes, fome round and others flat; a pair of round-pointed and flat fciffars; and a wheel to wind off the thread. The packthread is to be of different ftrength and thicknefs, according to the fort of birds to be taken; and the general fize of the mefhes, if not for very fmall birds, is two inches from point to point. The nets fhould neither be made too deep nor too long, for they are then difficult to manage; and they muft be verged on each fide with twifted thread. The natural colour of the thread is too bright and pale, and is therefore in many cafes to be altered. The moft ufual colour is the ruffet; which is to be obtained by plunging the net, after it is made, into a tanner's pit, and letting it lie there till it be fufficiently tinged: this is of a double fervice to the net, fince it preferves the thread as well as alters the colour. The green colour is given by chopping fome green wheat and boiling it in water, and then foaking the net in this green tincture. The yellow colour is given in the fame manner with the decoction of celandine; which gives a pale ftraw-colour, which is the colour of ftubble in the harveft-time. The brown nets are to be ufed on ploughed lands, the green on grafs-grounds, and the yellow on ftubble-lands.

NET, *Neat*, in commerce, fomething pure, and unadulterated with any foreign mixture.

Thus, wine is faid to be *net* when not falfified or balderdafhed; and coffee, rice, pepper, &c. are *net* when the filth and ordures are feparated from them. See NEAT.

A diamond is faid to be *net* when it has no ftains or flaws; a cryftal, when tranfparent throughout.

NET is alfo ufed for what remains after the tare has been taken out of the weight of any merchandife; *i. e.* when it is weighed clear of all package. See TARE.

Thus we fay, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remains *net* 400 pounds.

NET *Produce*, a term ufed to exprefs what any commodity has yielded, all tare and charges deducted.

The merchants fometimes ufe the Italian words *netto proceduto*, for net produce.

NETHERLANDS, anciently called *Belgia*, but fince denominated *Low Countries* or *Netherlands*, from their low fituation, are fituated between 2° and 7° of eaft longitude, and between 50° and 53° 30′ of north latitude: and are bounded by the German fea on the north, Germany on the eaft, by Lorrain and France on the fouth, and by another part of France and the Britifh feas on the weft; extending near 300 miles in length from north to fouth, and 200 miles in breadth from eaft to weft. They confift of 17 provinces; 10 of which are called the *Auftrian and French Netherlands*, and the other feven the *United Provinces*.

The *Auftrian Netherlands* confift of the greateft part of the duchies of Brabant, Limburg, and Luxemburg, with a part of that of Gueldres; and of the counties of Flanders, Hennegau, and Namur. The Netherlands formerly made a part of the circle of Burgundy, the whole of which once belonged to the houfe of Auftria, and on the death of Charles V. devolved to the Burgundian Spanifh line of that houfe; but was all afterwards loft, except the abovementioned countries, which, on the death of Charles II. king of Spain, fell to the German line of the Auftrian family. Thefe Auftrian Netherlands are ftill confidered as a circle of the empire, of which the archducal houfe, as being fovereign of the whole, is the fole director and fummoning prince. This circle contributes its fhare to the impofts of the empire, and fends an envoy to the diet; but is not fubject to the judicatories of the empire. It is wholly Catholic, and under a governor-general appointed by the court of Vienna.

The *French Netherlands* confift of a part of the duchy of Luxemburg, of the province of Hainault, of the earldom of Flanders, the bifhopric of Liege, the Cambrefis, and the county of Namur; and this government, the greateft part of which belongs to the parliament of Douay, comprehends French Flanders, the

the Cambrefis, French Hainault, and the French part of the earldom of Namur.—French Flanders abounds in grain, vegetables, flax, and cattle, but is in want of wood.

For the *Dutch Netherlands*, fee UNITED *Provinces*.

NETSCHER (Gafpard), an eminent painter, born at Prague in Bohemia in 1639. His father dying while he was an engineer in the Polifh fervice, his mother was obliged, on account of her religion, fuddenly to leave Prague with her three fons. When fhe had proceeded three leagues, fhe ftopped at a caftle; which being foon after befieged, two of her fons were ftarved to death; but fhe herfelf found means to efcape out of the fortrefs by night, and to fave her only remaining child. Carrying him in her arms, fhe reached Arnheim in Guelderland, where fhe found means to fup port herfelf, and breed up her fon. At length a doctor of phyfic took young Netfcher into his patronage, with the view of giving him an education proper for a phyfician: but Netfcher's genius leading him to painting, he could not forbear fcrawling out defigns upon the paper on which he wrote his themes; and it being found impoffible to conquer his fondnefs for drawing, he was fent to a glazier, who was the only perfon in the town that underftood drawing. Netfcher foon finding himfelf above receiving any farther affiftance from his mafter, was fent to Deventer, to a painter named *Terburg*, who was an able artift and burgomafter of the town; and having acquired under him a great command of his pencil, went to Holland, where he worked a long time for the dealers in pictures, who paid him very little for his pieces, which they fold at a high price. Difgufted at this ungenerous treatment, he refolved to go to Rome, and for that purpofe embarked on board a veffel bound for Bourdeaux. But his marrying in that city prevented his travelling into Italy: and therefore, returning into Holland, he fettled at the Hague; where obferving that portait-painting was the moft profitable, he applied himfelf folely to it, and acquired fuch reputation, that there is not a confiderable family in Holland that has not fome of his portraits; and befides, the greateft part of the foreign minifters could not think of quitting Holland without carrying with them one of Netfcher's portraits, whence they are to be feen all over Europe. He died at the Hague, in 1684; leaving two fons, Theodore and Conftantine Netfcher, both of them good portrait-painters.

NETTINGS, in a fhip, a fort of grates made of fmall ropes feized together with rope-yarn or twine, and fixed on the quarters and in the tops; they are fometimes ftretched upon the ledges from the wafte-trees to the roof-trees, from the top of the forecaftle to the poop, and fometimes are laid in the wafte of a fhip to ferve inftead of gratings.

NETTLE, in botany. See URTICA.

Sea-NETTLE. See MEDUSA, and ANIMAL-*Flower*.

NETTLE-*Tree*. See CELTIS.

NETTUNO, a handfome town of Italy, in the Campagnia of Rome. It is but thinly peopled, though feated in a fertile foil. The inhabitants are almoft all hunters. E. Long. 12. 57. N. Lat. 41. 30.

NEWBURG, the name of feveral towns of Germany, two of which are the chief towns of duchies of the fame name; one in Bavaria, and the other in the Palatinate.

NEVERS, a confiderable town of France, and capital of Nivernois, in Orleanois, with the title of a duchy, an ancient caftle, and a bifhop's fee. It is built in the form of an amphitheatre, and contains feveral fine buildings. It is feated on the river Loir, over which there is an handfome bridge, and at the end of it a fine large caufeway reaching to the town. E. Long. 3. 14. N. Lat. 46. 59.

NEUFCHATTEAU, a town of France, in Lorrain, and capital of the chatellenie of Chatenoi. It is an handfome, populous, trading town; having an abbey of the nuns of St Clair, a commandery of Malta, and feveral convents of monks and nuns. It is feated in a bottom, in a foil fertile in corn, wine, and all the neceffaries of life, on the river Mouzon. E. Long. 5. 45. N. Lat. 48. 20.

NEUFCHATTEL, a fovereign county of Swifferland, bounded on the weft by the Franche Comte, on the north by the bifhopric of Bafle, and on the eaft and fouth by the cantons of Berne and Friburg; it is about 40 miles in length, and 20 in breadth. It had its own counts for a long time; the laft of whom dying in 1694 without iffue, it came to Mary of Orleans, duchefs of Nemours, his only fifter, who died without iffue in 1703: there were then 13 competitors; but, at an affembly of the ftates in 1707, they unanimoufly chofe the king of Pruffia for their fovereign, who has placed a governor therein. It is well peopled; and contains three cities, one town, 90 villages, and about 300 houfes difperfed in the mountains. The inhabitants are all Proteftants, except two Roman Catholic villages; and in 1529 they entered into a ftrict alliance with the cantons of Berne, Friburg, Soleure, and Lucern. The air is healthy and temperate, but the foil not every where equally fertile; however, there are large vineyards, which produce white and red wine, which laft is excellent. The paftures on the mountains feed a great number of all forts of cattle; and there are plenty of deer in the forefts; befides large trouts, and other good fifh, in the lakes and rivers. The people are ingenious, polite, active, induftrious, and laborious.

NEUFCHATTEL, an handfome town of Swifferland, capital of a county of the fame name. There are feveral ancient ruins near it, which fhew its former extent; and there are two large churches, befides a caftle where the governor refides. It is feated on a lake of the fame name, 17 miles in length and five in breadth, and the fide of the harbour is the ufual walk of the inhabitants. It has a grand and little council: the firft is compofed of 40 perfons, with two mafters of the keys; the little council confifts of 24 members, comprehending the mayor, who is prefident. Thefe two councils affemble regularly every month. The ecclefiaftics likewife affemble every month, to confult on affairs belonging to the church, and to fill up the places of minifters that die. They choofe a dean every year, who is prefident of the general affemblies, which are called *claffes*; and fometimes he is confirmed in this dignity. E. Long. 7. 10. N. Lat. 47. 5.

NEVIS, one of the Caribbee iflands, lying about feven leagues north of Montferrat, and feparated from St Chriftopher's by a narrow channel. It makes a beautiful appearance from the fea, being a large conical

cal mountain covered with fine trees, of an eafy afcent on every fide, and entirely cultivated. The circumference is about 21 miles, with a confiderable tract of level ground all around. The climate in the lower part is reckoned to be warmer than Barbadoes, but it is more temperate towards the fummit. The foil is very fine in the lower part, but grows coarfer as we afcend. The productions are nearly the fame with thofe of St Chriftopher. There are three pretty good roads or bays, with fmall towns in their vicinity; Charles-town, Moreton-Bay, and Newcaftle. This pleafant ifland was fettled under the aufpices of Sir Thomas Warner from St Chriftopher's. His fucceffor, governor Lake, was confidered as the Solon of this little country, in which he difpofed of every thing with fuch prudence, wifdom, and juftice, as procured him an high reputation with the French as well as Englifh. In the Dutch war they met with fome difturbance from the French; but by being covered by an Englifh fquadron, the enemy were obliged to defift from their intended invafion, after a fmart engagement in fight of the ifland. Sir William Stapleton fometimes refided here, and Sir Nathaniel Johnfon conftantly, at which time the inhabitants of Nevis were computed at 30,000. In the war immediately after the revolution, they exerted themfelves gallantly, and had two regiments of 300 men each. In that of queen Anne they behaved equally well, tho' they were lefs fortunate; for the French landing with a fuperior force, and having inveigled moft of their flaves, they were forced to capitulate. About 4000 of thefe flaves the French carried away and fold to the Spaniards, to work in their mines. The parliament, after making due inquiry into the loffes they had fuftained, voted them about a third part of the fum in which they had fuffered. Thefe loffes by war, an epidemic difeafe, and repeated hurricanes, exceedingly diminifhed the number of the people. They are now thought not to exceed 2000 or 3000 whites, and 6000 blacks. There is here a lieutenant-governor, with a council, and an affembly, which is compofed of three members from each of the five parifhes into which the ifland is divided. The commodities are cotton and fugar; and about 20 fail of fhips are annually employed in this trade.

NEURITICS, in pharmacy, medicines good in diforders of the nerves.

NEUROGRAPHY, fignifies a defcription of the nerves. See Anatomy, n° 400.

NEUROPTERA. See Zoology.

NEUTER, a perfon indifferent, who has efpoufed neither party, and is neither friend nor foe.

A judge ought to be neuter in the caufes he judges; in queftions, where reafon appears neuter, a man fhould ever incline to the fide of the unhappy.

Neuter, in grammar, denotes a fort of gender of nouns, which are neither mafculine nor feminine. See Gender.

The Latins have three kinds of genders, mafculine, feminine, and neuter. In Englifh, and other modern tongues, there is no fuch thing as neuter nouns. See Noun.

Verbs Neuter, by fome grammarians called *intranfitive verbs*, are thofe which govern nothing, and that are neither active nor pofitive. See Verb.

When the action expreffed by the verb has no object to fall upon, but the verb alone fupplies the whole idea of the action; the verb is faid to be *neuter*: as, I fleep, thou yawneft, he fneezes, we walk, ye run, they ftand ftill.

Some divide verbs neuter into, 1. Such as do not fignify any action, but a quality; as *albet*, "it is white;" or a fituation, as *fedet*, "he fits:" or have fome relation to place; as *adeft*, "he is prefent;" or to fome other ftate or attribute, as *regnat*, "he rules," &c. And, 2. Thofe that do fignify actions, though thofe fuch as do not pafs into any fubject different from the actor; as to dine, to fup, to play, &c.

But this latter kind fometimes ceafe to be *neuter*, and commence active; efpecially in Greek and Latin, when a fubject is given them: as, *vivere vitam*, *ambulare viam*, *pugnare pugnam*. Thus the old French poets fay, *Soupirer fon tourment*; the Englifh, to *figh his woes*, &c.

But this is obferved only to obtain where fomething particular is to be expreffed, not contained, in the verb: as, *vivere vitam beatam*, to live a happy life; *pugnare bonam pugnam*, to fight a good fight, &c.

According to the abbot de Dangeau, *verbs neuter* may be divided into *active* and *paffive*; the firft, thofe that form their tenfes in Englifh, by the auxiliary verb *to have*; in French, by *avoir*. The fecond, thofe that form them in Englifh with the verb *to be*; in French *etre*.—Thus, to fleep, to yawn, *dormir* and *eternuer*, are *neuters active*.—To come, and to arrive, are *neuters paffive*.

Neutral *Salts*, among chemifts, thofe compounded of an acid with any other fubftance capable of uniting with it and deftroying its acidity. Thofe in which the acid is faturated with an earth or a metal are called *imperfect*, but thofe in which a pure alkali is employed are called *perfect*, neutrals.

NEUTRALITY, the ftate of a perfon or thing that is neuter, or that takes part with neither fide.

NEWCASTLE, the capital of the county of Northumberland in England, a large, populous, and flourifhing town, fituated on the north bank of the river Tyne, about 300 miles to the northward of London. It is connected, by means of a bridge with the fuburbs of Gatefhead, which, being on the fouthern fide of the river, is part of the bifhopric of Durham. Near the fpot where the town now ftands, there was of old a fort called *Moncafter*; and Robert, fon of William the Conqueror, having built another to overawe the Scots, beftowed upon it the name of *Newcaftle*, in contradiftinction to the old fortrefs. Divers monafteries and hofpitals being raifed around it, the place, in a little time, fwelled into a town; and the walls of it were begun in the reign of Edward I. by a rich burgher, who had been taken by the Scots, and paid a large ranfom for his liberty. It is at prefent furrounded by a ftrong wall, in which there are feven gates and as many turrets, with fome cafemates faid to be bomb-proof. It was created a borough by king Richard II. who granted permiffion to carry a fword before the mayor; and king Henry VI. erected it into a town and county incorporate, independent of Northumberland. The magiftracy confifts of a mayor, 19 aldermen, a fheriff, a recorder, a town-clerk, a clerk of the chambers, two coroners, eight chamberlains, a fword-bearer, with a cap

Newcaſtle ‖ Newforeſt.

cap of maintenance, a water-bailiff with a great mace, and ſeven ſerjeants at mace. Newcaſtle has been expoſed to frequent incurſions and ſieges of the Scots, before the union of the two crowns; and in the great rebellion, the army of that kingdom, under the command of Leſlie, took it by ſtorm: but it has long ago retrieved all its loſſes, and become the great emporium of the north of England for coal and other merchandize. The town is built upon the declivity of a hill, which renders the ſtreets ſteep and incommodious. The houſes are crowded together ſo as to exhibit but a diſagreeable appearance: yet one or two of the ſtreets are large, ſpacious, and well paved. The town is overlooked by the old ruinous caſtle: the exchange and cuſtom-houſe are magnificent buildings, but too cloſe to the river; along the bank of which there is a fine key or wharf faced with freeſtone, to which ſhips of ordinary burden can carry their broadſides to be loaded or unloaded. But the coal-ſhips are loaded at or near Shields, ſeven miles farther down the river; their lading being conveyed thither in lighters, which they call *keels*. The number of the keelmen who work in theſe lighters, exceed 6000, who live in a ſuburb called *Sandgate*. They have, by a contribution among themſelves, built a noble hoſpital for ſuch of their poor brethren as are diſabled by accident, or ſuperannuated and paſt labour. The principal church of Newcaſtle, called *St Nicholas*, is a ſtately old fabric, built by David king of Scotland, with a fine ſteeple of rare architecture: here are, beſides, ſix churches or chapels. We may number among the public edifices, an elegant manſion-houſe for the mayor; a noble hall for the ſurgeons, with a muſeum; a ſtately infirmary on the model of that at Edinburgh; a library belonging to the corporation; a large priſon called *Newgate;* ſeveral meeting-houſes, and charity-ſchools well endowed. The number of inhabitants amounts to above 40,000; and many of them are wealthy, and live with ſplendour. They are generally bold, rough, and induſtrious; enriching themſelves with the coal-trade, and other branches of commerce and manufacture, ſuch as ſhip-building, glaſs-making, ſalt-works, and hard-ware or wrought iron. The place is particularly famous for grind-ſtones, which are exported to all the countries in Europe. The faſhionable people live in the upper part of the town, at a diſtance from the river, where they poſſeſs elegant houſes and gardens, and enjoy themſelves at comedies, aſſemblies, and other polite diverſions. The houſes are chiefly built of ſtone, ſome are of brick, and a very few of timber. The revenue of the town, amounting to 8000 l. a-year, is conſiderably larger than that of any other corporation-borough in England: and from this the mayor is indulged with an annual allowance of 600 l. beſides the maintenance of a coach, barge, and manſion-houſe.

Newcastle (Duke of). See Cavendish.

NEWEL, in architecture, is the upright poſt which a pair of winding ſtairs turn about; this is properly a cylinder of ſtone, which bears on the ground, and is formed by the end of the ſteps of the winding ſtairs.

NEWFIDLER-sea, a lake in Hungary, 17 miles in length, and 6 in breadth.

NEWFOREST, a part of Hampſhire, lying on the Engliſh channel, oppoſite to the Iſle of Wight. It was made by William the Conqueror, who cauſed 36 churches, and all the houſes belonging thereto, to be pulled down, that there might be no obſtruction in hunting the game. It is now appropriated by act of parliament for the production of oaks, to be employed in building the royal navy.

Newfoundland.

NEWFOUNDLAND, a large iſland of North America, belonging to Great Britain, lying between 46. 50. and 51. 30. N. Lat. and between 53. 30. and 58. 20. W. Long. from London. The form is that of an irregular triangle, the baſe or ſouth ſide being 80 leagues in extent; the eaſt ſide is the longeſt; and the whole circumference about 150 leagues. It is bounded on the north by the Straits of Belleiſle, which ſeparate it from Labrador; on the eaſt and ſouth it hath the Atlantic Ocean, and on the weſt the Gulph of St Laurence. The climate is rather ſevere; and the ſoil, at leaſt on the ſea-coaſt, which is all that we know of it, is poor and barren. A few kitchen vegetables with ſtrawberries and raſberries are all its produce. The country within land is mountainous, and abounds with timber; there are ſeveral rivers which are plentifully ſtored with various ſorts of fiſh, abundance of deep bays, and many good ports. St John's and Placentia are the two principal ſettlements, and at each of theſe there is a fort; the number of people who remain here in the winter hath been computed at 4000. The French, by the treaty of Utrecht, were permitted to fiſh from Cape Bonaviſta on the eaſt ſide round the north of the iſland to Point Rich on the weſt; and by the treaty of Paris, they are allowed the iſles of St Pierre and Miquelon, upon which they are to dry their fiſh, but not to erect fortifications of any kind.

The great importance of this place ariſes from its fiſhery, which is in part carried on by the inhabitants at the ſeveral harbours, which are about 20 in number, who take vaſt quantities of cod near the coaſt, which they bring in and cure at their leiſure, in order to have it ready for the ſhips when they arrive. But the great and extenſive fiſhery is on the banks at ſome diſtance from the iſland. The great bank lies 20 leagues from the neareſt point of land from the latitude of 41 to 49, ſtretching 300 miles in length and 75 in breadth. To the eaſt of this lies the Falſe Bank; the next is ſtyled *Vert* or *the Green Bank*, about 240 miles long, and 120 over; then Banquero, about the ſame ſize; the ſhoals of Sand Iſland, Whale Bank, and the Bank of St Peter's, with ſeveral others of leſs note, all abounding with fiſh.

The cod are caught only by a hook, and an expert fiſher will take from 150 to 300 and upwards in a day; for the fiſh never bite in the night, and the labour is very great. The ſeaſon is from May to October, in the height of which there are from 500 to 700 ſail upon the banks at a time. The fiſh caught in the ſpring-months are beſt; they are cured in very different ways. Some are ſtyled *white fiſh*, others *mud fiſh*, which are ſtowed and ſalted in the hold, and will not keep long; but the beſt and moſt valuable are the dried cod. The quantity taken is prodigious; yet in ſome ſeaſons and in different places varies conſiderably, as the fiſh frequently change their ſtations. The *fiſhing-ſhips*, as they are called, lie upon the banks, with the help of their

Newfound-land ‖ Newton.

their boats take and cure their own fifh, and as foon as they are full fail for a market. The fack-fhips proceed directly to the ifland, where they purchafe fifh from the inhabitants either by barter or bills of exchange. The principal markets for cod are Spain, Portugal, Italy, and the Weft Indies. The value of this fifhery is computed at fome hundred thoufand pounds anually; employing, befides feveral hundred fhips, fome thoufands of feamen, and affording a maintenance to a number of tradefmen of different occupations, by which many large towns on the weft fide of England accumulate much wealth, and at the fame time contribute in many refpects to the benefit of the public.

The great utility of this fifhery was very early feen, and very vigoroufly purfued; for in the beginning of the reign of king James I. we had two hundred and fifty fail employed therein. It is computed, that three quintals of wet fifh make one quintal of dried cod. Befides, the livers of every hundred quintals make a hogfhead of oil; and exclufive of thefe, there are many leffer advantages that go in diminution of the expence. The fifhery, as we have faid above, produces differently in different feafons; but it is judged to be a very good one when it produces 300,000 quintals of fifh, and 3000 barrels of oil, both equally faleable and valuable commodities. As every fhip carries 12, and each of their boats eight men, and as thefe return home in fix months, there cannot be a more noble nurfery for feamen. The artificers and traders employed in building, victualling, and repairing thefe veffels, are very numerous in the refpective ports from which they fail. Thefe circumftances juftify the particular attention paid by government to this branch of the public fervice; in refpect to which, that they may be well informed, an annual and very diftinct account, by which the whole is feen at one view, is delivered by the proper officer to the governor of Newfoundland, that is, to the commodore of his majefty's fquadron.

NEWMARKET, a town of England, partly in Cambridgefhire, and partly in Suffolk. It confifts of one well-built ftreet, feated on the great road, and full of inns. It is chiefly noted for its horfe-races. E. Long. 0. 25. N. Lat. 52. 16.

NEWT, or Eft, in zoology, the common lizard. See Lacerta.

NEWTON (Sir Ifaac), one of the greateft philofophers and mathematicians the world has produced, was the only child of Mr John Newton of Colefworth, not far from Grantham in Lincolnfhire, who had an eftate of about 120*l. per annum*, which he kept in his own hands. He was born at that place on Chriftmas-day 1642. His father dying when he was young, his mother's brother, a clergyman of the name of *Ayfcough*, or *Afkew*, who lived near her, and directed all her affairs after the death of Mr Newton, put her fon to fchool at Grantham. When he had finifhed his fchool-learning, his mother took him home; intending, as fhe had no other child, to have the pleafure of his company; and that he, as his father had done, fhould occupy his own eftate. But his uncle happening to find him in a hay-loft at Grantham, working a mathematical problem, and having otherwife obferved the boy's mind to be uncommonly bent upon learning, he prevailed upon her to part with him; and fhe fent him to Trinity College in Cambridge, where her brother, having himfelf been a member of it, had ftill many friends. Ifaac was foon taken notice of by Dr Ifaac Barrow; who, obferving his bright genius, contracted a great friendfhip for him. M. De Fontenelle tells us, "That in learning mathematics he did not ftudy Euclid, who feemed to him too plain and fimple, and unworthy of taking up his time. He underftood him almoft before he read him, and a caft of his eye upon the contents of his theorems was fufficient to make him mafter of them. He advanced at once to the geometry of Des Cartes, Kepler's optics, &c. It is certain, that he had made his great difcoveries in geometry, and laid the foundation of his two famous works the *Principia* and the *Optics*, by the time he was 24 years of age."

Newton.

In 1664, he took the degree of bachelor of arts; and in 1668 that of mafter, being elected the year before fellow of his college. He had before this time difcovered the method of fluxions; and in 1669, he was chofen profeffor of mathematics in the univerfity of Cambridge, upon the refignation of Dr Barrow. The fame year, and the two following, he read a courfe of optical lectures in Latin, in the public fchools of the univerfity; an Englifh tranflation of which was printed at London in 1728 in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correfpondence, by letters, with Mr Henry Oldenburg, fecretary of the royal fociety, and Mr John Collins, fellow of that fociety; which letters contain a variety of curious obfervations.

Concerning the origin of his difcoveries, we are told that as he fat alone in a garden, the falling of fome apples from a tree led him into a fpeculation on the power of gravity; that as this power is not diminifhed at the remoteft diftance from the centre of the earth to which we can rife, it appeared to him reafonable to conclude, that it muft extend much farther than was ufually thought; and purfuing this fpeculation by comparing the periods of the feveral planets with their diftances from the fun, he found, that if any power like gravity held them in their courfes, its ftrength muft decreafe in the duplicate proportion of the increafe of diftance. This inquiry was dropped; but refumed again, and gave rife to his writing the treatife which he publifhed in 1687 under the name of *Mathematical Principles of Natural Philofophy*; a work looked upon as the production of a celeftial intelligence rather than of a man. The very fame year in which this great work was publifhed, the univerfity of Cambridge was attacked by king James II. when he was one of its moft zealous defenders, and was accordingly nominated one of the delegates of that univerfity to the high-commiffion court; and the next year he was chofen one of their members for the convention-parliament, in which he fat till it was diffolved. In 1696, Mr Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him of the king, the office of warden of the mint; in which employment he was of fignal fervice, when the money was called in to be recoined. Three years after, he was appointed mafter of the mint; a place of very confiderable profit, which he held till his death. In 1699, he was elected one of the members of the royal academy of ſciences at Paris. In 1701, he was a ſecond time choſen member of parliament for the univerſity of Cambridge. In 1704, he publiſhed his *Optics;* which is a piece of philoſophy ſo new, that the ſcience may be conſidered as entirely owing to our author. In 1705, he was knighted by queen Anne. In 1707, he publiſhed his *Arithmetica Univerſalis.* In 1711, his *Analyſis per Quantitatum Series, Fluxiones et Differentias,* &c. was publiſhed by William Jones Eſq. In 1712, ſeveral letters of his were publiſhed in the *Commercium Epiſtolicum.* In the reign of George I. he was better known at court than before. The princeſs of Wales, afterwards qneen-conſort of England, uſed freqnently to propoſe queſtions to him, and to declare that ſhe thought herſelf happy to live at the ſame time with him, and have the pleaſure and advantage of his converſation. He had written a treatiſe of ancient chronology, which he did not think of publiſhing; but the princeſs deſired an abſtract, which ſhe would never part with. However, a copy of it ſtole abroad, and was carried into France; where it was tranſlated and printed, with ſome obſervations, which were afterwards anſwered by Sir Iſaac. But, in 1728, the Chronology itſelf was publiſhed at London in quarto; and was attacked by ſeveral perſons, and as zealouſly defended by Sir Iſaac's friends. The main deſign of it was to find out, from ſome tracts of the moſt ancient Greek aſtronomy, what was the poſition of the colures with reſpect to the fixed ſtars, in the time of Chiron the centaur. As it is now known that theſe ſtars have a motion in longitude of one degree in 72 years, if it is once known thro' what fixed ſtars the colure paſſed in Chiron's time, by taking the diſtance of theſe ſtars from thoſe through which it now paſſes, we might determine what number of years is elapſed ſince Chiron's time. As Chiron was one of the Argonants, this would fix the time of that famons expedition, and conſequently that of the Trojan war; the two great events upon which all the ancient chronology depends. Sir Iſaac places them 500 years nearer the birth of Chriſt than other chronologers generally do.

This great man had all along enjoyed a ſettled and equal ſtate of health to the age of 80, when he began to be afflicted with an incontinence of urine. However, for the five following years, he had great intervals of eaſe, which he procured by the obſervance of a ſtrict regimen. It was then believed that he certainly had the ſtone; and when the paroxyſms were ſo violent, that large drops of ſweat ran down his face, he never uttered the leaſt complaint, or expreſſed the ſmalleſt degree of impatience; but, as ſoon as he had a moment's eaſe, would ſmile and talk with his uſual cheerfulneſs. Till then he always read and wrote ſeveral hours in a day. He had the perfect uſe of all his ſenſes and underſtanding till the day before he died, which was on the 20th of March 1726-7, in the 85th year of his age.—He lay in ſtate in the Jeruſalem chamber at Weſtminſter, and on the 28th of March his body was conveyed into Weſtminſter abbey; the pall being ſupported by the lord chancellor, the dukes of Montroſe and Roxburgh, and the earls of Pembroke, Suſſex, and Macclesfield. The biſhop of Rocheſter read the funeral office, being attended by all the clergy of the church. The corps was interred juſt at the entrance into the choir, where a noble monument is erected to his memory.

Sir Iſaac was of a middling ſtature, and in the latter part of his life ſomewhat inclined to be fat. His countenance was pleaſing, and at the ſame time venerable. He never made uſe of ſpectacles, and loſt but one tooth during his whole life.

His temper is ſaid to have been ſo equal and mild, that no accident could diſturb it. Of this the following remarkable inſtance is related. Sir Iſaac had a favourite little dog, which he called *Diamond;* and being one day called out of his ſtudy into the next room, Diamond was left behind. When Sir Iſaac returned, having been abſent but a few minutes, he had the mortification to find, that Diamond having thrown down a lighted candle among ſome papers, the nearly finiſhed labour of many years was in flames, and almoſt conſumed to aſhes. This loſs, as Sir Iſaac was then very far advanced in years, was irretrievable; yet, without once ſtriking the dog, he only rebuked him with this exclamation, "Oh! Diamond! Diamond! thou little knoweſt the miſchief thou haſt done!"

He was a great lover of peace; and would rather have choſen to remain in obſcurity, than to have the calm of life ruffled by thoſe ſtorms and diſputes which genius and learning always draw upon thoſe that are too eminent for them. In contemplating his genius, it preſently becomes a doubt, which of theſe endowments had the greateſt ſhare, ſagacity, penetration, ſtrength, or diligence: and, after all, the mark that ſeems moſt to diſtinguiſh it is, that he himſelf made the juſteſt eſtimation of it, declaring, that, if he had done the world any ſervice, it was due to nothing but induſtry and patient thought; that he kept the ſubject under conſideration conſtantly before him, and waited till the firſt dawning opened gradually, by little and little, into a full and clear light. It is ſaid, that when he had any mathematical problems or ſolutions in his mind, he would never quit the ſubject on any account. Dinner has been often three hours ready for him before he could be brought to table: that his man often ſaid, when he has been getting up in a morning, he has ſometimes begun to dreſs, and with one leg in his breeches, ſat down again on the bed, where he has remained for hours before he got his cloaths on. From his love of peace, no doubt, aroſe that unuſual kind of horror which he had for all diſputes; a ſteady unbroken attention, free from thoſe frequent recoilings inſeparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controverſy was looked on as his bane. When ſome objections, haſtily made to his diſcoveries concerning light and colours, induced him to lay aſide the deſign he had of publiſhing his optic lectures; we find him reflecting on that diſpute, into which he was unavoidably drawn thereby, in theſe terms: "I blamed my own imprudence for parting with ſo real a bleſſing as my quiet, to run after a ſhadow." It is true this ſhadow, as Mr Fontenelle obſerves, did not eſcape him afterwards, nor did it coſt him that quiet which he ſo much valued, but proved as much a real happineſs to him as his quiet itſelf; yet this was a happineſs of his own making: he took a reſolution, from theſe diſputes, not to publiſh any more about that theory, till he had put it above the reach of of controverfy, by the exacteft experiments, and the ftricteft demonftrations; and accordingly it has never been called in queftion fince. In the fame temper, after he had fent the manufcript of his *Principia* to the Royal Society, with his confent to the printing of it by them; yet upon Mr Hooke's injurioufly infifting that himfelf had demonftrated Kepler's problem before our author, he determined, rather than be involved again in a controverfy, to fupprefs the third book, and was very hardly prevailed upon to alter that refolution. It is true, the public was thereby a gainer; that book, which is indeed no more than a corollary of fome propofitions in the firft, being originally drawn up in the popular way, with a defign to publifh it in that form; whereas he was now convinced that it would be beft not to let it go abroad without a ftrict demonftration.

After all, notwithftanding his anxious care to avoid every occafion of breaking his intenfe application to ftudy, he was at a great diftance from being fteeped in philofophy: on the contrary, he could lay afide his thoughts, though engaged in the moft intricate refearches, when his other affairs required his attendance; and, as foon as he had leifure, refume the fubject at the point where he had left off. This he feems to have done not fo much by any extraordinary ftrength of memory, as by the force of his inventive faculty, to which every thing opened itfelf again with eafe, if nothing intervened to ruffle him. The readinefs of his invention made him not think of putting his memory much to the trial; but this was the offspring of a vigorous intenfenefs of though, out of which he was but a common man. He fpent, therefore, the prime of his age in thofe abftrufe refearches, when his fituation in a college gave him leifure, and even while ftudy was his proper profeffion. But, as foon as he was removed to the mint, he applied himfelf chiefly to the bufinefs of that office; and fo far quitted mathematics and philofophy, as not to engage in any purfuits of either kind afterwards.

The amiable quality of modefty is reprefented as ftanding foremoft in the character of this great man's mind and manners. It was in reality greater than can be eafily imagined, or will be readily believed: yet it always continued fo without any alteration, though the whole world, fays Fontenelle, confpired againft it; let us add, though he was thereby robbed of his invention of fluxions. Nicholas Mercator publifhing his *Logarithmotechnia* in 1668, where he gave the quadrature of the hyperbola by an infinite feries, which was the firft appearance in the learned world of a feries of this fort drawn from the particular nature of the curve, and that in a manner very new and abftracted; Dr Barrow, then at Cambridge, where Mr Newton, then about 26 years of age, refided, recollected, that he had met with the fame thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all forts of curves, even fuch as are mechanical; to their quadratures, their rectifications, and their centres of gravity; to the folids formed by their relations, and to the fuperficies of thofe folids; fo that, when their determinations were poffible, the feries ftopped at a certain point, or at leaft their fums were given by ftated rules: and, if the abfolute determinations were impoffible, they could yet be infinitely approximated; which is the happieft and moft refined method, fays Mr Fontenelle, of fupplying the defects of human knowledge that man's imagination could poffibly invent. To be mafter of fo fruitful and general a theory was a mine of gold to a geometrician; but it was a greater glory to have been the difcoverer of fo furprifing and ingenious a fyftem. So that Mr Newton, finding by Mercator's book, that he was in the way to it, and that others might follow in his tract, fhould naturally have been forward to open his treafures, and fecure the property, which confifted in making the difcovery; but he contented himfelf with his treafure which he had found, without regarding the glory. What an idea does it give us of his unparallelled modefty, when we fee him declaring, that he thought Mercator had intirely difcovered his fecret, or that others would, before he was of a proper age for writing? His MS. upon infinite feries was communicated to none but Mr John Collins and the Lord Brounker; and even that had not been complied with, but for Dr Barrow, who would not fuffer him to indulge his modefty fo much as he defired.

It is further obferved, concerning this part of his character, that he never talked either of himfelf or others, nor ever behaved in fuch a manner as to give the moft malicious cenfurers the leaft occafion even to fufpect him of vanity. He was candid and affable, and always put himfelf upon a level with his company. He never thought either his merit or his reputation fufficient to excufe him from any of the common offices of focial life; no fingularities, either natural or affected, diftinguifhed him from other men. Though he was firmly attached to the church of England, he was averfe to the perfecution of the non-conformifts. He judged of men by their manners; and the true fchifmatics, in his opinion, were the vicious and the wicked. Not that he confined his principles to natural religion, for he was thoroughly perfuaded of the truth of revelation; and amidft the great variety of books which he had conftantly before him, that which he ftudied with the greateft application was the Bible: and he underftood the nature and force of moral certainty as well as he did that of a ftrict demonftration.

Sir Ifaac did not neglect the opportunities of doing good, when the revenues of his patrimony, and a profitable employment, improved by a prudent œconomy, put it in his power. We have two remarkable inftances of his bounty and generofity; one to Mr M'Laurin, profeffor of mathematics at Edinburgh, to whom he offered 20l. per annum; and the other to his niece Barton, who had an annuity of 100l. per annum fettled upon her by him. When decency upon any occafion required expence and fhew, he was magnificent without grudging it, and with a very good grace; at all other times, that pomp which feems great to low minds only, was utterly retrenched, and the expence referved for better ufes. He never married, and perhaps he never had leifure to think of it. Being immerfed in profound ftudies during the prime of his age, and afterwards engaged in an employment of great importance, and even quite taken up with the company which his merit drew to him, he was not fenfible of any vacancy in life, nor of the want of a companion at home. He left 32,000l. at his death; but made no will, which

Mr

Newtonian Philosophy

Mr Fontenelle tells us was becaufe he thought a legacy was no gift. As to his works, befides what were publifhed in his life-time, there were found after his death, among his papers, feveral difcourfes upon the fubjects of antiquity, hiftory, divinity, chemiftry, and mathematics, feveral of which were publifhed at different times.

NEWTONIAN *Philofophy*, the doctrine of the univerfe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Ifaac Newton.

1 Different opinions concerning this philofophy.

The term *Newtonian philofophy* is applied very differently; whence divers confufed notions relating thereto.—Some authors, under this philofophy, include all the corpufcular philofophy, confidered as it now ftands corrected and reformed by the difcoveries and improvements made in feveral parts thereof by Sir Ifaac Newton. In which fenfe it is that Gravefande calls his elements of phyfics, *Introductio ad Philofophiam Newtonianam*. And in this fenfe the Newtonian is the fame with the new philofophy; and ftands contradiftinguifhed from the Cartefian, the Peripatetic, and the ancient Corpufcular.

Others, by *Newtonian philofophy*, mean the method or order which Sir Ifaac Newton obferves in philofophifing; *viz.* the reafoning and drawing of conclufions directly from phænomena, exclufive of all previous hypothefes; the beginning from fimple principles; deducing the firft powers and laws of nature from a few felect phenomena, and then applying thofe laws, &c. to account for other things. And in this fenfe the *Newtonian philofophy* is the fame with the *experimental philofophy*, and ftands oppofed to the ancient *Corpufcular*.

Others, by *Newtonian philofophy*, mean that wherein phyfieal bodies are confidered mathematically, and where geometry and mechanics are applied to the folution of phænomena. In which fenfe the Newtonian is the fame with the *mechanical* and *mathematical philofophy*.

Others again, by *Newtonian philofophy*, underftand that part of phyfical knowledge which Sir Ifaac Newton has handled, improved, and demonftrated, in his *Principia*.

Others, laftly, by *Newtonian philofophy*, mean the new principles which Sir Ifaac Newton has brought into philofophy; the new fyftem founded thereon; and the new folutions of phænomena thence deduced; or that which characterizes and diftinguifhes his philofophy from all others.—Which is the fenfe wherein we fhall chiefly confider it.

As to the hiftory of this philofophy, we have nothing to add to what has been given in the preceding article. It was firft made public in the year 1687, by the author, then a fellow of Trinity-college, Cambridge; and in the year 1713, republifhed with confiderable improvements.—Several authors have fince attempted to make it plainer; by fetting afide many of the more fublime mathematical refearches, and fubftituting either more obvious reafonings or experiments in lieu thereof; particularly Whifton in his *Prælect. Phyf. Mathemat.* Gravefande in *Element. & Inftit.* and Dr Pemberton in his *View*.

The whole of the *Newtonian philofophy*, as delivered by the author, is contained in his *Principia*, or *Mathematical Principles of Natural Philofophy*. He founds his fyftem on the following definitions.

2 Definitions on which the philofophy is founded.

1. The quantity of matter is the meafure of the fame, arifing from its denfity and bulk conjunctly.—Thus air of a double denfity, in a double fpace, is quadruple in quantity; in a triple fpace, fextuple in quantity, &c.

2. The quantity of motion is the meafure of the fame, arifing from the velocity and quantity of matter conjunctly. This is evident, becaufe the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3 *Vis infita* defined and objected to.

3. The *vis infita*, or innate force of matter, is a power of refifting, by which every body, as much as in it lies, endeavours to perfevere in its prefent ftate, whether it be of reft, or moving uniformly forward in a right line.—This definition is proved to be juft, only by the difficulty we find in moving any thing out of its place; and this difficulty is by fome reckoned to proceed only from gravity. They contend, that in thofe cafes where we can prevent the force of gravity from acting upon bodies, this power of refiftance becomes infenfible, and the greateft quantities of matter may be put in motion by the very leaft force. Thus there have been balances formed fo exact, that when loaded with 200 weight in each fcale, they would turn by the addition of a fingle drachm. In this cafe 400 ℔. of matter was put in motion by a fingle drachm, *i. e.* by $\frac{1}{51200}$ parts of its own quantity: and even this fmall weight, they fay, is only neceffary on account of the inaccuracy of the machine; fo that we have no reafon to fuppofe, that, if the friction could be entirely removed, it would take more force to move a tun weight than a grain of fand. This objection, however, is not taken notice of by Sir Ifaac; and he beftows on the refifting power abovementioned, the name of *vis inertiæ*.

4. An impreffed force is an action exerted upon a body, in order to change its ftate, either of reft, or of moving uniformly forward in a right line.—This force confifts in the action only; and remains no longer in the body when the action is over. For a body maintains every new ftate it acquires by its *vis inertiæ* only.

5. A centripetal force is that by which bodies are drawn, impelled, or any way tend towards a point, as to a centre.—The quantity of any centripetal force may be confidered as of three kinds, abfolute, accelerative, and motive.

6. The abfolute quantity of a centrifugal force is the meafure of the fame, proportional to the efficacy of the caufe that propagates it from the centre, through the fpaces round about.

7. The accelerative quantity of a centripetal force is the meafure of the fame, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force is a meafure of the fame, proportional to the motion which it generates in a given time.—This is always known by the quantity of a force equal and contrary to it, that is juft fufficient to hinder the defcent of the body.

SCHOLIA.

4 Of time.

I. Abfolute, true, and mathematical time, of itfelf, and from its own nature, flows equably, without regard

gard to any thing external, and, by another name, is called *duration*. Relative, apparent, and common time, is ſome ſenſible and external meaſure of duration, whether accurate or not, which is commonly uſed inſtead of true time; ſuch as an hour, a day, a month, a year, &c.

5 Space.

II. Abſolute ſpace, in its own nature, without regard to any thing external, remains always ſimilar and immoveable. Relative ſpace is ſome moveable dimenſion or meaſure of the abſolute ſpaces; and which is vulgarly taken for immoveable ſpace. Such is the dimenſion of a ſubterraneous, an aerial, or celeſtial ſpace, determined by its poſition to bodies, and which is vulgarly taken for immoveable ſpace; as the diſtance of a ſubterraneous, an aerial, or celeſtial ſpace, determined by its poſition in reſpect of the earth. Abſolute and relative ſpace are the ſame in figure and magnitude; but they do not remain always numerically the ſame. For if the earth, for inſtance, moves, a ſpace of our air which, relatively and in reſpect of the earth, remains always the ſame, will at one time be one part of the abſolute ſpace into which the air paſſes; at another time it will be another part of the ſame; and ſo, abſolutely underſtood, it will be perpetually mutable.

6 Place defined.

III. Place is a part of ſpace which a body takes up; and is, according to the ſpace, either abſolute or relative. Our author ſays it is *part* of ſpace; not the ſituation, nor the external ſurface of the body. For the places of equal ſolids are always equal; but their ſuperficies, by reaſon of their diſſimilar figures, are often unequal. Poſitions properly have no quantity, nor are they ſo much the places themſelves as the properties of places. The motion of the whole is the ſame thing with the ſum of the motions of the parts; that is, the tranſlation of the whole out of its place is the ſame thing with the ſum of the tranſlations of the parts out of their places: and therefore the place of the whole is the ſame thing with the ſum of the places of the parts; and for that reaſon it is internal, and in the whole body.

7 Of motion.

IV. Abſolute motion is the tranſlation of a body from one abſolute place into another, and relative motion the tranſlation from one relative place into another. Thus, in a ſhip under ſail, the relative place of a body is that part of the ſhip which the body poſſeſſes, or that part of its cavity which the body fills, and which therefore moves together with the ſhip; and relative reſt is the continuance of the body in the ſame part of the ſhip, or of its cavity. But real abſolute reſt is the continuance of the body in the ſame part of that immoveable ſpace in which the ſhip itſelf, its cavity, and all that it contains, is moved. Wherefore, if the earth is really at reſt, the body which relatively reſts in the ſhip will really and abſolutely move with the ſame velocity which the ſhip has on the earth. But if the earth alſo moves, the true and abſolute motion of the body will ariſe, partly from the true motion of the earth in immoveable ſpace; partly from the relative motion of the ſhip on the earth: and if the body moves alſo relatively in the ſhip, its true motion will ariſe partly from the true motion of the earth in immoveable ſpace, and partly from the relative motions as well of the ſhip on the earth, as of the body in the ſhip; and from theſe relative motions will ariſe the relative motion of the body on the earth. As if that part of the earth where the ſhip is, was truly moved towards the eaſt, with a velocity of 10010 parts; while the ſhip itſelf with a freſh gale is carried towards the weſt, with a velocity expreſſed by 10 of theſe parts; but a ſailor walks in the ſhip towards the eaſt with one part of the ſaid velocity: then the ſailor will be moved truly and abſolutely in immoveable ſpace towards the eaſt with a velocity of 10001 parts; and relatively on the earth towards the weſt, with a velocity of 9 of thoſe parts.

Abſolute time, in aſtronomy, is diſtinguiſhed from relative, by the equation or correction of the vulgar time. For the natural days are truely unequal, though they are commonly conſidered as equal, and uſed for a meaſure of time: aſtronomers correct this inequality for their more accurate deducing of the celeſtial motions. It may be that there is no ſuch thing as an equable motion whereby time may be accurately meaſured. All motions may be accelerated or retarded; but the true or equable progreſs of abſolute time is liable to no change. The duration or perſeverance of the exiſtence of things remains the ſame, whether the motions are ſwift or ſlow, or none at all; and therefore ought to be diſtinguiſhed from what are only ſenſible meaſures thereof, and out of which we collect it by means of the aſtronomical equation. The neceſſity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum-clock, as by eclipſes of the ſatellites of Jupiter. 8

Immutability of time and ſpace.

As the order of the parts of time is immutable, ſo alſo is the order of the parts of ſpace. Suppoſe thoſe parts to be moved out of their places, and they will be moved (if we may be allowed the expreſſion) out of themſelves. For times and ſpaces are, as it were, the places of themſelves as of all other things. All things are placed in time as to order of ſucceſſion; and in ſpace as to order of ſituation. It is from their eſſence or nature that they are places; and that the primary places of things ſhould be moveable, is abſurd. Theſe are therefore the abſolute places; and tranſlations out of thoſe places are the only abſolute motions.

But becauſe the parts of ſpace cannot be ſeen, or diſtinguiſhed from one another by the ſenſes, therefore in their ſtead we uſe ſenſible meaſures of them. For, from the poſitions and diſtances of things from any body, conſidered as immoveable, we define all places; and then with reſpect to ſuch places, we eſtimate all motions, conſidering bodies as transferred from ſome of thoſe places into others. And ſo, inſtead of abſolute places and motions, we uſe relative ones; and that without any inconvenience in common affairs: but in philoſophical diſquiſitions we ought to abſtract from our ſenſes, and conſider things themſelves diſtinct from what are only ſenſible meaſures of them. For it may be, that there is no body really at reſt, to which the places and motions of others may be referred.

But we may diſtinguiſh reſt and motion, abſolute and relative, one from the other by their properties, cauſes, and effects. It is a property of reſt, that bodies really at reſt do reſt in reſpect of each other. And therefore, as it is poſſible, that, in the remote regions

Newtonian Philosophy

gions of the fixed ftars, or perhaps far beyond them, there may be fome body abfolutely at reft, but impoffible to know from the pofition of bodies to one another in our regions, whether any of thefe do keep the fame pofition to that remote body; it follows, that abfolute reft cannot be determined from the pofition of bodies in our regions.

9
Of the motion of different bodies with refpect to one another.

It is a property of motion, that the parts which retain given pofitions to their wholes do partake of the motions of their wholes. For all parts of revolving bodies endeavour to recede from the axis of motion; and the impetus of bodies moving forwards arifes from the joint impetus of all the parts. Therefore if furrounding bodies are moved, thofe that are relatively at reft within them will partake of their motion. Upon which account the true and abfolute motion of a body cannot be determined by the tranflation of it from thofe only which feem to reft; for the external bodies ought not only to appear at reft, but to be really at reft. For otherwife all included bodies, befide their tranflation from near the furrounding ones, partake likewife of their true motions; and though that tranflation was not made, they would not really be at reft, but only feem to be fo. For the furrounding bodies ftand in the like relation to the furrounded, as the exterior part of a whole does to the interior, or as the fhell does to the kernel; but if the fhell moves, the kernel will alfo move, as being part of the whole, without any removal from near the fhell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes alfo of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and abfolute motions; and every entire motion is compofed out of the motion of the body out of its firft place, and the motion of this place out of its place; and fo on, until we come to fome immoveable place, as in the above-mentioned example of the failor. Wherefore entire and abfolute motions can be no otherwife determined than by immoveable places. Now, no other places are immoveable but thofe that from infinity to infinity do all retain the fame given pofitions one to another; and upon this account muft ever remain unmoved, and do thereby conftitute what we call *immoveable fpace.*

The caufes by which true and relative motions are diftinguifhed one from the other, are the forces impreffed upon bodies to generate motion. True motion is neither generated nor altered, but by fome force impreffed upon the body moved: but relative motion may be generated or altered without any force impreffed upon the body. For it is fufficient only to imprefs fome force on other bodies with which the former is compared, that, by their giving way, that relation may be changed, in which the relative reft or motion of the other body did confift. Again, true motion fuffers always fome change from any force impreffed upon the moving body; but relative motion does not neceffarily undergo any change by fuch force. For if the fame forces are likewife impreffed on thofe other bodies with which the comparifon is made, that the relative pofition may be preferved; then that condition will be preferved; in which the relative motion confifts. And therefore any relative motion may be changed when the true motion remains unaltered, and the relative may be preferved when the true motion fuffers fome change. Upon which account true motion does by no means confift in fuch relations.

10
Abfolute and relative motion diftinguifhed.

The effects which diftinguifh abfolute from relative motion are, the forces of receding from the axis of circular motion. For there are no fuch forces in a circular motion purely relative: but, in a true and abfolute circular motion, they are greater or lefs according to the quantity of the motion. If a veffel, hung by a long cord, is fo often turned about that the cord is ftrongly twifted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is untwifting itfelf, the furface of the water will at firft be plain, as before the veffel began to move; but the veffel, by gradually communicating its motion to the water, will make it begin fenfibly to revolve, and recede by little and little from the middle, and afcend to the fides of the veffel, forming itfelf into a concave figure; and the fwifter the motion becomes, the higher will the water rife, till at laft, performing its revolutions in the fame times with the veffel, it becomes relatively at reft in it. This afcent of the water fhews its endeavour to recede from the axis of its motion; and the true and abfolute circular motion of the water, which is here directly contrary to the relative, difcovers itfelf, and may be meafured by this endeavour. At firft, when the relative motion in the water was greateft, it produced no endeavour to recede from the axis; the water fhewed no tendency to the circumference, nor any afcent towards the fides of the veffel, but remained of a plain furface; and therefore its true circular motion had not yet begun. But afterwards, when the relative motion of the water had decreafed, the afcent thereof towards the fides of the veffel, proved its endeavour to recede from the axis; and this endeavour fhewed the real circular motion of the water perpetually increafing, till it had acquired its greateft quantity, when the water refted relatively in the veffel. And therefore this endeavour does not depend upon any tranflation of the water in refpect of the ambient bodies; nor can true circular motion be defined by fuch tranflations. There is only one real circular motion of any one revolving body, correfponding to only one power of endeavouring to recede from its axis of motion, as its proper and adequate effect: but relative motions in one and the fame body are innumerable, according to the various relations it bears to external bodies; and, like other relations, are altogether deftitute of any real effect, otherwife than they may perhaps participate of that only true motion. And therefore, in the fyftem which fuppofes that our heavens, revolving below the fphere of the fixed ftars, carry the planets along with them, the feveral parts of thofe heavens and the planets, which are indeed relatively at reft in their heavens, do yet really move. For they change their pofition one to another, which never happens to bodies truly at reft; and being carried together with the heavens, participate of their motions, and, as parts of revolving wholes, endeavour to recede from the axis of their motion.

Wherefore relative quantities are not the quantities themfelves whofe names they bear, but thofe fenfible mea-

Newtonian Philoſophy

meaſures of them, either accurate or inaccurate, which are commonly uſed inſtead of the meaſured quantities themſelves. And then, if the meaning of words is to be determined by their uſe, by the names *time*, *ſpace*, *place*, and *motion*, their meaſures are properly to be underſtood; and the expreſſion will be unuſual and purely mathematical, if the meaſured quantities themſelves are meant.

It is indeed a matter of great difficulty to diſcover, and effectually to diſtinguiſh, the true motions of particular bodies from thoſe that are only apparent: becauſe the parts of that immoveable ſpace in which thoſe motions are performed, do by no means come under the obſervation of our ſenſes. Yet we have ſome things to direct us in this intricate affair; and theſe ariſe partly from the apparent motions which are the difference of the true motions, partly from the forces which are the cauſes and effects of the true motions. For inſtance, if two globes, kept at a given diſtance one from the other by means of a cord that connects them, were revolved about their common centre of gravity; we might, from the tenſion of the cord, diſcover the endeavour of the globes to recede from the axis of motion, and from thence we might compute the quantity of their circular motions. And then, if any equal forces ſhould be impreſſed at once on the alternate faces of the globes to augment or diminiſh their circular motions, from the increaſe or decreaſe of the tenſion of the cord we might infer the increment or decrement of their motions; and thence would be found on what faces thoſe forces ought to be impreſſed, that the motions of the globes might be moſt augmented; that is, we might diſcover their hindermoſt faces, or thoſe which follow in the circular motion. But the faces which follow being known, and conſequently the oppoſite ones that precede, we ſhould likewiſe know the determination of their motions. And thus we might find both the quantity and determination of this circular motion, even in an immenſe vacuum, where there was nothing external or ſenſible, with which the globes might be compared. But now, if in that ſpace ſome remote bodies were placed that kept always a given poſition one to another, as the fixed ſtars do in our regions; we could not indeed determine from the relative tranſlation of the globes among thoſe bodies, whether the motion did belong to the globes or to the bodies. But if we obſerved the cord, and found that its tenſion was that very tenſion which the motions of the globes required, we might conclude the motion to be in the globes, and the bodies to be at reſt; and then, laſtly, from the tranſlation of the globes among the bodies, we ſhould find the determination of their motions.

Having thus explained himſelf, Sir Iſaac propoſes to ſhow how we are to collect the true motions from their cauſes, effects, and apparent differences; and *vice verſa*, how, from the motions, either true or apparent, we may come to the knowledge of their cauſes and effects. In order to this, he lays down the following axioms or laws of motion.

12 Laws of motion.

1. Every body perſeveres in its ſtate of reſt, or of uniform motion in a right line, unleſs it is compelled to change that ſtate by forces impreſſed upon it.—Sir Iſaac's proof of this action is as follows: "Projectiles perſevere in their motions, ſo far as they are not retarded by the reſiſtance of the air, or impelled downwards by the force of gravity. A top, whoſe parts, by their coheſion, are perpetually drawn aſide from rectilinear motions, does not ceaſe its rotation otherwiſe than as it is retarded by the air. The greater bodies of the planets and comets, meeting with leſs reſiſtance in more free ſpaces, preſerve their motions, both progreſſive and circular, for a much longer time."—Notwithſtanding this demonſtration, however, the axiom hath been violently diſputed. It hath been argued, that bodies continue in their ſtate of motion becauſe they are ſubjected to the continual impulſe of an inviſible and ſubtile fluid, which always pours in from behind, and of which all places are full. They affirm that motion is as natural to this fluid as reſt is to all other matter. They ſay, moreover, that it is impoſſible we can know in what manner a body would be influenced by moving forces if it was entirely deſtitute of gravity. According to what we can obſerve, the momentum of a body, or its tendency to move, depends very much on its gravity. A heavy cannon-ball will fly to a much greater diſtance than a light one, though both are actuated by an equal force. It is by no means clear therefore, that a body totally deſtitute of gravity would have any proper momentum of its own; and if it had no momentum, it could not continue its motion for the ſmalleſt ſpace of time after the moving power was withdrawn. Some have imagined that matter was capable of beginning motion of itſelf, and conſequently that the axiom was falſe; becauſe we ſee plainly that matter in ſome caſes hath a tendency to change from a ſtate of motion to a ſtate of reſt, and from a ſtate of reſt to a ſtate of motion. A paper appeared on this ſubject in the firſt volume of the Edinburgh Phyſical and Literary Eſſays; but the hypotheſis never gained any ground.

13 Objections to the firſt law.

2. The alteration of motion is ever proportional to the motive force impreſſed; and is made in the direction of the right line in which that force is impreſſed. Thus, if any force generates a certain quantity of motion, a double force will generate a double quantity, whether that force be impreſſed all at once, or in ſucceſſive moments.

14 Objections to the third law.

3. To every action there is always oppoſed an equal re-action: or the mutual actions of two bodies upon each other are always equal, and directed to contrary parts.—This axiom is alſo diſputed by many. In the abovementioned paper in the Phyſical Eſſays, the author endeavours to make a diſtinction between re-action and reſiſtance; but this cannot be ſufficiently explained, and therefore the hypotheſis hath not been adopted. Others grant that Sir Iſaac's axiom is very true in reſpect to terreſtrial ſubſtances; but they affirm, that, in theſe, both action and re-action are the effects of gravity. Subſtances void of gravity would have no momentum; and without this they could not act; they would be moved by the leaſt force, and therefore could not reſiſt or re-act. If therefore there is any fluid which is the cauſe of gravity, though ſuch fluid could act upon terreſtrial ſubſtances, yet theſe could not re-act upon it; becauſe they have no force of their own, but depend entirely upon it for their momentum. In this manner, ſay they, we may conceive that the planets circulate, and all the operations of nature are carried on by means of a ſubtile fluid; which being per-

fectly active, and the reft of matter altogether paffive, there is neither refiftance, nor lofs of motion.

From the preceding axiom Sir Ifaac draws the following corollaries.

1. A body by two forces conjoined will defcribe the diagonal of a parallelogram in the fame time that it would defcribe the fides by thofe forces apart.

2. Hence we may explain the compofition of any one direct force out of any two oblique ones, *viz.* by making the two oblique forces the fides of a parallelogram, and the direct one the diagonal.

3. The quantity of motion, which is collected by taking the fum of the motions directed towards the fame parts, and the difference of thofe that are directed to contrary parts, fuffers no change from the action of bodies among themfelves; becaufe the motion which one body lofes is communicated to another: and if we fuppofe friction and the refiftance of the air to be abfent, the motion of a number of bodies which mutually impelled one another would be perpetual, and its quantity always equal.

4. The common centre of gravity of two or more bodies does not alter its ftate of motion or reft by the actions of the bodies among themfelves; and therefore the common centre of gravity of all bodies acting upon each other (excluding outward actions and impediments) is either at reft, or moves uniformly in a right line.

5. The motions of bodies included in a given fpace are the fame among themfelves, whether that fpace is at reft, or moves uniformly forward in a right line without any circular motion. The truth of this is evidently fhewn by the experiment of a fhip; where all motions happen after the fame manner, whether the fhip is at reft, or proceeds uniformly forward in a ftraight line.

6. If bodies, any how moved among themfelves, are urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themfelves, after the fame manner as if they had been urged by no fuch forces.

The whole of the mathematical part of the Newtonian philofophy depends on the following lemmas; of which the firft is the principal.

Lem. I. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before that time approach nearer the one to the other than by any given difference, become ultimately equal. If you deny it; fuppofe them to be ultimately unequal, and let D be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference D; which is againft the fuppofition.

16 Objections to the firft lemma.

Concerning the meaning of this lemma philofophers are not agreed; and unhappily it is the very fundamental pofition on which the whole of the fyftem refts. Many objections have been raifed to it by people who fuppofed themfelves capable of underftanding it. They fay, that it is impoffible we can come to an end of any infinite feries, and therefore that the word *ultimate* can in this cafe have no meaning. In fome cafes the lemma is evidently falfe. Thus, fuppofe there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, doth not vary, yet the difference between them perpetually becomes lefs, as well as the quantities themfelves, until both the difference and quantities themfelves become lefs than any affignable quantity; yet the difference will never totally vanifh, nor the quantities become equal, as is evident from the two following feries.

$$\frac{1}{2}\ \frac{1}{4}\ \frac{1}{8}\ \frac{1}{16}\ \frac{1}{32}\ \frac{1}{64}\ \frac{1}{128}\ \frac{1}{256}\ \frac{1}{512}\ \frac{1}{1024},\ \&c.$$
$$\frac{1}{3}\ \frac{1}{6}\ \frac{1}{12}\ \frac{1}{24}\ \frac{1}{48}\ \frac{1}{96}\ \frac{1}{192}\ \frac{1}{384}\ \frac{1}{768}\ \frac{1}{1536},\ \&c.$$
$$\text{Diff. } \frac{1}{6}\ \frac{1}{12}\ \frac{1}{24}\ \frac{1}{48}\ \frac{1}{96}\ \frac{1}{192}\ \frac{1}{384}\ \frac{1}{768}\ \frac{1}{1536}\ \frac{1}{3072},\ \&c.$$

Thus we fee, that though the difference is continually diminifhing, and that in a very large proportion, there is no hope of its vanifhing, or the quantities becoming equal. In like manner, let us take the proportions or ratios of quantities, and we fhall be equally unfuccefsful. Suppofe two quantities of matter, one containing 8 and the other 10 pounds; thefe quantites already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is in vain to hope for a perfect coincidence. Thus,

$$8\ \ 10\ \ 12\ \ 14\ \ 16\ \ 18\ \ 20\ \ 22\ \ 24,\ \&c.$$
$$10\ \ 12\ \ 14\ \ 16\ \ 18\ \ 20\ \ 22\ \ 24\ \ 26,\ \&c.$$
$$\text{Ratio } \frac{4}{5}\ \frac{5}{6}\ \frac{6}{7}\ \frac{7}{8}\ \frac{8}{9}\ \frac{9}{10}\ \frac{10}{11}\ \frac{11}{12}\ \frac{12}{13},\ \&c.$$

For this and his other lemmas Sir Ifaac makes the following apology. 17 Anfwered. "Thefe lemmas are premifed, to avoid the tedioufnefs of deducing perplexed demonftrations *ad abfurdum*, according to the method of ancient geometers. For demonftrations are more contracted by the method of indivifibles: but becaufe the hypothefis of indivifibles feems fomewhat harfh, and therefore that method is reckoned lefs geometrical, I chofe rather to reduce the demonftrations of the following propofitions to the firft and laft fums and ratios of nafcent and evanefcent quantities, that is, to the limits of thofe fums and ratios; and fo to premife, as fhort as I could, the demonftrations of thofe limits. For hereby the fame thing is performed as by the method of indivifibles; and now thofe principles being demonftrated, we may ufe them with more fafety. Therefore, if hereafter I fhould happen to confider quantities as made up of particles, or fhould ufe little curve lines for right ones; I would not be underftood to mean indivifibles, but evanefcent divifible quantities; not the fums and ratios of determinate parts, but always the limits of fums and ratios; and that the force of fuch demonftrations always depends on the method laid down in the foregoing lemmas.

"Perhaps it may be objected, that there is no ultimate proportion of evanefcent quantities, becaufe the proportion before the quantities have vanifhed, is not the ultimate, and, when they are vanifhed, is none. But by the fame argument it may be alleged, that a body arriving at a certain place, and there ftopping, has no ultimate velocity; becaufe the velocity before the body comes to the place is not its ultimate velocity; when it is arrived, it has none. But the anfwer is eafy: for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceafes, nor after; but at the very inftant it arrives; that is, that velocity with which the body arrives at its laft place, and with which the motion ceafes. And in like manner, by the ultimate ratio of evanefcent quantities is to be under-

understood the ratio of the quantities, not before they vanish, nor afterwards, but with which they vanish. In like manner, the first ratio of nascent quantities is that with which they begin to be. And the first or last sum is that with which they begin and cease to be (or to be augmented and diminished). There is a limit which the velocity at the end of the motion may attain, but not exceed; and this is the ultimate velocity. And there is the like limit in all quantities and proportions that begin and cease to be. And, since such limits are certain and definite, to determine the same is a problem strictly geometrical. But whatever is geometrical we may be allowed to make use of in determining and demonstrating any other thing that is likewise geometrical.

"It may be also objected, that if the ultimate ratios of evanescent quantities are given, their ultimate magnitudes will also be given; and so all quantities will consist of indivisibles, which is contrary to what Euclid has demonstrated concerning incommensurables, in the 10th book of his Elements. But this objection is founded on a false supposition. For those ultimate ratios with which quantities vanish are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities decreasing continually approach."

Lem. II. If in any figure A *a c* E (Pl. CCIV. fig. 2.) terminated by the right line A*a*, AE, and the curve *a c* E, there be inscribed any number of parallelograms A*b*, B*c*, C*d*, &c. comprehended under equal bases AB, BC, CD, &c. and the sides B*b*, C*c*, D*d*, &c. parallel to one side A*a* of the figure; and the parallelograms *a* K *b l*, *b* L *c m*, *c* M *d n*, &c. are completed. Then if the breadth of those parallelograms be supposed to be diminished, and their number augmented *in infinitum*; the ultimate ratios which the inscribed figure A K *b* L *c* M *d* D, the circumscribed figure A *a l b m c n d o* E, and curvilinear figure A *a b c d* E, will have to one another, are ratios of equality.—For the difference of the inscribed and circumscribed figures is the sum of the parallelograms K *l*, L *m*, M *n*, D *o*; that is, (from the equality of all their bases), the rectangle under one of their bases K *b*, and the sum of their altitudes A *a*, that is, the rectangle A B *l a*. But this rectangle, because its breadth AB is supposed diminished *in infinitum*, becomes less than any given space. And therefore, by lem. 1. the figures inscribed and circumscribed become ultimately equal the one to the other; and much more will the intermediate curvilinear figure be ultimately equal to either.

Lem. III. The same ultimate ratios are also ratios of equality, when the breadths AB, BC, DC, &c. of the parallelograms are unequal, and are all diminished *in infinitum*.—The demonstration of this differs but little from that of the former.

In his succeeding lemmas, Sir Isaac goes on to prove, in a manner similar to the above, that the ultimate ratios of the sine, chord, and tangent of arcs infinitely diminished, are ratios of equality, and therefore that in all our reasonings about these we may safely use the one for the other:—that the ultimate form of evanescent triangles made by the arc, chord, and tangent, is that of similitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, we may safely use these triangles for each other, whether made with the sine, the arc, or the tangent.—He then shews some properties of the ordinates of curvilinear figures; and proves that the spaces which a body describes by any finite force urging it, whether that force is determined and immutable, or is continually augmented or continually diminished, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And lastly, having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, and which depends on the following theorems.

Theor. I. The areas which revolving bodies describe by radii drawn to an immoveable centre of force, lie in the same immoveable planes, and are proportional to the times in which they are described.—For, suppose the time to be divided into equal parts, and in the first part of that time, let the body by its innate force describe the right line AB (fig. 3.); in the second part of that time, the same would, by law 1. if not hindered, proceed directly to *c* along the line B *c* = AB; so that by the radii AS, BS, *c* S, drawn to the centre, the equal areas ASB, B S *c*, would be described. But, when the body is arrived at B, suppose the centripetal force acts at once with a great impulse, and, turning aside the body from the right line B *c*, compels it afterwards to continue its motion along the right line BC. Draw *c* C parallel to BS, meeting BC in C; and at the end of the second part of the time, the body, by cor. 1. of the laws, will be found in C, in the same plane with the triangle ASB. Join SC; and because SB and *c* C are parallel, the triangle SBC will be equal to the triangle SBC, and therefore also to the triangle SAB. By the like argument, if the centripetal force acts successively in C, D, E, &c. and makes the body in each single particle of time to describe the right lines CD, DE, EF, &c. they will all lie in the same plane; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SEF to SDE. And therefore, in equal times, equal areas are described in one immoveable plane; and, by composition, any sums SADS, SAFS, of those areas are, one to the other, as the times in which they are described. Now, let the number of those triangles be augmented, and their size diminished *in infinitum*; and then, by the preceding lemmas, their ultimate perimeter ADF will be a curve line: and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually; and any described areas SADS, SAFS, which are always proportional to the times of description, will, in this case also, be proportional to those times. Q. E. D.

Cor. 1. The velocity of a body attracted towards an immoveable centre, in spaces void of resistance is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the velocities in these places A, B, C, D, E, are as the bases AB, BC, DE, EF, of equal triangles; and these bases are reciprocally as the perpendiculars let fall upon them.

Cor. 2. If the chords AB, BC, of two arcs successively described in equal times by the same body, in spaces void of resistance, are completed into a pa-

parallelogram ABCV, and the diagonal BV of this parallelogram, in the pofition which it ultimately acquires when thofe arcs are diminifhed *in infinitum* is produced both ways, it will pafs through the centre of force.

Cor. 3. If the chords AB, BC, and DE, EF, of arcs defcribed in equal times, in fpaces void of refiftance are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when thofe arcs are diminifhed *in infinitum*. For the motions BC and EF of the body (by cor. 1. of the laws), are compounded of the motions B*c*, BV and E*f*, EZ; but BV and EZ, which are equal to C*c*= and F*f*, in the demonftration of this propofition, were generated by the impulfes of the centripetal force in B and E, and are therefore proportional to thofe impulfes.

Cor. 4. The forces by which bodies, in fpaces void of refiftance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the verfed fines of arcs defcribed in equal times; which verfed fines tend to the centre of force, and bifect the chords when thefe arcs are diminifhed to infinity. For fuch verfed fines are the halfs of the diagonals mentioned in cor. 3.

Cor. 5. And therefore thofe forces are to the force of gravity, as the faid verfed fines to the verfed fines perpendicular to the horizon of thofe parabolic arcs which projectiles defcribe in the fame time.

Cor. 6. And the fame things do all hold good (by cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in thofe planes, are not at reft, but move uniformly forward in right lines.

Theor. II. Every body that moves in any curve line defcribed in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, defcribes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

Case I. For every body that moves in a curve line is (by law 1.) turned afide from its rectilinear courfe by the action of fome force that impels it; and that force by which the body is turned off from its rectilinear courfe, and made to defcribe in equal times the leaft equal triangles SAB, SBC, SCD, &c. about the immoveable point S, (by Prop. 40. E. 1. and law 2.) acts in the place B according to the direction of a line parallel to C; that is, in the direction of the line BS; and in the place C according to the direction of a line parallel to d D, that is, in the direction of the line CS, &c.; and therefore acts always in the direction of lines tending to the immoveable point S. Q. E. D.

Case II. And (by cor. 5. of the laws) it is indifferent whether the fuperficies in which a body defcribes a curvilinear figure be quiefcent, or moves together with the body, the figure defcribed, and its point S, uniformly forward in right lines.

Cor. 1. In non-refifting fpaces or mediums, if the areas are not proportional to the times, the forces are not directed to the point in which the radii meet; but deviate therefrom *in confequentia*, or towards the parts to which the motion is directed, if the defcription of the areas is accelerated; but *in antecedentia* if retarded.

Cor. 2. And even in refifting mediums, if the defcription of the areas is accelerated, the directions of the forces deviate from the point in which the radii meet, towards the parts to which the motion tends.

Scholium.

A body may be urged by a centripetal force compounded of feveral forces. In which cafe the meaning of the propofition is, that the force which refults out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the defcribed furface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminifh the quantity of the defcribed furface; and is therefore not to be neglected in the compofition of forces.

Theor. III. Every body that, by a radius drawn to the centre of another body, howfoever moved, defcribes areas about that centre proportional to the times, is urged by a force compounded out of the centripetal forces tending to that other body, and of all the accelerative force by which that other body is impelled.—The demonftration of this is a natural confequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, defcribes areas proportional to the times, and from the whole force by which the firft body L is urged, (whether that force is fimple, or, according to cor. 2. of the laws, componnded out of feveral forces), we fubduct that whole accelerative force by which the other body is urged; the whole remaining force by which the firft body is urged will tend to the other body T, as its centre.

And *vice verfa*, if the remaining force tends nearly to the other body T, thofe areas will be nearly proportional to the times.

If the body L, by a radius drawn to the other body T, defcribes areas, which, compared with the times, are very unequal; and that other body T be either at reft, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body T is either none at all, or it is mixed and combined with very powerful actions of other forces: and the whole force compounded of them all, if they are many, is directed to another (immoveable or moveable) centre. The fame thing obtains when the other body is actuated by any other motion whatever; provided that centripetal force is taken which remains after fubducting that whole force acting upon that other body T.

Scholium.

Becaufe the equable defcription of areas indicates that a centre is refpected by that force with which the body is moft affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to ufe the equable defcription of areas as an indication of a centre about which all circular motion is performed in free fpaces.

Theor. IV. The centripetal forces of bodies which by equable motions defcribe different circles, tend to the centres of the fame circles; and are one to the other as the fquares of the arcs defcribed in equal times applied to the radii of circles.—For thefe forces tend

Newtonian Philosophy

tend to the centres of the circles, (by theor. 2. and cor. 2. theor. 1.) and are to one another as the verfed fines of the leaft arcs defcribed in equal times, (by cor. 4. theor. 1.) that is, as the fquares of the fame arcs applied to the diameters of the circles, by one of the lemmas; and therefore, fince thofe arcs are as arcs defcribed in any equal times, and the diameters are as the radii, the forces will be as the fquares of any arcs defcribed in the fame time, applied to the radii of the circles. Q. E. D.

Cor. 1. Therefore, fince thofe arcs are as the velocities of the bodies, the centripetal forces are in a ratio compounded of the duplicate ratio of the velocities directly, and of the fimple ratio of the radii inverfely.

Cor. 2. And fince the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inverfely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inverfely.

Cor. 3. Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be alfo as the radii; and the contrary.

Cor. 4. If the periodic times and the velocities are both in the fubduplicate ratio of the radii, the centripetal forces will be equal among themfelves; and the contrary.

Cor. 5. If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

Cor. 6. If the periodic times are in the fefquiplicate ratio of the radii, and therefore the velocities reciprocally in the fubduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inverfely; and the contrary.

Cor. 7. And univerfally, if the periodic time is as any power R^n of the radius R, and therefore the velocity reciprocally as the power R^{n-1} of the radius, the centripetal force will be reciprocally as the power R^{2n-2} of the radius; and the contrary.

Cor. 8. The fame things all hold concerning the times, the velocities, and forces, by which bodies defcribe the fimilar parts of any fimilar figures, that have their centres in a fimilar pofition within thofe figures, as appears by applying the demonftrations of the preceding cafes to thofe. And the application is eafy, by only fubftituting the equable defcription of areas in the place of equable motion, and ufing the diftances of the bodies from the centres inftead of the radii.

Cor. 9. From the fame demonftration it likewife follows, that the arc which a body uniformly revolving in a circle by means of a given centripetal force defcribes in any time, is a mean proportional between the diameter of the circle, and the fpace which the fame body, falling by the fame given force, would defcend through in the fame given time.

" By means of the preceding propofition and its corollaries, (fays Sir Ifaac), we may difcover the proportion of a centripetal force to any other known force, fuch as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the defcent of heavy bodies, the time of one entire revolution, as well as the arc defcribed in any given time, is given (by cor. 9. of this theorem). And by fuch propofitions Mr Huygens, in his excellent book *De Horologio Ofcillatorio*, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding propofition may alfo be demonftrated in the following manner. In any circle fuppofe a polygon to be infcribed of any number of fides. And if a body, moved with a given velocity along the fides of the polygon, is reflected from the circle at the feveral angular points; the force with which, at every reflection, it ftrikes the circle will be as its velocity: and therefore the fum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is, (if the fpecies of the polygon be given), as the length defcribed in that given time, and increafed or diminifhed in the ratio of the fame length to the radius of the circle; that is, as the fquare of that length applied to the radius; and therefore, if the polygon, by having its fides diminifhed *in infinitum*, coincides with the circle, as the fquare of the arc defcribed in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On thefe principles hangs the whole of Sir Ifaac Newton's mathematical philofophy. He now fhews how to find the centre to which the forces impelling any body are directed, having the velocity of the body given: and finds the centrifugal force to be always as the verfed fine of the nafcent arc directly, and as the fquare of the time inverfely; or directly as the fquare of the velocity, and inverfely as the chord of the nafcent arc. From thefe premiffes he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point is near or at an immenfe diftance; fo that all the lines drawn from it may be taken for parallels. The fame thing he fhews with regard to bodies revolving in fpirals, ellipfes, hyperbolas, or parabolas.—Having the figures of the orbits given, he fhews alfo how to find the velocities and moving powers; and, in fhort, folves all the moft difficult problems relating to the celeftial bodies with an aftonifhing degree of mathematical fkill. Thefe problems and demonftrations are all contained in the firft book of the *Principia:* but to give an account of them here would exceed our limits; neither would many of them be intelligible, excepting to firft-rate mathematicians.

18 Rules for philofophical reafoning.

In the fecond book Sir Ifaac treats of the properties of fluids, and their powers of refiftance; and here he lays down fuch principles as entirely overthrow the doctrine of Des Cartes's vortices, which was the fafhionable fyftem in his time. In the third book, he begins particularly to treat of the natural phenomena, and apply to them the mathematical principles formerly demonftrated; and, as a neceffary preliminary to this part, he lays down the following rules for reafoning in natural philofophy.

1. We are to admit no more caufes of natural things

Newtonian Philoſophy

things than ſuch as are both true and ſufficient to explain their natural appearances.

2. Therefore to the ſame natural effects we muſt always aſſign, as far as poſſible, the ſame cauſes.

3. The qualities of bodies which admit neither intenſion nor remiſſion of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be eſteemed the univerſal qualities of all bodies whatſoever.

4. In experimental philoſophy, we are to look upon propoſitions collected by general induction from phenomena as accurately or very nearly true, notwithſtanding any contrary hypotheſes that may be imagined, till ſuch time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.

The phenomena firſt conſidered, are, 1. That the ſatellites of Jupiter by radii drawn to the centre of their primary, deſcribe areas proportional to the times of their deſcription; and that their periodic times, the fixed ſtars being at reſt, are in the ſeſquiplicate ratio of their diſtances from its centre. 2. The ſame thing is likewiſe obſerved of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, with their ſeveral orbits, encompaſs the ſun. 4. The fixed ſtars being ſuppoſed at reſt, the periodic times of the five primary planets, and of the earth, about the ſun, are in the ſeſquiplicate proportion of their mean diſtances from the ſun. 5. The primary planets, by radii drawn to the earth, deſcribe areas no ways proportionable to the times: but the areas which they deſcribe by radii drawn to the ſun are proportional to the times of deſcription. 6. The moon, by a radius drawn to the centre of the earth, deſcribes an area proportional to the time of deſcription. All theſe phenomena are undeniable from aſtronomical obſervations, and are explained at large under the article Astronomy. The mathematical demonſtrations are next applied by Sir Iſaac Newton in the following propoſitions.

Prop. I. The forces by which the Satellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet; and are reciprocally as the ſquares of the diſtances of thoſe ſatellites from that centre. The former part of this propoſition appears from theor. 2. or 3. and the latter from cor. 6. of theor. 5.; and the ſame thing we are to underſtand of the ſatellites of Saturn.

Prop. II. The forces by which the primary planets are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the ſun; and are reciprocally as the ſquares of the diſtances from the ſun's centre. The former part of this propoſition is manifeſt from phænomenon 5. juſt mentioned, and from theor. 2.; the latter from phænom. 4. and cor. 6. of theor. 4. But this part of the propoſition is with great accuracy deducible from the quieſcence of the aphelion points. For a very ſmall aberration from the reciprocal duplicate proportion would produce a motion of the apſides, ſenſible in every ſingle revolution, and in many of them enormouſly great.

Prop. III. The force by which the moon is retained in its orbit, tends towards the earth; and is reciprocally as the ſquare of the diſtance of its place from the centre of the earth. The former part of this propoſition is evident from phænom. 5. and theor. 2.; the latter from phænom. 6. and theor. 2. or 3. It is alſo evident from the very ſlow motion of the moon's apogee; which, in every ſingle revolution, amounting but to 3° 3′ *in conſequentia*, may be neglected: and this more fully appears from the next propoſition.

Prop. IV. The moon gravitates towards the earth, and by the force of gravity is continually drawn off from a rectilinear motion, and retained in its orbit.—The mean diſtance of the moon from the earth in the ſyzigies in ſemidiameters of the latter, is about $60\frac{1}{2}$. Let us aſſume the mean diſtance of 60 ſemidiameters in the ſyzigies; and ſuppoſe one revolution of the moon in reſpect of the fixed ſtars to be completed in $27^{d}. 7^{h}. 43'$, as aſtronomers have determined; and the circumference of the earth to amount to 123,249,600 Paris feet. Now, if we imagine the moon, deprived of all motion, to be let go, ſo as to deſcend towards the earth with the impulſe of all that force by which it is retained in its orbit, it will, in the ſpace of one minute of time, deſcribe in its fall $15\frac{1}{4}$ Paris feet. For the verſed ſine of that arc which the moon, in the ſpace of one minute of time, deſcribes by its mean motion at the diſtance of 60 ſemidiameters of the earth, is nearly $15\frac{1}{12}$ Paris feet; or more accurately, 15 feet 1 inch and 1 line $\frac{4}{9}$. Wherefore ſince that force, in approaching to the earth, increaſes in the reciprocal duplicate proportion of the diſtance; and, upon that account, at the ſurface of the earth is 60×60 times greater than at the moon; a body in our regions, falling with that force, ought, in the ſpace of one minute of time, to deſcribe $60\times60\times15\frac{1}{12}$ Paris feet; and in the ſpace of one ſecond of time to deſcribe $15\frac{1}{12}$ of thoſe feet; or, more accurately, 15 feet 1 inch, 1 line $\frac{4}{9}$. And with this very force we actually find that bodies here on earth do really deſcend. For a pendulum oſcillating ſeconds in the latitude of Paris, will be three Paris feet and $8\frac{1}{2}$ lines in length, as Mr Huygens has obſerved. And the ſpace which a heavy body deſcribes by falling one ſecond of time, is to half the length of the pendulum in the duplicate ratio of the circumference of the circle to its diameter; and is therefore 15 Paris feet, 1 inch, 1 line $\frac{7}{9}$. And therefore the force by which the moon is retained in its orbit, becomes, at the very ſurface of the earth, equal to the force of gravity which we obſerve in heavy bodies there. And therefore (by rule 1. and 2.) the force by which the moon is retained in its orbit is that very ſame force which we commonly call *gravity*. For were gravity another force different from that, then bodies deſcending to the earth with the joint impulſe of both forces, would fall with a double velocity, and, in the ſpace of one ſecond of time, would deſcribe $30\frac{1}{6}$ Paris feet; altogether againſt experience.

The demonſtration of this propoſition may be more diffuſely explained after the following manner. Suppoſe ſeveral moons to revolve about the earth, as in the ſyſtem of Jupiter or Saturn, the periodic times of thoſe moons would (by the argument of induction) obſerve the ſame law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the ſquares of the diſtances from the centre of the earth by Prop. I. Now, if the

Newtonian Philosophy

the loweſt of theſe were very ſmall, and were ſo near the earth as almoſt to touch the tops of the higheſt mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terreſtrial bodies that ſhould be found upon the tops of theſe mountains; as may be known from the foregoing calculation. Therefore if the ſame little moon ſhould be deſerted by its centrifugal force that carries it through its orb, it would deſcend to the earth; and that with the ſame velocity as heavy bodies do actually deſcend with upon the tops of thoſe very mountains, becauſe of the equality of forces that oblige them both to deſcend. And if the force by which that loweſt moon would deſcend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terreſtrial bodies do on the tops of mountains, it would then deſcend with twice the velocity, as being impelled by both theſe forces conſpiring together. Therefore, ſince both theſe forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, reſpect the centre of the earth, and are ſimilar and equal between themſelves, they will (by rule 1. and 2.) have the ſame cauſe. And therefore the force which retains the moon in its orbit, is that very force which we commonly call *gravity;* becauſe otherwiſe this little moon at the top of a mountain muſt either be without gravity, or fall twice as ſwiftly as heavy bodies uſe to do.

Having thus demonſtrated that the moon is retained in its orbit by its gravitation towards the earth, it is eaſy to apply the ſame demonſtration to the motions of the other ſecondary planets, and of the primary planets round the ſun, and thus to ſhew that gravitation prevails throughout the whole creation; after which, Sir Iſaac proceeds to ſhew from the ſame principles, that the heavenly bodies gravitate towards each other, and contain different quantities of matter, or have different denſities in proportion to their bulks.

Prop. V. All bodies gravitate towards every planet; and the weights of bodies towards the ſame planet at equal diſtances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all ſorts of heavy bodies (allowance being made for the inequality of retardation by ſome ſmall reſiſtance of the air) deſcend to the earth from equal heights in equal times; and that equality of times we may diſtinguiſh to a great accuracy, by the help of pendulums. Sir Iſaac Newton tried the thing in gold, ſilver, lead, glaſs, ſand, common ſalt, wood, water, and wheat. He provided two wooden boxes, round and equal, filled the one with wood, and ſuſpended an equal weight of gold in the centre of oſcillation of the other. The boxes hanging by equal threads of 11 feet, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the reſiſtance of the air. And placing the one by the other, he obſerved them to play together forwards and backwards, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or *vis motrix*) upon all the gold, to the action of the ſame upon all the wood; that is, as the weight of the one to the weight of the other. And the like happened in the other bodies. By theſe experiments, in bodies of the ſame weight, he could manifeſtly have diſcovered a difference of matter leſs than the thouſandth part of the whole, had any ſuch been. But, without all doubt, the nature of gravity towards the planets, is the ſame as towards the earth. For, ſhould we imagine our terreſtrial bodies removed to the orb of the moon, and there, together with the moon, deprived of all motion, to be let go, ſo as to fall together towards the earth; it is certain, from what we have demonſtrated before, that, in equal times, they would deſcribe equal ſpaces with the moon, and of conſequence are to the moon, in quantity of matter, as their weights to its weight. Moreover, ſince the ſatellites of Jupiter perform their revolutions in times which obſerve the ſeſquiplicate proportion of their diſtances from Jupiter's centre, their accelerative gravities towards Jupiter will be reciprocally as the ſquares of their diſtances from Jupiter's centre; that is, equal at equal diſtances. And therefore, theſe ſatellites, if ſuppoſed to fall towards Jupiter from equal heights, would deſcribe equal ſpaces in equal times, in like manner as heavy bodies do on our earth. And by the ſame argument, if the circumſolar planets were ſuppoſed to be let fall at equal diſtances from the ſun, they would, in their deſcent towards the ſun, deſcribe equal ſpaces in equal times. But forces, which equally accelerate unequal bodies, muſt be as thoſe bodies; that is to ſay, the weights of the planets towards the ſun muſt be as their quantities of matter. Further, that the weights of Jupiter and of his ſatellites towards the ſun are proportional to the ſeveral quantities of their matter, appears from the exceeding regular motions of the ſatellites. For if ſome of thoſe bodies were more ſtrongly attracted to the ſun in proportion to their quantity of matter than others, the motions of the ſatellites would be diſturbed by that inequality of attraction. If, at equal diſtances from the ſun, any ſatellite, in proportion to the quantity of its matter, did gravitate towards the ſun, with a force greater than Jupiter in proportion to his, according to any given proportion, ſuppoſe of *d* to *e;* then the diſtance between the centres of the ſun and of the ſatellite's orbit would be always greater than the diſtance between the centres of the ſun and of Jupiter, nearly in the ſubduplicate of that proportion. And if the ſatellite gravitated towards the ſun with a force, leſſer in the proportion of *e* to *d*, the diſtance of the centre of the ſatellite's orb from the ſun, would be leſs than the diſtance of the centre of Jupiter's from the ſun, in the ſubduplicate of the ſame proportion. Therefore, if, at equal diſtances from the ſun, the accelerative gravity of any ſatellite towards the ſun, were greater or leſs than the accelerating gravity of Jupiter towards the ſun, but by one $\frac{1}{1000}$ part of the whole gravity; the diſtance of the centre of the ſatellite's orbit from the ſun would be greater or leſs than the diſtance of Jupiter from the ſun, by one $\frac{1}{2000}$ part of the whole diſtance; that is, by a fifth part of the diſtance of the utmoſt ſatellite from the centre of Jupiter; an excentricity of the orbit, which would be very ſenſible. But the orbits of the ſatellites are concentric to Jupiter; therefore the accelerative gravities of Jupiter, and of all its ſatellites, towards the ſun, are equal among themſelves. And by the ſame argument, the weight of Saturn and of his ſatellites towards the ſun, at equal diſtances from the ſun, are as their ſeveral quantities of of matter; and the weights of the moon and of the earth towards the fun, are either none, or accurately proportional to the maffes of matter which they contain.

But further, the weights of all the parts of every planet towards any other planet, are one to another as the matter in the feveral parts. For if fome parts gravitated more, others lefs, than for the quantity of their matter; then the whole planet, according to the fort of parts with which it moft abounds, would gravitate more or lefs, than in proportion to the quantity of matter in the whole. Nor is it of any moment whether thefe parts are external or internal. For if, for example, we fhould imagine the terreftrial bodies with us to be raifed up to the orb of the moon, to be there compared with its body; if the weights of fuch bodies were to the weights of the external parts of the moon, as the quantities of matter in the one and in the other refpectively; but to the weights of the internal parts, in a greater or lefs proportion; then likewife the weights of thofe bodies would be to the weight of the whole moon, in a greater or lefs proportion; againft what we have fhewed above.

Cor. 1. Hence the weights of bodies do not depend upon their forms and textures. For if the weights could be altered with the forms, they would be greater or lefs, according to the variety of forms in equal matter; altogether againft experience.

Cor. 2. Univerfally, all bodies about the earth gravitate towards the earth; and the weights of all, at equal diftances from the earth's centre, are as the quantities of matter which they feverally contain. This is the quality of all bodies within the reach of our experiments; and therefore (by rule 3.) to be affirmed of all bodies whatfoever. If the ether, or any other body, were either altogether void of gravity, or were to gravitate lefs in proportion to its quantity of matter; then, becaufe (according to Ariftotle, Des Cartes, and others) there is no difference betwixt that and other bodies, but in mere form of matter, by a fucceffive change from form to form, it might be changed at laft into a body of the fame condition with thofe which gravitate moft in proportion to their quantity of matter; and, on the other hand, the heavieft bodies, acquiring the firft form of that body, might by degrees quite lofe their gravity. And therefore the weights would depend upon the forms of bodies, and with thofe forms might be changed, contrary to what was proved in the preceding corollary.

Cor. 3. All fpaces are not equally full. For if all fpaces were equally full, then the fpecific gravity of the fluid which fills the region of the air, on account of the extreme denfity of the matter, would fall nothing fhort of the fpecific gravity of quick-filver, or gold, or any other the moft denfe body; and therefore, neither gold, nor any other body, could defcend in air. For bodies do not defcend in fluids, unlefs they are fpecifically heavier than the fluids. And if the quantity of matter in a given fpace can by any rarefaction be diminifhed, what fhould hinder a diminution to infinity?

Cor. 4. If all the folid particles of all bodies are of the fame denfity, nor can be rarefied without pores, a void fpace or vacuum muft be granted. [By bodies of the fame denfity, our author means thofe whofe *vires inertiæ* are in the proportion of their bulks.]

Prop. VI. That there is a power of gravity tending to all bodies, proportional to the feveral quantities of matter which they contain.

That all the planets mutually gravitate one towards another, we have proved before; as well as that the force of gravity towards every one of them, confidered apart, is reciprocally as the fquare of the diftance of places from the centre of the planet. And thence it follows, that the gravity tending towards all the planets, is proportional to the matter which they contain.

Moreover, fince all the parts of any planet *A* gravitate towards any other planet *B*; and the gravity of every part is to the gravity of the whole, as the matter of the part to the matter of the whole; and (by law 3.) to every action correfponds an equal re-action: therefore the planet *B* will, on the other hand, gravitate towards all the parts of the planet *A*; and its gravity towards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole. *Q. E. D.*

Cor. 1. Therefore the force of gravity towards any whole planet, arifes from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole arifes from the attractions towards the feveral parts. The thing may be eafily underftood in gravity, if we confider a greater planet as formed of a number of leffer planets, meeting together in one globe. For hence it would appear that the force of the whole muft arife from the forces of the component parts. If it be objected, That, according to this law, all bodies with us muft mutually gravitate one towards another, whereas no fuch gravitation any where appears; it is anfwered, That fince the gravitation towards thefe bodies is to the gravitation towards the whole earth, as thefe bodies are to the whole earth, the gravitation towards them muft be far lefs than to fall under the obfervation of our fenfes. [The experiments with regard to the attraction of mountains, however, have now further elucidated this point.]

Cor. 2. The force of gravity towards the feveral equal particles of any body, is reciprocally as the fquare of the diftance of places from the particles.

Prop. VII. In two fpheres mutually gravitating each towards the other, if the matter, in places on all fides round about and equidiftant from the centres, is fimilar; the weight of either fphere towards the other, will be reciprocally as the fquare of the diftance between their centres.

For the demonftration of this, fee the *Principia*, book i. prop. 75 and 76.

Cor. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets, are as the diameters of the circles directly, and the fquares of their periodic times reciprocally; and their weights at the furfaces of the planets, or at any other diftances from their centres, are (by this prop.) greater or lefs, in the reciprocal duplicate proportion of the diftances. Thus from the periodic times of Venus, revolving about the fun, in 224^{d}. $16\frac{3}{4}^{h}$; of the utmoft circumjovial fatellite revolving about Jupiter, in 16^{d}. $16\frac{8}{15}^{h}$; of the Huygenian fatellite about Saturn in 15^{d}. $22\frac{2}{3}^{h}$; and of the moon about the earth in 27^{d}. 7^{h}.

7h. 43′; compared with the mean diſtance of Venus from the ſun, and with the greateſt heliocentric elongations of the outmoſt circumjovial ſatellite from Jupiter's centre, 8′ 16″; of the Huygenian ſatellite from the centre of Saturn, 3′ 4″; and of the moon from the earth, 10′ 33″; by computation our author found, that the weight of equal bodies, at equal diſtances from the centres of the ſun, of Jupiter, of Saturn, and of the earth, towards the ſun, Jupiter, Saturn, and the earth, were one to another, as $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$ reſpectively. Then, becauſe, as the diſtances are increaſed or diminiſhed, the weights are diminiſhed or increaſed in a duplicate ratio; the weights of equal bodies towards the ſun, Jupiter, Saturn, and the earth, at the diſtances 10000, 997, 791, and 109, from their centres, that is, at their very ſuperficies, will be as 10000, 943, 529, and 435 reſpectively.

Cor. 2. Hence likewiſe we diſcover the quantity of matter in the ſeveral planets. For their quantities of matter are as the forces of gravity at equal diſtances from their centres, that is, in the ſun, Jupiter, Saturn, and the earth, as 1, $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$ reſpectively. If the parallax of the ſun be taken greater or leſs than 10″ 30‴, the quantity of matter in the earth muſt be augmented or diminiſhed in the triplicate of that proportion.

Cor. III. Hence alſo we find the denſities of the planets. For (by prop. 72. book 1.) the weights of equal and ſimilar bodies towards ſimilar ſpheres, are, at the ſurfaces of thoſe ſpheres, as the diameters of the ſpheres. And therefore the denſities of diſſimilar ſpheres are as thoſe weights applied to the diameters of the ſpheres. But the true diameters of the ſun, Jupiter, Saturn, and the earth, were one to another as 10000, 997, 791, and 109; and the weights towards the ſame, as 10000, 943, 529, and 435 reſpectively; and therefore their denſities are as 100, 94½, 67, and 400. The denſity of the earth, which comes out by this computation, does not depend upon the parallax of the ſun, but is determined by the parallax of the moon, and therefore is here truly defined. The ſun therefore is a little denſer than Jupiter, and Jupiter than Saturn, and the earth four times denſer than the ſun; for the ſun, by its great heat, is kept in a ſort of a rarefied ſtate. The moon is denſer than the earth.

Cor. 4. The ſmaller the planets are, they are, *cæteris paribus*, of ſo much the greater denſity. For ſo the powers of gravity on their ſeveral ſurfaces come nearer to equality. They are likewiſe, *cæteris paribus*, of the greater denſity as they are nearer to the ſun. So Jupiter is more denſe than Saturn, and the earth than Jupiter. For the planets were to be placed at different diſtances from the ſun, that, according to their degrees of denſity, they might enjoy a greater or leſs proportion of the ſun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mercury would quickly fly away in vapour. For the light of the ſun, to which its heat is proportional, is ſeven times denſer in the orb of Mercury than with us: and by the thermometer Sir Iſaac found, that a ſevenfold heat of our ſummer-ſun will make water boil. Nor are we to doubt, that the matter of Mercury is adapted to its heat, and is therefore more denſe than the matter of our earth; ſince, in a denſer matter, the operations of nature require a ſtronger heat.

It is ſhewn in the ſcholium of prop. 22. book 2. of the *Principia*, that at the height of 200 miles above the earth, the air is more rare than it is at the ſuperficies of the earth, in the ratio of 30 to 0,0000000000003998, or as 75000000000000 to 1 nearly. And hence the planet Jupiter, revolving in a medium of the ſame denſity with that ſuperior air, would not loſe by the reſiſtance of the medium the 1000000th part of its motion in 1000000 years. In the ſpaces near the earth, the reſiſtance is produced only by the air, exhalations, and vapours. When theſe are carefully exhauſted by the air-pump from under the receiver, heavy bodies fall within the receiver with perfect freedom, and without the leaſt ſenſible reſiſtance; gold itſelf, and the lighteſt down, let fall together, will deſcend with equal velocity; and though they fall through a ſpace of four, ſix, and eight feet, they will come to the bottom at the ſame time; as appears from experiments. And therefore the celeſtial regions being perfectly void of air and exhalations, the planets and comets meeting no ſenſible reſiſtance in thoſe ſpaces, will continue their motions through them for an immenſe ſpace of time.

NIAGARA, a fort of North America taken from the French during the laſt war, which in a manner commands all the interior parts of the continent, and is a key to the whole of North America. It is ſituated on the lake Ontario; and about ſix leagues from it is the greateſt cataract in the world, known by the name of the *water-fall of Niagara*. The river at this fall runs from S. S. E. to N. N. W. and the rock of the fall croſſes it not in a right line, but forming a kind of figure like an hollow ſemicircle or horſeſhoe. Above the fall, in the middle of the river, is an iſland about 800 or 1000 feet long; the lower end of which is juſt at the perpendicular edge of the fall. On both ſides of this iſland runs all the water that comes from the lakes of Canada; viz. Lake Superior, Lake Miſchigan, Lake Huron, and Lake Erie, which have ſome large rivers that open themſelves into them. Before the water comes to this iſland, it runs but ſlowly compared with its motion afterwards, when it grows the moſt rapid in the world, running with a ſurpriſing ſwiftneſs before it comes to the fall. It is perfectly white, and in many places is thrown high up into the air. The water that runs down on the weſt ſide is more rapid, in greater abundance, and whiter, than that on the eaſt ſide; and ſeems almoſt to outfly an arrow in ſwiftneſs. When you are at the fall, and look up the river, you may ſee that the water is every where exceedingly ſteep, almoſt like the ſide of an hill; but when you come to look at the fall itſelf, it is impoſſible to expreſs the amazement it occaſions. The height of it, as meaſured by mathematical inſtruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great height in the air. The noiſe may be heard at the diſtance of 45 miles, but ſeldom further; nor can it be heard even at Fort Niagara, which is only ſix leagues diſtant, unleſs Lake Ontario is calm. At that fort it is obſerved, that when they hear the noiſe of the fall more loud than ordinary, they are ſure that a north-eaſt wind will follow; which is the more ſur-

Niagara. prifing, as the fort lies fouth-weft from the fall. At fome times the fall makes a much greater noife than at others; and this is held for an infallible fign of approaching rain or other bad weather.

From the place where the water falls there arifes abundance of vapour like very thick fmoke, infomuch that when viewed at a diftance you would think that the Indians had fet the forefts on fire. Thefe vapours rife high in the air when it is calm, but are difperfed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is fo penetrating, that a few moments you will be as wet as if you had been nnder water. Some are of opinion, that when birds come flying into this fog or fmoke of the fall, they drop down and perifh in the water; either becaufe their wings are become wet, or that the noife of the fall aftonifhes them, and they know not where to go in the darknefs: but others think that feldom or never any bird perifhes there in that manner; becaufe, among the abundance of birds found dead below the fall, there are no other forts than fuch as live and fwim frequently in the water; as fwans, geefe, ducks, water-hens, teal, and the like. And very often great flocks of them are feen going to deftruction in this manner: they fwim in the river above the fall, and fo are carried down lower and lower by the water; and as water-fowl commonly take great delight in being carried with the ftream, they indulge themfelves in enjoying this pleafure fo long, till the fwiftnefs of the water becomes fo great, that it is no longer poffible for them to rife, but they are driven down the precipice, and perifh. They are obferved, when they draw nigh the fall, to endeavour with all their might to take wing and leave the water; but they cannot. In the months of September and October fuch abundant quantities of dead water-fowl are found every morning below the fall, on the fhore, that the garrifon of the fort for a long time live chiefly upon them. Befides the fowl, they find alfo feveral forts of dead fifh, alfo deer, bears, and other animals which have tried to crofs the water above the fall; the larger animals are generally found broken to pieces. Juft below, a little way from the fall, the water is not rapid, but goes all in circles, and whirls like a boiling pot; which however does not hinder the Indians going upon it in fmall canoes a-fifhing; but a little further, and lower, the other fmaller falls begin. When you are above the fall, and look down, your head begins to turn; even fuch as have been here numberlefs times, will feldom venture to look down, without at the fame time keeping faft hold of fome tree with one hand.

It was formerly thought impoffible for any body living to come at the ifland that is in the middle of the fall: but an accident that happened 34 years ago, or thereabouts, made it appear otherwife. The hiftory is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an ifland that is in the middle of the river, or ftrait, above the great fall, on which there ufed to be abundance of deer. They took fome French brandy with them from the fort, which they tafted feveral times as they were going over the carrying-place; and when they were in their canoe, they took now and then a dram, and fo went along up the ftrait towards the ifland where they propofed to hunt; but growing fleepy, they laid themfelves down in the canoe, which getting loofe drove back with the ftream, farther and farther down, till it came nigh that ifland that is in the middle of the fall. Here one of them, awakened by the noife of the fall, cries out to the other, that they were gone: Yet they tried if poffible to fave life. This ifland was nigheft, and with much working they got on fhore their. At firft they were glad; but when they had confidered every thing, they thought themfelves hardly in a better ftate than if they had gone down the fall, fince they had now no other choice, than either to throw themfelves down the fame, or perifh with hunger. But hard neceffity put them on invention. At the lower end of the ifland the rock is perpendicular, and no water is running there. The ifland has plenty of wood; they went to work then, and made a ladder or fhrouds of the bark of the lind-tree (which is very tough and ftrong) fo long till they could with it reach the water below; one end of this bark-ladder they tied faft to a great tree that grew at the fide of the rock above the fall, and let the other end down to the water. So they went down along their new-invented ftairs, and when they came to the bottom in the middle of the fall they refted a little; and as the water next below the fall is not rapid, as before-mentioned, they threw themfelves out into it, thinking to fwim on fhore. We have faid before, that one part of the fall is on one fide of the ifland, the other on the other fide. Hence it is, that the waters of the two cataracts running againft each other, turn back againft the rock that is juft under the ifland. Therefore, hardly had the Indians begun to fwim, before the waves of the eddy threw them down with violence againft the rock from whence they came. They tired it feveral times, but at laft grew weary; and by being often thrown againft the rock they were much bruifed, and the fkin torn off their bodies in many places. So they were obliged to climb up ftairs again to the ifland, not knowing what to do. After fome time they perceived Indians on the fhore, to whom they cried out. Thefe faw and pitied them, but gave them little hope or help: yet they made hafte down to the fort, and told the commandant where two of their brothers were. He perfuaded them to try all poffible means of relieving the two poor Indians; and it was done in the following manner.

The water that runs on the eaft fide of this ifland is fhallow, efpecially a little above the ifland towards the eaftern fhore. The commandant caufed poles to be made and pointed with iron; two Indians took upon them to walk to this ifland by the help of thefe poles, to fave the other poor creatures, or perifh themfelves. They took leave of all their friends, as if they were going to death. Each had two fuch poles in his hands, to fet to the bottom of the ftream, to keep them fteady. So they went and got to the ifland, and having given poles to the two poor Indians there, they all returned fafely to the main. Thefe two Indians who in the abovementioned manner were firft brought to this ifland were nine days on the ifland, and almoft ready to ftarve to death. Now fince the road to this ifland has been found, the Indians go there often to kill deer, which have tried to crofs the river above the fall, and are driven upon the ifland by the ftream. On the

the weſt ſide of this iſland are ſome ſmall iſlands or rocks, of no conſequence. The eaſt ſide of the river is almoſt perpendicular, the weſt ſide more ſloping. In former times a part of the rock at the fall which is on the weſt ſide of the iſland, hung over in ſuch a manner, that the water which fell perpendicularly from it, left a vacancy below, ſo that people could go under between the rock and the water; but the prominent part ſome years ſince broke off and fell down. The breadth of the fall, as it runs in a ſemi-circle, is reckoned to be about 300 feet. The iſland is in the middle of the fall, and from it on each ſide is almoſt the ſame breadth; the breadth of the iſland at its lower end is about 100 feet. Below the fall, in the holes of the rocks, are great plenty of eels, which the Indians and French catch with their hands without any other means. Every day when the ſun ſhines, you ſee here from ten o'clock in the morning to two in the afternoon, below the fall, and under you, where you ſtand at the ſide of the fall, a glorious rainbow, and ſometimes two, one within the other. The more vapours, the brighter and clearer is the rainbow. When the wind carries the vapours from that place, the rainbow is gone, but appears again as ſoon as new vapours come. From the fall to the landing above it, where the canoes from Lake Erie put aſhore (or from the fall to the upper end of the carrying-place) is half a mile. Lower the canoes dare not come, leſt they ſhould be obliged to try the fate of the two Indians, and perhaps with leſs ſucceſs. They have often found below the fall pieces of human bodies, perhaps drunken Indians, that have unhappily come down to the fall. The French ſay, that they have often thrown whole great trees into the water above, to ſee them tumble down the fall: they went down with ſurpriſing ſwiftneſs, but could never be ſeen afterwards; whence it was thought there was a bottomleſs deep or abyſs juſt under the fall. The rock of the fall conſiſts of a grey limeſtone.

NICÆA, (anc. geogr.), the metropolis of Bithynia; ſituate on the lake Aſcanius, in a large and fertile plain; in compaſs 16 ſtadia: firſt built by Antigonus, the ſon of Philip, and thence called *Antigonea;* afterwards completed by Lyſimachus, who called it *Nicæa*, after his conſort the daughter of Antipater. According to Stephanus, it was originally a colony of the Bottiæi, a people of Thrace, and called *Ancore;* and afterwards called *Nicæa*. Now *Nice* in Aſia the Leſs. Famous for the firſt general council.—A ſecond *Nicæa*, (Diodorus Siculus,) of Corſica.—A third, of the Hither India, (Arrian); ſituate on the weſt ſide of the Hydaſpes, oppoſite to Buciphale, on the eaſt ſide.—A fourth *Nicæa*, a town of Liguria, at the Maritime Alps, on the eaſt ſide of the river Paulon near its mouth, which runs between the Varus and Nicæa, (Mela). A colony of the Maſſilians, (Stephanus); the laſt town of Italy to the weſt. Now *Nizza* or *Nice*, capital of the county of that name, on the Mediterranean.—A fifth, of Locris, (Strabo); a town near Thermopylæ; one of the keys of that paſs. It ſtood on the Sinus Maliacus.

NICANDER *of* Colophon, a celebrated grammarian, poet, and phyſician, who lived about the 160th Olympiad, 140 years before Chriſt, in the reign of Attalus king of Pergamus, who overcame the Gallo-Greeks. He lived many years in Etolia, of which country he wrote a hiſtory. He wrote alſo many other works, of which only two are now remaining. The one is intitled *Theriaca*, deſcribing in verſe the accidents attending wounds made by venomous beaſts, with the proper remedies; the other bearing the title of *Alexipharmaca*, wherein he treats poetically of poiſons and their antidotes. This Nicander is not to be confounded with Nicander of Thyatira.

NICARAGUA, a large river of South America, in a province of the ſame name, whoſe weſtern extremity lies within 5 miles of the South Sea. It is full of dreadful cataracts, and falls at length into the North Sea.

Nicaragua, a maritime province of South America, in Mexico, bounded on the north by Honduras, on the eaſt by the North Sea, on the ſouth-eaſt by Coſta Rica, and on the ſouth-weſt by the South Sea; being 400 miles in length from eaſt to weſt, and 120 in breadth from north to ſouth. It is one of the moſt fruitful and agreeable provinces in Mexico, and is well watered with lakes and rivers. The air is wholeſome and temperate; and this country produces plenty of ſugar, cochineal, and fine chocolate. One of the lakes is 200 miles in circumference, has an iſland in the middle, and, as ſome ſay, has a tide. Leon de Nicaragua is the capital town.

NICARIA, an iſland of the Archipelago, between Samos and Tine, about 50 miles in circumference. A chain of high mountains run thro' the middle, covered with wood, and ſupply the country with ſprings. The inhabitants are very poor, and of the Greek communion; however, they have a little wheat, and a good deal of barley, figs, honey, and wax.

NICASTRO, an epiſcopal town of Italy, in the kingdom of Naples, and in the Farther Calabria; 16 miles ſouth of Coſenza. E. Long. 15. 59. N. Lat. 39. 15.

NICE, an ancient, handſome, and conſiderable town on the confines of France and Italy, and capital of a county of the ſame name, with a ſtrong citadel, a biſhop's ſee, and a ſenate, which is a kind of a democracy. It has been ſeveral times taken by the French, and laſt of all in 1744, but rendered back after the treaty of Aix-la-Chapelle. It is very agreeably ſituated, four miles from the mouth of the river Var, 83 miles S. by W. of Turin, and 83 eaſt of Aix. E. Long. 6. 22. N. Lat. 43. 42.

Nice, a county and province in the dominions of the duke of Savoy, bounded on the eaſt by the territory of Genoa and Proper Piedmont, on the north by the marquiſate of Saluces and Dauphiny, on the weſt by Provence and the Mediterranean ſea, and on the ſouth by the principality of Monaco. The inhabitants ſupply Genoa with a great deal of timber for building ſhips; and carry on a great trade in linen-cloth, paper, oil, wine, and honey. Nice is the capital town.

Nice, an ancient town of Aſia, in Natolia, now called *Iſnick*, with a Greek archbiſhop's ſee. It is famous for the general council aſſembled here in 325, who endeavoured to ſuppreſs the doctrines of Arius. It was formerly a large, populous, and well-built place, and now is not inconſiderable. See Isnic.

NICEPHORUS (Gregorius), a Greek hiſtorian in the 14th century, was librarian to the church of Conſtantinople, and had a great ſhare in the tranſactions of his time. He wrote a hiſtory, which extends from the year 1204 to 1341. The beſt edition of this work is that of the Louvre, in Greek and Latin, in 1702.

NICEPHORUS (Caliſtus), a Greek hiſtorian, who flouriſhed in the 14th century under the emperor Andronicus Paleologus the elder, wrote an eccleſiaſtical hiſtory in 23 books; 18 of which are ſtill extant, containing the tranſactions of the church from the birth of Chriſt to the death of the emperor Phocas in 610. We have nothing elſe but the arguments of the other five books from the commencement of the reign of the emperor Heraclius to the end of that of Leo the philoſopher, who died in the year 911. Nicephorus dedicated his hiſtory to Andronicus Paleologus the Elder. It was tranſlated into Latin by John Langius; and has gone through ſeveral editions, the beſt of which is that of Paris in 1630.

NICERON (John Francis), an ingenious minim, born at Paris in 1613, who diſtinguiſhed himſelf by his knowledge in Optics, concerning which he wrote ſome treatiſes, though he died at the age of 33.

NICERON (John Peter), was born at Paris, of an ancient and noble family, in the year 1685. He entered young into the order of Barnabites, and was profeſſor of rhetoric and philoſophy in the college of Montargis. He is ſufficiently known for conducting the "Memoirs of men illuſtrious in the republic of letters," of which he publiſhed 39 volumes. He alſo tranſlated ſome Engliſh works into French.

NICETAS (David), a Greek hiſtorian, a native, as ſome relate, of Paphlagonia, who lived about the end of the 9th century. He wrote, The life of St Ignatius, patriarch of Conſtantinople; which was tranſlated into Latin by Frederic Mutius biſhop of Termoli: he compoſed alſo ſeveral panegyrics in honour of the apoſtles and other ſaints, which are inſerted in the laſt continuation of the *Bibliotheca Patrum* by Combeſis.

NICETAS (ſurnamed SERRON), deacon of the church of Conſtantinople, cotemporary with Theophylact in the 11th century, and afterwards biſhop of Heraclea, wrote a Catena upon the book of Job, compiled from paſſages of ſeveral of the fathers, which was printed at London in folio, 1637. We have alſo, by the ſame writer, ſeveral *catenæ* upon the Pſalms and Canticles, Baſil 1552; together with a Commentary on the poems of Gregory Nazianzen.

NICETAS (Arhominatis), a Greek hiſtorian of the 13th century, called *Coniates*, as being born at Chone, or Coloſſus, in Phrygia. He was employed in ſeveral conſiderable affars at the court of Conſtantinople; and when that city was taken by the French in 1204, he withdrew with a young girl taken from the enemy, to Nice in Bithynia, where he married his captive, and died in 1206. He wrote a Hiſtory, or Annals, from the death of Alexius Comnenus in the year 1118, to that of Badouin in 1205: of which work we have a Latin tranſlation by Jerome Wolfius, printed at Baſil in 1557; and it has been inſerted in the body of the Byzantine Hiſtorians, printed in France at the Louvre.

NICHE, in architecture, a hollow ſunk into a wall, for the commodious and agreeable placing of a ſtatue. The word comes from the Italian *nechia*, "ſea-ſhell;" in regard the ſtatue is here incloſed in a ſhell, or perhaps on account of the ſhell wherewith the tops of ſome of them are adorned.

NICIAS, a celebrated painter of Athens, flouriſhed about 322 years before the Chriſtian æra; and was univerſally extolled for the great variety and noble choice of his ſubjects, the force and relievo of his figures, his ſkill in the diſtribution of the lights and ſhadows, and his dexterity in repreſenting all ſorts of four-footed animals, beyond any maſter of his time. His moſt celebrated piece was that of Tartarus or Hell, as it is deſcribed by Homer, for which king Ptolemy the ſon of Lagus offered him 60 talents, or 11,250l. which he refuſed, and generouſly preſented it to his own country. He was likewiſe much eſteemed by all his cotemporaries, for his excellent talent in ſculpture.

NICKEL, a ſemi-metal, firſt deſcribed by Mr Cronſtedt in the Swediſh Memoirs for the years 1751 and 1754. The properties there attributed to it are, 1. That it is of a white colour, inclining to red. 2. Its texture is ſolid, and ſhining in its fractures. 3. Its ſpecific gravity is to that of water as 8500 to 1000. 4. It is conſiderably fixed in the fire. 5. It is calcinable, and its calx is green. 6. This calx is not very fuſible; but it nevertheleſs tinges glaſs of a tranſparent reddiſh brown, or jacinth colour. 7. It diſſolves in aquafortis, aqua regia, and marine acid, but difficultly in vitriolic acid. All theſe ſolutions have a deep-green colour. The vitriol formed of it is alſo of the ſame colour; and the colcothar of this vitriol, and alſo the precipitates from the ſolutions, are rendered by calcination of a light-green colour. 8. Theſe precipitates are ſoluble by ſpirit of ſal ammoniac, and the ſolution has a blue colour. But no copper can be produced by a reduction of the precipitates. 9. It ſtrongly attracts ſulphur. 10. It unites with all metallic ſubſtances, excepting ſilver, quickſilver, and zinc. Its attraction to regulus of cobalt is the ſtrongeſt, next to which is that to iron, and then to arſenic. 11. It retains its phlogiſton a long time in the fire, and its calx is reducible by a very ſmall quantity of inflammable matter. It requires, however, a ſtrong red heat before it can be fuſed, and melts a little ſooner, or as ſoon as gold or copper. Nickel is contained in the reddiſh-yellow mineral, called *Kupfer-nickel*, which, beſides nickel, contains alſo iron, regulus of cobalt, arſenic, and ſulphur.

NICOBAR ISLANDS, the name of ſeveral iſlands in Aſia, lying at the entrance of the gulph of Bengal. The largeſt of theſe iſlands is about 40 miles long and 15 broad, and the inhabitants are ſaid to be a harmleſs ſort of people, ready to ſupply the ſhips that ſtop there with proviſions.

NICOLAITANS, in church-hiſtory, Chriſtian heretics who aſſumed this name from Nicholas of Antioch; who, being a Gentile by birth, firſt embraced Judaiſm, and then Chriſtianity; when his zeal and devotion recommended him to the church of Jeruſalem, by whom he was choſen one of the firſt deacons. Many of the primitive writers believe that Nicholas

cholas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the Spirit of God himself, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives, and made no distinction between ordinary meats and those offered to idols. According to Eusebius, they subsisted but a short time; but Tertullian says that they only changed their name, and that their heresies passed into the sect of the Cainians.

NICOLAS (St), an island of the Atlantic Ocean, and one of the most considerable of those of Cape Verde, lying between Santa Lucia and St Jago. It is of a triangular figure, and about 75 miles in length. The land is stony, mountainous, and barren; but there are a great many goats in a valley inhabited by the Portuguese. W. Long. 33. 35. N. Lat. 17. 0.

NICOLE (Peter), one of the finest writers in Europe, was born at Chartres in 1625, of a conspicuous family. He adhered to the Jansenists; and joined in the composition of several works with Mr Arnauld, whose faithful companion he was during the 10 or 12 years of his retirement. He gave a Latin translation of Pascal's *Provinciales*, and added a commentary to them. One of his finest works is his *Essais de Morale*. He wrote very subtilely against the Protestants. His treatise on the unity of the church is esteemed a masterly piece. He died at Paris in 1695, a few days after the publication of his treatise concerning the Quietists. He was greatly skilled in polite literature. To him is ascribed a collection of Latin epigrams, and of Greek, Spanish, and Italian sentences, which has borne several impressions, and has a learned preface to it.

NICOLO (St), the most considerable, strongest, and best peopled of the isles of Tremeti in the gulf of Venice, to the east of St Domino, and to the south of Capparata. It has a harbour defended by several towers; and a fortress, in which is an abbey, with a very handsome church. E. Long. 15. 37. N. Lat. 42. 7.

NICOMEDES, the name of several kings of the ancient Bithynia. See BITHYNIA.

NICOMEDIA (anc. geogr.), metropolis of Bithynia, built by Nicomedes the grandfather of Prusias. Situated on a point of the Sinus Astacenus, (Pliny); surnamed the *Beautiful*, (Athenæus): the largest city of Bithynia, (Pausanias), who says it was formerly called *Astacus;* though Pliny distinguishes Astacum and Nicomedia as different cities. Nicomedia was very famous, not only under its own kings, but under the Romans: the royal residence of Dioclesian, and of Constantine while Constantinople was building, if we may credit Nicephorus. It is still called *Nicomedia*, at the bottom of a bay of the Propontis in the Hither Asia. E. Long. 30. 0. N. Lat. 41. 20. It is a place of consequence; carries on a trade in silk, cotton, glass, and earthen-ware, and is the see of a Greek archbishop.

NICOPOLI, a town of Turkey in Europe, and in Bulgaria, famous for being the place where the first battle was fought between the Turks and Christians in 1396; and where the latter were defeated with the loss of 20,000 men. E. Long. 25. 33. N. Lat. 43. 46.

NICOSIA, the capital of the island of Cyprus, where a Turkish bashaw resides. It is delightfully situated between the mountains of Olympus, and a chain of others; and was formerly well fortified by the Venetians; but the works are now in ruins. E. Long. 33. 35. N. Lat. 35. 1.

NICOT (John), lord of Vilemain, and master of requests of the French king's household, was born at Nismes, and was sent ambassador to Portugal in 1559; whence he brought the plant which, from his name, was called *Nicotiana*, but is now more known by the name of *tobacco*. He died at Paris in 1603. He wrote a French and Latin dictionary in folio; a treatise on navigation; and other works.

NICOTIANA, TOBACCO; a genus of the monogynia order, belonging to the pentandria class of plants. There are seven species, of which the most remarkable is the tabacum, or common tobacco-plant. This was first discovered in America by the Spaniards about the year 1560, and by them imported into Europe. It had been used by the inhabitants of America long before; and was called by those of the islands *yoli*, and *pætun* by the inhabitants of the continent. It was sent into Spain from Tabaco, a province of Yucatan, where it was first discovered, and from whence it takes its common name. Sir Walter Raleigh first introduced it into England about the year 1585, and was the first who taught them how to smoke it. Tobacco is commonly used among the oriental nations, though it is uncertain by whom it was introduced among them. Considerable quantities of it are cultivated in the Levant, on the coasts of Greece and the Archipelago, in Italy, and in the island of Malta.

There are two varieties of that species of Nicotiana which is cultivated for common use, and which are distinguished by the names of *Oronokoe*, and *sweet-scented tobacco*. They differ from each other only in the figure of their leaves; those of the former being longer and narrower than the latter. They are tall herbaceous plants, growing erect with fine foliage, and rising with a strong stem from six to nine feet high. The stalk, near the root, is upwards of an inch diameter, and surrounded with a kind of hairy or velvet clammy substance, of a yellowish-green colour. The leaves are rather of a deeper green, and grow alternately at the distance of two or three inches from each other. They are oblong, of a spear-shaped oval, and simple; the largest about 20 inches long, but decreasing in size as they ascend, till they come to be only 10 inches long, and about half as broad. The face of the leaves is much corrugated, like those of spinage when full ripe. Before they come to maturity, when they are about five or six inches long, the leaves are generally of a full green, and rather smooth; but as they increase in size, they become rougher, and acquire a yellowish cast. The stem and branches are terminated by large bunches of flowers collected into clusters, of a delicate red; the edges, when full-blown, inclining to a pale purple. They continue in succession till the end of the summer; when they are succeeded by seeds of a brown colour, and kidney-shaped. These are very small, each capsule containing about 1000; and the

 the whole produce of a fingle plant is reckoned at about 350,000. The feeds ripen in the month of September.

Mr Carver informs us, that the Oronokoe, or, as it is called, the *long Virginia tobacco*, is the kind beft fuited for bearing the rigour of a northern climate, the ftrength as well as the fcent of the leaves being greater than that of the other. The *fweet-fcented* fort flourifhes moft in a fandy foil, and in a warm climate, where it greatly exceeds the former in the celerity of its growth; and is likewife, as its name intimates, much more mild and pleafant.

Tobacco thrives beft in a warm, kindly, rich foil, that is not fubject to be over-run by weeds. In Virginia, the foil in which it thrives beft is warm, light, and inclining to be fandy; and therefore, if the plant is to be cultivated in Britain, it ought to be planted in a foil as nearly of the fame kind as poffible. Other kinds of foils might probably be brought to fuit it, by a mixture of proper manure; but we muft remember, that whatever manure is made ufe of muft be thoroughly incorporated with the foil. The beft fituation for a tobacco plantation is the fouthern declivity of a hill rather gradual than abrupt, or a fpot that is fheltered from the north winds: but at the fame time it is neceffary that the plants enjoy a free air; for without that they will not profper.

As tobacco is an annual plant, thofe who intend to cultivate it ought to be as careful as poffible in the choice of the feeds; in which, however, with all their care, they may be fometimes deceived. The feeds are to be fown about the middle of April, or rather fooner in a forward feafon, in a bed prepared for this purpofe of fuch foil as hath been already defcribed, mixed with fome warm rich manure. In a cold fpring, hot-beds are moft eligible for this purpofe, and gardeners imagine that they are always neceffary: but Mr Carver tells us, that he is convinced, when the weather is not very fevere, the tobacco-feeds may be raifed without doors; and for this purpofe gives us the following directions.

Treatife on the culture of Tobacco.

"Having fown the feed in the manner above directed, on the leaft apprehenfion of a froft after the plants appear, it will be neceffary to fpread mats over the beds, a little elevated from the ground by poles laid acrofs, that they may not be crufhed. Thefe, however, muft be removed in the morning foon after the fun appears, that they may receive as much benefit as poffible from its warmth, and from the air. In this manner proceed till the leaves have attained about two inches in length, and one in breadth; which they will do in about a month after they are fown, or near the middle of May, when the frofts are ufually at an end. One invariable rule for their being able to bear removal is, when the fourth leaf is fprouted, and the fifth juft appears. Then take the opportunity of the firft rains or gentle fhowers to tranfplant them into fuch a foil and fituation as before defcribed; which muft be done in the following manner.—The land muft be ploughed, or dug up with fpades, and made as mellow and light as poffible. Where the plants are to be placed, raife with the hoe fmall hillocks at the diftance of two feet or a little more from each other, taking care that no hard fods or lumps are in it; and then juft indent the middle of each, without drilling holes, as for fome other plants.

"When your ground is thus prepared, dig in a gentle manner from their native bed fuch plants as have attained the proper growth for tranfplanting abovementioned; and drop, as you pafs, one on every hillock. Infert a plant gently into each centre, preffing the foil around it gently with your fingers; and taking the greateft care, during the operation, that you do not break off any of the leaves, which are at this time exquifitely tender. If the weather proves dry after they are thus tranfplanted, they muft be watered with foft water, in the fame manner as is ufually done to coleworts, or plants of a fimilar kind. But though you now feem to have a fufficient quantity of plants for the fpace you intend to cultivate, it is yet neceffary that you continue to attend to your bed of feedlings, that you may have enough to fupply any deficiencies which through accident may arife. From this time great care muft be taken to keep the ground foft and free from weeds, by often ftirring with your hoe the mould round the roots; and to prune off the dead leaves that fometimes are found near the bottom of the ftalk.

"The difference of this climate from that in which I have been accuftomed to obferve the progrefs of this plant, will not permit me to direct with certainty the time which is moft proper to take off the top of it, to prevent it from running to feed. This knowledge can only be acquired by experience. When it has rifen to the height of more than two feet, it commonly begins to put forth the branches on which the flowers and feeds are produced; but as this expanfion, if fuffered to take place, would drain the nutriment from the leaves, which are the moft valuable part, and thereby leffen their fize and efficacy, it becomes needful at this ftage to nip off the extremity of the ftalk to prevent its growing higher. In fome other climates, the top is commonly cut off when the plant has 15 leaves; but if the tobacco is intended to be a little ftronger than ufual, this is done when it has only 13; and fometimes, when it is defigned to be remarkably powerful, 11 or 12 are only allowed to expand. On the contrary, if the planter is defirous of having his crop very mild, he fuffers it to put forth 18 or 20: but in this calculation, the three or four lower leaves next the ground, which do not grow fo large and fine as the others, are not to be reckoned.

"This operation, denominated *topping* the tobacco, is much better performed by the finger and thumb than with any inftrument; becaufe the grafp of the fingers clofes the pores of the plant; whereas, when it is done by inftruments, the juices are in fome degree exhaufted. Care muft alfo be taken to nip off the fprouts that will be continually fpringing up at the junction of the leaves with the ftalks. This is termed *fuccouring*, or *fuckering*, the tobacco; and ought to be repeated as often as occafion requires.

"As it is impoffible to afcertain the due time for topping the plant, fo it is equally impoffible, without experiment, to afcertain the time it will take to ripen in this country. The apparent figns of its maturity are thefe: The leaves, as they approach a ftate of ripenefs, become more corrugated or rough; and when fully ripe, appear mottled with yellowifh fpots on the raifed parts; whilft the cavities retain their ufual green colour.

They

 They are at this time alfo thicker than they have before been; and are covered with a downy velvet, like that formerly mentioned, on the ftalks. If heavy rains happen at this critical period, they will wafh off this excrefcent fubftance, and thereby damage the plants. In this cafe, if the frofty nights are not begun, it is proper to let them ftand a few days longer; when, if the weather be moderate, they will recover this fubftance again. But if a froft unexpectedly happens during the night, they muft be carefully examined in the morning, before the fun has any influence upon them; and thofe which are found to be covered with frofty particles, whether thoroughly ripe or not, muft be cut up; for though they may not all appear to be arrived at a ftate of maturity, yet they cannot be far from it, and will differ but little in goodnefs from thofe that are perfectly fo."

Tobacco is fubject to be deftroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may foon be loft. This animal is of the horned fpecies, and appears to be peculiar to the tobacco-plant; fo that in many parts of America it is diftinguifhed by the name of the *tobacco-worm*. In what manner it is firft produced, or how propagated, is unknown: but it is not difcernible till the plants have attained about half their height; and then appears to be nearly as large as a gnat. Soon after this it lengthens into a worm; and by degrees increafes in magnitude to the bignefs of a man's finger. In fhape it is regular from its head to its tail, without any diminution at either extremity. It is indented or ribbed round at equal diftances, nearly a quarter of an inch from each other; and having at every one of thefe divifions a pair of feet or claws, by which it faftens itfelf to the plant. Its mouth, like that of the caterpillar, is placed under the fore-part of the head. On the top of the head, between the eyes, grows a horn about half an inch long, and greatly refembling a thorn; the extreme part of which is of a brown colour, a firm texture, and the extremity fharp-pointed. It is eafily crufhed; being only, to appearance, a collection of green juice inclofed in a membranaceous covering, without the internal parts of an animated being. The colour of its fkin is in general green, interfperfed with feveral fpots of a yellowifh white; and the whole covered with a fhort hair fcarcely to be difcerned. Thefe worms are found the moft predominant during the latter end of July and the beginning of Auguft; at which time the plants muft be particularly attended to, and every leaf carefully fearched. As foon as a wound is difcovered, and it will not be long before it is perceptible, care muft be taken to deftroy the caufe of it, who will be found near it, and from his unfubftantial texture may eafily be crufhed: but the beft method is to pull it away by the horn, and then crufh it.

When the tobacco is fit for being gathered, as will appear from an attention to the foregoing directions, on the firft morning that promifes a fair day, before the fun is rifen, take an ax or a long knife, and holding the ftalk near the top with one hand, fever it from its root with the other, as low as poffible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain expofed to the rays of the fun throughout the day, or until the leaves, according to the American expreffion, are entirely *wilted*; that is, till they become limber; and will bend any way without breaking. But if the weather fhould prove rainy without any intervals of funfhine, and the plants appear to be fully ripe, they muft be houfed immediately. This muft be done, however, with great care, that the leaves, which are in this ftate very brittle, may not be broken. They are next to be placed under proper fhelter, either in a barn or covered hovel, where they cannot be affected by rain or too much air, thinly fcattered on the floor; and if the fun does not appear for feveral days, they muft by left to will in that manner; but in this cafe the quantity of the tobacco will not be quite fo good.

When the leaves have acquired the above-mentioned flexibility, the plants muft be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to fweat. But during this time, when they have lain for a little while, and begin to foment, it will be neceffary to turn them; bringing thofe which are in the middle to the furface, and placing thofe which are at the furface in the middle. The longer they lie in this fituation, the darker-coloured is the tobacco; and this is termed *fweating* the tobacco. After they have lain in this manner for three or four days, for a longer continuance might make the plants turn mouldy, they may be faftened together in pairs with chords or wooden pegs, near the bottom of the ftalk, and hung acrofs a pole, with the leaves fufpended in the fame covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This ftate may be afcertained by their appearing of the fame colour with thofe imported from America. But this can be done only in wet weather.—The tobacco is exceedingly apt to attract the humidity of the atmofphere, which gives it a pliability that is abfolutely neceffary for its prefervation; for if the plants are removed in a very dry feafon, the external parts of the leaves will crumble into duft, and a confiderable wafte will enfue.

As foon as the plants are taken down, they muft again be laid in a heap, and preffed with heavy logs of wood for about a week; but this climate may poffibly require a longer time. While they remain in this ftate, it will be neceffary to introduce your hand frequently into the heap, to difcover whether the heat be not too intenfe; for in large quantities this will fometimes be the cafe, and confiderable damage will be occafioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate glowing warmth, part of the weight by which they are preffed muft be taken away; and the caufe being removed, the effect will ceafe. This is called the *fecond* or *laft fweating*; and, when completed, which it generally will be about the time juft mentioned, the leaves may be ftripped from the ftalks for ufe. Many omit this laft fweating; but Mr Carver thinks that it takes away any remaining harfhnefs, and renders the tobacco more mellow. The ftrength of the ftalk alfo is diffufed by it through the leaves, and the whole mafs becomes equally meliorated.—When the leaves are ftripped from the ftalks, they are to be tied up in bunches or *hands*, and kept in a cellar or other damp place; though if not handled in dry weather,

weather, but only during a rainy feafon, it is of little confequence in what part of the houfe or barn they are laid up. At this period the tobacco is thoroughly cured, and as proper for manufacturing with that imported from the colonies.

Our author advifes the tobacco-planter, in his firft trials, not to be too avaricious, but to top his plants before they have gained their utmoft height; leaving only about the middle quantity of leaves directed before, to give it a tolerable degree of ftrength. For tho' this, if exceffive, might be abated during the cure by an increafe of fweating, or be remedied the next feafon by fuffering more leaves to grow, it can never be added, and, without a certain degree of ftrength, the tobacco will always be taftelefs, and of little value. On the contrary, though it be ever fo much weakened by fweating, and thereby rendered mild, yet it will never lofe the aromatic flavour which accompanied that ftrength, and which greatly adds to its value. A fquare yard of land, he tells us, will rear about 500 plants, and allow proper fpace for their nurture till they are fit for tranfplanting.

Tobacco has fometimes been prefcribed internally; in which cafe it proves violently cathartic and emetic, occafioning almoft intolerable cardialgic anxieties. By boiling in water its virulence is abated, and at length deftroyed. An extract made by long coction is recommended by Stahl and other German phyficians, as a fafe and moft effectual aperient, expectorant, detergent, &c. but this medicine, which, according to Dr Lewis, is extremely precarious and uncertain in ftrength, has never come into efteem in this country. Tobacco is fometimes ufed externally in unguents for deftroying cutaneous infects, cleanfing old ulcers, &c. Beaten into a mafh with vinegar or brandy, it has fometimes proved ferviceable for removing hard tumours of the hypochondres: an account is given in the Edinburgh Effays of two cafes of this kind cured by it. The moft common ufes of this plant, however, are, either as a fternutatory when taken by way of fnuff, as a mafticatory by chewing it in the mouth, or as effluvia by fmoking it; and when taken in moderation, it is not an unhealthy amufement. Before pipes were invented, it was ufually fmoked in fegars, and they are ftill in ufe among fome of the fouthern nations. The method of preparing thefe is at once fimple and expeditious: A leaf of tobacco being formed into a fmall twifted roll, fomewhat larger than the ftem of a pipe, and about eight inches long, the fmoke is conveyed through the winding folds which prevent it from expanding, as through a tube; fo that one end of it being lighted, and the other applied to the mouth, it is in this form ufed without much inconvenience. But, in procefs of time, pipes being invented, they were found more commodious vehicles for the fmoke, and are now in general ufe.

Among all the productions of foreign climes introduced into thefe kingdoms, fcarce any has been held in higher eftimation by perfons of every rank than tobacco. In the countries of which it is a native, it is confidered by the Indians as the moft valuable offering that can be made to the beings they worfhip. They ufe it in all their civil and religious ceremonies. When once the fpiral wreaths of its fmoke afcend from the feathered pipe of peace, the compact that has been juft made is confidered as facred and inviolable. Likewife, when they addrefs their great Father, or his guardian fpirits, refiding as they believe in every extraordinary production of nature, they make liberal offerings to them of this valuable plant, not doubting but that they are thus fecured of protection.

Tobacco is made up into rolls by the inhabitants of the interior parts of America by means of a machine called a *tobacco-wheel*. With this machine they fpin the leaves, after they are cured, into a twift of any fize they think fit; and having folded it into rolls of about 20 pounds each, they lay it by for ufe. In this ftate it will keep for feveral years, and be continually improving, as it always grows milder. The Illinois ufually form it into carrots; which is done by laying a number of leaves, when cured, on each other, after the ribs have been taken out, and rolling them round with pack-thread till they become cemented together. Thefe rolls commonly meafure about 18 or 20 inches long, and nine round in the middle part.

Tobacco forms a very confiderable article in commerce; for an account of which fee the articles GLASGOW and VIRGINIA.

NICTITATING MEMBRANE, a thin membrane chiefly found in the bird and fifh kind, which covers the eyes of thefe animals, fheltering them from the duft or too much light; yet is fo thin and pellucid, that they can fee pretty well through it.

NIDUS, among naturalifts, fignifies a neft, or proper repofitory for the eggs of birds, infects, &c. where the young of thefe animals are hatched and nurfed.

NIDIFICATION, a term generally applied to the formation of a bird's neft, and its hatching or bringing forth its young. See ORNITHOLOGY.

NIECE, a brother's or fifter's daughter, which in the civil law is reckoned the third degree of confanguinity.

NIEMEN, a large river of Poland, which rifes in Lithuania, where it paffes by Bielica, Grodno, and Konno: it afterwards runs thro' part of Samogitia and Ducal Pruffia, where it falls into the lake called the *Curifch-haff*, by feveral mouths, of which the moft northern is called the *Rufs*, being the name of a town it paffes by.

NIENBURG, a rich and ftrong town of Germany, in the duchy of Brunfwic-Lunenburg, with a ftrong caftle. It carries on a confiderable trade in corn and wool, and is feated in a fertile foil on the river Wefer. E. Long. 9. 26. N. lat. 52. 44.

NIEPER, a large river of Europe, and one of the moft confiderable of the North, formerly called the Borifthenes. Its fource is in the middle of Mufcovy, running weft by Smolenfko, as far as Orfa; and then turns fouth, paffing by Mohilow, Bohaczo, Kiow, Czyrkaffy, the fortrefs of Kudak, Deffau, and Oczakow, falling into the Black Sea; as alfo in its courfe it divides Little Tartary from Budziac Tartary.

NIESTER, a large river of Poland, which has its fource in the Lake Neifter, in the palatinate of Lemburg, where it paffes by Halicz. Then it feparates Podolia and Oczakow Tartary from Moldavia and Budziac Tartary; and falls into the Black Sea at Belgorod, between the mouths of the Nieper and the Danube.

NIEU-

NIEUWENTYT (Bernard), an able philofopher and learned mathematician, was born at Weftgraafdyk, in the year 1654, and became counfellor and burgomafter of the town of Purmerend, where he was efteemed for his integrity and learning, and died in 1718. He wrote, in Dutch, 1. An excellent treatife, intitled, The Exiftence of God demonftrated by the works of nature. 2. A refutation of Spinoza. 3. Some pieces againft the Infiniteffimals, &c.

NIGELLA, FENNEL-FLOWER, or *Devil in a bufh;* a genus of the pentagynia order, belonging to the polyandria clafs of plants. There are five fpecies, all of them natives of the warm parts of Europe, and rifing from a foot to a foot and an half high, adorned with blue or yellow flowers. They are propagated by feeds, which in a dry and warm fituation will thrive very well; and the plants ripen feeds in this country.

NIGER, a great river of Africa, fuppofed to have its origin near that of the Nile; but this is very uncertain. We are affured, however, that it is a river of very great extent: efpecially if we fuppofe, according to the opinion of the beft modern geographers, that it has its fource in the kingdom of Gorhan, not far from the confines of Upper Ethiopia; for then it will crofs almoft the whole continent of Africa, where it is wideft. In its courfe it receives many confiderable rivers, which fwell it high enough to be able at all times to carry veffels of good burden; fo it fplits itfelf into feveral branches, which uniting again form very large and fertile iflands, well filled with towns and villages. It paffes alfo through feveral lakes, and has many cataracts. After having run from eaft to weft, during a prodigious long courfe, it turns at laft fhort to the fouth, at a leagne and a half diftance from the weftern ocean; leaving but a very narrow tract between it and the fea, into which it opens its way in lat. 15. 55. after having run about 25 leagues from north to fouth. Its mouth is fometimes half a league broad; but is fhut up by a bank of quick-fand called the *bar of Senegal,* where the water is fo fhallow, that it is very difficult and dangerous to pafs over it. The bar is formed by the mud and fand which the river brings with it during the inundation, and which the fea continually drives back upon the fhore. This would effectually exclude all fhipping, had not the violence of the current, and the weight of the waters, made two openings or channels, which are commonly called the *paffes of the bar.* The largeft of thefe is generally not above 150 or 200 fathoms broad, and about 10 feet deep, fo that none but barks of 40 or 50 tons can get through this channel; the other is fo narrow and fhallow, that it is paffable by canoes only. Thefe channels are not always in the fame place; for the river, as it is more or lefs fwelled, or the current more or lefs rapid, opens thofe paffes fometimes in one place, and fometimes in another. The bar itfelf alfo frequently fhifts its place; fo that the ifland of Senegal is fometimes four leagues diftant from it, at other times only two. It is this bar only which hinders fhips of 400 or 500 tons to go up the river.

NIGHT, that part of the natural day during which the fun is underneath the horizon; or that fpace wherein it is dufky.

Night was originally divided by the Hebrews and other eaftern nations into three parts or watches.

The Romans, and after them the Jews, divided the night into four parts or watches; the firft of which began at funfet, and lafted till nine at night, according to our way of reckoning; the fecond lafted till midnight; the third till three in the morning; and the fourth ended at funrife. The ancient Gauls and Germans divided their time not by days but nights; and the people of Iceland and the Arabs do the fame at this day. The like is obferved of the Anglo-Saxons.

NIGHT-*Angling,* a method of catching large and fhy fifh in the night-time. Trout, and many other of the better forts of fifh, are naturally fhy and fearful; they therefore prey in the night as the fecureft time.—The method of taking them on this plan is as follows. The tackle muft be ftrong, and need not be fo fine as for day-fifhing, when every thing is feen; the hook muft be baited with a large earth-worm, or a black fnail, and thrown out into the river; there muft be no lead to the line, fo that the bait may not fink, but be kept drawling along, upon or near the furface. Whatever trout is near the place will be brought thither by the motion of the water, and will feize the worm or fnail. The angler will be alarmed by the noife which the fifh makes in rifing, and is to give him line, and time to fwallow the hook; then a flight touch fecures him. The beft and largeft trouts are found to bite thus in the night; and they rife moftly in the ftill and clear deeps, not in the fwift and fhallow currents. Sometimes, though there are fifh about the place, they will not rife at the bait; in this cafe the angler muft put on fome lead to his line, and fink it to the bottom.

NIGHT-*Mare,* or *Incubus.* See MEDICINE, n° 430.

NIGHT-*Walkers,* in medicine. See NOCTAMBULI.

NIGHT-*Walkers,* in law, are fuch perfons as fleep by day and walk by night, being oftentimes pilferers or difturbers of the public peace. Conftables are authorifed by the common law to arreft night-walkers and fufpicious perfons, &c. Watchmen may alfo arreft night-walkers, and hold them until the morning: and it is faid, that a private perfon may arreft any fufpicious night-walker, and detain him till he give a good account of himfelf. One may be bound to the good behaviour for being a night-walker; and common night-walkers, or haunters of bawdy-houfes, are to be indicted before juftices of peace, &c. But it is not held lawful for a conftable, &c. to take up any woman as a night-walker on bare fufpicion only of being of ill fame, unlefs fhe be guilty of a breach of the peace, or fome unlawful act, and ought to be found mifdoing. *Blackft. Comment.*

NIGHTINGALE, in ornithology; a fpecies of MOTACILLA; under which article it happened to be omitted.

The nightingale takes its name from *night,* and the Saxon word *galan,* "to fing;" expreffive of the time of its melody. In fize it is equal to the redftart; but longer-bodied, and more elegantly made. The colours are very plain. The head and back are of a pale tawny, dafhed with olive: the tail is of a deep tawny red: the throat, breaft, and upper part of the belly, of a light gloffy afh-colour: the lower belly almoft white: the exterior webs of the quill-feathers are of a dull reddifh brown; the interior of brownifh afh-colour: the irides are hazel, and the eyes remarkably large and piercing: the legs and feet a deep aſh-colour.

This bird, the moſt famed of the feathered tribe, for the variety, length, and ſweetneſs of its notes, viſits England the beginning of April, and leaves us in Auguſt. It is a ſpecies that does not ſpread itſelf over the iſland. It is not found in North Wales; or in any of the Engliſh counties north of it, except Yorkſhire, where they are met with in great plenty about Doncaſter. They have been alſo heard, but rarely, near Shrewſbury. It is alſo remarkable, that this bird does not migrate ſo far weſt as Devonſhire and Cornwall; counties where the ſeaſons are ſo very mild, that myrtles flouriſh in the open air during the whole year: neither are they found in Ireland. Sibbald places them in his liſt of Scotch birds; but they certainly are unknown in that part of Great Britain, probably from the ſcarcity and the recent introduction of hedges there. Yet they viſit Sweden, a much more ſevere climate. In England they frequent thick hedges, and low coppices; and generally keep in the middle of the buſh, ſo that they are very rarely ſeen. They form their neſt of oak leaves, a few bents and reeds. The eggs are of a deep brown. When the young ones firſt come abroad, and are helpleſs, the old birds make a plaintive and jarring noiſe with a ſort of ſnapping as if in menace, purſuing along the hedge the paſſengers.

They begin their ſong in the evening, and continue it the whole night These their vigils did not paſs unnoticed by the ancients: the ſlumbers of theſe birds were proverbial; and not to reſt as much as the nightingale, expreſſed a very bad ſleeper (A). This was the favourite bird of the Britiſh poet, who omits no opportunity of introducing it, and almoſt conſtantly noting its love of ſolitude and night. How finely does it ſerve to compoſe part of the ſolemn ſcenery of his *Penſeroſo;* when he deſcribes it

> In her ſaddeſt ſweeteſt plight,
> Smoothing the rugged brow of night;
> While *Cynthia* checks her dragon yoke,
> Gently o'er th' accuſtom'd oak.
> Sweet bird, that ſhunn'ſt the noiſe of folly,
> Moſt muſical, moſt melancholy!
> Thee, chauntreſs, oft the woods among,
> I woo to hear thy evening ſong.

In another place he ſtyles it the *ſolemn bird;* and again ſpeaks of it,

> As the wakeful bird
> Sings darkling, and, in ſhadieſt covert hid,
> Tunes her nocturnal note.

The reader will excuſe a few more quotations from the ſame poet, on the ſame ſubject; the firſt deſcribes the approach of evening, and the retiring of all animals to their repoſe.

> Silence accompanied; for beaſt and bird,
> They to their graſſy couch, theſe to their neſts
> Were ſlunk; all but the wakeful *nightingale,*
> She all night long her amorous deſcant ſung.

When Eve paſſed the irkſome night preceding her fall, ſhe, in a dream, imagines herſelf thus reproached with loſing the beauties of the night by indulging too long a repoſe.

> Why ſleep'ſt thou, *Eve?* now is the pleaſant time,
> The cool, the ſilent, ſave where ſilence yields
> To the night-warbling bird, that now awake
> Tunes ſweeteſt his love-labour'd ſong.

The ſame birds ſing their nuptial ſong, and lull them to reſt. How rapturous are the following lines! how expreſſive of the delicate ſenſibility of our Milton's tender ideas!

> The earth
> Gave ſign of gratulation, and each hill;
> Joyous the birds; freſh gales and gentle airs
> Whiſper'd it to the woods, and from their wings
> Flung roſe, flung odours from the ſpicy ſhrub,
> Diſporting, till the amorous bird of night
> Sung ſpouſal, and bid haſte the evening ſtar
> On his hill-top to light the bridal lamp.
> Theſe, lull'd by *nightingales,* embracing ſlept;
> And on their naked limbs the flowery roof
> Shower'd roſes, which the morn repair'd.

Theſe quotations from the beſt judge of melody, we thought due to the ſweeteſt of our feathered choiriſters; and we believe no reader of taſte will think them tedious.

Virgil ſeems to be the only poet among the ancients who hath attended to the circumſtance of this bird's ſinging in the night time.

> *Qualis populeâ mœrens* Philomela *ſub umbrâ*
> *Amiſſos queritur fœtus, quos durus arator*
> *Obſervans nido implumes detraxit: at illa*
> *Flet noctem, ramoque ſedens miſerabile carmen*
> *Integrat, et mœſtis late loco queſtibus implet.*
> Georg. IV. l. 511.

> As *Philomel* in poplar ſhades, alone,
> For her loſt offspring pours a mother's moan,
> Which ſome rough ploughman marking for his prey,
> From the warm neſt, unfledg'd hath dragg'd away;
> Percht on a bough, ſhe all night long complains,
> And fills the grove with ſad repeated ſtrains. *F. Warton.*

Pliny has deſcribed the warbling notes of this bird, with an elegance that beſpeaks an exquiſite ſenſibility of taſte, *lib.* x. *c.* 29.

If the nightingale is kept in a cage, it often begins to ſing about the latter end of November, and continues its ſong more or leſs till June.—A young canary-bird, linnet, ſky-lark, or robin (who have never heard any other bird), are ſaid beſt to learn the note of a nightingale.

NIGHTSHADE, in botany. See SOLANUM.

Deadly NIGHTSHADE. See ATROPA. The berries of this plant are of a malignant poiſonous nature; and, being of a ſweet taſte, have frequently proved deſtructive to children. A large glaſs of warm vinegar, taken as ſoon as poſſible after eating the berries, will prevent their bad effects.

NIGIDIUS FIGULUS (Publius), one of the moſt learned men of ancient Rome, flouriſhed at the ſame time with Cicero. He wrote on various ſubjects; but his pieces appeared ſo refined and difficult, that they were not regarded. He aſſiſted Cicero, with great prudence, in defeating Catiline's conſpiracy, and did him many ſervices in the time of his adverſity. He adhered to Pompey, in oppoſition to Cæſar; which occaſioned his exile, he dying in baniſhment. Cicero, who had always entertained the higheſt eſteem for him, wrote a beautiful conſolatory letter to him, (the 13th of *lib.* 4. *ad Familiares.*)

NIGRITIA. See NEGROLAND.

NILE, a great river of Egypt in Africa, which has

(A) *Ælian var. hiſt.* 577. both in the text and note. It muſt be remarked, that nightingales ſing alſo in the day.

has its ſource in Abyſſinia, in about eight degrees north latitude. It runs generally from ſouth to north through Abyſſinia, Senna, and Nubia, into Egypt in one ſtream, till it comes below Cairo to the Delta, where it divides into ſeveral branches, the two principal of which diſcharge themſelves into the Mediterranean, the one at Damietta, and the other at Roſetta. There are ſeveral cataracts in this river in Upper Egypt, but not ſo dreadful as ancient authors have reported. There are great rejoicings every year in Egypt when the Nile riſes to a certain height, becauſe their future harveſt depends upon it. At the time of its riſing they publiſh every day how many cubits and inches it is riſen. But to know this, we muſt remember, that each cubit contains 24 inches: when the water is augmented to 16 cubits, then they open a ſluice, which runs croſs the city of Cairo; and when it is come to 22 cubits, it is reckoned very advantageous, if it aſcends no higher: but if it riſes to 24, it puts them into a terrible conſternation, and then they publiſh that it extends from one mountain to the other. They are likewiſe in a great fright when the water aſcends very ſlowly, becauſe they are then afraid that it will not riſe high enough to render the land fertile. The inundation generally continues from the 20th of July to the beginning of November; at which time the dry land begins to appear, if it can be called dry, after it has been ſo long ſoaked in the water. As ſoon as the land is fit, they ſow their corn, and in April it becomes yellow and fit for reaping. When the water is let into the great canal, it is conveyed from thence into reſervoirs and ciſterns, to be diſtributed into their fields and gardens. But all the low wet places are ſowed with rice, which grows beſt in the water. This overflowing of the Nile is owing to the great rains which fall annually between the tropics upon the high mountains of Abyſſinia, near which the ſource of the Nile is, and from which the water falls down in great torrents into that river. The Nile does not contain a great number of fiſh, perhaps becauſe there are ſo many crocodiles and other voracious animals. The water, when it is clear, is very fit for drinking.

NIMBUS, in antiquity, a circle obſerved on certain medals, or round the heads of ſome emperors; anſwering to the circles of light drawn round the images of ſaints.

NIMEGUEN, a large, handſome, and ſtrong town of the Netherlands, and capital of Dutch Guelderland, with a citadel, an ancient palace, and ſeveral forts. It is noted for the peace concluded there in 1679. It has a magnificent town-houſe, and the inhabitants are greatly addicted to trade. It is ſeated on the Vahal or Wahal, between the Rhine and the Maeſe, in Long. 5. 50. Lat. 51. 55.

NIMETULAHITES, a kind of Turkiſh monks, ſo called from their founder Nimetulahi, famous for his doctrines and the auſterity of his life.

NIMPO, a city and ſea-port town of China, in the province of Chekiang. It is ſeated on the eaſtern ſea of China, over-againſt Japan. It is a city of the firſt rank, and ſtands at the confluence of two ſmall rivers, which, after their union, form a channel that reaches to the ſea, and is deep enough to bear veſſels of 200 tons burthen. The walls of Nimpo are 5000 paces in circumference, and are built with free-ſtone.

There are five gates, beſides two water-gates for the paſſage of barks into the city; a tower ſeveral ſtories high, built of bricks; and a long bridge of boats, faſtened together with iron chains, over a very broad canal. This city is commanded by a citadel built on a very high rock, by the foot of which all veſſels muſt neceſſarily paſs. The Chineſe merchants of Siam and Batavia go to this place yearly to buy ſilks, which are the fineſt in the empire. They have alſo a great trade with Japan, it being but two days ſail from hence: thither they carry ſilks, ſtuffs, ſugar, drugs, and wine; and bring back copper, gold, and ſilver. E. Long. 122. 0. N. Lat. 30. 0.

NINEVEH (anc. geogr.), a city of Aſſyria, which is thought to be one of the moſt ancient in the world. It was enlarged by Ninus, who ſome take to be the *Nimrod* of Moſes. When Jonas went to preach againſt it, he was ſaid to be three days in paſſing through it. It was a long while the capital of the Aſſyrian empire; but is now ruined, and it is hard to find the place where it ſtood.

NINON LENCLOS, a celebrated lady in the court of France, was of a noble family, and born at Paris in the year 1615; but rendered herſelf famous by her wit and gallantries. Her mother was a lady of exemplary piety; but her father early inſpired her with the love of pleaſure. Having loſt her parents at 14 years of age, and finding herſelf miſtreſs of her own actions, ſhe reſolved never to marry: ſhe had an income of 10,000 livres a-year; and, according to the leſſons ſhe had received from her father, drew up a plan of life and gallantry, which ſhe purſued till her death. Never delicate with reſpect to the number, but always in the choice, of her pleaſures, ſhe ſacrificed nothing to intereſt; but loved only while her taſte for it continued; and had among her admirers the greateſt lords of the court. But though ſhe was light in her amours, ſhe had many virtues.—She was conſtant in her friendſhips; faithful to what are called the *laws of honour;* of ſtrict veracity; diſintereſted; and more particularly remarkable for the exacteſt probity. Women of the moſt reſpectable characters were proud of the honour of having her for their friend: at her houſe was an aſſemblage of every thing moſt agreeable in the city and the court; and mothers were extremely deſirous of ſending their ſons to that ſchool of politeneſs and good taſte, that they might learn ſentiments of honour and probity, and thoſe other virtues that render men amiable in ſociety. But the illuſtrious Madame de Sevigné with great juſtice remarks in her letters, that this ſchool was dangerous to religion and the Chriſtian virtues; becauſe Ninon Lenclos made uſe of ſeducing maxims, capable of depriving the mind of thoſe invaluable treaſures. Ninon was eſteemed beautiful, even in old age; and is ſaid to have inſpired violent paſſions at 80. She died at Paris in 1705. This lady had ſeveral children; one of whom, named *Chevalier de Villiers*, occaſioned much diſcourſe by the tragical manner in which he ended his life. He became in love with Ninon, without knowing that ſhe was his mother; and when he diſcovered the ſecret of his birth, ſtabbed himſelf in a fit of deſpair. There have been publiſhed the pretended Letters of Ninon Lenclos to the marquis de Sevigné.

NINTH, in muſic. See INTERVAL.

NINUS, the firſt king of the Aſſyrians, was, it is ſaid, the ſon of Belus. It is added, that he enlarged Nineveh and Babylon; conquered Zoroaſter king of the Bactrians; married Semiramis of Aſcalon; ſubdued almoſt all Aſia; and died after a glorious reign of 52 years, about 1150 B. C.; but all theſe facts are uncertain. See SEMIRAMIS.

NIO, an iſland of the Archipelago, between Naxi to the north, Armago to the eaſt, Santerino to the ſouth, and Sikino to the weſt, and is about 35 miles in circumference. It is remarkable for nothing but Homer's tomb, which they pretend is in this iſland; for they affirm that he died here in his paſſage from Samos to Athens. The iſland is well cultivated, and not ſo ſteep as the other iſlands, and the wheat which it produces is excellent; but oil and wood are ſcarce. It is ſubject to the Turks. E. Long. 25. 53. N. Lat. 36. 35.

NIOBE, in fabulous hiſtory, the daughter of Tantalus, and the wife of Amphion king of Thebes, was a princeſs of great beauty; but being the mother of ſeven ſons and as many daughters, ſhe had the preſumption to prefer herſelf to Latona, who had only Apollo and Diana. Latona enraged at this contempt, cauſed Apollo and Diana to kill Niobe's 14 children with their arrows, the former ſlaying the ſons, and the latter the daughters, in the embraces of their mother. On which Niobe being filled with the deepeſt grief, Jupiter, in compaſſion to her inceſſant tears, turned her into ſtone.

NIPHON, the largeſt of the Japan iſlands, being 600 miles long, and 100 broad. See JAPAN.

NIPPERS, in the menage, are four teeth in the fore-part of a horſe's mouth, two in the upper, and two in the lower jaw. A horſe puts them forth between the ſecond and third year.

NIPPLES, in anatomy. See there, n° 376, c.

NIPPLE-WORT, in botany. See LAPSANA.

NISI PRIUS, in law, a judicial writ which lies in caſes where the jury being impanelled and returned before the juſtices of the bank, one of the parties requeſts to have ſuch a writ for the eaſe of the country, in order that the trial may come before the juſtices in the ſame county on their coming thither. The purport of a writ of *niſi prius* is, that the ſheriff is thereby commanded to bring to Weſtminſter the men impanelled, at a certain day, before the juſtices, "*niſi prius juſticiarii domini regis ad aſſiſas capiendas venerint.*"

NISIBIS (anc. geog.), a city both very ancient and noble, ſituate in a diſtrict called *Mygdonia*, in the north of Meſopotamia, towards the Tigris, from which it is diſtant two days journey. Some aſcribe its origin to Nimrod, and ſuppoſe it to be the *Achad* of Moſes. The Macedonians called it *Antiochia of Mygdonia*, (Plutarch); ſituate at the foot of mount Maſius, (Strabo). It was the Roman bulwark againſt the Parthians and Perſians, down to the emperor Jovianus; who, by an ignominious peace, delivered it up to the Perſians. A colony, called *Septimia Neſibitana.*— Another *Niſibis*, of Aria, (Ptolemy), near the lake Arias.

NISMES, an ancient, large, and flouriſhing town of France, in Languedoc, with a biſhop's ſee, and an academy. There are ſeveral monuments of antiquity, of which the amphitheatre is the principal, built by the Romans. The *maiſon quarrée*, or the ſquare-houſe, is a piece of architecture of the Corinthian order, and one of the fineſt in the world. The temple of Diana is in part gone to ruin. It was taken by the Engliſh in 1417. The inhabitants were all Calviniſts; but Lewis XIV. demoliſhed their church in 1685, and built a caſtle to keep them in awe. It is ſeated in a delightful plain, abounding in wine, oil, game, and cattle. E. Long. 4. 26. N. Lat. 43. 50.

NITHSDALE, NITHISDALE, or *Niddiſdale*, a diviſion of Dumfriesſhire in Scotland, lying to the weſtward of Anandale. It is a large and mountainous tract, deriving its name from the river Nid, which iſſues from a lake called *Loch-cure*, runs by the towns of Sanquhar, Morton, and Drumlanrig, and diſcharges itſelf into the Solway Frith. This country was formerly ſhaded with noble foreſts, which are now almoſt deſtroyed; ſo that, at preſent, nothing can be more naked, wild, and ſavage. Yet the bowels of the earth yields lead, and, as is ſaid, ſilver and gold: the mountains are covered with ſheep and black cattle; and here are ſtill ſome conſiderable remains of the ancient woods, particularly that of Holywood, three miles from Dumfries, noted for an handſome church built out of the ruins of an ancient abbey; and alſo for being the birth-place of the famous aſtrologer, hence called *Joannes de Sacro Boſco.*

NITRE, or SALTPETRE. See CHEMISTRY, n° 184.

Calcareous NITRE. Ibid. n° 191.

Cubic NITRE. Ibid. n° 185.

NITROUS, any thing impregnated with nitre.

NITROUS *Air.* See AIR, n° 36, 39.; EUDIOMETER, note (B); and AIR, in the APPENDIX.

NIVELLE, a town of the Auſtrian Netherlands, in the province of Brabant, remarkable for its abbey of Canoneſſes. Here is a manufacture of cambrics, and the town enjoys great privileges. The abbey juſt mentioned is inhabited by young ladies of the firſt quality, who are not confined therein as in nunneries, but may go out and marry whenever they ſee convenient, or a proper match offers. E. Long. 4. 20. N. Lat. 50. 46.

NIVELLE *de la Chauſſée* (Peter Claude), a comic poet, born at Paris; acquired great reputation by inventing a new kind of entertainment, which was called *the Weeping Comedy.* Inſtead of imitating Ariſtophanes, Terence, Moliere, and the other celebrated comic poets who had preceded him; and inſtead of exciting laughter by painting the different ridiculous characters, giving ſtrokes of humour and abſurdities in conduct; he applied himſelf to repreſent the weakneſſes of the heart, and to touch and ſoften it. In this manner he wrote five comedies: 1. *La fauſſe Antipathie.* 2. *Le Préjugé à la Mode;* this piece met with great ſucceſs. 3. *Mélanide.* 4. *Amour pour Amour;* and, 5. *L'Ecole des Meres.* He was received into the French academy in 1736; and died at Paris in 1754, at 63 years of age. He alſo wrote a tragedy, intitled, *Maximianus;* and an epiſtle to Clio, an ingenious didactic poem.

NIVERNOIS, a province of France, with the title of a *duchy*, between Burgundy, Bourbonnois, and Barri. It is pretty fertile in wine, fruit, and corn; except the part

part called *Morvant*, which is a mountainous country, and barren. There is agreat deal of wood, and ſeveral iron mines; as alſo mines of pit-coal, which ſerves to work their forges. This province is watered by a great number of rivers; of which the Allier, the Loire, and the Yonne, are navigable. Nevers is the capital city.

NIXAPA, a rich and conſiderable town in New Spain, with a rich convent of Dominicans. The country about it abounds in cochineal, indigo, and ſugar. E. Long. 97. 25. N. Lat. 15. 20.

NO, (Jeremiah, Ezekiel), No-AMMON, (Nahum); a conſiderable city of Egypt, thought to be the name of an idol which agrees with Jupiter-Ammon. The Septuagint tranſlate the name in Ezekiel, *Dioſpolis*, "the city of Jupiter." Bochart takes it to be *Thebes* of Egypt; which, according to Strabo and Ptolemy, was called *Dioſpolis*. Jerome, after the Chaldee paraphraſt Jonathan, ſuppoſes it to be Alexandria, named by way of anticipation; or an ancient city of that name is ſuppoſed to have ſtood on the ſpot where Alexandria was built.

No-*Man's-Land*, a ſpace between the after-part of the belfrey and the fore-part of a ſhip's boat, when the ſaid boat is ſtowed upon the booms, as in a deep-waiſted veſſel. Theſe booms are laid from the fore-caſtle nearly to the quarter-deck, where their after-ends are uſually ſuſtained by a frame called the *gallows*, which conſiſts of two ſtrong poſts, about ſix feet high, with a croſs piece reaching from one to the other, athwart-ſhips, and ſerving to ſupport the ends of thoſe booms, maſts, and yards, which lie in reſerve to ſupply the place of others carried away, &c. The ſpace called *No-man's-land* is uſed to contain any blocks, ropes, tackles, &c. which may be neceſſary on the forecaſtle. It probably derives this name from its ſituation, as being neither on the ſtarboard nor larboard ſide of the ſhip, nor on the waiſt or forecaſtle; but, being ſituated in the middle, partakes equally of all thoſe places.

NOAH, a famous patriarch, was the ſon of Lamech, and was born in 2978 B. C. He alone with his family were preſerved from the univerſal deluge, when God exterminated the reſt of the human race on account of their crimes. Having by the divine command built an ark, he entered it with his wife, his three ſons and their wives, and animals of every kind, who were to multiply upon the earth after the deluge. Noah and all the living creatures ſtaid a year in that veſſel; and, on his coming out, he immediately expreſſed his gratitude by erecting an altar to the Lord, and offering ſacrifices.—On which God bleſſed Noah and his family, and promiſed that the waters ſhould no more overflow the whole earth. He died at the age of 950, 350 years after the deluge; leaving three ſons, Shem, Ham, and Japheth, from whom ſprung the whole human race.

NOBILIARY, in literary hiſtory, a book containing the hiſtory of the noble families of a nation, or province: ſuch are Choriere's Nobiliary of Dauphine, and Caumartin's Nobiliary of Provence. The Germans are ſaid to be particularly careful of their Nobiliaries, in order to keep up the dignity of their families.

NOBILITY, a quality that ennobles, and raiſes a perſon poſſeſſed of it above the rank of a commoner.

The origin of nobility in Europe is by ſome referred to the Goths; who, after they had ſeized a part of Europe, rewarded their captains with titles of honour, to diſtinguiſh them from the common people.—In this place we ſhall conſider the manner in which they may be created, and the incidents attending them.

1. The right of peerage ſeems to have been originally territorial; that is, annexed to lands, honours, caſtles, manors, and the like, the proprietors and poſſeſſors of which were (in right of thoſe eſtates) allowed to be peers of the realm, and were ſummoned to parliament to do ſuit and ſervice to their ſovereign: and, when the land was alienated, the dignity paſſed with it as appendant. Thus the biſhops ſtill ſit in the houſe of lords in right of ſucceſſion to certain ancient baronies annexed, or ſuppoſed to be annexed, to their epiſcopal lands; and thus, in 11 Hen. VI. the poſſeſſion of the caſtle of Arundel was adjudged to confer an earldom on its poſſeſſor. But afterwards, when ALIENATIONS grew to be frequent, the dignity of peerage was confined to the lineage of the party ennobled, and inſtead of territorial became perſonal. Actual proof of a tenure by barony became no longer neceſſary to conſtitute a lord of parliament; but the record of the writ of ſummons to him or his anceſtors was admitted as a ſufficient evidence of the tenure.

Peers are now created either by writ or by patent: for thoſe who claim by preſcription muſt ſuppoſe either a writ or patent made to their anceſtors; tho' by length of time it is loſt. The creation by writ, or the king's letter, is a ſummons to attend the houſe of peers, by the ſtyle and title of that barony which the king is pleaſed to confer: that by patent is a royal grant to a ſubject of any dignity and degree of peerage. The creation by writ is the more ancient way; but a man is not ennobled thereby, unleſs he actually take his ſeat in the houſe of lords: and ſome are of opinion that there muſt be at leaſt two writs of ſummons, and a ſitting in two diſtinct parliaments, to evidence an hereditary barony: and therefore the moſt uſual, becauſe the ſureſt, way is to grant the dignity by patent, which endures to a man and his heirs according to the limitations thereof, though he never himſelf makes uſe of it. Yet it is frequent to call up the eldeſt ſon of a peer to the houſe of lords by writ of ſummons, in the name of his father's barony: becauſe in that caſe there is no danger of his children's loſing the nobility in caſe he never takes his ſeat; for they will ſucceed to their grandfather. Creation by writ has alſo one advantage over that by patent: for a perſon created by writ holds the dignity to him and his heirs, without any words to that purport in the writ; but in latters patent there muſt be words to direct the inheritance, elſe the dignity endures only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not deſcend to their heirs at all, or deſcend only to ſome particular heirs: as where a peerage is limited to a man and the heirs male of his body by Elizabeth his preſent lady, and not to ſuch heirs by any former or future wife.

Blackſt. Comment.

2. Let us next take a view of a few of the principal incidents attending the nobility,—excluſive of their capacity

capacity as members of parliament, and as hereditary counfellors of the crown, both of which we have confidered under the articles LORDS and PARLIAMENT. And firft we muft obferve, that in criminal cafes a nobleman fhall be tried by his peers. The great are always obnoxious to popular envy: were they to be judged by the people, they might be in danger from the prejudice of their judges; and would moreover be deprived of the privilege of the meaneft fubjects, that of being tried by their equals, which is fecured to all the realm by magna carta, c. 29. It is faid, that this does not extend to bifhops; who, though they are lords of parliament, and fit there by virtue of their baronies which they hold *jure ecclefiæ*, yet are not ennobled in blood, and confequently not peers with the nobility. As to peereffes, no provifion was made for their trial when accufed of treafon or felony, till after Eleanor duchefs of Gloucefter, wife to the lord protector, had been accufed of treafon, and found guilty of witchcraft, in an ecclefiaftial fynod, through the intrigues of cardinal Beaufort. This very extraordinary trial gave occafion to a fpecial ftatute, 20 Hen. VI. c. 9. which enacts, that peereffes, either in their own right or by marriage, fhall be tried before the fame judicature as peers of the realm. If a woman, noble in her own right, marries a commoner, fhe ftill remains noble, and fhall be tried by her peers: but if fhe be only noble by marriage, then by a fecond marriage with a commoner fhe lofes her dignity; for by marriage it is gained, by marriage it is alfo loft. Yet if a duchefs-dowager marries a baron, fhe continues a duchefs ftill; for all the nobility are *pares*, and therefore it is no degradation. A peer or peerefs (either in her own right or by marriage) cannot be arrefted in civil cafes: and they have alfo many peculiar privileges annexed to their peerage in the courfe of judicial proceedings. A peer fitting in judgment, gives not his verdict upon oath, like an ordinary jury-man, but upon his honour; he anfwers alfo to bills in chancery upon his honour, and not upon his oath; but, when he is examined as a witnefs either in civil or criminal cafes, he muft be fworn; for the refpect which the law fhews to the honour of a peer does not extend fo far as to overturn a fettled maxim, that *in judicio non creditur nifi juratis*. The honour of peers is however fo highly tendered by the law, that it is much more penal to fpread falfe reports of them, and certain other great officers of the realm, than of other men: fcandal againft them being called by the peculiar name of *fcandalum magnatum*, and fubjected to peculiar punifhment by divers ancient ftatutes.

A peer cannot lofe his nobility but by death or attainder; though there was an inftance, in the reign of Edward the fourth, of the degradation of George Nevile duke of Bedford by act of parliament, on account of his poverty, which rendered him unable to fupport his dignity. But this is a fingular inftance: which ferves at the fame time, by having happened, to fhew the power of parliament; and, by having happened but once, to fhew how tender the parliament hath been, in exerting fo high a power. It hath been faid indeed, that if a baron waftes his eftate, fo that he is not able to fupport the degree, the king may degrade him: but it is exprefsly held by later authorities, that a peer cannot be degraded but by act of parliament.

NOBLE, a money of account containing fix fhillings and eight pence.

The noble was anciently a real coin ftruck in the reign of Edward III. and then called the *penny of gold;* but it was afterwards called a *rofe-noble*, from its being ftampted with a rofe: it was current at 6s. 8 d.

NOCERA, an ancient town of Italy, in the duchy of Spoletto, and in the territory of the pope, with a bifhop's fee; feated at the foot of the Appennines, E. Long. 12. 55. N. Lat. 43. 2.

Terra NOCERIANA, *Earth of Nocera*, in the materia medica, a fpecies of bole remarkably heavy, of a greyifh-white colour, of an infipid tafte, and generally with fome particles in it which grit between the teeth. It is much efteemed by the Italians, as a remedy for venomous bites, and in fevers; but, excepting as an abforbent and aftringent, no dependence is to be had on it.

NOCTAMBULI, NOCTAMBULONES, or *Night-walkers;* a term of equal import with *fomnambuli*, applied to perfons who have a habit of rifing and walking about in their fleep. The word is a compound of the Latin *nox*, "night," and *ambulo*, "I walk."

Schenckius, Horftius, Clauderus, and Hildanus, who have wrote of fleep, give us divers unhappy hiftories of fuch noctambuli. When the difeafe is moderate, the perfons affected with it only repeat the actions of the day on getting out of bed, and go quietly to the places they frequented at other times; but thofe who have it in the moft violent degree, go up to dangerous places, and do things which would terrify them to think of when they are awake. Thefe are by fome caled *lunatic* night-walkers, becaufe fits are obferved to return with the moft frequency and violence at the changes of the moon.—For the cure fome recommend purging and a cooling regimen: others are of opinion that the beft method is to place a veffel of water at the patient's bed-fide in fuch a manner that he will naturally ftep into it when he gets out of bed; or if that fhould fail, a perfon fhould fit up to watch and beat him every time it happens.

NOCTILUCA, a fpecies of phofphorus, fo called becaufe it fhines in the dark without any light being thrown upon it: fuch is the phofphorus made of urine.

NOCTURNAL, fomething relating to the night, in contradiction to diurnal.

NOCTURNAL, *Nocturlabium*, an inftrument chiefly ufed at fea, to take the altitude or depreffion of fome ftars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemifpheres, or planifpheres, on the plane of the equinoctial. Thofe commonly in ufe among feamen are two; the one adapted to the polar ftar, and the firft of the guards of the little bear; the other to the pole ftar, and the pointers of the great bear.

This inftrument confifts of two circular plates, applied to each other. The greater, which has a handle to hold the inftrument, is about $2\frac{1}{4}$ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month fubdivided into every

fifth

fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. These twenty-four hours are noted by twenty-four teeth to be told in the night. Those at the hours 12, are distinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate. And the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

Plate CCI. fig. 2.

To use the nocturnal, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate: then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole star through the hole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the little bear, (if the instrument be fitted to that star): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour-circle: which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

NODATED HYPERBOLA, a name given by Sir Isaac Newton to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODE, a tumour arising on the bones, and usually proceeding from some venereal cause; being much the same with what is otherwise called *exostosis*.

NODES, in astronomy, the two points where the orbit of a planet intersects the ecliptic.

Plate CCIV. fig. 4. n° 1.

Such are the two points C and D; of which the node C, where the planet ascends northward above the plane of the ecliptic, is called the *ascending node*, or the *dragon's head*, and is marked thus ☊. The other node D, where the planet descends to the south, is called the *descending node*, or the *dragon's tail*, marked thus ☋.

The line CD, wherein the two circles C E D F and C G D H intersect, is called the *line of nodes*. It apprears from observation, that the line of the nodes of all the planets, constantly changes its place, and shifts its situation from east to west, contrary to the order of the signs; and that the line of the moon's nodes, by a retrograde motion, finishes it circulation in the compass of 19 years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the same again; and when the moon is in the node, she is also seen in the ecliptic. If the line of nodes were immoveable, that is, if it had no other motion than that whereby it is carried round the sun, it would always look to the same point of the ecliptic, or would keep parallel to itself, as the axis of the earth does.

From what hath been said, it is evident, that the moon can never be observed precisely in the ecliptic, but twice in every period; that is, when she enters the nodes. When she is at her greatest distance from the nodes; viz. in the points E, F, she is said to be in her limits.

The moon must be in or near one of the nodes, when there is an eclipse of the sun or moon.

To make the foregoing account of the motion of moon's nodes still clearer, let the plane of n° 2. *ibid.* represent that of the ecliptic, S the sun, T the centre of the earth, L the moon in her orbit D N *d n*. N *n* is the line of the nodes passing between the quadrature Q, and the moon's place L, in her last quarter. Let now L P, or any part L S, represent the excess of the sun's action at T; and this being resolved into the force L R, perpendicular to the plane of the moon's orbit, and P R parallel to it, it is the former only that has any effect to alter the position of the orbit, and in this it is wholly exerted. Its effect is twofold: 1. It diminishes its inclination by a motion which we may conceive as performed round the diameter D *d*, to which L T is perpendicular. 2. Being compounded with the moon's tangential motion at L, it gives it an intermediate direction L *t*, through which, and the centre, a plane being drawn, must meet the ecliptic nearer the conjunction C than before.

NODUS, or node, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture, are shewn. See DIALLING.

NOEOMAGUS LEXUVIORUM, (Ptol.); thought to be the *Civitas Lexoviorum* of the lower age. Now *Lisieux*, a city in Normandy.—Another of the *Tricastini*; a town of Gallia Narbonensis; thought to be *S. Pol de Trois Châteaux*, six miles to the west of Nyons in Dauphiné.

NOETIANS, in church-history, Christian heretics in the third century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses sent by God, and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations given to God in consequence of different operations: that as Creator, he is called *Father*; as Incarnate, *Son*; and as descending on the apostles, *Holy Ghost*.

NOLA, a very ancient city, formerly populous and strong, situate in a plain to the north-east of Vesuvius in Campania, said to be built by the Chalcidians, (Justin, Silius Italicus); according to others, by the Tuscans. At this place Hannibal met with the first check by Marcellus. Vespasian added the appellation *Augusta Colonia*, (Frontinus). At this place, or in its neighbourhood, Augustus is said to have expired. At this day retaining its old name, but fallen short of its ancient splendour. A town of the kingdom of Naples. E. Long. 15. N. Lat. 41. 5.

NOLLE PROSEQUI, is where a plaintiff in an action does not declare in a reasonable time; in which case it is usual for the defendant's attorney to enter a rule for the plaintiff to declare, after which a *non pros* may be entered. A *nolle prosequi* is esteemed a voluntary confession, that the plaintiff has no cause of action: and therefore if a plaintiff enter his *nolle prosequi*, he shall be amerced; and if an informer cause the same to be entered, the defendant shall have costs.

NOMADES,

NOMADES, a name given, in antiquity, to feveral nations or people whofe whole occupation was to feed and tend their flocks; and who had no fixed place of abode, but were conftantly fhifting, according to the conveniencies of pafturage.—The word comes from the Greek νεμω, *pafco*, "I feed."

The moft celebrated among the Nomades were thofe of Africa, who inhabited between Africa, properly fo called, to the eaft, and Mauritania to the weft. They are alfo called *Numidæ*, or *Numidians*.—Salluft fays, they were a colony of Perfians brought into Africa with Hercules.

The Nomades of Afia inhabited the coafts of the Cafpian Sea.—The Nomades of Scythia were the inhabitants of Little Tartary; who ftill retain the ancient manner of living.

NOMARCHA, in antiquity, the governor or commander of a nome, or nomos.—Egypt was anciently divided into feveral regions or quarters, called *nomes*, from the Greek νομος, taken in the fenfe of a divifion; and the officer who had the adminiftration of each *nome*, or *nomos*, from the king, was called *monarcha*, from νομος and αρχη, "command."

NOMBRE-DE-DIOS, a town of Mexico, in the province of Darien, a little to the eaftward of Porto-Bello. It was formerly a famous place; but it is now abandoned, on account of its unhealthy fituation. W. Long. 78. 35. N. Lat. 9. 43.

NOMBRIL POINT, in heraldry, is the next below the fefs point, or the very centre of the efcutcheon. Suppofing the efcutcheon divided into two equal parts below the fefs, the firft of thefe divifions is the nombril, and the lower the bafe.

NOME, or NAME, in algebra, denotes any quantity with a fign prefixed or added to it, whereby it is connected with fome other quantity, upon which the whole becomes a binomial, trinomial, or the like. See ALGEBRA.

NOMENCLATOR, in Roman antiquity, was ufually a flave who attended upon perfons that ftood candidates for offices, and prompted or fuggefted to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the higheft piece of civility.

NOMENCLATORS, among the botanical authors, are thofe who have employed their labours about fettling and adjufting the right names, fynonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of feveral of the more ufual words in any language, with their fignifications, compiled in order to facilitate the ufe of fuch words to thofe who are to learn the tongue: fuch are our Latin, Greek, French, &c. Nomenclatures.

NOMENEY, a town of Germany, in the duchy of Lorrain, fituated on the river Seille, 15 miles north of Nancy.

NOMINALS, or NOMINALISTS, a fect of fchool-philofophers, the difciples and followers of Occam, or Ocham, an Englifh cordelier, in the 14th century. They were great dealers in words, whence they were vulgarly denominated *Word-fellers*; but had the denomination of *Nominalifts*, becaufe that, in oppofition to the *Realifts*, they maintained, that words, and not things, were the object of dialectics.

NOMINATIVE, in grammar, the firft CASE of NOUNS which are declinable.

The fimple pofition, or laying down of a noun, or name, is called the *nominative cafe*; yet it is not fo properly a cafe, as the matter or ground, whence the other cafes are to be formed, by the feveral changes and inflections given to this firft termination. Its chief ufe is to be placed in difcourfe before all verbs, as the fubject of the propofition or affirmation.

NONAGE, in law, generally fignifies all the time a perfon continues under the age of 21; but, in a fpecial fenfe, it is all the time that a perfon is under the age of 14.

NON-CAPE, a promontory on the weft coaft of Africa, oppofite to the Canary iflands. W. Long. 12. 0. N. Lat. 44. 28.

NONCONFORMISTS, thofe who refufe to join the eftablifhed worfhip.

Nonconformifts, in England, are of two forts. Firft, fuch as abfent themfelves from divine worfhip in the eftablifhed church through total irreligion, and attend the fervice of no other perfuafion. Thefe, by the ftat. 1 Eliz. c. 2. 23 Eliz. c. 1. and 3 Jac. I. c. 4. forfeit one fhilling to the poor every Lord's-day they fo abfent themfelves, and 20l. to the king if they continue fuch default for a month together. And if they keep any inmate thus irreligioufly difpofed in their houfes, they forfeit 10l. *per* month. *Blackft. Comment.*

The fecond fpecies of nonconformifts are thofe who offend through a miftaken or perverfe zeal. Such were efteemed, by the Englifh laws enacted fince the time of the Reformation, to be Papifts and Proteftant diffenters: both of which were fuppofed to be equally fchifmatics, in not communicating with the national church; with this difference, that the Papifts divided from it upon material, though erroneous, reafons; but many of the diffenters upon matters of indifference, or, in other words, upon no reafon at all. "Yet certainly (fays Sir William Blackftone) our anceftors were miftaken in their plans of compulfion and intolerance. The fin of fchifm, as fuch, is by no means the object of temporal coercion and punifhment. If, through weaknefs of intellect, through mifdirected piety, through perverfenefs and acerbity of temper, or (which is often the cafe) through a profpect of fecular advantage in herding with a party, men quarrel with the ecclefiaftical eftablifhment, the civil magiftrate has nothing to do with it; unlefs their tenets and practice are fuch as threaten ruin or difturbance to the ftate. He is bound indeed to protect the eftablifhed church: and if this can be better effected by admitting none but its genuine members to offices of truft and emolument, he is certainly at liberty fo to do; the difpofal of offices being matter of favour and difcretion. But, this point being once fecured, all perfecution for diverfity of opinions, however ridiculous or abfurd they may be, is contrary to every principle of found policy and civil freedom. The names and fubordination of the clergy, the pofture of devotion, the materials and colour of the minifter's garment, the joining in a known or unknown form of prayer, and other matters of the fame kind, muft be left to the option of every man's private judgment.

Nonconformists.

Blackst. Comment.

" With regard therefore to *Protestant dissenters*, although the experience of their turbulent disposition in former times occasioned several disabilities and restrictions (which I shall not undertake to justify) to be laid upon them by abundance of statutes; yet at length the legislature, with a true spirit of magnanimity, extended that indulgence to these sectaries, which they themselves, when in power, had held to be countenancing schism, and denied to the church of England. The penalties are conditionally suspended by the statute 1 W. & M. st. 1. c. 18. " for exempting their Majesties Protestant subjects, dissenting from the church of England, from the penalties of certain laws," commonly called the *toleration act*; which declares, that neither the laws above-mentioned, nor the statutes 1 Eliz. c. 2. § 14. 3 Jac. I. c. 4. & 5. nor any other penal laws made against Popish recusants (except the test-acts) shall extend to any dissenters, other than Papists and such as deny the Trinity: provided, 1. That they take the oaths of allegiance and supremacy, (or make a similar affirmation, being Quakers), and subscribe the declaration against Popery. 2. That they repair to some congregation certified to, and registered in the court of the bishop or archdeacon, or at the county-sessions. 3. That the doors of such meeting-house shall be unlocked, unbarred, and unbolted; in default of which, the persons meeting there are still liable to all the penalties of the former acts. Dissenting teachers, in order to be exempted from the penalties of the statutes 13 & 14 Car. II. c. 4. 17 Car. II. c. 2. and 22 Car. II. c. 1. are also to subscribe the articles of religion mentioned in the statute 13 Eliz. c. 12. (viz. those which only concern the confession of the true Christian faith, and the doctrine of the sacraments), with an express exception of those relating to the government and powers of the church, and to infant-baptism. And by statute 10 Ann. c. 2. this toleration is ratified and confirmed; and it is declared, that the said act shall at all times be inviolably observed for the exempting such Protestant dissenters as are thereby intended, from the pains and penalties therein mentioned. Thus, though the offence of nonconformity is by no means universally abrogated, it is suspended, and ceases to exist with regard to these Protestant dissenters, during their compliance with the conditions imposed by the act of toleration: and, under these conditions, all persons, who will approve themselves no Papists or oppugners of the Trinity, are left at full liberty to act as their consciences shall direct them in the matter of religious worship. And if any person shall wilfully, maliciously, or contemptuously disturb any congregation, assembled in any church or permitted meeting-house, or shall misuse any preacher or teacher there, he shall (by virtue of the same statute) be bound over to the sessions of the peace, and forfeit 20 l. But by statute 5 Geo. I. c. 4. no mayor or principal magistrate must appear at any dissenting meeting with the ensigns of his office, on pain of disability to hold that or any other office: the legislature judging it a matter of propriety, that a mode of worship, set up in opposition to the national, when allowed to be exercised in peace, should be exercised also with decency, gratitude, and humility. Neither doth the act of toleration extend to enervate those clauses of the statutes 14 & 13 Car. II. c. 4. & 17 Car. II. c. 2. which prohibit (upon pain of fine and imprisonment) all persons from teaching school, unless they be licensed by the ordinary, and subscribe a declaration of conformity to the liturgy of the church, and reverently frequent divine service *established* by the laws of this kingdom.

" As to *Papists*, what has been said of the Protestant dissenters would hold equally strong for a general toleration of them; provided their separation was founded only upon difference of opinion in religion, and their principles did not also extend to a subversion of the civil government. If once they could be brought to renounce the supremacy of the Pope, they might quietly enjoy their seven sacraments; their purgatory, and auricular confession; their worship of relics and images; nay, even their transubstantiation. But while they acknowledge a foreign power, superior to the sovereignty of the kingdom, they cannot complain if the laws of that kingdom will not treat them upon the footing of good subjects.

" The following are the laws that have been enacted against the Papists; who may be divided into three classes, persons professing Popery, Popish recusants convict, and Popish priests. 1. Persons professing the Popish religion, besides the former penalties for not frequenting their parish-church, are disabled from taking any lands either by descent or purchase, after 18 years of age, until they renounce their errors; they must at the age of 21 register their estates before acquired, and all future conveyances and wills relating to them; they are incapable of presenting to any advowson, or granting to any other person any avoidance of the same; they may not keep or teach any school under pain of perpetual imprisonment; and, if they willingly say or hear mass, they forfeit the one 200, the other 100 merks, and each shall suffer a year's imprisonment. Thus much for persons who, from the misfortune of family-prejudices, or otherwise, have conceived an unhappy attachment to the Romish church from their infancy, and publicly profess its errors. But if any evil industry is used to rivet these errors upon them; if any person sends another abroad to be educated in the Popish religion, or to reside in any religious house abroad for that purpose, or contributes to their maintenance when there; both the sender, the sent, and the contributor, are disabled to sue in law or equity, to be executor or administrator to any person, to take any legacy or deed of gift, and to bear any office in the realm; and shall forfeit all their goods and chattels, and likewise all their real estate for life. And where these errors are also aggravated by apostacy or perversion; where a person is reconciled to the see of Rome, or procures others to be reconciled, the offence amounts to high-treason. 2. Popish recusants, convicted in a court of law of not attending the service of the church of England, are subject to the following disabilities, penalties, and forfeitures, over and above those beforementioned. They are considered as persons excommunicated; they can hold no office or employment; they must not keep arms in their houses, but the same may be seized by the justices of the peace; they may not come within 10 miles of London, on pain of 100 l.; they can bring no action at law or suit in equity; they are not permitted to travel above five miles from home, unless by licence, Noncon-formists.

cenfe, upon pain of forfeiting all their goods; and they may not come to court under pain of 100l. No marriage or burial of fuch recufant, or baptifm of his child, fhall be had otherwife than by the minifters of the church of England, under other fevere penalties. A married woman, when recufant, fhall forfeit two thirds of her dower or jointure, may not be executrix or adminiftratrix to her hufband, nor have any part of his goods; and during the coverture may be kept in prifon, unlefs her hufband redeems her at the rate of 10l. a month, or the third part of all his lands. And laftly, as a feme-covert recufant may be imprifoned, fo all others muft, within three months after conviction, either fubmit and renounce their errors, or, if required fo to do by four juftices, muft abjure and renounce the realm: and if they do not depart, or if they return without the king's licence, they fhall be guilty of felony, and fuffer death as felons without benefit of clergy. There is alfo an inferior fpecies of recufancy, (refufing to make the declaration againft Popery enjoined by ftatute 30 Car. II. ft. 2. when tendered by the proper magiftrate); which, if the party refides within ten miles of London, makes him an abfolute recufant convict; or, if at a greater diftance, fufpends him from having any feat in parliament, keeping arms in his houfe, or any horfe above the value of 5l. 3. Popifh priefts are in a ftill more dangerous condition. By ftatute 11 & 12 W. III. c. 4. Popifh priefts, or bifhops, celebrating mafs or exercifing any part of their functions in England, except in the houfes of ambaffadors, are liable to perpetual imprifonment. And by the ftatute 27 Eliz. c. 2. any Popifh prieft, born in the dominions of the crown of England, who fhall come over hither from beyond fea, (unlefs driven by ftrefs of weather and tarrying only a reafonable time), or fhall be in England three days without conforming and taking the oaths, is guilty of high treafon: and all perfons harbouring him are guilty of felony without the benefit of clergy.

This is a fhort fummary of the laws againft the Papifts; of which the prefident Montefquieu obferves, that they are fo rigorous, though not profeffedly of the fanguinary kind, that they do all the hurt that can poffibly be done in cold blood. But in anfwer to this it may be obferved, (what foreigners who only judge from our ftatute-book are not fully apprized of) that thefe laws are feldom exerted to their utmoft rigour: and indeed, if they were, it would be very difficult to excufe them. For they are rather to be accounted for from their hiftory, and the urgency of the times which produced them, than to be approved (upon a cool review) as a ftanding fyftem of law. The reftlefs machinations of the Jefuits during the reign of Elizabeth, the turbulence and uneafinefs of the Papifts under the new religious eftablifhment, and the boldnefs of their hopes and wifhes for the fucceffion of the queen of Scots, obliged the parliament to counteract fo dangerous a fpirit by laws of a great, and then perhaps neceffary, feverity. The powder-treafon, in the fucceeding reign, ftruck a panic into James I. which operated in different ways: it occafioned the enacting of new laws againft the Papifts; but deterred him from putting them in execution. The intrigues of queen Henrietta in the reign of Charles I. the profpect of a Popifh fucceffor in that of Char. II. the affaffination-plot in the reign of king William, and the avowed claim of a Popifh pretender to the crown in fubfequent reigns, will account for the extenfion of thefe penalties at thofe feveral periods of our hiftory." But now that all juft fears of a pretender may be faid to have vanifhed; and the power and influence of the pope has become feeble, ridiculous, and defpicable, not only in Britain, but in almoft every kingdom of Europe; and as in fact the Britifh Catholics folemnly difclaim the dangerous principles afcribed to them †; the Britifh legiflature, giving way to that liberality of fentiment becoming Proteftants, have lately repealed the moft rigorous of the above edicts, *viz.* The punifhment of Popifh priefts or Jefuits who fhould be found to teach or officiate in the fervices of that church; which acts were felony in foreigners, and high treafon in the natives of this kingdom:—The forfeitures of Popifh heirs, who had received their education abroad; and whofe eftates went to the next Proteftant heir:—The power given to the fon, or other relation, being a Proteftant, to take poffeffion of the father's or other relation's eftate, during the life of the real proprietor:—And the debarring Papifts from the power of acquiring any legal property by purchafe.—In propofing the repeal of thefe penalties, it was obferved, That, befides that fome of them had now ceafed to be neceffary, others were at all times a difgrace to humanity. The imprifonment of a Popifh prieft for life, only for officiating in the fervices of his religion, was horrible in its nature: And although the mildnefs of government had hitherto foftened the rigour of the law in the practice, it was to be remembered that the Roman Catholic priefts conftantly lay at the mercy of the bafeft and moft abandoned of mankind—of common informers; for on the evidence of any of thefe wretches, the magifterial and judicial powers were of neceffity bound to enforce all the fhameful penalties of the act. Others of thefe penalties held out the moft powerful temptations for the commiffion of acts of depravity, at the very thought of which our nature recoils with horror: They feemed calculated to loofen all the bands of fociety; to diffolve all civil, moral, and religious obligations and duties, to poifon the fources of domeftic felicity, and to annihilate every principle of honour. The encouragement given to children to lay their hands upon the eftates of their parents, and the reftriction which debars any man from the honeft acquifition of property, need only to be mentioned to excite indignation in an enlightened age.

† See their loyal Addrefs to the throne, May 1. 1778, as inferted in the Magazines or Annual Regifter for that year.

In order the better to fecure the Englifh eftablifhed church againft perils from non-conformifts of all denominations, infidels, Turks, Jews, heretics, Papifts, and fectaries, there are, however, two bulwarks erected; called the *corporation* and *teft acts*: By the former of which, no perfon can be legally elected to any office relating to the government of any city or corporation, unlefs, within a twelvemonth before, he has received the facrament of the Lord's fupper according to the rights of the church of England; and he is alfo enjoined to take the oaths of allegiance and fupremacy at the fame time that he takes the oath of office: or, in default of either of thefe requifites, fuch election fhall be void. The other, called the *teft act*, directs all officers civil and military to take the oaths and make the declaration againft tranfubftantion, in any of of the king's courts at Weftminfter, or at the quarter-feffions, within fix calendar months after their admiffion; and alfo within the fame time to receive the facrament of the Lord's fupper, according to the ufage of the church of England, in fome public church immediately after divine fervice and fermon, and to deliver into court a certificate thereof figned by the minifter and church-warden, and alfo to prove the fame by two credible witneffes; upon forfeiture of 500l. and difability to hold the faid office. And of much the fame nature with thefe is the ftatute 7 Jac. I. c. 2. which permits no perfons to be naturalifed or reftored in blood, but fuch as undergo a like teft: which teft having been removed in 1753, in favour of the Jews, was the next feffion of parliament reftored again with fome precipitation.

NON-*Naturals*, in medicine, fo called, becaufe by their abufe they become the caufes of difeafes.

Phyficians have divided the non-naturals into fix claffes, viz. the air, meats and drinks, fleep and watching, motion and reft, the paffions of the mind, the retentions and excretions. See MEDICINE, n° 147, &c.

NON *Obftante, (notwithftanding,)* a claufe frequent in ftatutes and letters-patent, importing a licence from the king to do a thing, which at common law might be lawfully done, but being reftrained by act of parliament cannot be done without fuch licence.

NON *Pros.* See NOLLE *Profequi.*

NON-*Suit*, fignifies the dropping of a fuit or action, or a renouncing thereof by the plaintiff or defendant; which happens moft commonly upon the difcovery of fome error in the plaintiff's proceedings when the caufe is fo far proceeded in, that the jury is ready at the bar to deliver in their verdict.

NONES, (NONÆ,) in the Roman kalendar, the fifth day of the months January, February, April, June, Auguft, September, November, and December; and the feventh of March, July, and October. March, May, July, and October, had fix days in their nones; becaufe thefe alone, in the ancient conftitution of the year by Numa, had 31 days a-piece, the reft having only 29, and February 30: but when Cæfar reformed the year, and made other months contain 31 days, he did not allot them fix days of nones.

NONIUS (Peter), in Spanifh *Nunes*, a learned Portuguefe, and one of the ableft mathematicians of the 16th century, was born at Alcacer. He was preceptor to Don Henry, king Emmanuel's fon, and taught the mathematics in the univerfity of Coimbra. He publifhed the following works, by which he gained great reputation: 1. *De arte navigandi.* 2. *Annotationes in theorias planetarum Purbachii;* which are greatly efteemed. 3. A treatife *De crepufculis.* 4. A treatife on algebra. It is obferved in Furetiere's dictionary, that Peter Nonius, in 1530, firft invented the angles of 45 degrees made in every meridian, and that he called them *rhumbs* in his language, and calculated them by fpherical triangles. Nonius died in 1577, aged 80.

NONIUS (Marcellus), a grammarian and Peripatetic philofopher, born at Tivoli, wrote a treatife, intitled *De proprietate fermonum.* This author is only valuable for his giving fragments of ancient authors that are nowhere elfe to be found. The above treatife was printed at Paris in 1614, with notes.

NONNIUS, or NONIUS (Lewis), a learned phyfician of Antwerp in the 17th century, wrote feveral works which are efteemed; the principal of which are, 1. An excellent treatife intitled *Ichthyophagia, five de Pifcium efu.* 2. *Hifpania;* which is of great ufe in underftanding the ancient geography of Spain. 3. A commentary on the medals of Greece, and thofe of Julius Cæfar, Auguftus, and Tiberius, in folio: it contains Goltzius's two works on the fame fubject. 4. A commentary on Goltzius's account of Greece, the iflands, &c. 5. Poems, &c.

NONNUS, a Greek poet of the 5th century, and native of Panopilis in Egypt, was the author of an heroic poem in 48 books, intitled *Dionyfiacorum*, and a paraphrafe in verfe of St John's Gofpel, which may ferve as a commentary upon it.

NORDEN (Frederic Lewis), an ingenious traveller and naval officer in the Danifh fervice, was born at Gluckftadt in Holftein in the year 1708. He was well fkilled in mathematics, fhip-building, and efpecially in architecture; and in 1732 obtained a penfion to enable him to travel for the purpofe of ftudying the conftruction of fhips, particularly the galleys and other rowing veffels ufed in the Mediterranean. He fpent near three years in Italy, and Chriftian VI. being defirous of obtaining a circumftantial account of Egypt, Mr Norden at Florence received an order to extend his travels to that country. How he acquitted himfelf in this commiffion, appears from his Travels into Egypt and Nubia, printed at Copenhagen in folio, 1756; and which were foon after tranflated into Englifh by Dr Peter Templeman. In the war between England and Spain, Mr Norden, then a captain in the Danifh navy, attended count Ulric Adolphus, a fea-captain, to England; and they went out volunteers under Sir John Norris, and afterwards under Sir Chaloner Ogle. During his ftay in London, Mr Norden was made a fellow of the royal fociety, and gave the public drawings of fome ruins and coloffal ftatues at Thebes in Egypt; with an account of the fame, in a letter to the royal fociety, 1741. His health at this time was declining; and taking a tour to France, he died at Paris in 1742.

NORFOLK, a county of England, fo called from its northern fituation in refpect of Suffolk, is bounded on the eaft and north by the German ocean; on the fouth by Suffolk, from which it is parted by the rivers Waveney, and the Leffer Oufe; and on the weft it is feparated from Cambridgefhire by the Greater Oufe, and from a fmall part of Lincolnfhire by the wafhes. According to Templeman, it extends in length 57 miles, in breadth 35, and 140 in circumference. It contains an area of 1426 fquare miles, one city, 32 market-towns, 711 villages, according to the book of rates; though fome make them 1500, and 236000 inhabitants, as fome have it, and 283000, according to others. It is divided into 31 hundreds, 164 vicarages, and 660 parifhes.

The air differs in different parts of the county, according to the foil, which in fome parts is marfhy, efpecially on the fea-coaft, and there the air is foggy and unwholefome: in others it is clayey and chalky, poor, lean, and fandy; and there the air is good. The county is almoft all champaign, except in fome places, where

where rife gentle hills. The marfh-lands yield rich pafture for cattle; the clay-grounds peafe, rye, and barley; and the fandy-heaths feed vaft flocks of large fheep, of which fome villages are faid to keep 4000 or 5000. Thefe heaths abound alfo in rabbits of a filver-grey colour. Walfingham is noted for producing the beft faffron. Great quantities of mackarel and herring are caught upon the coafts of this county, the former in the fpring, and the latter in September; efpecially at Yarmouth, where they are cured in a particular manner, and to great perfection. Wood and honey are alfo very plentiful in this fhire; and on the coafts jet and ambergreafe are fometimes found. The inhabitants are generally ftrong and active, fagacious and acute. That they are fo robuft, is the more to be wondered at, becaufe the common people live much on puddings, *Norfolk dumplings*. They are for the moft part in eafy circumftances, and were formerly very quarrelfome and litigious. In confequence of this difpofition, lawyers fwarmed among them to fuch a degree, that a ftatute was made fo early as the reign of Henry VI. to reftrain their number. The manufactures of the county, which is exceedingly populous, are chiefly woollen and worfted ftuffs, and ftockings, for which they are well fupplied with wool from the vaft flocks of fheep bred in it. It gives title of duke to the elder branch of the family of Howard, lies in the diocefe of Norwich, and fends twelve members to parliament, viz. two knights for the fhire, two citizens for Norwich, and two burgeffes for each of the boroughs of Lynn Regis, Great Yarmouth, Thetford, and Caftle-rifing.

The county is well watered, and fupplied with fifh by the rivers Yare, Thyrn, Waveney, the Greater and Leffer Oufe, and the Bure, befides rivulets. The Bure abounds in excellent perch, and the Yare has a fifh peculiar to it called the *ruffe*. The latter rifes about the middle of the county; and after being joined by the Waveney and Bure, falls into the fea at Yarmouth. At the equinoxes, efpecially the autumnal, the Oufe is fubject to great inundations, heing forced back by the fea that enters it with great fury.

Norfolk, a county of Virginia contiguous to North Carolina.

NORMANDY, a province of France, bounded on the north by the Englifh channel; on the eaft by Picardy and the ifle of France; on the fouth by Perche and Maine, and one part of Bretague; and on the weft by the ocean. It is about 150 miles in length, 80 in breadth, and 600 in circumference. It is one of the moft fertile, and brings in the largeft revenue of the kingdom. It abounds in all things except wine, but they fupply that defect by cyder and perry. There are vaft meadows, fat paftures, and the fea yields plenty of fifh. It contains iron, copper, and a great number of rivers and harbours. It carries on a great trade, is very populous, and comprehends a vaft number of towns and villages. It is divided into the Upper and Lower; the Upper borders upon Picardy, and the Lower upon Bretagne. The inhabitants are ingenious, and capable of underftanding arts and fciences, but they are very fond of law. The Normans, a people of Denmark and Norway, having entered France under Rollo, Charles the Simple ceded this country to them in 912, which from that time was called *Normandy*. Rollo was the firft duke, and held it as a fief of the crown of France, and feveral of his fucceffors after him, till William, the feventh duke, conquered England in 1066: from which time it became a province of England, till it was loft in the reign of king John, and re-united to the crown of France; but the Englifh ftill keep the iflands on the coafts of Normandy.

NORTH (Dudley, lord), the third baron of that accomplifhed family, was one of the fineft gentlemen in the court of king James; but, in fupporting that character, diffipated and gamed away the greateft part of his fortune. In 1645, he appears to have acted with the parliament; and was nominated by them to be adminiftrator of the admiralty, in conjunction with the great earls of Northumberland, Effex, Warwick, and others. He lived to the age of 85, the latter part of which he paffed in retirement; and wrote a fmall folio of mifcellanies, in profe and verfe, under this title, A Foreft promifcuous of feveral Seafons Productions, in four parts, 1659.

North (Dudley, lord) fon of the former, was made knight of the bath in 1616, at the creation of Charles prince of Wales; and fat in many parliaments, till fecluded by the prevailing party in that which condemned the king. From that period lord North lived privately in the country, and towards the end of his life entertained himfelf with books, and, as his numerous iffue required, with œconomy, on which he wrote a little tract, called *Obfervations and advices œconomical*, 12mo. His other works are, Paffages relating to the long parliament; The hiftory of the life of the lord Edward North, the firft baron of the family, addreffed to his eldeft fon; and a volume of effays.

North (Francis lord Guilford, lord-keeper of the great-feal in the reigns of Charles II. and James II.) was a third fon of the fecond Dudley lord North, baron of Kertling; and ftudied at St John's college in Cambridge, from whence he removed to Middle Temple. He acquired French, Italian, Spanifh, and Dutch; and became not only a good lawyer, but was well verfed in hiftory, mathematics, philofophy, and mufic. He was afterwards made the king's folicitor-general, and was chofen to reprefent the borough of Lynn in parliament. He fucceeded Sir Heneage Finch in the poft of attorney-general; and lord chief-juftice Vaughan, in the place of lord chief-juftice of the common-pleas. He was afterwards made keeper of the great-feal; and in 1683 was created a baron, by the title of *lord Guilford*. He died at his houfe at Wroxton in 1685. He wrote a philofophical effay on mufic; a paper on the gravitation of fluids, confidered in the bladders of fifhes, printed in Lowthorp's abridgment of the Philofophical Tranfactions; and fome other pieces.

North, one of the four cardinal points. See Pole.

North-*Cape*, the moft northerly promontory in Europe, on the coaft of Norway. E. Long. 21. 0. N. Lat. 78. 0.

North-*Foreland*, a cape or promontory of Kent, in the ifle of Thanet, four miles eaft of Margate. Between this and the South-Foreland are the Downs, through which all fhips pafs that are bound to or from

the

the weſt. E. Long. 1. 25. N. Lat. 51. 25.

NORTH-*Weſt Paſſage*, a paſſage to the Pacific Ocean through Hudſon's Bay or Davis's Straits, and which hath been frequently attempted without ſucceſs; notwithſtanding which, many people are ſtill of opinion that it is practicable.

NORTH-*Eaſt Paſſage*, a paſſage to the Eaſt Indies along the northern coaſts of Aſia, which, like the former, hath frequently been attempted, but hitherto without ſucceſs. Concerning theſe paſſages an opinion hath lately been revived by the hon. Daines Barrington, namely, that they ought to be attempted by the pole itſelf; and he hath no doubt of the poſſibility of accompliſhing them by that means. See *North* POLE.

NORTHAMPTON, a town of England, capital of a county of the ſame name, ſituated in W. Long. 0. 55. N. Lat. 52. 15. According to Camden, it was formerly called *North-afandon*, from its ſituation to the north of the river Nen, called anciently *Auſona*, by which and another leſſer river it is almoſt encloſed. Dr Gibſon ſays, that the ancient Saxon annals called both it and Southampton ſimply *Hamton;* and afterwards, to diſtinguiſh them, called the one, from its ſituation, *Southamton*, and the other *Northamton;* but never *North-afandon*, Though it does not appear to be a place of very great antiquity, yet here was a caſtle, and a church dedicated to St Andrew, built by Simon de Sancto Licio, commonly called *Senlez*, the firſt earl of Northampton of that name. It is ſaid to have been burnt down during the Daniſh depredations; but in the reign of St Edward it appears to have been a conſiderable place. It was beſieged by the barons in their war with king John; at which time that military work called *Hunſhill*, is ſuppoſed to have been raiſed. In the time of Henry III. it ſided with the barons, when it was beſieged and taken by the king. Here the bloody battle was fought in which Henry VI. was taken priſoner; and ſeveral parliaments have been held in this town. It was entirely conſumed by a moſt dreadful fire in 1675; yet, by the help of liberal contributions from all parts of the kingdom, it hath ſo recovered itſelf, that it is now one of the neateſt and beſt-built towns of the kingdom. Among the public buildings, which are all lofty, the moſt remarkable are the church called *All-hallows*, the ſeſſions and aſſize houſe, and the George inn, which belongs to the poor of the town. There was formerly a nunnery in the neighbouring meadows. A county-hoſpital or infirmary has been lately built here, after the manner of thoſe of Bath, London, Briſtol, &c. It has a conſiderable manufacture of ſhoes and ſtockings; and its fairs are noted for horſes both for draught and ſaddle; beſides, it is a great thoroughfare for the north and weſt roads. It gives title of *earl* to the family of Compton.

NORTHAMPTONSHIRE, a county of England, is ſituated in the very heart of the kingdom: bounded on the eaſt by the counties of Bedford and Huntingdon; on the ſouth by thoſe of Buckingham and Oxford; on the weſt by Warwickſhire; and on the north by the counties of Leiceſter, Rutland, and Lincoln, which are ſeparated from it by the Leſſer Avon, and the Welland. Its greateſt length is about 50 miles, its greateſt breadth about 20, and its circumference about 130. It contains 33 pariſhes; in which are one city, 11 market-towns, and 150,000 inhabitants. Nine members are returned to parliament for this county, viz. two knights for the ſhire, two for the city of Peterborough, two for each of the towns of Northampton and Brockley, and one for Higham Ferrers. It lies in the Mid-land circuit, and the dioceſe of Peterborough. As this county is dry, well cultivated, free from marſhes, except the fens about Peterborough, in the centre of the kingdom, and of courſe at a diſtance from the ſea, it enjoys a very pure and wholeſome air. In conſequence of this it is very populous, and ſo full of towns and churches, that 30 ſpires or ſteeples may be ſeen in many places at one view; and even in the fens, the inhabitants ſeem to enjoy a good ſtate of health, and to be little affected by the water which frequently overflows their grounds, eſpecially in winter, but is never ſuffered to remain long upon it. Its ſoil is exceeding fertile both in corn and paſturage; but it labours under a ſcarcity of fuel, as it doth not produce much wood, and, by lying at a diſtance from the ſea, cannot be eaſily ſupplied with coal. Its commodities, beſides corn, are ſheep, wool, black cattle, and ſaltpetre; and its manufactures are ſerges, tammies, ſhalloons, boots, and ſhoes. Beſides many leſſer brooks and ſtreams, it is well watered by the rivers Nen, Welland, Ouſe, and Leam; the three firſt of which are large, and for the moſt part navigable.

NORTHUMBERLAND, the moſt northerly county of England, and formerly a diſtinct kingdom, is bounded on the north and weſt by the river Tweed, which divides it from Scotland, the Cheviot-hills, and part of Cumberland; waſhed on the eaſt by the German Ocean; and ſeparated from Durham on the ſouth by the rivers Tyne and Derwent. This county, which gives the title of *duke* to a nobleman who married the daughter of Algernoon duke of Somerſet, whoſe mother was heireſs of the Piercy family, extends about 50 miles in length from north to ſouth, and above 40 from eaſt to weſt; and is remarkably populous, containing 11 market-towns, 280 villages, and 46 pariſhes. The face of the country, eſpecially towards the weſt, is roughened with huge mountains, the moſt remarkable of which are the Cheviot-hills, and the high ridge called *Rideſdale;* but the lands are level towards the ſea-ſide and the borders of Durham. The climate, like that of every other mountainous country in the neighbourhood of the ſea, is moiſt and diſagreeable: the air, however, is pure and healthy, as being well ventilated by breezes and ſtrong gales of wind; and in winter mitigated by the warm vapours from the two ſeas, the Iriſh and the German Ocean, between which it is ſituated. The ſoil varies in different parts of the county. Among the hills it is barren; though it affords good paſture for ſheep, which cover thoſe mountains. The low country, when properly cultivated, produces plenty of wheat, and all ſorts of grain; and great part of it is laid out in meadow-lands and rich encloſures. Northumberland is well watered with many rivers, rivulets, and fountains: its greateſt rivers are the Tweed and the Tyne. The Tyne is compoſed of two ſtreams called *South* and *North Tyne:* the firſt riſes on the verge of Cumberland, near Alſton-moor; enters Northumberland,

Northumberland. land, running north to Haltwefel; then bends eafterly, and receiving the two fmall rivers Eaft and Weft Alon, unites above Hexham with the other branch, taking its rife at a mountain called *Fane-head* in the weftern part of the county, thence called *Tine-dale;* is fwelled in its courfe by the little river Shele; joins the Read near Billingham; and running in a direct line to the fouth-eaft, is united with the fouthern Tyne, forming a large river that wafhes Newcaftle, and falls into the German Ocean near Tinmouth.

In all probability the mountains of Northumberland contain lead-ore and other mineralized metals in their bowels, as they in all refpects refemble thofe parts of Wales and Scotland where lead mines have been found and profecuted. Perhaps the inhabitants are diverted from inquiries of this nature, by the certain profits and conftant employment they enjoy in working the coal-pits, with which this county abounds. The city of London, and the greateft part of England, are fupplied with fuel from thefe ftores of Northumberland, which are inexhauftible, enrich the proprietors, and employ an incredible number of hands and fhipping.

There are no natural woods of any confequence in this county; but many plantations belonging to the feats of noblemen and gentlemen, of which here is a great number. As for pot-herbs, roots, fallading, and every article of the kitchen-garden and orchard, they are here raifed in great plenty by the ufual means of cultivation; as are alfo the fruits of more delicate flavour, fuch as the apricot, peach, and nectarine. The fpontaneous fruits it produces in common with other parts of Great Britain, are the crab-apple, the floe or bullace, the hazle-nut, the acorn, hips, and haws, with the berries of the bramble, the juniper, wood-ftrawberries, cranberries, and bilberries.

Northumberland raifes a good number of excellent horfes and black cattle, and affords paftnre for numerous flocks of fheep; both the cattle and fheep are of a large breed, but the wool is coarfer than that which the more fouthern counties produce. The hills and mountains abound with a variety of game, fuch as red deer, foxes, hares, rabbits, heathcock, growfe, partridge, quail, plover, teal, and woodcock: indeed, this is counted one of the beft fporting counties in Great Britain. The fea and rivers are well ftocked with fifh; efpecially the Tweed, in which a vaft number of falmon is caught and carried to Tinmouth, where being pickled, they are conveyed by fea to London, and fold under the name of *Newcaftle falmon.*

The Northumbrians were anciently ftigmatized as a favage, barbarous people, addicted to cruelty, and inured to rapine. The truth is, before the union of the two crowns of England and Scotland, the borderers on each fide were extremely licentious and ungovernable, trained up to war from their infancy, and habituated to plunder by the mutual incurfions made into each kingdom; incurfions which neither truce nor treaty could totally prevent. People of a pacific difpofition, who propofed to earn their livelihood by agriculture, would not on any terms remain in a country expofed to the firft violence of a bold and defperate enemy: therefore the lands lay uncultivated, and in a great meafure deferted by every body but lawlefs adventurers, who fubfifted by theft and rapine. There was a tract 50 miles in length and 6 in breadth, between Berwick and Carlifle, known by the name of the *Debateable Land,* to which both nations laid claim, tho' it belonged to neither; and this was occupied by a fet of banditti who plundered on each fide, and what they ftole in one kingdom, they fold openly in the other: nay, they were fo dexterous in their occupation, that by means of hot bread applied to the horns of the cattle which they ftole, they twifted them in fuch a manner, that, when the right owners faw them in the market, they did not know their own property. Wardens were appointed to guard the marches or borders in each kingdom; and thefe offices were always conferred on noblemen of the firft character for influence, valour, and integrity. The Englifh border was divided into three marches, called the *eaft, weft,* and *middle marches;* the gentlemen of the country were conftituted deputy-wardens, who held march-courts, regulated the watches, difciplined the militia, and took meafures for affembling them in arms at the firft alarm: but in the time of peace between the two nations, they were chiefly employed in fuppreffing the infolence and rapine of the borderers. Since the union of the crowns, however, Northumberland is totally changed, both with refpect to the improvement of the lands, and the reformation of the inhabitants. The grounds, being now fecure from incurfion and infult, are fettled by creditable farmers, and cultivated like other parts of the kingdom. As hoftilities have long ceafed, the people have forgot the ufe of arms, and exercifed themfelves in the more eligible avocations of peace; in breeding fheep and cattle, manuring the grounds, working at the coal-pits, and in different branches of commerce and manufacture. In their perfons they are generally tall, ftrong, bold, hardy, and frefh-coloured; and though lefs unpolifhed than their anceftors, not quite fo civilized as their fouthern neighbours. The commonalty are well fed, lodged, and cloathed; and all of them remarkably diftinguifhed by a kind of *fhibboleth* or *whurle,* being a particular way of pronouncing the letter *R*, as if they hawked it up from the wind-pipe, like the cawing of rooks. In other refpects, the language they fpeak is an uncouth mixture of the Englifh and Scottifh dialects. There is no material diftinction between the fafhionable people of Northumberland, and thofe of the fame rank in other parts of the kingdom: the fame form of education will produce the fame effects in all countries. The gentlemen of Northumberland, however, are remarkable for their courage, hofpitality, and hard drinking.

A great number of Roman monuments have been found in this county; but the moft remarkable curiofity of that kind confifts in the remains of Hadrian's vallum and the wall of Severus See Adrian's *Wall,* and Severus's *Wall.*

The moft noted towns in Northumberland, are Newcaftle, Morpeth, Alnwick, Berwick, Hexham, and North Shields.

Northumberland, Norway.

NORWAY, a country of Europe, lying between the 57th and 72d degrees of north latitude, and between the 5th and 31ft degrees of longitude eaft from London; extending in length about 1000 miles, in a direct line from Lindefnaes, in the diocefe of Chri-

 Chriſtianſand, to the North Cape, at the extremity of Finmark. Its breadth, from the frontiers of Sweden weſtward to Cape Statt, may amount to about 300 miles; but from thence the country becomes gradually narrower towards the north. On the ſouth it is bounded by the Schagen-rock, or Categate, the entrance into the Baltic; on the eaſt it is divided from Sweden by a long ridge of high mountains; and on the weſt and north it is waſhed by the northern ocean.

The coaſt of Norway, extending above 300 leagues, is ſtudded with a multitude of ſmall iſlands, affording habitation to fiſhermen and pilots, and paſture to a few cattle. They form an infinite number of narrow channels, and a natural barrier of rocks, which renders Norway inacceſſible to the naval power of its enemies. Attempts of this kind are the more dangerous, as the ſhore is generally bold, ſteep, and impending; ſo that cloſe to the rocks the depth of the ſea amounts to 100, 200, or 300 fathoms. The perils of the north ſea are moreover increaſed by ſudden ſtorms, ſunk rocks, violent currents, and dreadful whirlpools. The moſt remarkable vortex on this coaſt is called *Moſkoeſtrom*, from the ſmall iſland Moſke, belonging to the diſtrict of Lofoden in the province of Nordland. In time of flood, the ſtream runs up between Lofoden and Moſkoe with the moſt boiſterous rapidity; but in its ebb to the ſea, it roars like a thouſand cataracts, ſo as to be heard at the diſtance of many leagues. The ſurface exhibits different vortices; and if in one of theſe any ſhip or veſſel is abſorbed, it is whirled down to the bottom, and daſhed in pieces againſt the rocks. Theſe violent whirlpools continue without intervals, except for a quarter of an hour, at high and low water, in calm weather; for the boiling gradually returns as the flood or ebb advances. When its fury is heightened by a ſtorm, no veſſel ought to venture within a league of it. Whales have been frequently abſorbed within the vortex, and howled and bellowed hideouſly in their fruitleſs endeavours to diſengage themſelves. A bear, in attempting to ſwim from Lofoden to Moſkoe, was once hurried into this whirlpool, from whence he ſtruggled in vain for deliverance, roaring ſo loud as to be heard on ſhore; but, notwithſtanding all his efforts, he was borne down and deſtroyed. Large trees being abſorbed by the current, are ſucked down, and riſe again all ſhattered into ſplinters. There are three vortices of the ſame kind near the iſlands of Ferroe.

Norway is divided into the four governments of Aggerhus, Bergen, Drontheim, and Wardhus, beſides that of Bahus, which is now ſubject to Sweden. The province of Aggerhus comprehends the ſouth-eaſt part of Norway, extending in length about 300 miles. Its chief towns are Chriſtiania, the ſee of a biſhop, ſuffragan to the metropolitan fee of Drontheim, where the ſovereign court of juſtice is held, in preſence of the viceroy and the governor of the province; Aggerhus, about 15 miles to the ſouthweſt of Chriſtiania; Frederickſhall, or Frederickſtadt, in the ſiege of which Charles XII. of Sweden loſt his life; Saltzberg, Tonſberg, Alleen, Hammar, and Hollen.

The government of Bergen lies in the moſt ſoutherly and weſterly part of Norway, including the city of the ſame name, which is an epiſcopal ſee, and a place of conſiderable trade; and Staff-hanger, ſituated in the bay of Buckenfior, about 80 miles to the ſouthward of Bergen. The third province, called *Drontheim* or *Trontheim*, extends about 500 miles along the coaſt; and is but thinly peopled. The chief town Drontheim, ſeated on a little gulph at the mouth of the river Nider, is the only Metropolitan ſee in Norway; and carries on a conſiderable trade in maſts, deals, tar, copper, and iron. Leetſtrand, Stronden, Scoerdale, Opdal, Romſdael, and Solendael, are likewiſe places of ſome traffic. The northern diviſion of Drontheim, called the *ſub-government of Salten*, comprehends the towns of Melanger and Scheen. The province of Wardhus, extending to the North Cape, and including the iſlands, is divided into two parts; namely, Finmark and Norwegian Lapland. The chief town, which is very inconſiderable, ſtands upon an iſland, called *Ward*, from whence the place and the government derive their name. The province of Bahus, though now yielded to the Swedes, is reckoned part of Norway, being a narrow track of land, about 90 miles in length, lying on the coaſt of the Categate.

The great chain of Norway mountains, running from north to ſouth, called indifferently *Rudfield*, *Sudefield*, *Skarsfield*, and *Scoreberg*, is known in different parts by other appellations; ſuch as *Dofrefield*, *Lamsfield*, *Sagnefield*, *Filefield*, *Halnefield*, *Hardangerfield*, *Joklefield*, *Byglefield*, *Hicklefield*, and *Hangfield*. The height and breadth of this extenſive chain likewiſe vary in different parts. To paſs the mountain Hardanger, a man muſt travel about 70 Engliſh miles whereas Filefield may be about 50 over. This laſt riſes about two miles and a half in perpendicular height; but Dofrefield is counted the higheſt mountain of Norway, if not of Europe. The river Drivane winds along the ſide of it in a ſerpentine courſe, ſo as to be met nine times by thoſe who travel the winter-road to the other ſide of the chain. The bridges are thrown over roaring cataracts, and but indifferently faſtened to the ſteep rocks on either ſide; ſo that the whole exhibits a very dreadful appearance, ſufficient to deter the traveller from hazarding ſuch a dangerous paſſage: for which reaſon, people generally chooſe the road over Filefield, which is much more tedious. This, however, is the poſt-road uſed by the king's carriages. The way is diſtinguiſhed by poſts fixed at the diſtance of 200 paces from each other, that, in ſnowy or dark weather, the traveller may not be bewildered. For the convenience of reſting and refreſhing, there are two mountain-ſtoves or houſes maintained on Filefield, as well as upon other mountains, at the expence of the public, and furniſhed with fire, light, and kitchen-utenſils. Nothing can be more diſmal and dreary than theſe mountains covered with eternal ſnow, where neither houſe, tree, nor living creature is to be ſeen, but here and there a ſolitary rein-deer, and perchance a few wandering Laplanders.

In travelling from Sweden to Nordenfields, there is only one way of avoiding this chain of mountains; and that is, where it is interrupted by a long deep valley, extending from Romſdale to Guldbrandſdale. In the year 1612, a body of 1000 Scots, commanded by Sinclair, and ſent over as auxiliaries to the Swedes, were put to the ſword in this defile, by the peaſants of Guld-

Norway. Guldbrand, who never give quarter.

Befides this chain, there is a great number of detached mountains over all the country, that form valleys and ridges, inhabited by the peafants. Some of thefe are of incredible height, and others exhibit very remarkable appearances. In failing up Joering Creek on the left hand, the fight is aftonifhed with a groupe of mountains, refembling the profpect of a city, with old Gothic towers and edifices. In the parifh of Oerfkong is the high mountain Skopfhorn, the top of which reprefents the figure of a fortification, with regular walls and baftions. In the diftrict of Hilgeland appears a very high range of mountains, with feven pinnacles or crefts, known by the appellation of the *Seven Sifters*, difcernible a great way off at fea. To the fouthward of this range, though in the fame diftrict, rifes the famous mountain *Torghatten*, fo called becaufe the fummit refembles a man's head with a hat on, under which appears a fingle eye, formed by an aperture through the mountain, 150 ells high, and 3000 ells in length. The fun may be feen through this furprifing cavity, which is paffable by the foot of travellers. On the top of the mountain we find a refervoir of water, as large as a moderate fifh-pond: in the lower part is a cavern, through which a line 400 fathoms in length, being let down, did not reach the bottom. At Herroe in Sundmoer is another cavern called *Dolfteen*, fuppofed to reach under the fea to Scotland; which, however, is no more than an idle tradition. In the year 1750, two clergymen entered this fubterranean cavity, and proceeded a confiderable way, until they heard the fea dafhing over their heads: the paffage was as wide and high as an ordinary church, the fides perpendicular, and the roof vaulted. They defcended one flight of natural ftairs; but arriving at another, they were afraid to penetrate farther: they had gone fo far, however, that two candles were confumed in their progrefs and return. A cavern of a very curious nature, ferving as a conduit to a ftream of water, penetrates through the fides of the mountain Limur. In the diftrict of Rake, in the neighbourhood of Frederickfhall, are three cavities in a rock; one of which is fo deep, that a fmall ftone dropped down, does not reach the bottom in lefs than two minutes; and then the found it produces is pleafant and melodious, not unlike the found of a bell.

The vaft mountains and rugged rocks that deform the face of this country, are productive of numberlefs inconveniences. They admit of little arable ground: they render the country in fome parts impaffable, and every where difficult to travellers: they afford fhelter to wild beafts, which come from their lurking holes, and make terrible havock among the flocks of cattle: they expofe the fheep and goats, as well as the peafant, to daily accidents of falling over precipices: they occafion fudden torrents, and falls of fnow, which defcend with incredible impetuofity, and often fweep away the labours of the hufbandman; and they are fubject to dreadful difruptions, by which huge rocks are rent from their fides, and, hurling down, overwhelm the plains below with inevitable ruin. The peafants frequently build their houfes on the edge of a fteep precipice, to which they muft climb by ladders, at the hazard of their lives; and when a perfon dies, the corpfe muft be let down with ropes, before it can be laid in the coffin. In winter the mail is often drawn up the fides of fteep mountains. Even in the king's road, travellers are expofed to the frequent rifks of falling over thofe dreadful rocks; for they are obliged to pafs over narrow pathways, without rails or rifing on the fides, either fhored up with rotten pofts, or fufpended by iron bolts faftened in the mountains. In the narrow pafs of Naeroe is a remarkable way of this kind, which, above 600 years ago, the famous king Surre caufed to be made for the paffage of his cavalry; and even this would have been found impaffable by any other horfes than thofe of Norway, which are ufed to climb the rocks like goats. Another very difficult and dangerous road is that between Shogftadt and Vang in Volders, along the fide of a fteep mountain, in fome places fo narrow, that if two travellers on horfeback fhould meet in the night, they would find it impracticable either to pafs each other, or turn back. In fuch a cafe their lives could not be faved, unlefs one of them fhould alight, and throw his horfe headlong into the lake below, and then cling to the rock, until the other could pafs. When a fheep or goat makes a falfe ftep to the projection of a rock, from whence it can neither afcend nor defcend, the owner hazards his own life to preferve that of the animal. He directs himfelf to be lowered down from the top of the mountain, fitting on a crofs ftick, tied to the end of a long rope; and when he arrives at the place where the creature ftands, he faftens it to the fame cord, and it is drawn up with himfelf. Perhaps the other end of the rope is held by one perfon only; and there are fome inftances, in which the affiftant has been dragged down by the weight of his friend, fo that both have perifhed. When either man or beaft has had the misfortune to fall over very high precipices, they have not only been fuffocated by the repercuffion of the air, but their bodies have been always burft before they reached the ground. Sometimes entire crefts of rocks, many fathoms in length and breadth, have fallen down at once, creating fuch a violent agitation of the air, as feemed a prelude to the world's diffolution. At Steenbroc in Laerdale, a ftupendous mafs, larger than any caftle in the univerfe, appears to have been fevered and tumbled from the mountain in large, fharp, and ragged fragments, thro' which the river roars with hideous bellowing. In the year 1731, a promontory on Sundmoer, called *Rammersfield*, that hung over Nordal Creek, fuddenly gave way, and plunged into the water; which fwelled to fuch a degree, that the church of Strand, tho' half a league on the other fide of the bank, was overflowed: the creek, however, was not filled up; on the contrary, the fishermen declare they find no difference in the depth, which is faid to exceed 900 fathoms.

The remarkable rivers of Norway are thefe: The Nied, iffuing from Tydalen, on the borders of Sweden, runs weftward into the lake Selboe; and afterwards, turning to the northward, paffes by the city of Drontheim, to which it anciently gave the name of *Nideros* and *Nidrofia*: Sule Ely, that defcending from Sulefield, runs with a rapid courfe thro' Nordale into the fea: Gulen, which rifes near Sffarsfield in the north; and running 20 leagues weftward, thro' Aalen, Hlotaalen, Storen, and Melhuus, difcharges itfelf into the fea, about a league to the weft of Drontheim.

In

Norway. In the year 1344, this river buried itſelf under ground: from whence it again burſt forth with ſuch violence, that the earth and ſtones thrown up by the eruption, filled the valley, and formed a dam; which, however, was ſoon broken and waſhed away by the force of the water. Divers churches, 48 farm-houſes, with 250 perſons, were deſtroyed on this occaſion. Otteroen, a large river, taking its riſe from the mountain Agde, runs about 30 leagues through Seeterdale and Eſie, and diſembogues itſelf into the cataract of Wiland. The river Syre riſes near the mountain Lang, and winds its courſe thro' the vale of Syre into the lake of Lunde in the dioceſe of Chriſtianſand: thence it continues its way to the ſea, into which it diſcharges itſelf through a narrow ſtrait formed by two rocks. This contraction augments its impetuoſity, ſo that it ſhoots like an arrow into the ſea, in which it produces a very great agitation. Nid and Sheen are two conſiderable rivers, iſſuing out of Tillemark. Their water-falls have been diverted, with infinite labour, by canals and paſſages cut through the rocks, for the convenience of floating down the timber. Tyrefiord, or Dramme, is in the neighbourhood of Honifoſſe, joined by two rivers from Oedale and Hadeland, and diſembogues iſelf into the ſea near Bragneſs. Loven riſes in the higheſt part of Nummedal, and runs through Konſberg to the ſea near Laurwig. Glaamen is the largeſt river of Norway, diſtinguiſhed by the name of *Stor-Elvin*, or the *great river*. It derives its origin from the mountain Doſre, from whence it winds all along the plains of Oeſterdale and Soloe; then joins the Vorme, another conſiderable river riſing out of Mioes and Guldſbrandſdale. Theſe being joined, traverſe the lake Oeyeren; and thence iſſuing, run on to Sarp near Frederickſtadt.

Norway abounds with freſh-water lakes; the principal of which are, Ryſvand in Nordland, Snaaſen, Selboe, the Greater and Leſſer Mioes, Slirevand, Sperdille, Rand, Veſtn, Saren, Modum, Lund, Norſoe, Huidſoe, Fariſvand, and Oeyevand: all theſe are well ſtocked with fiſh, and navigable for large veſſels. Wars have been formerly carried on upon theſe inland ſeas; in ſome of which are ſmall floating iſlands, or parcels of earth with trees on them, ſeparated from the main land, and probably preſerved in compact maſſes by the roots of trees, ſhrubs and graſs, interwoven in the ſoil. In the year 1702, the family-ſeat of Borge, near Frederickſtadt, being a noble edifice, with lofty towers and battlements, ſuddenly ſunk into an abyſs 100 fathoms deep, which was inſtantaneouſly filled by a piece of water 300 ells in length, and about half as broad. Fourteen perſons, with 200 head of cattle, periſhed in this cataſtrophe, which was occaſioned by the river Glaamen precipitating itſelf down a water-fall near Sarp, and undermining the foundation. Of all the water-falls in Norway this of Sarp is the moſt dangerous for its height and rapidity. The current drives 17 mills; and roars with ſuch violence, that the water, being daſhed and comminuted among the rocks, riſes in the form of rain, where a beautiful rainbow may be always ſeen when the ſun ſhines. In ancient times this cataract was made uſe of for the execution of traitors and other malefactors: they were thrown down alive, that they might be daſhed in pieces on the points of rocks, and die in a dreadful commotion, analagous to thoſe they had endeavoured to excite in the community.

Great part of Norway is covered with foreſts of wood, which conſtitute the principal article of commerce in this country. They chiefly conſiſt of fir and pine, for which great ſums are received from foreigners, who export an immenſe number of maſts, beams, planks, and boards. Beſides, an incredible quantity is conſumed at home, in building houſes, ſhips, bridges, piles, moles, and fences; over and above the vaſt demand for charcoal to the founderies, and fewel for domeſtic uſes. Nay, in ſome places, the trees are felled for no other purpoſe but to clear the ground and to be burned into aſhes for manure. A good quantity of timber is yearly exported to Scotland and Spain: but this is inconſiderable when compared to the vaſt exports from Drammen, Frederickſhall, Frederickſtadt, Chriſtiania, Skeen, Arendal, Chriſtianſand, Chriſtian's-bay, and Drontheim. The maſts and large beams are floated down the rivers, and the reſt is divided into boards at the ſaw-mills. Theſe works ſupply a vaſt number of families with a comfortable ſubſtance. A tenth part of all ſawed timber belongs to his Daniſh majeſty, and makes a conſiderable branch of his revenue. The foreſts in Norway are ſo vaſt and thick, that the people ſeem to think there can never be a ſcarcity of wood, eſpecially as the ſoil is peculiarly adapted for the production of timber: they therefore deſtroy it with a waſteful hand; inſomuch that more wood rots in Norway than is burned in the whole kingdom of Denmark. The beſt timber grows in the provinces of Saltan, Helleland, Romſdale, Guldbrandſdale, Oeſterdale, Soloe, Valders, Hallingdale, Sognifiord, Tellemark, and the lordſhip of Nedene.

The climate of Norway is very different in different parts of the kingdom. At Bergen the winter is ſo moderate, that the ſeas are always open and practicable both to mariners and fiſhermen, except in creeks and bays, that reach far up into the country towards Filefield, when the keen north-eaſt wind blows from the land. On the eaſt ſide of Norway from the frontiers of Sweden to Filefield, the cold generally ſets in about the middle of October with great ſeverity, and laſts till the middle of April; during which interval the waters are frozen to a very conſiderable thickneſs, and the face of the country is covered with ſnow. In the year 1719, 7000 Swedes, who intended to attack Drontheim, periſhed in the ſnow on the mountain of Ruden or Tydel, which ſeparates Jempteland in Sweden from the dioceſe of Drontheim. A company of 200 Norwegian ſledgemen under major Emahus, found them all frozen to death on the ridge of the mountain, where they had been ſurpriſed by a ſtorm accompained with ſnow, hail, and extreme cold. Some of theſe unhappy victims appeared ſitting, ſome lying, and others kneeling in a poſture of praying. They had cut in pieces their muſkets, and burned the little wood they afforded. The generals Labarre and Zoega loſt their lives; and of the whole corps, conſiſting originally of 10,000, no more than 2500 ſurvived this dreadful cataſtrophe.

The cold is ſtill more intenſe in that part of Norway called *Finmark*, ſituated in the frigid zone near the

Norway.

the polar circle. But if the winter is generally cold, the fummer is often exceffively hot, in Norway. The rays of the fun are reverberated from the fides of the mountains fo as to render the weather clofe and fultry in the valleys; befides the fun's abfence below the horizon is fo fhort, that the atmofphere and mountains have not time to cool. The heat is fo great, that vegetation is remarkably quick. Barley is fown, grows, ripens, and is reaped, in the fpace of fix weeks or two months.—The longeft day at Bergen confifts of 19 hours; the fun rifing at half an hour after two, and fetting at half an hour after nine. The fhorteft day does not exceed fix hours; for the fun rifes at nine in the morning, and fets at three in the afternoon. In the beginning of the year the daylight increafes with remarkable celerity; and, at the approach of winter, decreafes in the fame proportion. In fummer one may read and write at midnight by the light of the fky. Chriftian V. while he refided at Drontheim, ufed to fup at midnight without candles. In the diftrict of Tromfen, at the extremity of Norway, the fun is continually in view at midfummer. It is feen to circulate day and night round the north pole, contracting its orbit, and then gradually enlarging it, until at length it leaves the horizon. In the depth of winter, therefore, it is for fome weeks invifible; and all the light perceived at noon is a faint glimmering for about an hour and an half, proceeding from the reflection of the fun's rays from the higheft mountains. But the inhabitants of thefe provinces are fupplied with other lights that enable them to follow their employments in the open air. The fky being generally ferene, the moonfhine is remarkably bright, and, being reflected from the mountains, illuminates the valleys. They are alfo affifted by the Aurora Borealis, which is very frequent in the northern parts of Europe.

The air of Norway is generally pure and falubrious. On the fea-coafts, indeed, it is rendered moift by vapours and exhalations: but in the midland parts of the country, towards the mountains, the climite is fo dry, that meal may be kept for many years without being worm eaten or damaged in the leaft. The inhabitants have no idea of ficknefs except what is occafioned by exceffes. It is faid that in the vale of Guldbrand the inhabitants live to fuch extreme old age, that they become weary of life, and caufe themfelves to be removed to a lefs falubrious climate, whereby they may have a chance of dying the fooner. In confumptions, however, the moift air on the fea-fide is found to be moft agreeable to the lungs in refpiration. Norway, being a mountanious country interfected by creeks, abounding with lakes, rivers, and fnow, muft be fubject to frequent rains; and from fudden thaws the inhabitants are fometimes expofed to terrible diftafters. Vaft maffes of fnow falling from precipices, overwhelm men, cattle, boats, houfes, nay even whole villages. About two centuries ago, a whole parifh was covered and deftroyed by an immenfe mafs of fnow; and feveral domeftic utenfils, as fciffars, knives, and bafons, have been at different times brought to light by a rivulet that runs under the fnow, which has been gradually hardened and increafed by repeated frofts and annual acceffions.

The winds that chiefly prevail on the weftern coaft are thofe that blow from the fouth; whereas, on the other fide of Filefield, the winds that produce and continue the hard frofts are always northerly. In the fummer, there is a kind of regular trade-wind on the coaft of Bergen. In the forenoon the fea begins to be cooled with a wefterly breeze, which continues till midnight. Then the land breeze begins from the eaft, and blows till about ten in the morning. The coaft is likewife fubject to fudden fqualls and ftorms. Hurricanes fometimes rife at fea; and in thefe latitudes the phænomenon called a *water-fpout* is not uncommon. One of thefe in the neighbourhood of Ferro is faid to have fucked up with the water fome lafts of herrings, which were afterwards dropped on Kolter, a mountain 1200 feet high.

The frefh-water of Norway is not very light or pure; but on the contrary is generally turbid, and depofits a fediment of adventitious matter, being fometimes impregnated with oker, and particles of iron. Neverthelefs it is agreeable to the tafte, and remarkably falubrious; as appears from the good health of the common people, who drink little or no other liquor.

The foil of Norway varies in different places according to the fituation of rock or valley. The mountains here, as in every other country, are bare and barren; but the earth wafhed down from them by the rains, enriches and fertilizes the valleys. In thefe the foil generally confifts of black mould, fand, loam, chalk and gravel, lying over one another in unequal ftrata, and fometimes in three or four fucceffions: the mould that lies uppermoft is very fine and mellow, and fit to nourifh all forts of vegetables. There is alfo clay found in different parts of this kingdom, of which the inhabitants begin to make earthen ware; but bricks and tiles are not ufed in building. The face of the country is in many places deformed by large fwamps and marfhes, very dangerous to the traveller. Near Leeffoe in the diocefe of Chriftianfand, a wooden caufeway is extended near a mile over a morafs; and if a horfe or any other animal fhould make a falfe ftep, he will fink at once into the abyfs never to rife again.

In a cold country like Norway, roughened with rocks and mountains, interfperfed with bogs, and covered with forefts, we cannot expect to find agriculture in perfection. The ploughed lands, in refpect to mountains, woods, meadows, and waftes, do not exceed the proportion of 1 to 80; fo that the whole country does not produce corn to maintain above half the number of its inhabitaats. The peafants are difcouraged from the practice of hufbandry by the frequency of accidents that feem peculiar to the climate. Even in the fruitful provinces of Guldbrandfdale, Oefterdale, and Soloer, as well as in other places, when the corn appears in the moft flourifhing condition, the whole hope of the harveft is fometimes deftroyed in one night by a fudden froft that nips the blade and extinguifhes the vegetation. The kingdom is moreover vifited by fome unfavourable years, in which the fun feems to have loft his genial power; the vegetables are ftunted; the trees bud and bloom, yet bear no fruit; and the grain, though it rifes, will yet produce nothing but empty ears and ftraw. This calamity, however, rarely occurs; and in general the cultivated parts of Norway yield plentiful crops of excellent

cellent rye, barley, and oats. The moft fruitful provinces are Nordland, Inderbarre, and Numedale, in the diocefe of Drontheim; Sognifiord, and Vaas in that of Bergen; Jedderen, Ryefylfk, Raabygdelag, and the lordfhip of Nedenes, in the diocefe of Chriftianfand; Hedemark in the diocefe of Aggerhuis; Hadeland, Toten, Romerige, Ringerige, and Guldbrandfdale: thefe territories not only produce grain enough for their own confumption, but likewife fupport their neighbours, and even fupply part of Sweden. Peafe are likewife propagated in this country, together with wheat, buck-wheat, hops, hemp and flax, but not to any confiderable advantage. The meadows are well ftored with pafturage for fheep and cattle, and the fields are productive of thofe vegetables which are common in other northern countries. Within thefe 50 years the people of Norway have beftowed fome attention on the culture of gardens, which in former times was fo neglected, that the cities and towns were fupplied with leeks, cabbage, and roots, from England and Holland. At prefent, however, the Norwegians raife their own culinary and garden roots and vegetables, which thrive there as well as in any other country. The fcurvy being a difeafe that prevails along the fea-coaft, Nature has fcattered upon it a variety of herbs efficacious in the cure of that diftemper; fuch as angelica, rofe-wort, gentian, creffes, trefoil, forrel, fcurvy-grafs, and a plant called *erich's grafs*, that grows in great plenty on the iflands of Northland; from whence the people of the continent fetch away boat-loads of it, to be preferved in barrels as a fuccedaneum for cabbage. There are alfo a few noxious vegetables little known in any country but Norway. In Guldbrandfale is a fpecies of grafs called *felfnape*; the root of which is fo poifonous, that any beaft which eats of it dies immediately, the belly burfting; nay, the carnivorous fowls that prey upon the carcafe of the beaft meet with the fame fate: children have been more than once poifoned by this root which neverthelefs is fometimes ufed externally as an amulet for arthritic diforders. Another vegetable pernicious to the cattle is the *Gramen offifragum Norwegienfe*, which is faid to mollify the bones of the cattle which feed upon it. Among the noxious plants of Norway we may alfo reckon the igle-grafs, fatal to fheep and goats; the tour-grafs, which affects horfes and cows with a fort of lethargy; and the plant torboe, or hifte-fpring, which produces nearly the fame effect on horfes, but is not at all prejudicial to cows, fheep, or any ruminating animals. The herb turte, not unlike angelica, operates nearly in the fame manner: yet the bears are faid to feed upon it with peculiar relifh; and when their hair begins to fall off by feeding upon this plant, they cure themfelves by eating the flefh of animals.

The common fruit-trees thrive tolerably well in Norway, the inhabitants of which have plenty of cherries, apples, and pears. Some kinds of plums attain maturity; which is feldom the cafe with grapes, apricots, and peaches. But even the apples and pears that ripen here are fummer-fruit; that which grows till the winter feldom coming to perfection. Great variety of agreeable berries are produced in different parts of this kingdom; fuch as the hagebar, a kind floes; an infufion of which in wine makes a pleafant cooling liquor; juniper-berries, corinths red and white, foelbar or fun-berries, rafpberries, goofeberries, blackberries, ftrawberries, &c. with many other fpecies that feem to be natives of Norway and Sweden. Among thofe are the tranæbar, the produce of the myrtillus repens, red and auftere, found in the fpring in perfection under the fnow, and much relifhed by by the reindeer; crakebeer, refembling bilberries, deemed a powerful antifcorbutic; agerbeer, larger and blacker than bilberries, of a pleafant acid, ripened by cold, and ufed as cherries for an infufion in wine: and finally tylte-beer, a red pleafant berry growing on a fhort ftem, with leaves like thofe of box: they are plucked off by handfuls, and fent to Denmark to be preferved for the table, where they are eaten by way of defert.

Of the trees that grow wild in Norway, the principal are the fir and the pine. The firft yield an annual revenue of 1,000,000 of rix-dollars, if we include the advantages refulting from the faw-mills and the mafts; one of which laft has been known to fell for 200 rix-dollars. The red fir-tree, which grows on the mountains, is fo rich in turpentine as to be almoft incorruptible. Some of the houfes belonging to the Norway peafants, built of this timber, are fuppofed to be above 400 years ftanding. In Guldbrandfdale the houfe is ftill to be feen ftanding in which king Olaf lodged five nights, above 700 years ago, when he travelled round the kingdom to convert the people to the Chriftian faith. Even 100 years after the trunk of the fir-tree has been cut down, the peafants burn the roots for tar, which is a very profitable commodity. In the fens, the refin of the fir-tree is by nature transformed into a fubftance which may be called *Norway frankincenfe*. The buds or pine-apples of this tree, boiled in ftale beer, make an excellent medicine for the fcurvy; lefs unpleafant to the tafte, though as efficacious, as tar-water. The pine-tree is more tall and beautiful than the fir, though inferior to it in ftrength and quality; for which reafon the planks of it are fold at an inferior price, and the peafants wafte it without remorfe. Norway likewife produces fome forefts of oak, which is found to be excellent for fhip-building. Here alfo grow plenty of elm-trees; the bark of which, being powdered, is boiled up with other food to fatten hogs, and even mixed by the poor among their meal: alfo the afh, from which the peafants diftill a balfam ufed in certain diforders, and which is ufed both externally and internally. Many other trees flourifh in this country, an enumeration of which would prove too tedious. Hazles grow here in fuch abundance, that 100 tons of the nuts are annually exported from Bergen alone.

A great diverfity of ftones is found in Norway, fome of which are of a furprifing figure. Several mountains confift chiefly of a brown pebble, which decays with age; nay, it fometimes diffolves, and drops into the fea, and, the cement being thus loofened, a terrible difruption enfues. In fome places the grey and black pebbles are intermixed with iron, copper, lead, filver, and gold. The ground, in certain diftricts, is covered with the fragments of rocks that have been precipitated from the fummits of mountains, and broken by their fall into innumerable fhivers. Between 20 and 30 years ago, in the neighbourhood of Bergen, a man

man was fuddenly overwhelmed with fuch a mafs, which formed a kind of vault around him. In this dreadful tomb he remained alive for feveral weeks. By his loud cries the place of his confinement was difcovered; but it was found impoffible to remove the huge ftones by which he was inclofed. All that his friends could do for him was, to lower down meat and drink through fome crevices; but at length the ftones fell in, and crufhed him to death.

In Norway are inexhauftible quarries of excellent marble, black, white, blue, grey, and variegated; together with fome detached pieces of alabafter, feveral kinds of fpar, chalk-ftone, cement-ftone, fand-ftone, mill-ftone, baking-ftone, flate, talc, magnets; and fwine-ftone, a production natural to Norway and Sweden, of a brown colour, fetid fmell, in texture refembling cryftal, and deriving its name from a fuppofed efficacy in curing a diftemper incident to fwine. Here alfo is found the amianthus or ftone-flax, of which incombuftible cloth may be made. Norway, however, affords no flints, but plenty of pyrites or quartz, beautiful cryftals, granates, amethyfts, agate, thunder-ftones, and eagle-ftones. Gold has formerly been found in a fmall quantity in the diocefe of Chriftianfand, and coined into ducats. There is at prefent a very confiderable filver-mine wrought at Kongfberg on the account and rifk of his Danifh majefty: the ore is furprifingly rich, but interrupted in fuch a manner, that the vein is often loft. Many maffes of pure filver have been found; and, among the reft, one piece weighing 560 pounds, preferved in the royal mufeum at Copenhagen. Such is the richnefs of thefe mines, that the annual produce amounts in value to a tun and an half in gold. About 5000 people are daily employed, and earn their fubfiftence, in thofe ftupendous works. Other filver-mines are profecuted at Jarlfberg, but not to the fame advantage; and here the ore is mixed with lead and copper. In many parts of this country copper-mines have been difcovered; but the principal, and perhaps the richeft in all Europe, is at Roraas, about 100 Englifh miles from Drontheim. This work yields annually about 1100 fhip-pounds of pure copper: the founderies belonging to it confume yearly about 14,000 lafts of coal, and 500 fathoms of wood. The next in importance is the copper-work at Lykken, about 20 miles from Drontheim. A third mine is carried on at Indfet, or Quickne, at the diftance of 30 miles from the fame place; and here they precipitate the copper from its menftruum, by means of iron. There is a fourth copper-work at Silboe, about 30 miles diftant from Drontheim, though the leaft confiderable of the four. Other copper-mines of lefs note are worked in different parts of the kingdom. Iron is ftill in greater plenty, and was the firft metal wrought in this country. Many hundred thoufand quintals are annually exported, chiefly in bars, and part of it in ftoves, pots, kettles, and cannon: the national profit arifing from this metal is eftimated at 300,000 rix-dollars. There is a fpecies called *moor-iron*, found in large lumps among the moraffes: of this the peafants make their own domeftic tools and utenfils, fuch as knives, fcythes, and axes. The lead found mixed in the filver ore is an article of fmall importance in Norway; yet fome mines of this metal have been lately opened in the diftrict of Soloer, by the proprietors of the copper-work at Oudal. A vitriol work has been begun near Kongfberg: the mines yield great plenty of fulphur; which, however, the Norwegians will not take the trouble to melt and depurate, becaufe immenfe quantities are found at a cheaper rate in the ifland of Iceland. Alum is found between the flate-flakes near Chriftiana in fuch plenty, that works have been fet up for refining this mineral, though they have not yet brought it to any degree of tranfparency. His Danifh majefty has eftablifhed falt-works in the peninfula of Valoe, about fix Englifh miles from Tonfberg, where this mineral is extracted in large quantities from the fea-water.

Befides the animals common to other countries, Norway is faid to contain many of the uncommon and dubious kind; fuch as the kraken, mermaid, fea-ferpent, &c. See thefe articles.

Many Danifh, Englifh, Scotch, Dutch, and German families have fettled in Norway, and now form no inconfiderable part of the trading people: but the original inhabitants are the defcendants of thofe ferocious Normanni, who harraffed almoft all the coafts of Europe with piratical armaments in the 8th, 9th, and 10th centuries. They fpeak the fame language that is ufed in Denmark, though their original tongue is the dialect now fpoken in Iceland. They profefs the Lutheran religion, under an archbifhop eftablifhed at Drontheim, with four fuffragans; namely, of Bergen, Staffanger, Hammer, and Chriftiana. By the union of Calmar, the two kingdoms of Norway and Denmark were united under one monarch; and then the people of both nations enjoyed confiderable privileges: but the Danifh government is now become abfolute; and Norway is ruled defpotically by a viceroy, who refides in the capital, and prefides in the fupreme court, to which appeals are made from the fubordinate courts of judicature.

The Norwegians are generally well-formed, tall, fturdy, and robuft, brave, hardy, honeft, hofpitable, and ingenious: yet favage, rafh, quarrelfome, and litigious. The fame character will nearly fuit the inhabitants of every mountainous country in the northern climates. Their women are well-fhaped, tall, comely, remarkably fair and obliging. The nobility of Norway have been chiefly removed by the kings of Denmark, in order to prevent faction, and oppofition to the court; or are long ago degenerated into the rank of peafants: fome families, however, have been lately raifed to that dignity. Every freeholder in Norway enjoys the right of primogeniture, and power of redemption; and it is very ufual to fee a peafant inhabiting the fame houfe which has been poffeffed 400 years by his anceftors. The *odels-gads*, or freehold, cannot be alienated by fale or otherwife from the right heir, called *odels-mand:* if he is not able to redeem the eftate, he declares his incapacity every 10th year at the feffions; and if he, or his heirs, to the third generation, fhould acquire wealth enough for that purpofe, the poffeffor *pro tempore* muft refign his poffeffion.

The mountaineers acquire furprifing ftrength and dexterity by hard living, cold, laborious exercife, climbing rocks, fkating on the fnow, and handling arms, which they carry from their youth to defend themfelves againft the wild beafts of the forefts. Thofe who dwell

 dwell in the maritime parts of Norway exercife the employments of fifhing and navigation, and become very expert mariners.

The peafants of Norway never employ any handicraftfmen for neceffaries to themfelves and families: they are their own hatters, fhoe-makers, taylors, tanners, weavers, carpenters, fmiths, and joiners: they are even expert at fhip-building; and fome of them make excellent violins. But their general turn is for carving in wood, which they execute in a furprifing manner with a common knife of their own forging. They are taught in their youth to wreftle, ride, fwim, fkate, climb, fhoot, and forge iron. Their amufements confift in making verfes, blowing the horn, or playing upon a kind of guitarre, and the violin: this laft kind of mufic they perform even at funerals. The Norwegians have evinced their valour and fidelity in a thoufand different inftances. The country was always diftracted by inteftine quarrels, which raged from generation to generation. Even the farmers ftand upon their punctilio, and challenge one another to fingle combat with their knives. On fuch occafions they hook themfelves together by their belts, and fight until one of them is killed or mortally wounded. At weddings and public feafts they drink to intoxication, quarrel, fight, and murder generally enfues. The very common people are likewife paffionate, ambitious of glory and independence, and vain of their pedigree. The nobility and merchants of Norway fare fumptuoufly; but the peafant lives with the utmoft temperance and frugality, except at feftivals: his common bread is made of oat-meal, rolled into broad thin cakes, like thofe ufed in Scotland. In time of fcarcity, they boil, dry, and grind the bark of the fir-tree into a kind of flour which they mix with oat-meal: the bark of the elm-tree is ufed in the fame manner. In thofe parts where a fifhery is carried on, they knead the roes of cod with their oatmeal. Of thefe laft, mixed with barley-meal, they make hafty-pudding, and foup, enriched with a pickled herring or falted mackarel. Frefh fifh they have in plenty on the fea-coaft. They hunt and eat growfe, partridge, hare, red deer, and rein-deer. They kill cows, fheep, and goats, for their winter ftock: thefe they pickle, or fmoke, or dry for ufe. They make cheefe of their milk, and a liquor called *fyre* of their four whey: this they commonly drink mixed with water; but they provide a ftore of ftrong ale for Chriftmas, weddings, chriftenings, and other entertainments. From their temperance and exercife, joined to the purity and elafticity of their air, they enjoy good health, and often attain to a furprifing degree of longevity. Nothing is more common than to fee a hearty Norwegian turned of 100. In the year 1733, four couples danced before his Danifh majefty at Fredericks-hall: their ages, when joined, exceeded 800 years. Neverthelefs, the Norwegians are fubject to various difeafes; fuch as the fcab, the leprofy, the fcurvy, the catarrh, the rheumatifm, gout, and epilepfy. The drefs of the Norway peafants confifts of a wide loofe jacket made of coarfe cloath, with waiftcoat and breeches of the fame. Their heads are covered with flapped hats, or caps ornamented with ribbons. They wear fhoes without foles, and in the winter leathern bufkins. They have likewife fnow-fhoes and long fkates, with which they travel at a great pace, either on the land or ice. There is a corps of foldiers thus accoutred, who can out-march the fwifteft horfes. The Norwegian peafant never wears a neckcloth, except on extraordinary occafions: he opens his neck and breaft to the weather, and lets the fnow beat into his bofom. His body is girt round with a broad leathern belt, adorned with brafs plates, from which depends a brafs chain that fuftains a large knife, gimlet, and other tackle. The women are dreffed in clofe-laced jackets, having leathern girdles decorated with ornaments of filver. They likewife wear filver chains round their necks, to the ends of which are fixed gilt medals. Their caps and handkerchiefs are almoft covered with fmall plates of filver, brafs, and tin, large rings, and buttons. A maiden bride appears with her hair platted, and, together with her cloaths, hung full of fuch jingling trinkets.

The churches, public edifices, and many private houfes in Norway, are built of ftone: but the people in general live in wooden houfes, made of the trunks of fir and pine-tree laid upon each other, and joined by mortifes at the corners. Thefe are counted more dry, warm, and healthy, than ftone or brick buildings. In the whole diocefe of Bergen, one hardly fees a farm-houfe with a chimney or windows: they are generally lighted by a fquare hole in the top of the houfe, which lets in the light, and lets out the fmoke. In fummer this hole is left quite open: in the winter, it is covered with what they call a fiau; that is, the membrane of fome animal, ftretched upon a wooden frame that fits the hole, and tranfmits the rays of light. It is fixed or removed with a long pole, occafionally. Every perfon that enters the houfe, upon bufinefs or courtfhip, takes hold on this pole, according to ancient cuftom. The ceiling is about eight feet high in the middle; and, being arched like a cupola, the fmoke of the fire underneath rolls about, until it finds a vent at the hole, which is called *liur*. Under this opening ftands a thick table with benches, and an high feat at the upper end for the mafter of the family: he has likewife a fmall cupboard for his own ufe, in which he locks up his moft valuable effects. The boards of the roof are coated with the bark of birch-trees, which is counted incorruptible: this again is covered with turf, which yields a good crop of grafs for goats and fheep, and is often mowed as hay by the farmer.

The Norwegians carry on a confiderable trade with foreign nations. The duty on the produce of their own country exported, amounts annually to 100,000 rix-dollars. Thefe commodities are, copper wrought and unwrought; iron caft into cannon, ftoves, and pots, or forged into bars; lead, in fmall quantity; mafts, timber, deal-boards, planks, marble, millftones, herring, cod, ling, falmon, lobfters, flounders, cow-hides, goat-fkins, feal-fkins, the furs of bears, wolves, foxes, beavers, ermins, martens, &c. down, feathers, butter, tallow, train-oil, tar, juniper and other forts of berries, and nuts; falt, alum, glafs, vitriol, and pot-afhes. All other commodities and articles of luxury, the Norwegians import from different nations. The nature of the ground does not admit of much improvement in agriculture: neverthelefs, the farmers are not deficient in induftry, and fkill to to drain marshes, and render the ground arable and fit for pasture. Many are employed in grazing and breeding cattle: but a much greater number is engaged in felling wood, floating timber, burning charcoal, and extracting tar from the roots of the trees which have been cut down; in the silver, copper, and iron mines; in the navigation and fishery. A considerable number of people earn a comfortable livelihood by hunting, shooting, and bird-catching. Every individual is at liberty to pursue the game, especially in the mountains and commons: therefore every peasant is expert in the use of fire-arms; and there are excellent marksmen among the mountains, who make use of the bow to kill those animals whose skins, being valuable, would be damaged by the shot of fire arms.

Norway can produce above 14,000 excellent seamen. The army of this country amounts to 30,000 effective men; and the annual revenue exceeds 800,000 rixdollars.

Norway-*Rat*, in zoology. See Mus.

NORWICH, the capital of the county of Norfolk in England, situated in E. Long. 1. 26. N. Lat. 52. 40. It is supposed to have had its name, which signifies "a castle to the north," from its situation in respect of Castor, the ancient Venta Icenorum, three or four miles to the south of it, out of whose ruins it seems to have risen. In its infancy, in the reign of Etheldred, it was plundered and burnt by Sueno the Dane, when he invaded England with a great army. Afterwards it recovered; and in the reign of Edward the Confessor was a considerable place, having 1320 burghers. But it suffered again much in the reign of William I. by being the seat of a civil war, which Ralph, earl of the East Angles, raised against that king. So much was it impaired by the siege it then underwent, that there were scarce 560 burghers left in it, as appears from Doomsday-book. From that time forward it began by little and little to recover, especially after bishop Herbert translated the episcopal see hither from Thetford in the reign of William Rufus in 1096; and built a beautiful cathedral, of which he himself laid the first stone, with this inscription, *Dominus Herbertus posuit primum lapidem, in Nomine Patris, Filii, & Spiritus Sancti*, Amen, i. e. "Lord (bishop) Herbert laid the first stone, in the name of the Father, Son, and Holy Ghost;" and by a licence from pope Paschal, declared it the mother-church of Norfold and Suffolk. After this, as Malmsbury has it, it became a town famous for merchandize and the number of inhabitants. Yet it was miserably harrassed in the reign of Henry II. by Hugh Bigod, earl of Norfolk, who was an adherent of Henry's son, called the *junior king*. In the time of Edward I. it was walled round by the citizens, who had presented a petition to Parliament for liberty to do it. Henry IV. allowed them, instead of bailiffs, which they had before, to elect a mayor yearly, and made the city a county of itself. In the year 1348, near 58 persons were carried off by the plague; and in 1507, the city was almost consumed by fire. For the flourishing state to which the city is now arrived, they are much indebted to the Flemings, who fled hither from the tyranny of the duke of Alva and the inquisition, and taught them the manufacture of those striped and flowered damasks, camblets, druggets, black and white crape, for which the place is now so noted, and which have been computed to yield sometimes 160,000 l. a-year. In the year 1583, the citizens, by the help of an engine, conveyed water thro' pipes to the highest parts of the city, which is pleasantly seated along the side of a hill, extending a mile and a half in length from north to south; but the breadth is much less, and it contracts itself by degrees towards the south. It is now one of the most considerable cities in Britain for wealth, populousness, neat buildings, beautiful churches, of which it had once 50, but now about 30, and the industry and civility of the inhabitants. The cathedral is a very venerable structure, with a curious roof, adorned with the history of the Bible in little images, carved to the life, and a lofty steeple 105 yards high. The wall of flint stone, beautified with 40 towers and 12 gates, finished in 1309, is now much decayed. The city, though there is a great deal of waste ground within the walls, was computed, upwards of 40 years ago, to contain 8000 houses, and 50,000 inhabitants. Besides the cathedral already mentioned, the most remarkable buildings are, the duke of Norfolk's house, one of the largest in England; the castle, which is now the county-gaol, and stands in the heart of the city, with a deep moat round it, over which is a bridge of one very large arch; the Town-hall; the Guild-hall, formerly the church belonging to the monastery of Black-Friars; the house of correction; the shire-house, where the assizes are held; a lofty market-cross, built after the manner of a piazza; the bishop's palace; the king's school, founded by Edward VI. the boys to be nominated by the mayor for the time being, with the consent of the majority of aldermen. There having been formerly many thatched houses, an order was made, that all houses that should hereafter be built should be covered with tiles. The city is interspersed with gardens, orchards, and trees, which make it both pleasant and healthful. It has four hospitals, in which a great number of old men and women, boys and girls, are maintained; and a dozen charity-schools. Here are two churches for the Dutch and French Flemings; who have particular privileges, and are very numerous. Some of the churches are thatched, and all of them crusted with flint stone curiously cut; which is the more wonderful, as Norwich stands in a clay country, and has no flint within 20 miles of it. It is now governed by a mayor, recorder, steward, two sheriffs, 24 aldermen, 60 common-council, with a town-clerk, sword-bearer, and other inferior officers. The mayor is chosen on May-day by the freemen, and sworn in on the Tuesday before Midsummer-eve. The sheriffs are also chosen annually, on the first Tuesday in August, one by the freemen, the other by the aldermen, and sworn in on Michaelmas-day. The freemen of the several wards chuse each their alderman. The common-council is chosen in Midlent. The mayor is a justice of the peace and quorum, during his year (as are also the recorder and steward) within the city and liberties; and after his mayoralty, he is a justice during life. The trade and manufactures of the city are very considerable. At Yarmouth they export large quantities of their manufactures, most of which are sent to London, and import a great deal of wine, coal, fish, oil, &c.

&c. All the city and country round are employed in the worſted manufacture, brought hither, as already obſerved, by the Flemings, in which they not only conſume the wool of their own county, in ſpinning, weaving, &c. but uſe many thouſand packs of yarn, which they receive from other parts of England, as far as Yorkſhire and Weſtmoreland. There are eight wardens of the weavers choſen annually, and ſworn to take care that there be no frauds committed in ſpinning, weaving, or dying the ſtuffs. It is computed that there are not leſs than 120,000 people employed in and about the city in the ſilk and woollen manufactures. Their markets are thought to be the greateſt in England, and furniſhed with a ſurpriſing plenty and variety of goods and proviſions. At a ſmall village to the north of the city called *St Faith's*, not leſs than 40,000 head of Scotch cattle are ſaid to be yearly bought up by the Norfolk graziers, and fattened in their meadows and marſhes. Its markets are on Wedneſday, Friday, and Saturday. It has a great number of fairs, and gives the title of earl to the duke of Norfolk.

NOSE, in anatomy; ſee there, n° 20, &c. The uſes of the noſe are, its giving us the ſenſe of ſmelling *; its ſerving in the great office of reſpiration, and in modelling voice; in receiving the abundant humours from the eyes, and in adding to the beauty of the face.

* See *Anatomy*, n° 404.

In Tartary, the greateſt beauties are thoſe who have the leaſt noſes. Ruybrock mentions the wife of the great Jenghiz Khan as a celebrated beauty, becauſe ſhe had only two holes for a noſe. In moſt other countries, China excepted, great noſes are in honour.

The Crim-Tartars break the noſes of their children while young, as thinking it a great piece of folly to have their noſes ſtand before their eyes.

NOSOLOGY, in medicine. See p. 4631—4643.

NOSTOCH, the name of a vegetable ſubſtance which ſeems to differ from moſt of the other bodies of that kind in ſeveral particulars. It is a ſubſtance of an irregular figure, of a greeniſh brown colour, and ſomewhat tranſparent. It trembles at the touch, in the manner of a jelly; but it does not melt when held in the hand. It has therefore ſomewhat of the characters of a vegetable leaf, but it has neither veins nor fibres. It is found in all ſorts of ſoils; but moſt frequently in ſandy ones, ſometimes on the gravel of garden walks, and moſt uſually makes its appearance after rain. It is found only in the ſummer-months; and retains its humidity and perfect figure as long as it is a moiſt ſeaſon, but immediately dries up and withers away on the ſun or the wind's affecting it. Many people have ſuppoſed this not to be a plant. It appears all on a ſudden, and, as it were, by a ſort of miracle, either from the earth or clouds; and ſome have called it *flower of earth*, others *flower of heaven*: and the obſcurity of its origin occaſioned its being held in great eſteem among the chemiſts; ſome of whom ſuppoſed it to contain an univerſal ſpirit, capable of converting other metals into gold. Mr Magnol and Mr Tournefort were the firſt authors who aſſerted its true origin, and ranged it among the plants. Its nature, however, was never perfectly diſcovered till Mr Reaumur took it under conſideration. He found that it was a leaf which naturally imbibed water in a very particular manner; that when it had enough of this liquor in it, it then appeared in its natural flouriſhing ſtate; and when it loſt this again, it became thin, wrinkled, and was not to be known for the ſame ſubſtance, or, indeed, ſcarce to be ſeen at all. Hence appears the reaſon of its ſuppoſed production and ſudden decay. If it has, ever ſo long, lain in the walks of a garden in its empty wrinkled ſtate, it is never taken notice of; but, on a ſhower of rain, it ſwells out into its jelly-like ſtate, and on the ſun's evaporating that moiſture it falls into its undiſtinguiſhable ſtate again; and theſe changes may affect the ſame plant alternately for many days together.

Mr Geoffroy imagined that he had found roots to the noſtoch; but Mr Reaumur poſitively aſſerts that it has none. He obſerved indeed, at certain times, on the ſurface of certain ſpecimens of this, a vaſt number of round tubercles of different ſizes, which appeared to be the ſeeds of the plant. Theſe he regularly ſowed in earthen pots of mould; and theſe produced young plants like the parent noſtoch: But even theſe were never diſcovered to have any appearance of roots; and to try farther whether they had any, Mr Reaumur turned all the plants bottom upwards, and they received no harm from it, but grew juſt as vigorouſly as before. If the noſtoch has truly no roots, as appears to be very evidently the caſe, it follows, that it imbibes its nouriſhment in the manner of ſea-plants, which imbibe the water at all their pores. It ſhould ſeem, that there are two ſpecies of this noſtoch: the one a plain, flat, leaf; the other curled, wrinkled, and variouſly undulated: and it is on this laſt that the fruits which produce the young plants are principally found. It may be, however, that the one of theſe may be the male and the other the female of the ſame ſpecies, as in many large plants; or poſſibly the being in the ſtate of fructification alone may make the difference.

NOSTRADAMUS (Michael), an able phyſician and famous aſtrologer, born at St Remy, a ſmall town, four leagues from Arles, in 1503. He ſtudied at Montpelier, and afterwards travelled to Toulouſe and Bourdeaux. At his return into Provence, he publiſhed, in 1555, his *Seven firſt prophetical centuries*. Theſe were ſo highly valued by the French king, Henry II. that he reſolved to ſee the author; and having cauſed him to be brought to him, gave him 200 golden crowns, and ſent him to ſee the princes his ſons at Blois. Charles IX. in paſſing through Provence, alſo gave him public marks of his eſteem. Noſtradamus publiſhed his three laſt Centuries in 1556; and died at Salon in 1566. He wrote other works, and after his death was collected an 11th and 12th Century from his writings. The following diſtich, attributed to Stephen Jodelle, on Noſtradamus's character, is well known.

Noſtra damus, cum falſa damus, nam fallere noſtrum eſt:
Et cum falſa damus, nil niſi Noſtra damus.

NOSTRE (Andrew le), comptroller of the buildings of the French king, and deſigner of his gardens, diſtinguiſhed himſelf by carrying the art of laying out gardens to great perfection. He was born at Paris in 1631; and was near 40 years of age when M. Fouquet ſuperintendant of the finances gave him an an opportunity of becoming known by the fine gardens of Vaux-le-Vicomte. He was afterwards employed by Lewis XIV. at Verfailles, Triannon, St Germains, &c. and difcovered an admirable tafte in all his works. In 1678 he went to Rome, with the permiffion of the French king, to improve his fkill; but he found nothing there comparable to what he himfelf had done. Pope Innocent XI. refolved to fee Le Noftre, and gave him a pretty long audience; at the conclufion of which Le Noftre faid, "I have feen the two greateft men in the world; your holinefs, and the king my mafter." There is a great difference, anfwered the pope: "The king is a great victorious prince; and I am a poor prieft, the fervant of the fervants of God." Le Noftre, charmed with this anfwer, and forgetting who he was with, clapped the pope on the fhoulder, faying, "Reverend father, you look extremely well, and will live to bury all the facred college." The pope laughed at his prediction. Le Noftre, charmed more and more at the goodnefs of the fovereign pontiff, and the fingular efteem he fhewed for the king, threw his arms about the pope's neck and kiffed him. It was his cuftom to behave in the fame manner to all who fpoke in praife of Lewis XIV. and he even embraced the king himfelf whenever that prince returned from the country. Le Noftre had alfo a talent for painting. He preferved his good fenfe and vivacity of mind to the end of his life; and died at Paris in 1700, aged 87.

NOTARY, (NOTARIUS), fignifies a perfon, ufually fome fcrivener, who takes notes, or frames fhort draughts, of contracts, obligations, charter-parties, or other writings. At prefent we call him a *notary-public*, who publicly attefts deeds, or writings, in order to make them authentic in another nation: but he is principally employed in bufinefs concerning merchants; as making protefts of bills of exchange, &c. And noting a bill, is where he goes to take notice of a merchant's refufal to accept or pay the fame.

NOTATION, in arithmetic and algebra, the method of expreffing numbers or quantities by figns or characters appropriated for that purpofe. See ARITHMETIC and ALGEBRA.

NOTES, in mufic, characters which mark the founds, *i. e.* the elevations and fallings of the voice, and the fwiftnefs and flownefs of its motions.

NOTE is likewife ufed for a mark made in a book or writing, where there occurs fomething remarkable and worthy of particular notice: as alfo for an obfervation or explication of fome paffage in an author added in the margin, at the bottom of the page, or elfewhere; in which fenfe it ftands contradiftinguifhed to *text*.

NOTE, is alfo a minute, or fhort writing, containing fome article of bufinefs; in which fenfe we fay, promiffory note, note of hand, bank-note, &c.

NOTHUS, fignifies *fpurious*, or *baftard;* whence it is figuratively applied by phyficians to fuch difeafes as, though in a refpect of a fimilitude of fymptoms, &c. they have the fame denomination as fome others, yet are of a different origin, feat, or the like, from the fame.

NOTION, in logic, an idea or reprefentation of any thing in the mind. See LOGIC and METAPHYSICS.

NOTITIA, in literary hiftory, a book that gives an account of a particular country, city, or other place: fuch is the *Notitia Imperii Romani*, *Notitia Romæ Antiquæ*, &c.

NOTO, an ancient, large, and handfome town of Sicily, and capital of the Val-di-Noto. It was entirely ruined by an earthquake in 1693; but the inhabitants built another town at fome diftance from it, which they call *Noto Nuovo*. E. Long. 14. 0. N. Lat. 36. 50.

NOTO (*Val-di*), one of the three valleys or provinces into which Sicily is divided; and it lies between the fea, Val-di-Demona, and Val-di-Mazara. Noto is the capital town.

NOTONECTA, the BOAT-FLY; a genus of infects belonging to the order of hemiptera. It generally inhabits the water, and alway fwims on its back, and is very fwift in its motions. Its belly, which it fhews while in the water, is of a yellowifh white; its legs are long; when taken out of the water, it hops. It is indeed a very beautiful and very nimble little creature; and is common in the ponds of water in Hyde-park, and in feveral other places about London. It has four wings, fix legs, and no antennæ; it is eight inches long, three broad, and two and a half thick. The body is black, and of a very particular form, being flattifh at the belly, and rifing to a ridge on the middle of the back; fo that when it fwims, which is almoft always on the back, its body refmbles a boat in figure.

The belly is jointed, ftriated, and hairy; and has a large opening at the tail, out of which, when hurt, it thrufts forth fomething refembling a fting. The head and fhoulders are large, hard, and yellow, without any fpots; the eyes are large and red, and of a fomewhat triangular form. The nofe is a long, green, hollow probofcis, terminating in a hard and fharp brown point; this, in its natural pofture, is kept under the belly, and reaches to the middle pair of legs. The outer pair of wings are of a pale flefh-colour, with fpots of a dead white; thefe are long, narrow, and fomewhat tranfparent: they terminate in a roundifh point, and perfectly cover the whole body. The triangular piece which ftands between the top of the wings is hard, and perfectly black; the inner wings are broader and fhorter than the outer ones; they are thin and perfectly tranfparent, and are of a pale pearl colour. The legs are green and hairy; the foremoft pair are fhorteft; the middle ones longer than thefe; but the hinder pair are greatly longer than all the reft, fo that they ferve as oars, and are tufted with hair at the end to that purpofe. This creature moftly lives in the water, where it preys on fmall infects, killing them and fucking their juices with its probofcis, in the manner of the water-fcorpion and many other aquatic infects; and it feizes its prey violently, and darts with incredible fwiftnefs to a confiderable diftance after it.

Though it generally lives in the water, it fometimes, however, crawls out in good weather; and drying its wings by expanding them in the fun, takes flight, and becomes an inhabitant of the air, not to be known for the fame creature, unlefs to thofe who had accurately obferved it before; when tired of flying, or in danger of an enemy, it immediately plunges into the water. If taken into the hand, it ftings, and gives

Notteberg, Nottinghamshire.

gives an intolerable pain, but this goes off in a very few minutes. This is the ſpecies moſt frequently met with; but it is not the only *notonecta* we have, three or four other kinds, different in ſize and colour, being found not unfrequently in large waters.

NOTTEBURG, a town of Ruſſia, in the province of Ingria, ſeated on an iſland in the lake Ladoga, at the place where the river Nieva proceeds from this lake. It is ſtrong, has a good citadel, and was capital of the province before Peterſburg was built. E. Long. 31. 40. N. Lat. 60. 0.

NOTTINGHAMSHIRE, a county of England, bounded on the eaſt by Lincolnſhire, on the ſouth-eaſt and ſouth by Leiceſterſhire, on the weſt by Derbyſhire, and on the north and north-weſt by Yorkſhire. It extends in length 43 miles, 24 in breadth, and 110 miles in compaſs; containing 560,000 acres, 8 hundreds, 9 market-town, 168 pariſhes, 450 villages, about 17590 houſes, and 95000 inhabitants. No county in England enjoys a pleaſanter and healthier air. As for the ſoil, it differs widely in different parts of the county. Towards the weſt, where lies the foreſt of Sherwood, it is ſandy; and therefore that part of the county is called by the inhabitants, the *Sand:* but the ſouth and eaſt parts, watered by the Trent and the rivulets that fall into it, are clayey; and for that reaſon are called by the inhabitants, the *Clay*. The latter is fruitful both in corn and paſture; but the former produces little beſides wood, coal, and ſome lead. The county has a variety of commodities and manufactures, as wool, leather, tallow, butter, cheeſe, coal, marle, cattle, malt, liquorice, ſtockings, glaſs, earthen-wares, and ſtrong ale. The principal rivers are the Trent and Idle. The Trent, whoſe name is ſuppoſed to be derived from the French or Latin word ſignifying *thirty*, either becauſe it receives thirty ſmaller rivers, or has thirty different ſorts of fiſh in it, is inferior to no river in England, but the Severn, Thames, and Humber. It enters the county on the ſouth-weſt, and paſſes through it to the north-eaſt, where it enters Lincolnſhire, and after a long courſe falls at laſt into the Humber. The Idle riſes in Sherwood-foreſt; and after traverſing the northern part of the county, falls into the Trent upon the borders of Yorkſhire and Lincolnſhire.

The ſpacious foreſt of Sherwood lies in the weſt part of the county, and indeed takes up the greateſt part of it. It was formerly ſo thick, that it was hardly paſſable; but now it is much thinner. It feeds an infinite number of deer and ſtags; and has ſome towns in it, of which Mansfield is the chief. It abounds in coal, and a road lies through it for thirty miles together. Since the reign of king Edward I. the nobility and gentry have had grants of it. It is governed by a great number of officers under the earl of Cheſterfield, chief foreſter; whoſe anceſtor, Sir John Stanhope, had a grant of it, with liberty to deſtroy and kill at pleaſure, reſerving only an hundred deer in the whole walk. The principal town is

Nottingham, which gives name to the county. It is a handſome town, and a county of itſelf by charter. The name is derived from the Saxon word *Snottengham*, which ſignifies caves, from the caves and apartments anciently dug in the rocks on which the town ſtands. Theſe, being ſoft, eaſily yield to the ſpade and pick-axe; whence the townſmen have excellent cellars for the vaſt quantities of malt liquors made here, and ſent, as well as their malt, to moſt parts of England. The ſituation of the town is very pleaſant, having meadows on one hand, and hills of a gentle, eaſy aſcent, on the other. It is well ſupplied with fuel, both wood and coal, from the foreſt; and with fiſh by the Trent, which runs about a mile to the ſouth of it, and has been made navigable for barges: ſo that they receive by it not only great quantities of cheeſe from Warwickſhire and Staffordſhire; but all their heavy goods from the Humber, and even from Hull. It is of great antiquity; and had anciently a very ſtrong caſtle, where is now a fine ſeat belonging to the duke of Newcaſtle. It is noted for its horſe-races on a fine courſe on the north ſide of the town. The corporation is governed by a mayor, recorder, ſix aldermen, two coroners, two ſheriffs, two chamberlains, and twenty-four common-council men, eighteen of the ſenior-council, and ſix of the junior, a bell-bearer, and two pinders, one for the fields, and the other for the meadows. The town being within the juriſdiction of the foreſt, the former of theſe pindars is town-woodward, and attends the foreſt courts. It has three neat churches, the chief of which is St Mary's; and an alm-houſe, endowed with 100 l. a-year, for twelve poor people; with a noble town-houſe, ſurrounded with piazzas. A conſiderable trade is carried on in glaſs and earthen-wares, and frame-ſtockings, beſides the malt, and malt-liquors, mentioned above. Marſhal Tallard, when a priſoner in England, was confined to this town and county. In the duke of Newcaſtle's park there is a ledge of rocks hewn into a church, houſes, chambers, dove-houſes, &c. The altar of the church is natural rock, and between that and the caſtle there is an hermitage of the like workmanſhip. Upon the ſide of a hill there is a very extraordinary ſort of a houſe, where you enter at the garret, and aſcend to the cellar, which is at the top of the houſe. Here is a noted hoſpital founded by John Plumtree, Eſq; in the reign of Richard II. for thirteen poor old widows. There are four handſome bridges over the Trent and Lind. To keep theſe in repair, and other uſes, the corporation has good eſtates. This town and Winchelſea both give title of earl to the noble family of Finch. Here David, king of Scots, when a priſoner in England, reſided; and under-ground in a vault, called *Mortimer's hole*, becauſe Roger Mortimer, earl of March, is ſaid to have abſconded in it, when he was taken and hanged by order of Edward III.

NOVA-SCOTIA. See *Nova*-SCOTIA.

NOVA *Zembla*. See *Nova* ZEMBLA.

NOVALLE, a ſmall, rich, and populous town of Italy, between Padus and Treviſo. E. Long. 12. 5. N. Lat. 45. 35.

NOVARA, an ancient, well built, and ſtrong town of Italy, in the duchy of Milan, and capital of the Novareſe, with a biſhop's ſee; ſeated upon an eminence. E. Long. 8. 35. N. Lat. 45. 25.

NOVATIANS, a Chriſtian ſect which ſprung up in the third century, ſo called from Novatian a prieſt of Rome, or Novatus. See NOVATUS.

NOVATION, or INNOVATION, in the civil law, denotes the change of one kind of obligation for another;

Novatus ‖ Novelty.

ther; as when a promife is accepted inftead of a written obligation.

NOVATUS, a prieft of Carthage, in the third century, who, to avoid being punifhed for a crime, jonied with the deacon, named *Feliciffimus*, againft St Cyprian. He went to Rome in 251; and there found Novatian, a prieft who had acquired great reputation by his eloquence; but who murmured at his not being raifed to the fee of Rome in preference to pope Cornelius. Novatus contracted a friendfhip with him; and afterwards, it is faid, getting three ignorant bifhops, made them drunk, and then obliged them to ordain Novatian bifhop of Rome. This irregular ordination produced a very great fchifm; both Novatus and Novatian maintained, that the church had not the power to receive thofe to communion who were fallen into idolatry. There are attributed to Novatian, the treatife on the Trinity, and the book on Jewifh meats, which are among Tertullian's works; and it was he, and not Novatus, who gave his name to the fect called *Novatians*.

NOVEL, in matters of literature, a fictitious hiftory of a feries of entertaining events in common life, wherein the rules of probability are, or ought to be, ftrictly preferved.

Novel, in the civil law, a term ufed for the conftitutions of feveral emperors, more particularly thofe of Juftinian. They were called *novels*, either from their producing a great alteration in the face of the ancient law, or becaufe they were made on new cafes, and after the revifal of the ancient code.

NOVELTY, or Newness. Of all the circumftances that raife emotions, not excepting beauty, nor even greatnefs, fays Lord Kames †, novelty hath the moft powerful influence. A new object produceth inftantaneoufly an emotion termed *wonder*, which totally occupies the mind, and for a time excludes all other objects. Converfation among the vulgar never is more interefting than when it turns upon ftrange objects and extraordinary events. Men tear themfelves from their native country in fearch of things rare and new; and novelty converts into a pleafure, the fatigues and even perils of travelling. To what caufe fhall we afcribe thefe fingular appearances? To curiofity undoubtedly; a principle implanted in human nature for a purpofe extremely beneficial, that of acquiring knowledge; and the emotion of wonder raifed by new and ftrange objects, inflames our curiofity to know more of fuch objects. This emotion is different from *admiration:* novelty, wherever found, whether in a quality or action, is the caufe of wonder; admiration is directed to the perfon who performs any thing wonderful.

† *Elem. of Criticifm.*

During infancy, every new object is probably the occafion of wonder, in fome degree; becaufe, during infancy, every object at firft fight is ftrange as well as new: but as objects are rendered familiar by cuftom, we ceafe by degrees to wonder at new appearances, if they have any refemblance to what we are acquainted with; for a thing muft be fingular as well as new, to raife our wonder. To fave multiplying words, we would be underftood to comprehend both circumftances when we hereafter talk of novelty.

In an ordinary train of perceptions where one thing introduces another, not a fingle object makes its appearance unexpectedly †: the mind thus prepared for the reception of its objects, admits them one after another without perturbation. But when a thing breaks in unexpectedly, and without the preparation of any connection, it raifes an emotion, known by the name of *furprife*. That emotion may be produced by the moft familiar object, as when one unexpectedly meets a friend who was reported to be dead; or a man in high life, lately a beggar. On the other hand, a new object, however ftrange, will not produce the emotion, if the fpectator be prepared for the fight: an elephant in India will not furprife a traveller who goes to fee one; and yet its novelty will raife his wonder: an Indian in Britain would be much furprifed to ftumble upon an elephant feeding at large in the open fields; but the creature itfelf, to which he was accuftomed, would not raife his wonder.

† See the article Perceptions.

Surprife thus in feveral refpects differs from wonder: unexpectednefs is the caufe of the former emotion; novelty is the caufe of the latter. Nor differ they lefs in their nature and circumftances, as will be explained by and by. With relation to one circumftance they perfectly agree; which is, the fhortnefs of their duration: the inftantaneous production of thefe emotions in perfection, may contribute to that effect, in conformity to a general law, That things foon decay which foon come to perfection: the violence of the emotions may alfo contribute; for an ardent emotion, which is not fufceptible of increafe, cannot have a long courfe. But their fhort duration is occafioned chiefly by that of their caufes: we are foon reconciled to an object, however unexpected; and novelty foon degenerates into familiarity.

Whether thefe emotions be pleafant or painful, is not a clear point. It may appear ftrange, that our own feelings and their capital qualities, fhould afford any matter for a doubt: but when we are engroffed by any emotion, there is no place for fpeculation; and when fufficiently calm for fpeculation, it is not eafy to recal the emotion with accuracy. New objects are fometimes terrible, fometimes delightful: the terror which a tyger infpires is greateft at firft, and wears off gradually by familiarity: on the other hand, even women will acknowledge that it is novelty which pleafes the moft in a new fafhion. It would be rafh however to conclude, that wonder is itfelf neither pleafant nor painful, but that it affumes either quality according to circumftances. An object, it is true, that hath a threatening appearance, adds to our terror by its novelty: but from that experiment it doth not follow, that novelty is in itfelf difagreeable; for it is perfectly confiftent, that we be delighted with an object in one view, and terrified with it in another. A river in flood fwelling over its banks, is a grand and delightful object; and yet it may produce no fmall degree of fear when we attempt to crofs it: courage and magnanimity are agreeable; and yet, when we view thefe qualities in an enemy, they ferve to increafe our terror. In the fame manner, novelty may produce two effects clearly diftinguifhable from each other: it may, directly and in itfelf, be agreeable; and it may have an oppofite effect indirectly, which is, to infpire terror; for when a new object appears in any degree danger-

ous,

ous, our ignorance of its powers and faculties affords ample ſcope for the imagination to dreſs it in the moſt frightful colours. The firſt ſight of a lion, for example, may at the ſame inſtant produce two oppoſite feelings, the pleaſant emotion of wonder, and the painful paſſion of terror: the novelty of the object produces the former directly, and contributes to the latter indirectly. Thus when the ſubject is analiſed, we find, that the power which novelty hath indirectly to inflame terror, is perfectly conſiſtent with its being in every circumſtance agreeable. The matter may be put in the cleareſt light, by adding the following circumſtances. If a lion be firſt ſeen from a place of ſafety, the ſpectacle is altogether agreeable without the leaſt mixture of terror. If, again, the firſt ſight puts us within reach of that dangerous animal, our terror may be ſo great as quite to exclude any ſenſe of novelty. But this fact proves not that wonder is painful: it proves only, that wonder may be excluded by a more powerful paſſion. Every man may be made certain from his own experience, that wonder raiſed by a new object that is inoffenſive, is always pleaſant; and with reſpect to offenſive objects, it appears, from the foregoing deduction, that the ſame muſt hold as long as the ſpectator can attend to the novelty.

Whether ſurpriſe be in itſelf pleaſant and painful, is a queſtion not leſs intricate than the former. It is certain that ſurpriſe inflames our joy when unexpectedly we meet with an old friend; and not leſs our terror when we ſtumble upon any thing noxious. To clear that queſtion, the firſt thing to be remarked is, that in ſome inſtances an unexpected object overpowers the mind, ſo as to produce a momentary ſtupefaction: where the object is dangerous, or appears ſo, the ſudden alarm it gives, without preparation, is apt totally to unhinge the mind, and for a moment to ſuſpend all its faculties, even thought itſelf; in which ſtate a man is quite helpleſs; and if he move at all, is as like to run upon the danger as from it. Surpriſe carried to ſuch a height, cannot be either pleaſant or painful; becauſe the mind, during ſuch momentary ſtupefaction, is in a good meaſure, if not totally, inſenſible.

If we then inquire for the character of this emotion, it muſt be where the unexpected object or event produceth leſs violent effects. And while the mind remains ſenſible of pleaſure and pain, is it not natural to ſuppoſe, that ſurpriſe, like wonder, ſhould have an invariable character? It would appear, however, that ſurpriſe has no invariable character, but aſſumes that of the object which raiſes it. Wonder being an emotion invariably raiſed by novelty, and being diſtinguiſhable from all other emotions, ought naturally to poſſeſs one conſtant character. The unexpected appearance of an object, ſeems not equally intitled to produce an emotion diſtinguiſhable from the emotion, pleaſant or painful, that is produced by the object in its ordinary appearance: the effect it ought naturally to have, is only to ſwell that emotion, by making it more pleaſant or more painful than it commonly is. And that conjecture is confirmed by experience, as well as by language which is built upon experience: when a man meets a friend unexpectedly, he is ſaid to be agreeably ſurpriſed; and when he meets an enemy unexpectedly, he is ſaid to be diſagreeably ſurpriſed. It appears, then, that the ſole effect of ſurpriſe is to ſwell the emotion raiſed by the object. And that effect can be clearly explained: a tide of connected perceptions glide gently into the mind, and produce no perturbation; but an object breaking in unexpectedly, ſounds an alarm, rouſes the mind out of its calm ſtate, and directs its whole attention to the object, which, if agreeable, becomes doubly ſo. Several circumſtances concur to produce that effect: on the one hand, the agitation of the mind and its keen attention, prepare it in the moſt effectual manner for receiving a deep impreſſion: on the other hand, the object, by its ſudden and unforeſeen appearance, makes an impreſſion, not gradually as expected objects do, but as at one ſtroke with its whole force. The circumſtances are preciſely ſimilar where the object is in itſelf diſagreeable (A).

The pleaſure of novelty is eaſily diſtinguiſhed from that of variety: to produce the latter, a plurality of objects is neceſſary; the former ariſes from a circumſtance found in a ſingle object. Again, where objects, whether coexiſtent or in ſucceſſion, are ſufficiently diverſified, the pleaſure of variety is complete, though every ſingle object of the train be familiar; but the pleaſure of novelty, directly oppoſite to familiarity, requires no diverſification.

There are different degrees of novelty, and its effects are in proportion. The loweſt degree is found in objects ſurveyed a ſecond time after a long interval; and that in this caſe an object takes on ſome appear-

(A) What the Mareſchal Saxe terms *le cœur humain*, is no other than fear occaſioned by ſurpriſe. It is owing to that cauſe that an ambuſh is generally ſo deſtructive: intelligence of it beforehand renders it perfectly harmleſs. The Mareſchal gives from Cæſar's Commentaries two examples of what he calls *le cœur humain*. At the ſiege of Amiens by the Gauls, Cæſar came up with his army, which did not exceed 7000 men; and began to intrench himſelf in ſuch hurry, that the barbarians, judging him to be afraid, attacked his intrenchments with great ſpirit. During the time they were filling up the ditch, he iſſued out with his cohorts, and by attacking them unexpectedly ſtruck a panic that made them fly with precipitation, not a ſingle man offering to make a ſtand. At the ſiege of Aleſia, the Gauls infinitely ſuperior in number attacked the Roman lines of circumvallation, in order to raiſe the ſiege. Cæſar ordered a body of his men to march out ſilently, and to attack them on the one flank, while he with another body did the ſame on the other flank. The ſurpriſe of being attacked when they expected a defence only, put the Gauls into diſorder, and gave an eaſy victory to Cæſar.

A third may be added not leſs memorable. In the year 846, an obſtinate battle was fought between Xamire king of Leon, and Abdoulrahman the Mooriſh king of Spain. After a very long conflict, the night only prevented the Arabians from obtaining a complete victory. The king of Leon, taking advantage of the darkneſs, retreated to a neighbouring hill, leaving the Arabians maſters of the field of battle. Next morning, perceiving that he could not maintain his place for want of proviſions, nor be able to draw off his men in the face of a victorious army, he ranged his men in order of battle, and, without loſing a moment, marched to attack the enemy, reſolving to conquer or die. The Arabians, aſtoniſhed to be attacked by thoſe who were conquered the night before, loſt all heart: fear ſucceeded to aſtoniſhment, the panic was univerſal, and they all turned their backs without almoſt drawing a ſword.

ance of novelty, is certain from experience: a large building of many parts variously adorned, or an extensive field embellished with trees, lakes, temples, statues, and other ornaments, will appear new oftener than once: the memory of an object so complex is soon lost, of its parts at least, or of their arrangement. But experience teaches, that, even without any decay of remembrance, absence alone will give an air of novelty to a once familiar object; which is not surprising, because familiarity wears off gradually by absence: thus a person with whom we have been intimate, returning after a long interval, appears like a new acquaintance. And distance of place contributes to this appearance, not less than distance of time: a friend, for example, after a short absence in a remote country, has the same air of novelty as if he had returned after a longer interval from a place nearer home: the mind forms a connection between him and the remote country, and bestows upon him the singularity of the objects he has seen. For the same reason, when two things equally new and singular are presented, the spectator balances between them; but when told that one of them is the product of a distant quarter of the world, he no longer hesitates, but clings to it as the more singular: hence the preference given to foreign luxuries, and to foreign curiosities, which appear rare in proportion to their original distance.

The next degree of novelty, mounting upward, is found in objects of which we have some information at second hand; for description, though it contribute to familiarity, cannot altogether remove the appearance of novelty when the object itself is presented: the first sight of a lion occasions some wonder, after a thorough acquaintance with the correctest pictures and statues of that animal.

A new object that bears some distant resemblance to a known species, is an instance of a third degree of novelty: a strong resemblance among individuals of the same species, prevents almost entirely the effect of novelty, unless distance of place or some other circumstance concur; but where the resemblance is faint, some degree of wonder is felt, and the emotion rises in proportion to the faintness of the resemblance.

The highest degree of wonder ariseth from unknown objects that have no analogy to any species we are acquainted with. Shakespeare in a simile introduces that species of novelty:

> As glorious to the sight
> As is a winged messenger from heaven
> Unto the white up-turned wond'ring eye
> Of mortals, that fall back to gaze on him
> When he bestrides the lazy-pacing clouds
> And sails upon the bosom of the air.
>
> *Romeo and Juliet.*

One example of that species of novelty deserves peculiar attention; and that is, when an object altogether new is seen by one person only, and but once. These circumstances heighten remarkably the emotion: the singularity of the spectator concurs with the singularity of the object, to inflame wonder to its highest pitch.

In explaining the effects of novelty, the place a being occupies in the scale of existence, is a circumstance that must not be omitted. Novelty in the individuals of a low class is perceived with indifference, or with a very slight emotion: thus a pebble, however singular in its appearance, scarce moves our wonder. The emotion rises with the rank of the object; and, other circumstances being equal, is strongest in the highest order of existence; a strange insect affects us more than a strange vegetable; and a strange quadruped more than a strange insect.

However natural novelty may be, it is a matter of experience, that those who relish it the most are careful to conceal its influence. Love of novelty, it is true, prevails in children, in idlers, and in men of shallow understanding: and yet, after all, why should one be ashamed of indulging a natural propensity? A distinction will afford a satisfactory answer. No man is ashamed of curiosity when it is indulged to acquire knowledge. But to prefer any thing merely because it is new, shows a mean taste which one ought to be ashamed of: vanity is commonly at the bottom, which leads those who are deficient in taste to prefer things odd, rare, or singular, in order to distinguish themselves from others. And in fact, that appetite, as abovementioned, reigns chiefly among persons of a mean taste, who are ignorant of refined and elegant pleasures.

One final cause of wonder, hinted above, is, that this emotion is intended to stimulate our curiosity. Another, somewhat different, is, to prepare the mind for receiving deep impressions of new objects. An acquaintance with the various things that may affect us, and with their properties, is essential to our well-being: nor will a slight or superficial acquaintance be sufficient; they ought to be so deeply engraved on the mind, as to be ready for use upon every occasion. Now, in order to a deep impression, it is wisely contrived, that things should be introduced to our acquaintance with a certain pomp and solemnity productive of a vivid emotion. When the impression is once fairly made, the emotion of novelty being no longer necessary, vanisheth almost instantaneously; never to return, unless where the impression happens to be obliterated by length of time or other means, in which case the second introduction hath nearly the same solemnity with the first.

Designing wisdom is no where more eligible than in this part of the human frame. If new objects did not affect us in a very peculiar manner, their impressions would be so slight as scarce to be of any use in life: on the other hand, did objects continue to affect us as deeply as at first, the mind would be totally engrossed with them, and have no room left either for action or reflection.

The final cause of surprise is still more evident than of novelty. Self-love makes us vigilantly attentive to self-preservation; but self-love, which operates by means of reason and reflection, and impels not the mind to any particular object or from it, is a principle too cool for a sudden emergency; an object breaking in unexpectedly, affords no time for deliberation; and in that case, the agitation of surprise comes in seasonably to rouse self-love into action: surprise gives the alarm; and if there be any appearance of danger, our whole force is instantly summoned to shun or to prevent it.

NOVELLARA, a handsome town of Italy, and capital of a small district of the same name, with a handsome castle, where their sovereign resides. E. Lon. 10.

Novemviri 10. 37. N. Lat. 45. 50.

Novemviri || Noviodunum.

NOVEMVIRI, nine magistrates of Athens, whose government lasted but for one year. The first of whom was called *archon*, or prince; the second *basilius*, or king; the third *polemarchus*, or general of the army: the other six were called *thesmothetæ*, or lawgivers. They took an oath to observe the laws; and in case of failure, obliged themselves to bestow upon the commonwealth a statue of gold as big as themselves. Those who discharged their office with honour, were received into the number of the senators of Areopagus.

NOVI, a town of Italy, in the territory of Genoa, on the confines of the Milanese. It was taken by the Piedmontese in 1746. E. Long. 8. 48. N. Lat. 44. 45.

Novi-*Bazar*, a considerable town of Turkey in Europe, and in Servia, near the river Oresco. E. Long. 20. 24. N. Lat. 43. 25.

NOVIGRAD, a small but strong town of Upper Hungary, capital of a county of the same name, with a good castle, seated on a mountain near the Danube. E. Long. 18. 10. N. Lat. 47. 50.

Novigrad, a small but strong town of Dalmatia, with a castle, and subject to the Turks; seated on a lake of the same name, near the gulph of Venice. E. Long. 16. 45. N. Lat. 44. 30.

Novigrad, a very strong place of Servia, subject to the Turks; seated near the Danube. E. Long. 26. 5. N. Lat. 45. 5.

NOVICE, a person not yet skilled or experienced in an art or profession.

In the ancient Roman militia, *novicii*, or *novitii*, were the young raw soldiers, distinguished by this appellation from the veterans.

In the ancient orders of knighthood, there were novices, or clerks in arms, who went through a kind of apprenticeship ere they were admitted knights. See Knight.

Novice is more particularly used in monasteries for a religious yet in his, or her, year of probation, and who has not made the vows.

In some convents, the sub-prior has the direction of the novices. In nunneries, the novices wear a white veil; the rest a black one.

NOVICIATE, a year of probation appointed for the trial of religious, whether or no they have a vocation, and the necessary qualities for living up to the rule; the observation whereof they are to bind themselves to by vow. The noviciate lasts a year at least; in some houses more. It is esteemed the bed of the civil death of a novice, who expires to the world by profession.

NOVIODUNUM (Cæsar), a town of the Ædui, commodiously seated on the Liguris: the *Nivernum* of Antonine. Now *Nevers* in the Orleanois, on the Loire.—A second *Noviodunum* of the Aulerci Diablintes, in Gallia Celtica, (Antonine); called *Noviodunum*, (Ptolemy), and *Noningentum Rotrudum* by the moderns: *Nogente le Rotrou*, capital of the duchy of Perche.—A third, of the Bituriges, (Cæsar): Now *Nueve sur Baranion;* a village 15 miles to the north of Bourges, towards Orleans.—A fourth, of Mœsia Inferior, (Ptolemy), situate on the Ister: now *Nivorz*, in Bessarabia.—A fifth, of Pannonia Superior, (Antonine); now *Gurkfeld* in Carinthia.—A sixth *Noviodunum Suessionum*, the same with *Augusta Suessionum*. —A seventh, *Noviodunum* of the Veromandui in Gallia Belgica, (Cæsar): now *Noyon* in the Isle of France, on the borders of Picardy.

Novogorod || Nubecula.

NOVOGOROD welicki, or *Great Novogorod*, a rich and very large town of the Russian empire, and capital of a duchy of the same name, with an archbishop's see, and a castle where the archbishop and the waiwode reside. It is commonly called the *grand magazine*, because hither they bring their rich merchandises that come from the Levant. It contains 180 churches and monasteries, and carries on a great trade in Russia leather. It is seated on the river Wolcoff, near the lake Honen. E. Long. 33. 40. N. Lat. 58. 23.

Novogorod *Welicki*, a province of Moscow, bounded on the north by Ingria; on the east by part of the duchy of Belozero, and that of Tuera, which also bounds it on the south, with the province of Rzeva; and on the west by Plescow. It is full of lakes and forests; however, there are some places which produce corn, flax, hemp, honey, and wax.

Novogorod *Serpskoi*, a strong town of the Russian empire, and capital of a province of Siberia of the same name, seated on the river Dubica, in E. Long. 33. 20. N. Lat 52. 30.

NOVOGORODECK, a town of Lithuania, and capital of a palatinate of the same name. It is a large town, and situated in a vast plain, in E. Long. 25. 30. N. Lat. 53. 45.

NOURISHMENT. See Nutrition.

Nourishment *of Vegetables*. See Agriculture, Part I. Sect. 1. and 2. and Plants; also the article Composts.

NOWED, in heraldry, signifies "knotted," from the Latin *nodatus;* being applied to the tails of such creatures as are very long, and sometimes represented in coat-armour as tied up in a knot.

NUAYHAS, the Ague-tree; a name given by the Indians to a sort of Bamboo-cane, the leaves of which falling into the water, are said to impregnate it with such virtue, that the bathing in it afterwards will cure the ague. They use also a decoction of the leaves to dissolve coagulated blood, giving it internally, and at the same time rubbing the bruised part externally with it. It is said that this plant bears its flowers only once in its life; that it lives 60 years before these make their appearance; but that when they begin to shew themselves, it withers away in about a month afterwards; that is, as soon as it has ripened the seed. There seems to be something of fiction in the account of many other particulars relating to this tree in the *Hortus Malabaricus;* but it seems certain, that the length of the stalks, or trunk, must be very great: for, in the gallery of Leyden, there is preserved a cane of it 28 feet long; and another not much shorter in the Ashmolean museum at Oxford, and which is more than eight inches in diameter: yet both these appear to be only parts of the whole trunk, they being nearly as large at one end as at the other.

NUBECULA, little cloud, in medicine, a term sometimes used for disease in the eye, wherein objects appear as through a cloud or mist.

The

The nubecula feems to arife from certain grofs particles detained in the pores of the cornea, or fwimming in the aqueous humour, and thus intercepting the rays of light.

NUBECULA, or *Nubes*, is alfo ufed for what we otherwife call *albugo*. See ALBUGO.

NUBECULA is alfo ufed for a matter in form of a cloud, fufpended in the middle of the urine.

NUBIA, a country of Africa, bounded on the north by Egypt, on the fouth by Abyffinia, on the eaft by the coaft of Abefh or Abex, and on the weft by Zaara and Nigritia. It is faid to be 400 leagues in length, and 200 in breadth, and to be watered by a river which falls into the Nile; but of thefe dimenfions we have little certainty, and nothing can be depended upon concerning the nature of the country or its inhabitants.

NUCLEUS, in general, denotes the kernel of a nut, or even any feed inclofed within a hufk. The term *nucleus* is alfo ufed for the body of a comet, otherwife called its *head*.

NUDITIES, in painting and fculpture, thofe parts of an human figure which are not covered with any drapery; or thofe parts where the carnation appears.

NULLITY, in law, fignifies any thing that is null or void: thus there is a nullity of marriage, where perfons marry within the degrees, or where infants marry without confent of their parents or guardians.

NUMANTIA, a very noble city, the ornament of the Hither Spain, (Florus); as appears from the Numantine war: and though deftroyed by the Romans under Scipio Æmilianus, it was afterwards no doubt reftored, becaufe mentioned not only by Ptolemy, but alfo by Antonine, who determines its fituation between Uxama and Turiafo; and Strabo fays, the Durius run by it, while ftill recent and near its fource. With 4000 men it held out a fiege of 14 years, againft 40,000 Romans. And all this it did, like another Sparta, without walls and without turrets; but this is doubtfully mentioned by authors.—*Numantini*, the people; who, after a tedious and clofe fiege, and after ftruggling long with famine, at length deftroyed themfelves and their city by fire.

NUMBER, an affemblage of feveral units, or things of the fame kind. See ARITHMETIC; and METAPHYSICS, n° 62—65.

Number, fays Malcolm, is either abftract or applicate: Abftract, when referred to things in general, without attending to their particular properties; and applicate, when confidered as the number of a particular fort of things, as yards, trees, or the like.

When particular things are mentioned, there is always fomething more confidered than barely their numbers; fo that what is true of numbers in the abftract, or when nothing but the number of things is confidered, will not be true when the queftion is limited to particular things: for inftance, the number two is lefs than three; yet two yards is a greater quantity than three inches: and the reafon is, becaufe regard muft be had to their different natures as well as number, whenever things of a different fpecies are confidered; for though we can compare the number of fuch things abftractedly, yet we cannot compare them in any applicate fenfe. And this difference is neceffary to be confidered, becaufe upon it the true fenfe, and the poffibility or impoffibility, of fome queftions depend.

Number is unlimited in refpect of increafe; becaufe we can never conceive a number fo great, but ftill there is a greater. However, in refpect of decreafe, it is limited; unity being the firft and leaft number, below which therefore it cannot defcend.

Kinds and Diftinctions of NUMBERS. Mathematicians, confidering number under a great many relations, have eftablifhed the following diftinctions.

Broken numbers are the fame with fractions.

Cardinal numbers are thofe which exprefs the quantity of units, as 1, 2, 3, 4, &c. whereas ordinal numbers are thofe which exprefs order, as 1ft, 2d, 3d, &c.

Compound number, one divifible by fome other number befides unity; as 12, which is divifible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have fome common meafure befides unity, are faid to be compound numbers among themfelves.

Cubic number is the product of a fquare number by its root: fuch is 27, as being the product of the fquare number 9, by its root 3. All cubic numbers, whofe root is lefs than 6, being divided by 6, the remainder is the root itfelf: thus $27 \div 6$ leaves the remainder 3, its root; 215, the cube of 6, being divided by 6, leaves no remainder; 343, the cube of 7, leaves a remainder 1, which, added to 6, is the cube root; and 512, the cube of 8, divided by 6, leaves a remainder 2, which, added to 6, is the cube root. Hence the remainders of the divifions of the cubes above 216, divided by 6, being added to 6, always gives the root of the cube fo divided, till that remainder be 5, and confequently 11, the cube-root of the number divided. But the cubic numbers above this, being divided by 6, there remains nothing, the cube root being 12. Thus the remainders of the higher cubes are to be added to 12, and not to 6; till you come to 18, when the remainder of the divifion muft be added to 18; and fo on *ad infinitum*.

Determinate number is that referred to fome given unit, as a ternary or three: whereas an indeterminate one is that referred to unity in general, and is called *quantity*.

Homogeneal numbers, are thofe referred to the fame unit; as thofe referred to different units are termed *heterogeneal*.

Whole numbers are others called *integers*.

Rational number, is one commenfurable with unity; as a number, incommenfurable with unity, is termed *irrational*, or a *furd*.

In the fame manner, a rational whole number is that whereof unity is an aliquot part; a rational broken number, that equal to fome aliquot part of unity; and a rational mixed number, that confifting of a whole number and a broken one.

Even number, that which may be divided into two equal parts without any fraction, as 6, 12, &c. The fum, difference, and product, of any number of even numbers, is always an even number.

An evenly even number, is that which may be meafured, or divided, without any remainder, by another even number, as 4 by 2.

An unevenly even number, when a number may be equally divided by an uneven number, as 20 by 5.

Uneven number, that which exceeds an even number, at leaft by unity, or which cannot be divided into two

two equal parts, as 3, 5, *&c.*

The fum or difference of two uneven numbers makes an even number; but the factum of two uneven ones makes an uneven number.

If an even number be added to an uneven one, or if the one be fubtracted from the other, in the former cafe the fum, in the latter the difference, is an uneven number; but the factum of an even and uneven number is even.

The fum of any even number of uneven numbers is an even number; and the fum of any uneven number of uneven numbers is an uneven number.

Primitive or prime numbers, are thofe divifible only by unity, as 5, 7, *&c.* And prime numbers among themfelves, are thofe which have no common meafure befides unity, as 12 and 19.

Perfect number, that whofe aliquot parts added together make the whole number, as 6, 28; the aliquot parts of 6 being 3, 2, and $1=6$; and thofe of 28, being 14, 7, 4, 2, $1,=28$.

Imperfect numbers, thofe whofe aliquot parts added together make either more or lefs than the whole. And thefe are diftinguifhed into abundant and defective: an inftance in the former cafe is 12, whofe aliquot parts 6, 4, 3, 2, 1, make 16; and in the latter cafe 16, whofe aliquot parts 8, 4, 2, and 1, make but 15.

Plain number, that arifing from the multiplication of two numbers, as 6, which is the product of 3 by 2; and thefe numbers are called the *fides of the plane.*

Square number is the product of any number multiplied by itfelf; thus 4, which is the factum of 2 by 2, is a fquare number.

Even fquare number added to its root makes an even number.

Polygonal or polygonous numbers, the fums of arithmetical progreffions beginning with unity: thefe, where the common difference is 1, are called *triangular numbers;* where 2, *fquare numbers;* where 3, *pentagonal numbers;* where 4, *hexagonal numbers;* where 5, *heptagonal numbers,* &c.

Pyramidal numbers, the fums of polygonous numbers, collected after the fame manner as the polygons themfelves, and not gathered out of arithmetical progreffions, are called *firft pyramidal numbers:* the fums of the firft pyramidals are called *fecond pyramidals,* &c.

If they arife out of triangular numbers, they are called *triangular pyramidal numbers;* if out of pentagons, *firft pentagonal pyramidals.*

From the manner of fumming up polygonal numbers, it is eafy to conceive how the prime pyramidal numbers are found, *viz.* $\frac{(a-2)n^3+3n^3-(a-5)n}{6}$ expreffes all the prime pyramidals.

The following curious property of the number 9 deferves to be remarked, That its products compofe always either 9 or fome leffer product of 9; if you add together all the characters, of which any of the former products is compofed. Thus, of 18, 27, 36, which are products of 9, you make 9 by adding 1 to 8, 2 to 7, 3 to 6. Thus 369 is a product alfo of 9; and if you add 3, 6, and 9, you make 18, a leffer product of 9.

Golden NUMBER, See ASTRONOMY, n° 304—307.

NUMBERS, in poetry, oratory, &c. are certain meafures, proportions, or cadences, which render a verfe, period, or fong, agreeable to the ear,

Poetical numbers confift in a certain harmony in the order, quantities, &c. of the feet and fyllables, which make the piece mufical to the ear, and fit for finging, for which all the verfes of the ancients were intended. See POETRY.—It is of thefe numbers Virgil fpeaks in his ninth Eclogne, when he makes Lycidas fay, *Numeros memini, fi verba tenerem;* meaning, that although he had forgot the words of the verfes, yet he remembered the feet and meafure of which they were compofed.

Rhetorical or profaic numbers are a fort of fimple unaffected harmony, lefs glaring than that of verfe, but fuch as is perceived and affects the mind with pleafure.

The numbers are that by which the ftyle is faid to be eafy, free, round, flowing, &c. Numbers are things abfolutely neceffary in all writing, and even in all fpeech. Hence Ariftotle, Tully, Quintilian, &c. lay down abundance of rules as to the beft manner of intermixing dactyles, fpondees, anapefts, &c. in order to have the numbers perfect. The fubftance of what they have faid, is reducible to what follows. 1. The ftyle becomes numerous by the alternate difpofition and temperature of long and fhort fyllables, fo as that the multitude of fhort ones neither render it too hafty, nor that of long ones too flow and languid: fometimes, indeed, long and fhort fyllables are thrown together defignedly without any fuch mixture, to paint the flownefs or celerity of any thing by that of the numbers; as in thefe verfes of Virgil:

Illi inter fefe magna vi brachia tollunt;

and

Radit iter liquidum, celeres neque commovet alas.

2. The ftyle becomes numerous, by the intermixing words of one, two, or more fyllables; whereas the too frequent repetition of monofyllables renders the ftyle pitiful and grating, 3. It contributes greatly to the numeroufnefs of a period, to have it clofed by magnificent and well-founding words. 4. The numbers depend not only on the noblenefs of the words in the clofe, but of thofe in the whole tenor of the period. 4. To have the period flow eafily and equally; the harfh concurrence of letters and words is to be ftudioufly avoided, particularly the frequent meeting of rough confonants; the beginning the firft fyllable of a word with the laft of the preceding; the frequent repetition of the fame letter or fyllable; and the frequent ufe of the like ending words. Laftly, the utmoft care is to be taken left, in aiming at oratorial numbers, you fhould fall into poetical ones; and inftead of profe, write verfe.

Book of NUMBERS, the fourth book of the Pentateuch, taking its denomination from its numbering the families of Ifrael.

A great part of this book is hiftorical, relating to feveral remarkable paffages in the Ifraelites march through the wildernefs. It contains a diftinct relation of their feveral movements from one place to another, or their 42 ftages through the wildernefs, and many other things, whereby we are inftructed and confirmed.

ed in ſome of the weightieſt truths that have immediate reference to God and his providence in the world. But the greateſt part of this book is ſpent in enumerating thoſe laws and ordinances, whether civil or ceremonial, which were given by God, but not mentioned before in the preceding books.

NUMERAL LETTERS, thoſe letters of the alphabet which are generally uſed for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thouſand, &c.

It is not agreed how the Roman numerals originally received their value. It has been ſuppoſed that the Romans uſed M to denote 1000, becauſe it is the firſt letter of *mille*, which is Latin for 1000; and C to denote 100, becauſe it is the firſt letter of *centum*, which is Latin for 100. It has alſo been ſuppoſed, that D being formed by dividing the old M in the middle, was therefore appointed to ſtand for 500, that is, half as much as the M ſtood for when it was whole; and that L being half a C, was, for the ſame reaſon, uſed to denominate 50. But what reaſon is there to ſuppoſe, that 1000 and 100 were the numbers which letters were firſt uſed to expreſs? And what reaſon can be aſſigned why D, the firſt letter in the Latin word *decem*, ten, ſhould not rather have been choſen to ſtand for that number, than for 500 becauſe it had a rude reſemblance to half an M? But if theſe queſtions could be ſatisfactorily anſwered, there are other numeral letters which have never yet been accounted for at all. Theſe conſiderations render it probable, that the Romans did not, in their original intention, uſe letters to expreſs numbers at all; the moſt natural account of the matter ſeems to be this:

The Romans probably put down a ſingle ſtroke, I, for one, as is ſtill the practice of thoſe who ſcore on a ſlate or with chalk: this ſtroke, I, they doubled, trebled, and quadrupled, to expreſs 2, 3, and 4: thus, II. III. IIII. So far they could eaſily number the minums, or ſtrokes, with a glance of the eye. But they preſently found, that if more were added, it would ſoon be neceſſary to tell the ſtrokes one by one: for this reaſon, when they came to 5, they expreſſed it by joining two ſtrokes together in an acute angle thus, V; which will appear the more probable, if it be conſidered, that the progreſſion of the Roman numbers is from 5 to 5, *i. e.* from the fingers on one hand to the fingers on the other.—Ovid has touched upon the original of this in his *Faſtorum* lib. iii. and *Vitruv.* lib. c. 1. has made the ſame remark.

After they had made this acute angle V. for five, they added the ſingle ſtrokes to it to the number of 4, thus, VI. VII. VIII. VIIII. and then as the minums could not be further multiplied without confuſion, they doubled their acute angle, by prolonging the two lines beyond their interſection thus, X. to denote two fives, or ten. After this they doubled, trebled, and quadrupled, this double acute angle thus, XX. XXX. XXXX. they then, for the ſame reaſon which induced them firſt to make a ſingle and then to double it, joined two ſingle ſtrokes in another form, and inſtead of an acute angle, made a right angle L, to denote fifty. When this 50 was doubled, they then doubled the right angle thus ⊏, to denote 100, and having numbered this double right angle four times, thus ⊏⊏. ⊏⊏⊏. ⊏⊏⊏⊏; when they came to the fifth number, as before, they reverted it, and put a ſingle ſtroke before it thus I⊐, to denote 500; and when this 500 was doubled, then they alſo doubled their double right angle, ſetting two double right angles oppoſite to each other, with a ſingle ſtroke between them, thus ⊏I⊐ to denote 1000: when this note for 1000 had been four times repeated, then they put down I⊐⊐ for 5,000, ⊏⊏I⊐⊐ for 10,000, and I⊐⊐⊐ for 50,000, ⊏⊏⊏I⊐⊐⊐ for 100,000, I⊐⊐⊐⊐ for 500,000, and ⊏⊏⊏⊏I⊐⊐⊐⊐ for one million.

That the Romans did not originally write M for 1000, and C for 100, but ſquare characters, as they are written above, we are expreſsly informed by Paulus Manutius; but the corners of the angles being cut off by the tranſcribers for diſpatch, theſe figures were gradually brought into what are now numeral letters. When the corners of ⊏I⊐, were made round, it ſtood thus CIↃ, which is ſo near the Gothic *m*, that it ſoon deviated into that letter; ſo I⊐ having the corner made round, it ſtood thus IↃ, and then eaſily deviated into D. ⊏ alſo became a plain C by the ſame means; the ſingle rectangle which denoted 50, was, without alteration, a capital L; the double acute angle was an X; the ſingle acute angle a V conſonant; and a plain ſingle ſtroke, the letter I; and thus theſe ſeven letters, M, D, C, L, X, V, I, became numerals.

NUMERATION, or NOTATION, in arithmetic, the art of expreſſing in characters any number propoſed in words, or of expreſſing in words any number propoſed in characters. See ARITHMETIC, p. 653.

NUMERICAL, NUMEROUS, or *Numeral*, ſomething belonging to numbers; as numerical algebra is that which makes uſe of numbers, inſtead of letters of the alphabet.—Alſo numerical difference is that by which one man is diſtinguiſhed from another. Hence a thing is ſaid to be numerically the ſame, when it is ſo in the ſtricteſt ſenſe of the word.

NUMIDA, in ornithology, a genus belonging to the order of gallinæ. On each ſide of the head there is a kind of coloured fleſhy horn; and the beak is furniſhed with cere near the noſtrils. There is but one ſpecies, the meleagris, or Guinea-hen; a native of Africa. It is of the ſize of the common hen, but with a longer neck. Its body is ſloped like that of a partridge, and its colour is all over a dark grey, very beautifully ſpotted with ſmall white ſpecks; there is a black ring round the neck; its head is reddiſh, and it is blue under the eyes. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. Barbot informs us, that in Guinea they are in flocks of 200 or 300, that perch in trees, and feed on worms and graſhoppers; that they are run down and taken by dogs; and that their fleſh is tender and ſweet, generally white, though ſometimes black. They breed very well with us.

NUMIDIA, an ancient kingdom of Africa, bounded on the north by the Mediterranean Sea; on the ſouth by Gætulia, or part of Libya Interior; on the weſt by the Mulucha, a river which ſeparated it from Mauritania; and on the eaſt by the Tuſca, another river which bounded it in common with Africa Propria. Dr Shaw has rendered it probable, that the river which formerly went under the denominations of

Malva,

Numidia. *Malva*, *Malvana*, *Mulucha*, and *Molochath*, is the same with that now called MULLOOIAH by the Algerines; in which case, the kingdom of Numidia must have extended upwards of 500 miles in length: its breadth, however, cannot be so well ascertained; but supposing it to have been the same with that of the present kingdom of Algiers, in the narrowest part it must have been at least 40 miles broad, and in the widest upwards of 100.

1 Ancient division. This county included two districts; one inhabited by the *Massyli*, and the other by the *Masæsyli;* the latter being also called in after-times, *Mauritania Cæsariensis*, and the former *Numidia Propria.* The country of the Massyli, or, as some call it, *Terra Metagonitis*, was separated from the proper territory of Carthage by its eastern boundary the river Tusca, and from the kingdom of the Masæsyli, or Mauritania Cæsariensis, by the river Ampsaga. It seems to correspond with that part of the province of Constantina lying between the Zaine and the Wed al Kibeer, which is above 130 miles long, and more than 100 broad. The sea-coast of this province is for the most part mountainous and rocky, answering to the appellation given to it by Abulfeda, viz. *El Edwaa*, *the high* or *lofty*. It is far from being equal in extent to the ancient country of the Masæsyli, which, Strabo informs us, was yet inferior to the country of the Massyli. Its capital was Cirta, a place of very considerable note among the ancients.

2 Peopled by the descendants of Phut. The most celebrated antiquarians agree, that the tract, extending from the isthmus of Suez to the lake Tritonis, was chiefly peopled by the descendants of Mizraim; and that the posterity of his brother Put, or Phut, spread themselves all over the country between that lake and the Atlantic ocean. To this notion Herodotus gives great countenance: for he tells us, that the Libyan Nomades, whose territories to the west were bounded by the Triton, agreed in their customs and manners with the Egyptians; but that the Africans from that river to the Atlantic Ocean, differed in almost all points from them. Ptolemy mentions a city called *Putea* near Adrametum; and Pliny, a river of Mauritania Tingitana, known by the name of *Fut*, or *Phut;* and the district adjacent to this river was called *Regio Phutensis*, which plainly alludes to the name of *Phut.* That word signifies *scattered*, or *dispersed*, which very well agrees with what Mela and Strabo relate of the ancient Numidians; so that we may, without any scruple, admit the Aborigines of this country to have been the descendants of Phut.

3 Great part of the history unknown. The history of Numidia, during many of the early ages, is buried in oblivion. It is probable, however, that as the Phœnicians were masters of a great part of the country, these transactions had been recorded, and generally known to the Carthaginians. King Jarbas probably reigned here as well as in Africa Propria, if not in Mauritania, and other parts of Libya, when Dido began to build Byrsa. It appears from Justin, that about the age of Herodotus, the people of this country were called both *Africans* or *Libyans* and *Numidians*. Justin likewise intimates, that about this time the Carthaginians vanquished both the Moors or Mauritanians, and Numidians; in consequence of which they were excused from paying the tribute which had hitherto been demanded of them.

After the conclusion of the first Punic war, the African troops carried on a bloody contest against their masters the Carthaginians; and the most active in this rebellion, according to Diodorus Siculus, were a part of the Numidian nation named *Micatanians.* This so incensed the Carthaginians, that after Hamilcar had either killed or taken prisoners all the mercenaries, he sent a large detachment to ravage the country of those Numidians. The commandant of that detachment executed his orders with the utmost cruelty, plundering the district in a terrible manner, and crucifying all the prisoners, without distinction, that fell into his hands. This filled the rest with such indignation and resentment, that both they and their posterity ever afterwards bore an implacable hatred to the Carthaginians.

In the time of the second Punic war, Syphax, king of the Masæsyli, entered into an alliance with the Romans, and gave the Carthaginians a considerable defeat. This induced Gala, king of the Massyli, to conclude a treaty with the Carthaginians, in consequence of which his son Masinissa marched at the head of a powerful army to give Syphax battle. The contest ended in favour of Masinissa; 30,000 of the Masæsyli were put to the sword, and Syphax driven into Mauritania; and the like bad success attended Syphax in another engagement, where his troops were entirely defeated and dispersed. 4 History of Syphax and Masinissa.

Gala dying whilst his son Masinissa was acting at the head of the Numidian troops sent to the assistance of the Carthaginians in Spain, his brother Desalces, according to the established rules of succession in Numidia, took possession of the Massylian throne. That prince dying soon after his accession, Capusa his eldest son succeeded him. But he did not long enjoy his high dignity; for one Mezetulus, a person of the royal blood, but an enemy to the family of Gala, found means to excite a great part of his subjects to revolt. A battle soon took place between him and Capusa; in which the latter was slain with many of the nobility, and his army entirely defeated. But tho' Mezetulus thus became possessed of the sovereignty, he did not think proper to assume the title of *king*, but styled himself guardian to Lacumaces, the surviving son of Desalces, whom he graced with the royal title. To support himself in his usurpation, he married the dowager of Desalces, who was Hannibal's niece, and consequently of the most powerful family in Carthage. In order to attain the same end, he sent ambassadors to Syphax, to conclude a treaty of alliance with him. In the mean time Masinissa, receiving advice of his uncle's death, of his cousin's slaughter, and of Mezetulus's usurpation, immediately passed over to Africa, and went to the court of Bocchar king of Mauritania, to solicit succours. Bocchar, sensible of the great injustice done Masinissa, gave him a body of 4000 Moors to escort him to his dominions. His subjects, having been apprised of his approach, joined him upon the frontiers with a party of 500 men. The Moors, in pursuance of their orders, returned home, as soon as Masinissa reached the confines of his kingdom. Notwithstanding which, and the small body that declared for him having accidentally met Lacumaces at Thapsus with an escort going to

Numidia. to implore Syphax's affiftance, he drove him into the town, which he carried by affault, after a faint refiftance. However, Lacumaces, with many of his men, found means to efcape to Syphax. The fame of this exploit gained Mafiniffa great credit, infomuch that the Numidians flocked to him from all parts, and, amongft the reft, many of his father Gala's veterans, who preffed him to make a fpeedy and vigorous pufh for his hereditary dominions. Lacumaces having joined Mezetulus with a reinforcement of Maffæfylians, which he had prevailed upon Syphax to fend to the affiftance of his ally, the ufurper advanced at the head of a numerous army to offer Mafiniffa battle; which that prince, though much inferior in numbers, did not decline. Hereupon an engagement enfued; which, notwithftanding the inequality of numbers, ended in the defeat of Lacumaces. The immediate confequence of this victory to Mafiniffa, was a quiet and peaceable poffeffion of his kingdom; Mezetulus and Lacumaces, with a few that attended them, flying into the territories of Carthage. However, being apprehenfive that he fhould be obliged to fuftain a war againft Syphax, he offered to treat Lacumaces with as many marks of diftinction as his father Gala had Defalces; provided that prince would put himfelf under his protection. He alfo promifed Mezetulus pardon, and a reftitution of all the effects forfeited by his treafonable conduct, if he would make his fubmiffion to him. Both of them readily complied with the propofal, and immediately returned home; fo that the tranquillity and repofe of Numidia would have been fettled upon a folid and lafting foundation, had not this been prevented by Afdrubal, who was then at Syphax's court. He infinuated to that prince, who was difpofed to live amicably with his neighbours, "That he was greatly miftaken, if he imagined Mafiniffa would be fatisfied with his hereditary dominions. That he was a prince of much greater capacity and ambition, than either his father Gala, his uncle Defalces, or any of his family. That he had difcovered in Spain marks of a moft rare and uncommon merit. And that, in fine, unlefs his rifing flame was extinguifhed before it came to too great a head, both the Maffæfylian and Carthaginian ftates would be infallibly confumed by it." Syphax, alarmed by thefe fuggeftions, advanced with a numerous body of forces into a diftrict, which had long been in difpute between him and Gala, but was then in poffeffion of Mafiniffa. This brought on a general action between thefe two princes; wherein the latter was totally defeated, his army difperfed, and he himfelf obliged to fly to the top of mount Balbus, attended only by a few of his horfe. Such a decifive battle at the prefent juncture, before Mafiniffa was fixed in his throne, could not but put Syphax into poffeffion of the kingdom of the Maffyli. Mafiniffa in the mean time made nocturnal incurfions from his poft upon mount Balbus, and plundered all the adjacent country, particularly that part of the Carthaginian territory contiguous to Numidia. This diftrict he not only thoroughly pillaged, but likewife laid wafte with fire and fword, carrying off from thence an immenfe booty, which was bought by fome merchants, who had put into one of the Carthaginian ports for that purpofe. In fine, he did the Carthaginians more damage, not only by committing fuch dreadful devaftations, but by maffacring and carrying into captivity vaft numbers of their fubjects on this occafion, than they could have fuftained in a pitched battle, or one campaign of a regular war. Syphax, at the preffing and reiterated inftances of the Carthaginians, fent Bocchar, one of his moft active commanders, with a detachment of 4000 foot, and 2000 horfe, to reduce this peftilent gang of robbers, promifing him a great reward if he could bring Mafiniffa either alive or dead. Bocchar, watching an opportunity, furprifed the Maffylians, as they were ftraggling about the country without any order or difcipline; fo that he took many prifoners, difperfed the reft, and purfued Mafiniffa himfelf, with a few of his men, to the top of the mountain where he had before taken poft. Confidering the expedition as ended, he not only fent many head of cattle, and the other booty that had fallen into his hands, to Syphax, but likewife all the forces, except 500 foot and 200 horfe. With this detachment he drove Mafiniffa from the fummit of the hill, and purfued him through feveral narrow paffes and defiles, as far as the plains of Clupea. Here he fo furrounded him, that all the Maffylians, except four, were put to the fword, and Mafiniffa himfelf, after having received a dangerous wound, efcaped with the utmoft difficulty. As this was effected by croffing a rapid river, in which attempt two of his four attendants perifhed in the fight of the detachment that purfued him, it was rumoured all over Africa, that Mafiniffa alfo was drowned; which gave inexpreffible pleafure to Syphax and the Carthaginians. For fome time he lived undifcovered in a cave, where he was fupported by the robberies of the two horfemen that had made their efcape with him. But having cured his wound by the application of fome medicinal herbs, he boldly began to advance towards his own frontiers, giving out publicly that he intended once more to take poffeffion of his kingdom. In his march he was joined by about 40 horfe, and, foon after his arrival amongft the Maffyli, fo many people flocked to him from all parts, that out of them he formed an army of 6000 foot, and 4000 horfe. With thefe forces, he not only reinftated himfelf in the poffeffion of his dominions, but likewife laid wafte the borders of the Maffæfyli. This fo irritated Syphax, that he immediately affembled a body of troops, and encamped very commodioufly upon a ridge of mountains between Cirta and Hippo. His army he commanded in perfon; and detached his fon Vermina, with a confiderable force, to take a compafs, and attack the enemy in the rear. In purfuance of his orders, Vermina fet out in the beginning of the night, and took poft in the place appointed him, without being difcovered by the enemy. In the mean time Syphax decamped, and advanced towards the Maffyli, in order to give them battle. When he had poffeffed himfelf of a rifing ground that led to their camp, and concluded that his fon Vermina muft have formed the ambufcade behind them, he began the fight. Mafiniffa being advantageoufly pofted, and his foldiers diftinguifhing themfelves in an extraordinary manner, the difpute was long and bloody. But Vermina unexpectedly falling upon their rear, and by this means obliging them to divide their forces, which were fcarce able before to oppofe the main body under Syphax, Numidia. phax, they were foon thrown into confufion, and forced to betake themfelves to a precipitate flight. All the avenues being blocked up, partly by Syphax, and partly by his fon, fuch a dreadful flaughter was made of the unhappy Maffyli, that only Mafiniffa himfelf, with 60 horfe, efcaped to the Leffer Syrtis. Here he remained, betwixt the confines of the Carthaginians and Garamantes, till the arrival of Lælius and the Roman fleet on the coaft of Africa. What happened immediately after this junction with the Romans, belongs to the article ROME.

It will be fufficient therefore in this place to obferve, that, by the affiftance of Lælius, Mafiniffa at laft reduced Syphax's kingdom. According to Zonaras, Mafiniffa and Scipio, before the memorable battle of Zama, by a ftratagem deprived Hannibal of fome advantageous pofts; which, with a folar eclipfe happening during the heat of the action, and not a little intimidating the Carthaginian troops, greatly contributed to the victory the Romans obtained. At the conclufion therefore of the fecond Punic war, he was amply rewarded by the Romans for the important fervices he had done them. As for Syphax, after the lofs of his dominions, he was kept in confinement for fome time at Alba; from whence being removed in order to grace Scipio's triumph, he died at Tibur in his way to Rome. Zonaras adds, that his corpfe was decently interred; that all the Numidian prifoners were releafed; and that Vermina, by the affiftance of the Romans, took peaceable poffeffion of his father's throne. However, part of the Maffæfylian kingdom had been before annexed to Mafiniffa's dominions, in order to reward that prince for his fingular fidelity and clofe attachment to the Romans.

This feems to be countenanced by the epitomizer of Livy, who gives us fufficiently to underftand, that Syphax's family, for a confiderable term after the conclufion of the fecond Punic war, reigned in one part of Numidia. For he intimates, that Archobarzanes, Syphax's grandfon, and probably Vermina's fon, hovered with a powerful army of Numidians upon the Carthaginian frontiers a few years before the beginning of the third Punic war. This he feems to have done, either in order to cover them, or to enable the Carthaginians to make an irruption into Mafiniffa's territories. Cato, however, pretended that thefe forces, in conjunction with thofe of Carthage, had a defign to invade the Roman dominions, which he urged as a reafon to induce the confcript fathers to deftroy the African republic.

Nothing is further requifite, in order to complete the hiftory of this famous prince, than to exhibit to our readers view fome points of his conduct towards the decline, and at the clofe, of life; the wife difpofitions made after his death by Æmilianus, in order to the regulation of his domeftic affairs; and fome particulars relating to his character, genius, and habit of body, drawn from the moft celebrated Greek and Roman authors.

By drawing a line of circumvallation around the Carthaginian army under Afdrubal, pofted upon an eminence, Mafiniffa cut off all manner of fupplies from them; which introduced both the plague and famine into their camp. As the body of Numidian troops employed in this blockade was not near fo numerous as the Carthaginian forces, it is evident, that the line Numidia. here mentioned muft have been extremely ftrong, and confequently the effect of great labour and art. The Carthaginians, finding themfelves reduced to the laft extremity, concluded a peace upon the following terms, which Mafiniffa dictated to them: 1. That they fhould deliver up all deferters. 2. That they fhould recal their exiles, who had taken refuge in his dominions. 3. That they fhould pay him 5000 talents of filver within the fpace of 50 years. 4. That their foldiers fhould pafs under the jugum, each of them carrying off only a fingle garment. As Mafiniffa himfelf, though between 80 and 90 years of age, conducted the whole enterprife, he muft have been extremely well verfed in fortification, and other branches of the military art. His underftanding likewife he muft have retained to the laft. This happened a fhort time before the beginning of the third Punic war. See CARTHAGE.

5 Mafiniffa difpleafed with the Romans.

Soon after, the confuls landed an army in Africa, in order to lay fiege to Carthage, without imparting to Mafiniffa their defign. This not a little chagrined him, as it was contrary to the former practice of the Romans; who in the preceding war had communicated their intentions to him, and confulted him on all occafions. When, therefore, the confuls applied to him for a body of his troops to act in concert with their forces, he made anfwer, "That they fhould have a reinforcement from him when they ftood in need of it." It could not but be provoking to him to confider, that after he had extremely weakened the Carthaginians, and even brought them to the brink of ruin, his pretended imperious friends fhould come to reap the fruits of his victory, without giving him the leaft intelligence of it.

However, his mind foon returned to its natural bias, which was in favour of the Romans. Finding his end approaching, he fent to Æmilianus, then a tribune in the Roman army, to defire a vifit from him. What he propofed by this vifit, was to inveft him with full powers to difpofe of his kingdom and eftate as he fhould think proper, for the benefit of his children. The high idea he had entertained of that young hero's abilities and integrity, together with his gratitude and affection for the family into which he was adopted, induced him to take this ftep. But, believing that death would not permit him to have a perfonal conference with Æmilianus upon this fubject, he informed his wife and children in his laft moments, that he had impowered him to difpofe in an abfolute manner of all his poffeffions, and to divide his kingdom amongft his fons. To which he fubjoined, "I require, that whatever Æmilianus may decree, fhall be executed as punctually as if I myfelf had appointed it by my will." Having uttered thefe words, he expired, at above 90 years of age.

6 But leaves every thing to the difpofal of Æmilianus.

This prince, during his youth, had met with ftrange reverfes of fortune. However, fays Appian, being fupported by the divine protection, he enjoyed an uninterrupted courfe of profperity for a long feries of years. His kingdom extended from Mauritania to the weftern confines of Cyrenaica; from whence it appears, that he was one of the moft powerful princes of Africa. Many of the inhabitants of this vaft tract he civilized in a wonderful manner, teaching them to cultivate

Numidia.

tivate their ſoil, and to reap thoſe natural advantages which the fertility of ſome parts of their country offered them. He was of a more robuſt habit of body than any of his cotemporaries, being bleſſed with the greateſt health and vigour; which was doubtleſs owing to his extreme temperance, and the toils he inceſſantly ſuſtained. We are informed by Polybius, that ſometimes he ſtood upon the ſame ſpot of ground from morning till evening, without the leaſt motion, and at others continued as long in a ſitting poſture. He would remain on horſeback for ſeveral days and nights together, without being ſenſible of the leaſt fatigue. Nothing can better evince the ſtrength of his conſtitution, than his youngeſt ſon, named *Stembal*, *Sthemba*, or *Stembanus*, who was but four years old at his deceaſe. Though 90 years of age, he performed all the exerciſes uſed by young men, and always rode without a ſaddle. Pliny tells us, that he reigned above 60 years. He was an able commander, and much facilitated the reduction of Carthage. Plutarch from Polybius obſerves, that the day after a great victory won over the Carthaginians, Maſiniſſa was ſeen ſitting at the door of his tent, eating a piece of brown bread. Suidas relates, that, to the laſt, he could mount his horſe without any aſſiſtance. According to Appian, he left a numerous well-diſciplined army, and an immenſe quantity of wealth, behind him.

Maſiniſſa, before his death, gave his ring to his eldeſt ſon Micipſa; but left the diſtribution of all his other effects and poſſeſſions amongſt his children, entirely to Æmilianus. Of 54 ſons that ſurvived him, only three were legitimate, to wit, Micipſa, Guluſſa, and Maſtanabal. Æmilianus, arriving at Cirta after he had expired, divided his kingdom, or rather the government of it, amongſt theſe three, though to the others he gave conſiderable poſſeſſions. To Micipſa, who was a prince of a pacific diſpoſition, and the eldeſt ſon, he aſſigned Cirta, the metropolis, for the place of his reſidence, in excluſion of the others. Guluſſa, the next to him, being a prince of a military genius, had the command of the army, and the tranſacting of all affairs relating to peace or war, committed to his care. And Manaſtabal, the youngeſt, had the adminiſtration of juſtice, an employment ſuitable to his education, allotted him. They enjoyed in common the immenſe treaſures Maſiniſſa had amaſſed, and were all of them dignified by Æmilianus with the royal title. After he had made theſe wiſe diſpoſitions, that young nobleman departed from Cirta, taking with him a body of Numidian troops, under the conduct of Guluſſa, to reinforce the Roman army, that was then acting againſt the Carthaginians.

Maſtanabal and Guluſſa died ſoon after their father, as appears from the expreſs teſtimony of Salluſt. We find nothing more remarkable of theſe princes, beſides what has been already related, than that the latter continued to aſſiſt the Romans in the third Punic war; and that the former was pretty well verſed in the Greek language. Micipſa therefore became ſole poſſeſſor of the kingdom of Numidia. In his reign, and the conſulate of M. Plautius Hypſæus and M. Fulvius Flaccus, according to Oroſius, a great part of Africa was covered with locuſts, which deſtroyed all the produce of the earth, and even devoured dry wood. But at laſt they were all carried by the wind into the African ſea, out of which being thrown in vaſt heaps upon the ſhore, a plague enſued, which ſwept away an infinite number of animals of all kinds. In Numidia only, periſhed 800,000 men, and in Africa Propria 200,000: amongſt the reſt, 30,000 Roman ſoldiers quartered in and about Utica for the defence of the laſt province. At Utica, in particular, the mortality raged to ſuch a degree, that 1500 dead bodies were carried out of one gate in a day. Micipſa had two ſons, Adherbal and Hiempſal, whom he educated in his palace, together with his nephew Jugurtha. That young prince was the ſon of Maſtanabal; but his mother having been only a concubine, Maſiniſſa had taken no great notice of him. However, Micipſa conſidering him as a prince of the blood, took as much care of him as he did of his own children.

7 History of Jugurtha.

Jugurtha poſſeſſed ſeveral eminent qualities, which gained him univerſal eſteem. He was very handſome, endued with great ſtrength of body, and adorned with the fineſt intellectual endowments. He did not devote himſelf, as young men commonly do, to a life of luxury and pleaſure. He uſed to exerciſe himſelf, with perſons of his age, in running, riding, hurling the javelin, and other manly exerciſes, ſuited to the martial genius of the Numidians; and though he ſurpaſſed all his fellow ſportſmen, there was not one of them but loved him. The chace was his only delight; but it was that of lions, and other ſavage beaſts. Salluſt, to finiſh his character, tells us, that he excelled in all things, and ſpoke very little of himſelf.

So conſpicuous an aſſemblage of fine talents and perfections, at firſt charmed Micipſa, who thought them an ornament to his kingdom. However, he ſoon began to reflect, that he was conſiderably advanced in years, and his children in their infancy; that mankind naturally thirſted after power, and that nothing was capable of making men run greater lengths than a vicious and unlimited ambition. Theſe reflections ſoon excited his jealouſy, and determined him to expoſe Jugurtha to a variety of dangers, ſome of which, he entertained hopes, might prove fatal to him. In order to this, he gave him the command of a body of forces which he ſent to aſſiſt the Romans, who were at that time beſieging Numantia in Spain. But Jugurtha, by his admirable conduct, not only eſcaped all thoſe dangers, but likewiſe won the eſteem of the whole army, and the friendſhip of Scipio, who ſent a high character of him to his uncle Micipſa. However, that general gave him ſome prudent advice in relation to his future conduct; obſerving, no doubt, in him certain ſparks of ambition, which, if lighted into a flame, he apprehended might one day be productive of the moſt fatal conſequences.

8 Is dreaded by king Maſiniſſa.

Before this laſt expedition, Micipſa had endeavoured to find out ſome method of taking him off privately; but his popularity amongſt the Numidians obliged that prince to lay aſide all thoughts of this nature. After his return from Spain the whole nation almoſt adored him. The heroic bravery he had ſhewn there, his undaunted courage, joined to the utmoſt calmneſs of mind, which enabled him to preſerve a juſt medium between a timorous foreſight and an impetuous raſhneſs, a circumſtance rarely to be met with in perſons of his age, and above all the advantageous teſtimonials of his conduct given by Scipio, attracted an univerſal

Numidia. versal esteem. Nay, Micipsa himself, charmed with the high idea the Roman general had entertained of his merit, changed his behaviour towards him; resolving, if possible, to win his affection by kindness. He therefore adopted him, and declared him joint heir with his two sons to the crown. Finding, some few years afterwards, that his end approached, he sent for all three to his bed-side; where, in the presence of the whole court, he desired Jugurtha to recollect with what extreme tenderness he had treated him, and consequently to consider how well he had deserved at his hands.

9 Who nevertheless entrusts him with the care of his children.

He then intreated him to protect his children on all occasions; who, being before related to him by the ties of blood, were now by their father's bounty become his brethren. In order to fix him the more firmly in their interest, he likewise complimented him upon his bravery, address, and consummate prudence. He further insinuated, that neither arms nor treasures constitute the strength of a kingdom; but friends, who are neither won by arms nor gold, but by real services, and an inviolable fidelity. "Now where, (continued he), can we find better friends than in brothers? And how can that man who becomes an enemy to his relations, repose any confidence in, or depend upon strangers?" Then addressing himself to Adherbal and Hiempsal, "And you, (said he), I enjoin always to pay the highest reverence to Jugurtha. Endeavour to imitate, and if possible surpass, his exalted merit, that the world may not hereafter observe Micipsa's adopted son to have reflected greater glory upon his memory than his own children." Soon after, Micipsa, who, according to Diodorus, was a prince of an amiable character, expired. Though Jugurtha did not believe the king to speak his real sentiments with regard to him, yet he seemed extremely pleased with so gracious a speech, and made him an answer suitable to the occasion. However, that prince at the same time was determined within himself to put in execution the scheme he had formed at the siege of Numantia, which was suggested to him by some factious and abandoned Roman officers, with whom he there contracted an acquaintance. The purport of this scheme was, that he should extort the crown by force from his two cousins, as soon as their father's eyes were closed; which they insinuated might easily be effected by his own valour, and the venality of the Romans.

10 One of whom he murders, and drives out the other.

Accordingly, a short time after the old king's death, he found means to assassinate Hiempsal in the city of Thirmida where his treasures were deposited, and drive Adherbal out of his dominions. That unhappy prince found himself obliged to fly to Rome, where he endeavoured to engage the conscript fathers to espouse his quarrel; but, notwithstanding the justice of his cause, they had not virtue enough effectually to support him. Jugurtha's embassadors, by distributing vast sums of money amongst the senators, brought them so far over, that a majority palliated his inhuman proceedings. This encouraged those ministers to declare, that Hiempsal had been killed by the Numidians on account of his excessive cruelty; that Adherbal was the aggressor in the late troubles, and that he was only chagrined because he could not make that havoc amongst his countrymen he would willingly have done. They therefore intreated the senate to form a judgment of Jugurtha's behaviour in Africa from his conduct at Numantia, rather than from the suggestions of his enemies. Upon which, by far the greatest part of the senate discovered themselves prejudiced in his favour. A few however, that were not lost to honour, nor abandoned to corruption, insisted upon bringing him to condign punishment. But as they could not prevail, he had the best part of Numidia allotted him, and Adherbal was forced to rest satisfied with the other. Numidia.

11 Venality of the Romans.

Jugurtha finding now by experience, that every thing was venal at Rome, as his friends at Numantia had before informed him, thought he might pursue his towering projects without any obstruction from that quarter. He therefore, immediately after the last division of Micipsa's dominions, threw off the mask, and attacked his cousin by open force. As Adherbal was a prince of a pacific disposition, and almost in all respects the reverse of Jugurtha, he was by no means a match for him. The latter therefore pillaged the former's territories, stormed several of his fortresses, and over-ran a good part of his kingdom without opposition. Adherbal, depending on the friendship of the Romans, which his father in his last moments assured him would be a stronger support to him than all the troops and treasures in the universe, dispatched deputies to Rome to complain of these hostilities. But whilst he lost his time in sending thither fruitless deputations, Jugurtha overthrew him in a pitched battle, and soon after shut him up in Cirta. During the siege of this city, a Roman commission arrived there, in order to persuade both parties to an accommodation; but finding Jugurtha untractable, the commissioners returned home without so much as conferring with Adherbal. A second deputation, composed of senators of the highest distinction, with Æmilius Scaurus, president of the senate, at their head, landed some time after at Utica, and summoned Jugurtha to appear before them. That prince at first seemed to be under dreadful apprehensions, especially as Scaurus reproached him with his enormous crimes, and threatened him with the resentment of the Romans if he did not immediately raise the siege of Cirta. However, the Numidian by his address, and the irresistible power of gold, as was afterwards suspected at Rome, so mollified Scaurus, that he left Adherbal at his mercy. In fine, Jugurtha had at last Cirta surrendered to him; upon condition only, that he should spare the life of Adherbal. But the merciless tyrant, in violation of the laws of nature and humanity, as well as the capitulation, when he had got possession of the town, ordered him to be put to a most cruel death. The merchants likewise, and all the Numidians in the place capable of bearing arms, he caused, without distinction, to be put to the sword.

Every person at Rome inspired with any sentiments of humanity, was struck with horror at the news of this tragical event. However, all the venal senators still concurred with Jugurtha's ministers in palliating his enormous crimes. Notwithstanding which, the people, excited thereto by Caius Memmius their tribune, who bitterly inveighed against the venality of the senate, resolved not to let so flagrant an instance of villany go unpunished. This disposition in them induced the conscript fathers likewise to declare their intention to chastise Jugurtha. In order to this, an army was levied to invade Numidia, and the command of it given to the consul Calpurnius Bestia, a person of good abili-

Numidia.

abilities, but rendered unfit for the expedition he was to go upon by his infatiable avarice. Jugurtha being informed of the great preparations making at Rome to attack his dominions, fent his fon thither to avert the impending ftorm. The young prince was plentifully fupplied with money, which he had orders to diftribute liberally amongft the leading men. But Beftia, propofing to himfelf great advantages from an invafion of Numidia, defeated all his intrigues, and got a decree paffed, ordering him and his attendants to depart Italy in ten days, unlefs they were come to deliver up the king himfelf, and all his territories, to the republic by way of dedition. Which decree being notified to them, they returned without fo much as having entered the gates of Rome; and the conful foon after landed with a powerful army in Africa. For fome time he carried on the war there very brifkly, reduced feveral ftrongholds, and took many Numidians prifoners. But upon the arrival of Scaurus, a peace was granted Jugurtha upon advantageous terms. That prince coming from Vacca, the place of his refidence, to the Roman camp, in order to confer with Beftia and Scaurus, and the preliminaries of the treaty being immediately after fettled between them in private conferences, every body at Rome was convinced that the prince of the fenate and the conful had to their avarice facrificed the republic. The indignation therefore of the people in general, difplayed itfelf in the ftrongeft manner. Memmius alfo fired them with his fpeeches. It was therefore refolved to difpatch the prætor Caffius, a perfon they could confide in, to Numidia, to prevail upon Jugurtha to come to Rome, that they might learn from the king himfelf which of their generals and fenators had been feduced by the peftilent influence of corruption. Upon his arrival there, he found means to bribe one Bæbius Salca, a man of great authority amongft the plebeians, but of infatiable avarice, by whofe affiftance he efcaped with impunity. Nay, by the efficacy of gold, he not only eluded all the endeavours of the people of Rome to bring him to juftice, but likewife enabled Bomilcar, one of his attendants, to get Maffiva, an illegitimate fon of Micipfa, affaffinated in the ftreets of Rome. That young prince was advifed by many Romans of probity, well-wifhers to the family of Mafiniffa, to apply for the kingdom of Numidia; which coming to Jugurtha's ears, he prevented the application by this execrable ftep. However, he was obliged to leave Italy immediately.

Jugurtha had fcarce fet foot in Africa when he received advice, that the fenate had annulled the fhameful peace concluded with him by Beftia and Scaurus. Soon after, the conful Albinus tranfported a Roman army into Numidia, flattering himfelf with the hopes of reducing Jugurtha to reafon before the expiration of his confulate. In this, however, he found himfelf deceived; for that crafty prince, by various artifices fo amufed and impofed upon Albinus, that nothing of moment happened that campaign. This rendered him ftrongly fufpected of having betrayed his county, after the example of his predeceffors. His brother Aulus, who fucceeded him in the command of the army, was ftill more unfuccefsful; for after rifing from before Suthul, where the king's treafures were depofited, he marched his forces into a defile out of which he found it impoffible to extricate himfelf. He therefore was obliged to fubmit to the ignominious ceremony of paffing under the *jugum*, with all his men, and to quit Numidia entirely in ten days time, in order to deliver his troops from immediate deftruction. The avaricious difpofition of the Roman commander had prompted him to befiege Suthul, the poffeffion of which place he imagined would make him mafter of all the wealth of Jugurtha, and confequently paved the way to fuch a fcandalous treaty. However, this was declared void as foon as known at Rome, as being concluded without the authority of the people. The Roman troops retired into Africa Propria, which they had now reduced into the form of a Roman province, and there took up their winter-quarters.

In the mean time Caius Mamilius Limetanus, tribune of the people, excited the plebeians to inquire into the conduct of thofe perfons by whofe affiftance Jugurtha had found means to elude all the decrees of the fenate. This put the body of the people into a great ferment; which occafioned a profecution of the guilty fenators, that was carried on, for fome time, with the utmoft heat and violence. Lucius Metellus the conful, during thefe tranfactions, had Numidia affigned him for his province, and confequently was appointed general of the army deftined to act againft Jugurtha. As he perfectly difregarded wealth, the Numidian found him fuperior to all his temptations; which was a great mortification to him. To this he joined all the other virtues which conftitute the great captain; fo that Jugurtha found him in all refpects inacceffible. That prince therefore was now forced to regulate his conduct according to the motions of Metellus, with the greateft caution, and to exert his utmoft bravery, in order to compenfate for that hitherto fo favourable expedient which now began to fail him. Marius, Metellus's lieutenant, being likewife a perfon of uncommon merit, the Romans reduced Vacca, a large opulent city, and the moft celebrated mart in Numidia. They alfo defeated Jugurtha in a pitched battle; overthrew Bomilcar, one of his generals, upon the banks of the Muthullus; and, in fine, forced the Numidian monarch to take fhelter in a place rendered almoft inacceffible by the rocks and woods with which it was covered. However, Jugurtha fignalifed himfelf in a furprifing manner, exhibiting all that could be expected from the courage, abilities, and attention of a confummate general, to whom defpair adminifters frefh ftrength, and fuggefts new lights. But his troops could not make head againft the Romans; they were again worfted by Marius, though they obliged Metellus to raife the fiege of Zama. Jugurtha therefore, finding his country every where ravaged, his moft opulent cities plundered, his fortreffes reduced, his towns burnt, vaft numbers of his fubjects put to the fword and taken prifoners, began to think ferioufly of coming to an accommodation with the Romans. His favourite Bomilcar, in whom he repofed the higheft confidence, but who had been gained over to the enemy by Metellus, obferving this difpofition, found it no difficult matter to perfuade him to deliver up his elephants, money, arms, horfes, and deferters, in whom the main ftrength of his army confifted, into the hands of the Romans. Some of thefe laft, in order to avoid the punifhment due to their crime, retired to Bocchus king of Mauritania, and lifted in his fervice. But Metellus

12 Metellus fent againft Jugurtha.

13 Who is betrayed by Bomilcar.

ordering

Numidia. ordering him to repair to Tifidium, a city of Numidia, there to receive farther directions, and he refufing a compliance with that order, hoftilities were renewed with greater fury than ever. Fortune now feemed to declare in favour of Jugurtha: he retook Vacca, and maffacred all the Roman garrifon, except Turpilius the commandant. However, foon after, a Roman legion feized again upon it, and treated the inhabitants with the utmoft feverity. About this time, one of Maftanabal's fons, named *Gauda*, whom Micipfa in his will had appointed to fucceed to the crown in cafe his two legitimate fons and Jugurtha died without iffue, wrote to the fenate in favour of Marius, who was then endeavouring to fupplant Metellus. That prince having his underftanding impaired by a declining ftate of health, fell a more eafy prey to the bafe and infamous adulation of Marius. The Roman, foothing his vanity, affured him, that as he was the next heir to the crown, he might depend upon being fixed upon the Numidian throne, as foon as Jugurtha was either killed or taken; and that this muft in a fhort time happen, when once he appeared at the head of the Roman army with an unlimited commiffion. Soon after, Bomilcar and Nabdalfa formed a defign to affaffinate Jugurtha, at the inftigation of Metellus; but this being detected, Bomilcar and moft of his accomplices fuffered death. The plot however had fuch an effect upon Jugurtha, that he enjoyed afterwards no tranquillity or repofe. He fufpected perfons of all denominations, Numidians as well as foreigners, of fome black defigns againft him. Perpetual terrors fat brooding over his mind; infomuch that he never got a wink of fleep but by ftealth, and often changed his bed in a low plebeian manner. Starting from his fleep, he would frequently fnatch his fword, and break out into the moft doleful cries: So ftrongly was he haunted by a fpirit of fear, jealoufy, and diftraction!

14 A confpiracy againft him.

Jugurtha having deftroyed great numbers of his friends on fufpicion of their having been concerned in the late confpiracy, and many more of them deferting to the Romans and Bocchus king of Mauritania, he found himfelf, in a manner, deftitute of counfellors, generals, and all perfons capable of affifting him in carrying on the war. This threw him into a deep melancholy, which rendered him diffatisfied with every thing, and made him fatigue his troops with a variety of contradictory motions. Sometimes he would advance with great celerity againft the enemy, and at others retreat with no fmall fwiftnefs from them. Then he refumed his former courage; but foon after defpaired either of the valour or fidelity of the forces under his command. All his movements therefore proved unfuccefsful, and at laft he was forced by Metellus to a battle. That part of the Numidian army which Jugurtha commanded, behaved with fome refolution; but the other fled at the firft onfet. The Romans therefore entirely defeated them, took all their ftandards, and made a few of them prifoners. Not many of them were flain in the action; fince, as Salluft obferves, the Numidians trufted more to their heels than to their arms for fafety in this engagement.

15 He is defeated by Metellus.

Metellus purfued Jugurtha and his fugitives to Thala. His march to this place being through vaft deferts, was extremely tedious and difficult. But being fupplied with leathern bottles and wooden veffels of all fizes taken from the huts of the Numidians, which were filled with water brought by the natives, who had fubmitted to him, he advanced towards that city. He had no fooner begun his march, than a moft copious fhower of rain, a thing very uncommon in thofe defarts, proved a great and feafonable refrefhment to his troops. This fo animated them, that upon their arrival before Thala, they attacked the town with fuch vigour, that Jugurtha, with his family, and treafures depofited therein, thought proper to abandon it. After a brave defence, it was reduced; the garrifon, confifting of Roman deferters, fetting fire to the king's palace, and confuming themfelves, together with every thing valuable to them, in the flames. Jugurtha, being now reduced to great extremities, retired into Gætulia, where he formed a confiderable corps. From thence he advanced to the confines of Mauritania; and engaged Bocchus king of that country, who had married his daughter, to enter into an alliance with him. In confequence of which, having reinforced his Gætulian troops with a powerful body of Mauritanians, he turned the tables upon Metellus, and obliged him to keep clofe within his entrenchments. Salluft informs us, that Jugurtha bribed Bocchus's minifters to influence that prince in his favour; and that having obtained an audience, he infinuated, that, fhould Numidia be fubdued, Mauritania muft be involved in its ruin, efpecially as the Romans feemed to have vowed the deftruction of all the thrones in the univerfe. In fupport of what he advanced, he produced feveral inftances very appofite to the point in view. However, the fame author feems to intimate, that Bocchus was determined to affift Jugurtha againft his enemies by the flight the Romans had formerly fhewn him. That prince, at the firft breaking out of the war, had fent ambaffadors to Rome, to propofe an offenfive and defenfive alliance to the republic; which, though of the utmoft confequence to it at that juncture, a few of the moft venal and infamous fenators, who were abandoned to corruption, prevented from taking effect. This undoubtedly wrought more powerfully upon Bocchus in favour of Jugurtha, than the relation he ftood in to him: For both the Moors and Numidians adapted the number of their wives to their circumftances, fo that fome had 10, 20, &c. to their fhare; their kings therefore were unlimited in this particular, and of courfe all degrees of affinity refulting to them from marriage had little force. It is obfervable, that the pofterity of thofe ancient nations have the fame cuftom prevailing amongft them at this day. 16

Such was the fituation of affairs in Numidia, when Metellus received advice of the promotion of Marius to the confulate. But, notwithftanding this injurious treatment, he generoufly endeavoured to draw off Bocchus from Jugurtha, though this would facilitate the reduction of Numidia for his rival. To this end ambaffadors were difpatched to the Mauritanian court, who intimated to Bocchus, "That it would be highly imprudent to come to a rupture with the Romans without any caufe at all; and that he had now a fine opportunity of concluding a moft advantageous treaty with them, which was much preferable to a war. To which they added, that whatever dependence he might place upon his riches, he ought not

Marius fucceeds Metellus.

not to run the hazard of loſing his dominions by embroiling himſelf with other ſtates, when he could eaſily avoid this; that it was much eaſier to begin a war than to end it, which it was in the power of the victor alone to do; that, in fine, he would by no means conſult the intereſt of his ſubjects if he followed the deſperate fortunes of Jugurtha." To which Bocchus replied, "That for his part there was nothing he wiſhed for more than peace; but that he could not help pitying the deplorable condition of Jugurtha; that if the Romans, therefore, would grant that unfortunate prince the ſame terms they had offered him, he would bring about an accommodation." Metellus let the Mauritanian monarch know, that it was not in his power to comply with what he deſired. However, he took care to keep up a private negotiation with him till the new conſul Marius's arrival. By this conduct he ſerved two wiſe ends. Firſt, he prevented thereby Bocchus from coming to a general action with his troops; which was the very thing Jugurtha deſired, as hoping that this, whatever the event might be, would render a reconciliation betwixt him and the Romans impracticable. Secondly, this inaction enabled him to diſcover ſomething of the genius and diſpoſition of the Moors; a nation, of whom the Romans, till then, had ſcarce formed any idea; which, he imagined, might be of no ſmall ſervice, either to himſelf or his ſucceſſors, in the future proſecution of the war.

Jugurtha, being informed, that Marius, with a numerous army, was landed at Utica, adviſed Bocchus to retire, with part of the troops, to ſome place of difficult acceſs, whilſt he himſelf took poſt upon another inacceſſible ſpot with the remaining corps. By this meaſure, he hoped the Romans would be obliged to divide their forces, and conſequently be more expoſed to his efforts and attacks. He likewiſe imagined, that ſeeing no formidable body appear, they would believe the enemy in no condition to make head againſt them; which might occaſion a relaxation of diſcipline, the uſual attendant of a too great ſecurity, and conſequently produce ſome good effect. However, he was diſappointed in both theſe views. For Marius, far from ſuffering a relaxation of diſcipline to take place, trained up his troops, which conſiſted chiefly of new levies, in ſo perfect a manner, that they were ſoon equal in goodneſs to any conſular army that ever appeared in the field. He alſo cut off great numbers of the Gætulian marauders, defeated many of Jugurtha's parties, and had like to have taken that prince himſelf near the city of Cirta. Theſe advantages, though not of any great importance, intimidated Bocchus, who now made overtures for an accommodation; but the Romans, not being ſufficiently ſatisfied of his ſincerity, gave no great attention to them. In the mean time Marius puſhed on his conqueſts, reducing ſeveral places of leſs note, and at laſt reſolved to beſiege Capſa. That this enterprize might be conducted with the greater ſecrecy, he ſuffered not the leaſt hint of his deſign to tranſpire, even amongſt any of his officers. On the contrary, in order to blind them, he detached A. Manlius, one of his lieutenants, with ſome light-armed cohorts, to the city of Lares, where he had fixed his principal magazine, and depoſited the military cheſt. Before Manlius left the camp, that he might the more effectually amuſe him, he intimated, that himſelf with the army ſhould take the ſame route in a few days: but inſtead of that, he bent his march towards the Tanais, and in ſix days time arrived upon the banks of that river. Here he pitched his tents for a ſhort time, in order to refreſh his troops; which having done, he advanced to Capſa, and made himſelf maſter of it. As the ſituation of this city rendered it extremely commodious to Jugurtha, whoſe plan of operations, ever ſince the commencement of the war, it had exceedingly favoured, he levelled it with the ground after it had been delivered up to the ſoldiers to be plundered. The citizens likewiſe, being more ſtrongly attached to that prince than any of the other Numidians, on account of the extraordinary privileges he indulged them with, and of courſe bearing a more implacable hatred to the Romans, he put to the ſword or ſold for ſlaves. The true motive of the conſul's conduct on this occaſion ſeems here to be aſſigned; though we are told by Salluſt, in conformity to the Roman genius, that neither avarice nor reſentment prompted him to ſo barbarous an action, but only a deſire to ſtrike a terror into the Numidians.

17 He gains a great advantage over Jugurtha.

The Numidians, ever after this exploit, dreaded the very name of Marius; who now, in his own opinion, had eclipſed the glory of all his predeceſſor's great atchievements, particularly the reduction of Thala, a city, in ſtrength and ſituation, nearly reſembling Capſa. Following his blow, he gradually preſented himſelf before moſt of the places of ſtrength in the enemy's country; many of which either opened their gates, or were abandoned, at his approach, being terrified with what had happened to the unfortunate citizens of Capſa. Others taking by force, he laid in aſhes; and in ſhort, filled the greateſt part of Numidia with blood, horror, and confuſion. Then, after an obſtinate defence, he reduced a caſtle that ſeemed impregnable, ſeated not far from Mulucha, where Jugurtha kept part of his treaſures. In the mean time, Jugurtha not being able to prevail upon Bocchus, by his repeated ſolicitations, to advance into Numidia, where he found himſelf greatly preſſed, was obliged to have recourſe to his uſual method of bribing the Mauritanian miniſters, in order to put that prince in motion. He alſo promiſed him a third part of his kingdom, provided they could either drive the Romans out of Africa, or get all the Numidian dominions confirmed to him by treaty.

So conſiderable a ceſſion could not fail of engaging Bocchus to ſupport Jugurtha with his whole power. The two African monarchs therefore, having joined their forces, ſurpriſed Marius near Cirta as he was going into winter-quarters. The Roman general was ſo puſhed on this occaſion, that the barbarians thought themſelves certain of victory, and doubted not but they ſhould be able to extinguiſh the Roman name in Numidia. But their incaution and too great ſecurity enabled Marius to give them a total defeat; which was followed four days after by ſo complete an overthrow, that their numerous army, conſiſting of 90,000 men, by the acceſſion of a powerful corps of Moors, commanded by Bocchus's ſon Volux, was entirely ruined. Sylla, Marius's lieutenant, moſt eminently diſtinguiſhed himſelf in the laſt action, which laid the foundation of

18 Jugurtha entirely defeated.

Numidia. of his future greatneſs. Bocchus, now looking upon Jugurtha's condition as deſperate, and not being willing to run the riſk of loſing his dominions, ſhewed a diſpoſition to clap up a peace with Rome. However, the republic gave him to underſtand, that he muſt not expect to be ranked amongſt its friends, till he had delivered up into the conſul's hands Jugurtha, the inveterate enemy of the Roman name. The Mauritanian monarch, having entertained an high idea of an alliance with that ſtate, reſolved to ſatisfy it in this particular; and was confirmed in his reſolution by one Dabar, a Numidian prince, the ſon of Maſſugrada, and deſcended by his mother's ſide from Maſiniſſa. Being cloſely attached to the Romans, and extremely agreeable to Bocchus on account of his noble diſpoſition, he defeated all the intrigues of Aſpar, Jugurtha's miniſter. Upon Sylla's arrival at the Mauritanian court, the affair there ſeemed to be entirely ſettled. However, Bocchus, who was for ever projecting new deſigns, and, like the reſt of his countrymen, in the higheſt degree perfidious, debated within himſelf, whether he ſhould ſacrifice Sylla or Jugurtha, who were both then in his power. He was a long time fluctuating with uncertainty, and combated by a contrariety of ſentiments. The ſudden changes, which diſplayed themſelves in his countenance, his air, and his whole perſon, evidently ſhewed how ſtrongly his mind was agitated. But at laſt he returned to his firſt deſign, to which the bias of his mind ſeemed naturally to lead him. He therefore delivered up Jugurtha into the hands of Sylla, to be conducted to Marius; who, by that ſucceſsful event, happily terminated this dangerous war. The kingdom of Numidia was now reduced to a new form: Bocchus, for his important ſervices, had the country of the Maſſæſyli, contiguous to Mauritania, aſſigned him; which, from this time, took the name of *New Mauritania.* Numidia Propria, or the country of the Maſſyli, was divided into three parts; one of which was given to Hiempſal, another to Mandreſtal, both deſcendants of Maſiniſſa; and the third the Romans annexed to Africa Propria, or the Roman province adjacent to it. What became of Jugurtha after he had graced Marius's triumph, at which ceremony he was led in chains, together with his two ſons, through the ſtreets of Rome, our readers will find related at large in a former part of this work.

19 Bocchus delivers up Jugurtha to the Romans

20 Tranſactions after the death of Jugurtha.

Jugurtha's two ſons ſurvived him, but ſpent their lives in captivity at Venuſia. However, one of them, named *Oxyntas,* was, for a ſhort time, releaſed from his confinement by Aponius, who beſieged Acerræ in the war between the Romans and the Italian allies. That general brought this prince to his army, where he treated him as king, in order to draw the Numidian forces off from the Roman ſervice. Accordingly thoſe Numidians no ſooner heard that the ſon of their old king was fighting for the allies, than they began to deſert by campanies; which obliged Julius Cæſar the conſul to part with all his Numidian cavalry, and ſend them back into Africa. Some few years after this event, Pompey defeated Cneius Domitius Ahenobarbus, and Hiarbas, one of the kings of Numidia, killing 17,000 of their men upon the ſpot. Not ſatisfied with this victory, that general purſued the fugitives to their camp, which he ſoon forced, put Domitius to the ſword, and took Hiarbas priſoner. He then reduced that part of Numidia which belonged to Hiarbas, who ſeems to have ſucceeded Mandreſtal abovementioned; and gave it to Hiempſal, a neighbouring Numidian prince, deſcended from Maſiniſſa, who had always oppoſed the Marian faction. Numidia.

21 Cæſar inſults Juba.

Suetonius informs us, that a diſpute happened between Hiempſal and one Maſintha, a noble Numidian, whom, it is probable, he had in ſome reſpect injured when Julius Cæſar firſt began to make a figure in the world. The ſame author adds, that Cæſar warmly eſpouſed the cauſe of Maſintha, and even groſsly inſulted Juba, Hiempſal's ſon, when he attempted to vindicate his father's conduct on this occaſion. He pulled him by the beard, than which a more unpardonable affront could not be offered to an African. In ſhort, he ſcreened Maſintha from the inſults and violence of his enemies; from whence a reaſon may be aſſigned for Juba's adhering ſo cloſely afterwards to the Pompeian faction.

22 Juba defeats one of Cæſar's lieutenants.

In conſequence of the indignity Cæſar had offered Juba, and the diſpoſition it had occaſioned, that prince did Cæſar great damage in the civil wars betwixt him and Pompey. By a ſtratagem he drew Curio, one of his lieutenants, to a general action, which it was his intereſt at that time to have avoided. He cauſed it to be given out all over Africa Propria and Numidia, that he was retired into ſome remote country at a great diſtance from the Roman territories. This coming to Curio's ears, who was then beſieging Utica, it hindered him from taking the neceſſary precautions againſt a ſurpriſe. Soon after, the Roman general receiving intelligence that a ſmall body of Numidians was approaching his camp, he put himſelf at the head of his forces in order to attack them, and, for fear they ſhould eſcape, began his march in the night, looking upon himſelf as ſure of victory. Some of their advanced poſts he ſurpriſed aſleep, and cut them to pieces; which ſtill farther animated him. In ſhort, about day-break he came up with the Numidians, whom he attacked with great bravery, though his men were then faſting, and vaſtly fatigued by their forced and precipitate march. In the mean time, Juba, who, immediately after the propagation of the rumour abovementioned, had taken care to march privately, with the main body of the Numidian army, to ſupport the detachment ſent before to decoy Curio, advanced to the relief of his men. The Romans had met with a great reſiſtance before he appeared; ſo that he eaſily broke them, killed Curio, with a great part of his troops, upon the ſpot, purſued the reſt to their camp, which he plundered, and took many of them priſoners. Moſt of the fugitives, who endeavoured to make their eſcape on board the ſhips in the port of Utica, were either ſlain by the purſuers, or drowned. The remainder fell into the hands of Varus, who would have ſaved them; but Juba, who arrogated to himſelf the honour of this victory, ordered moſt of them to be put to the ſword.

23 Juba overthrown by Cæſar.

This victory infuſed new life and vigour into the Pompeian faction, who thereupon conferred great honours upon Juba, and gave him the title of *king of all Numidia.* But Cæſar and his adherents declared him an enemy to the ſtate of Rome, adjudging to Bocchus and Bogud, two African princes entirely in their intereſt, Numidia. tereſt, the ſovereignty of his dominions. Juba afterwards, uniting his forces with thoſe of Scipio, reduced Cæſar to great extremities, and would in all probability have totally ruined him, had he not been relieved by Publius Sittius. That general, having formed a conſiderable corps, conſiſting of Roman exiles, and Mauritanian troops ſent him by Bocchus, according to Dio, or, as Cæſar will have it, Bogud, made an irruption into Gætulia and Numidia, whilſt Juba was employed in Africa Propria. As he ravaged theſe countries in a dreadful manner, Juba immediately returned with the beſt part of his army, to preſerve them from utter deſtruction. However, Cæſar knowing his horſe to be afraid of the enemy's elephants, did not think proper to attack Scipio in the abſence of the Numidian, till his own elephants, and a freſh reinforcement of troops, hourly expected, arrived from Italy. With this acceſſion of ſtrength, he imagined himſelf able to give a good account, both of the Roman forces with which he was to cope, and the barbarians. In the mean time Scipio diſpatched reiterated expreſſes to Juba to haſten to his aſſiſtance; but could not prevail upon him to move out of Numidia, till he had promiſed him the poſſeſſion of all the Roman dominions in Africa, if they could from thence expel Cæſar. This immediately put him in motion; ſo that, having ſent a large detachment to make head againſt Sittius, he marched with the reſt of his troops to aſſiſt Scipio. However, Cæſar at laſt overthrew Scipio, Juba, and Labienus, near the town of Thapſus, and forced all their camps. As Scipio was the firſt ſurpriſed and defeated, Juba fled into Numidia, without waiting for Cæſar's approach; but the body of the Numidians detached againſt Sittius, having been broken and diſperſed by that general, none of his ſubjects there would receive him. Abandoned therefore to deſpair, he ſought death in a ſingle combat with Petreius, and, having killed him, cauſed himſelf to be diſpatched by one of his ſlaves.

24 Numidia reduced to the form of a province.

After this deciſive action, and the reduction of Africa Propria, Cæſar made himſelf maſter of Numidia, which he reduced to a Roman province, appointing Criſpus Salluſtius to govern it in quality of proconſul, with private inſtructions to pillage and plunder the inhabitants, and, by that means, put it out of their power ever to ſhake off the Roman yoke. However, Bocchus and Bogud ſtill preſerved a ſort of ſovereignty in the country of the Maſſæſyli and Mauritania, ſince the former of thoſe princes, having deſerted Cæſar, ſent an army into Spain to aſſiſt the Pompeians; and the latter, with his forces, determined victory to declare for Cæſar at the ever memorable battle of Munda. Bogud, afterwards ſiding with Anthony againſt Octavius, ſent a body of forces to aſſiſt him in Spain; at which time the Tingitanians revolting from him, Bocchus, with an army compoſed of Romans in the intereſt of Octavius, who paſſed over from Spain into Africa, and his own ſubjects, poſſeſſed himſelf of Mauritania Tingitana. Bogud fled to Antony; and Octavius, after the concluſion of the war, honoured the inhabitants of Tingi with all the privileges of Roman citizens. He likewiſe confirmed Bocchus king of Mauritania Cæſarienſis, or the country of the Maſſæſyli, in the poſſeſſion of Tingitania, which he had conquered, as a reward for his important ſervices. In this he imitated the example of his great predeceſſor Julius Cæſar, who divided ſome of the fruitful plains of Numidia among the ſoldiers of P. Sittius, who had conquered great part of that country, and appointed Sittius himſelf ſovereign of that diſtrict. Sittius, as has been intimated above, having taken Cirta, killed Sabura Juba's general, entirely diſperſed his forces, and either cut off or taken priſoners moſt of the Pompeian fugitives that eſcaped from the battle of Thapſus, highly deſerved to be diſtinguiſhed in ſo eminent a manner. After Bocchus's death, Mauritania and the Maſſæſylian Numidia were, in all reſpects, conſidered as Roman provinces.

NUMISMATOGRAPHIA, a term uſed for the deſcription and knowledge of ancient coins and medals, whether of gold, ſilver, or braſs. See Coins and Medals.

NUMITOR, the ſon of Procas king of Alba, and the brother of Amulius. Procas dying made him and Amulius joint heirs to the crown, on condition of their reigning annually by turns: but Amulius, on getting poſſeſſion of the throne, excluded Numitor, whoſe ſon Lauſus he ordered to be put to death, and obliged Rhea Sylvia, Numitor's only daughter, to become a veſtal. This princeſs becoming pregnant, declared that ſhe was with child by the god Mars; and afterwards brought forth Rhemus and Romulus, who at length killed Amulius, and reſtored Numitor to the throne, 754 B. C.

NUMMUS, a piece of money otherwiſe called *ſeſtertius*.

NUN, a woman, in ſeveral Chriſtian countries, who devotes herſelf, in a cloiſter or nunnery, to a religious life. See the article Monk.

There were women, in the ancient Chriſtian church, who made public profeſſion of virginity, before the monaſtic life was known in the world, as appears from the writings of Cyprian and Tertullian. Theſe, for diſtinction's ſake, are ſometimes called *eccleſiaſtical virgins*, and were commonly enrolled in the canon or matricula of the church. They differed from the monaſtic virgin chiefly in this, that they lived privately in their fathers houſes, whereas the others lived in communities: but their profeſſion of virginity was not ſo ſtrict as to make it criminal in them to marry afterwards, if they thought fit. As to the conſecration of virgins, it had ſome things peculiar in it: it was uſually performed publicly in the church by the biſhop. The virgin made a public profeſſion of her reſolution, and then the biſhop put upon her the accuſtomed habit of ſacred virgins. One part of this habit was a veil, called the *ſacrum velamen;* another was a kind of mitre or coronet worn upon the head. At preſent, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and ſhe herſelf, accompained by her neareſt relations, is conducted to the biſhop, who, after maſs and an anthem, the ſubject of which is, "that ſhe ought to have her lamp lighted, becauſe the bridegroom is coming to meet her, pronounces the benediction: then ſhe riſes up, and the biſhop conſecrates the new habit, ſprinkling it with holy-water. When the candidate has put on her religious habit, ſhe preſents herſelf before the biſhop, and ſings, on her knees, *Ancilla Chriſti ſum*, &c.; then ſhe receives the veil, and afterwards the ring,

by

by which ſhe is married to Chriſt; and laſtly, the crown of virginity. When ſhe is crowned, an anathema is denounced againſt all who ſhall attempt to make her break her vows.

NUNCIO, or Nuntio, an ambaſſador from the pope to ſome Catholic prince or ſtate, or a perſon who attends on the pope's behalf at a congreſs, or an aſſembly of ſeveral ambaſſadors.

NUNCUPATIVE, in the ſchools, ſomething that is only nominal, or has no exiſtence but in name.

Nuncupative *Will* or *Teſtament*, a will made verbally, and not put in writing. See the articles Will and Testament.

NUNDINA, a godeſs among the ancient Heathens, ſuppoſed to have the care of the purification of infants. And becauſe male-infants were purified nine days after their birth, her name is derived from nonus, or the ninth, though female-infants were purified the eighth day; which purification was called *luſtration* by the Romans.

NUNDINAL, (nundinalis,) a name which the Romans gave to the eight firſt letters of the alphabet, uſed in their kalendar.

This ſeries of letters, A, B, C, D, E, F, G, H, is placed and repeated ſucceſſively from the firſt to the laſt day of the year: one of theſe always expreſſed the market-days, or the aſſemblies called *nundinæ*, *quaſi novendinæ*, becauſe they returned every nine days. The country people, after working eight days ſucceſſively, came to town the ninth, to ſell their ſeveral commodities, and to inform themſelves of what related to religion and goverment. Thus the nundinal day being under A on the firſt, ninth, ſeventeenth, and twenty-fifth days of January, &c. the letter D will be the nundinal letter of the year following. Theſe nundinals bear a very great reſemblance to the dominical letters, which return every eight days, as the nundinals did every nine.

NUPTIAL rites, the ceremonies attending the ſolemnization of marriage, which are different in different ages and countries.

NUREMBERG, an imperial city of Germany, capital of a teritory of the ſame name, ſituated in E. Long. 11°, N. Lat. 49. 30. It ſtands on the Regnitz, over which it has ſeveral bridges, both of wood and ſtone, at the bottom of a hill, 60 miles from Augſburg, 87 from Munich, 46 from Wurtzburg, and 50 from Ratiſbon; and is thought by ſome to be the Segodunum, and by others the Caſtrum Noricum, of the ancients. It is large and well built, but not very populous. Its fortifications are a double wall, flanked with towers mounting cannon, and a deep ditch. The magiſtrates, and moſt of the inhabitants, are Lutherans. There are a great many churches and chapels in it. In that of St Sebald is a braſs monument of the ſaint; and a picture, repreſenting the creation of the world, by the celebrated Albert Durer, who was a native of the town; but the fineſt church in the town is that of St Giles. In that of the Holy Ghoſt are kept moſt of the jewels of the empire, together with the pretended ſpear with which our Saviour's ſide was pierced, a thorn of his crown, and a piece of the manger wherein he was laid. Here are alſo a great many hoſpitals, one in particular for foundlings, and another for pilgrims; with a

gymnaſium, an anatomical theatre, a granary, a fine public library, the old imperial fortreſs or caſtle, ſome remains of the old citadel of the burgraves of Nuremberg, ſeveral Latin ſchools, an academy of painting, a well furniſhed arſenal, a teutonic houſe in which the Roman-catholic ſervice is tolerated, and a mint. Mr Keyſler ſays, there are upwards of 500 ſtreets in it, about 140 fountains, 16 churches, 44 religious houſes, 12 bridges, 10 market-places, and 25000 inhabitants; and that its territories, beſides the capital and four other towns, contains above 500 villages, and about 160 mills on the Regnitz. The trade of this city, though upon the decline, is ſtill very great, many of its manufactures being ſtill exported to all parts of the world; among which may be reckoned a great variety of curious toys in ivory, wood, and metal. The city has alſo diſtinguiſhed itſelf in the arts of painting and engraving. When the emperor Henry VI. aſſiſted at a tournament in Nuremberg, he raiſed 38 burghers to the degree of nobility, the deſcendants of whom are called *patricians*, and have the government of the city entirely in their hands; the whole council, except eight maſters of companies, who are ſummoned only on extraordinary occcaſions, conſiſting of them. Among the fine braſs cannon in the arſenal, is one that is charged at the breech, and may be fired eight times in a minute; and two that carry balls of eighty pounds. The city keeps, in conſtant pay, ſeven companies, conſiſting each, in time of peace, of 100 men, but, in time of war, of 185; two troops of cuiraſſiers, each conſiſting of 85 men; and two companies of invalids. There are alſo 24 companies of burghers, well armed and diſciplined. On the new bridge, which is ſaid to have coſt 100,000 guilders, are two pyramids, on the top of one of which is a dove with an olive branch in her bill, and on the other an imperial black eagle. Muſic alſo flouriſhes greatly in Nuremberg; and thoſe who delight in mechanic arts and manufactures, cannot any where better gratify their curioſity. As an imperial city, it has a ſeat and voice at the diets of the empire and circle, paying to a Roman month one ſeventh part of the common impoſts of the circle, and to the chamber of Wetzlar 812 rix-dollars, each term. The territory belonging to the city is pretty large, containing, beſides two conſiderable foreſts of pine, called the *Sibald* and *Laurence foreſts*, ſeveral towns and villages.

NURSERY, in gardening, is a piece of land ſet apart for raiſing and propagating all ſorts of trees and plants to ſupply the garden and other plantations.

NURSING of children. See Lactatio.

The following obſervations are ſaid to be the reſult of long experience. A child, when it comes into the world, is almoſt a round ball; it is the nurſe's part to aſſiſt nature, in bringing it to a proper ſhape. The child ſhould be laid (the firſt month) upon a thin matraſs, rather longer than the child, which the nurſe will keep upon her lap, that the child may always lie ſtraight, and only ſit up as the nurſe ſlants the matraſs. To ſet a child quite upright before the end of the firſt month, hurts the eyes, by making the white part of the eye appear below the upper eye-lid. Afterwards the nurſe will begin to ſet it up and dance it

An. Reg. vol. vi. p. 130.

Nurfing. it by degrees. The child muft be kept as dry as poffible.

The cloathing fhould be very light, and not much longer than the child, that the legs may be got at with eafe, in order to have them often rubbed in the day with a warm hand or flannel, and in particular the infide of them.

Rubbing a child all over takes off fcurf, and makes the blood circulate. The breaft fhould be rubbed with the hands, one one way, and the other the other way, night and morning at leaft.

The ankle-bones and infide of the knees fhould be rubbed twice a-day; this will ftrengthen thofe parts, and make the child ftretch its knees and keep them flat, which is the foundation of an erect and graceful perfon.

A nurfe ought to keep a child as little in her arms as poffible, left the legs fhould be cramped, and the toes turned inwards. Let her always keep the child's legs loofe. The oftener the pofture is changed, the better.

Toffing a child about, and exercifing it in the open air in fine weather, is of the greateft fervice. In cities, children are not to be kept in hot rooms, but to have as much air as poffible.

Want of exercife is the caufe of large heads, weak and knotted joints, a contracted breaft, which occafions coughs and ftuffed lungs, an ill-fhaped perfon, and waddling gait, befides a numerous train of other ills.

The child's flefh is to be kept perfectly clean, by conftantly wafhing its limbs, and likewife its neck and ears; beginning with warm water, till by degrees it will not only bear, but like, to be wafhed with cold.

Rifing early in the morning is good for all children, provided they awake of themfelves, which they generally do; but they are never to be waked out of their fleep, and as foon as poffible to be brought to regular fleeps in the day.

When laid in bed or cradle, their legs are always to be laid ftraight.

Children, till they are two or three years old, they muft never be fuffered to walk long enough at a time to be weary.

Girls might be trained to the proper management of children, if a premium were given in free-fchools, workhoufes, &c. to thofe that brought up the fineft child to one year old.

If the mother cannot fuckle the child, get a wholefome cheerful woman, with a young milk, who has been ufed to tend young children. After the firft fix months, fmall broths, and innocent foods of any kind, may do as well as living wholly upon milk.

A principal thing to be always attended to is, to give young children conftant exercife, and to keep them in a proper pofture.

With regard to the child's drefs in the day, let it be a fhirt; a petticoat of fine flannel, two or three inches longer than the child's feet, with a dimitytop (commonly called a *bodice-coat)*, to tie behind; over that a furcingle made of fine buckram, two inches broad, covered over with fattin or fine ticken, with a ribbon faftened to it to tie it on, which anfwers every purpofe of ftays, and has none of their inconveniences. Over this put a robe, or a flip and frock, or whatever you like beft; provided it is faftened behind, and not much longer than the child's feet, that their motions may be ftrictly obferved.

Nufance ‖ Nutmeg.

Two caps are to be put on the head, till the child has got moft of its teeth.

The child's drefs for the night may be a fhirt, a blanket to tie on, and a thin gown to tie over the blanket.

NUSANCE, in law, a thing done to the annoyance of another.

Nufances are either public or private.—A public nufance is an offence againft the public in general, either by doing what tends to the annoyance of all the king's fubjects, or by neglecting to do what the common good requires: in which cafe, all annoyances and injuries to ftreets, highways, bridges, and large rivers, as alfo diforderly ale-houfes, bawdy-houfes, gaming-houfes, ftages for rope-dancers, &c. are held to be common nufances.—A private nufance is, when only one perfon or family is annoyed by the doing of any thing; as where a perfon ftops up the light of another's houfe, or builds in fuch a manner that the rain falls from his houfe upon his neighbour's.

NUT, among botanifts, denotes a PERICARPIUM of an extraordinary hardnefs, inclofing a kernel or feed.

NUTATION, in aftronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former pofition.

NUT-HATCH, in ornithology. See SITTA.

NUTMEG, the kernel of a large fruit, not unlike the peach.

The nutmeg, as we receive it, is of a roundifh or oval figure, of a tolerably compact and firm texture, but eafily cut with a knife, and falling to pieces on a fmart blow. Its furface is not fmooth, but furrowed with a number of wrinkles, running in various directions, though principally longitudinally. It is of a greyifh-brown colour on the outfide, and of a beautiful variegated hue within, being marbled with brown and yellow variegations, running in perfect irregularity through its whole fubftance. It is very unctuous and fatty to the touch, when powdered; and is of an extremely agreeable fmell, and of an aromatic tafte.

There are two kinds of nutmeg in the fhops; the one called by authors the *male*, and the other the *female*. The female is the kind in common ufe, and is of the fhape of an olive: the male is long and cylindric, and has lefs of the fine aromatic flavour than the other; fo that it is much lefs efteemed, and people who trade largely in nutmegs will feldom buy it. The *longer male nutmeg*, as we term it, is called by the Dutch the *wild nutmeg*. It is always diftinguifhable from the others, as well by its want of fragrancy, as by its fhape: it is very fubject to be worm-eaten; and is ftrictly forbid, by the Dutch, to be packed up among the other, becaufe it will give occafion to their being worm-eaten too, by the infects getting from it into them, and breeding in all parts of the parcel.

The largeft, heavieft, and moft unctuous of the nutmegs are to be chofen, fuch as are of the fhape of an an olive, and of the moft fragrant fmell. The Dutch import them from the Eaft-Indies.

The tree which produces the nutmeg grows only in the Banda iflands. It has a pithy wood, an afh-coloured bark, and flexible branches. The leaves are produced in pairs upon one fingle ftem; and, when bruifed, emit an agreeable odour. The fruit fucceeds the flowers, which refemble thofe of the cherry-tree. It is of the fize of an egg, and of the colour of an apricot. The outer rind is very thick, and refembles that of our nuts as they hang upon the tree, opening in the fame manner when ripe, and difcovering the nutmeg covered with its mace. It is then time to gather it, to prevent the mace or flower of the nutmeg from growing dry, and the nutmeg from lofing that oil which preferves it, and in which its excellence confifts. Thofe that are gathered before they are perfectly ripe, are preferved in vinegar or fugar, and admired only in Afia.

This fruit requires nine months to bring it to perfection. After it is gathered, the outer rind is ftripped off, and the mace feparated from it, and laid in the fun to dry. The nuts require more preparation.—They are fpread upon hurdles, and dried for fix weeks by a flow fire, in fheds erected for that purpofe. They are then feparated from the fhell, and thrown into lime-water, as a neceffary prefervative againft worms.

Nutmeg is greatly ufed in our foods, and is of excellent virtue as a medicine; it is a good ftomachic, promotes digeftion, and ftrengthens the ftomach. It alfo ftops vomiting; is an excellent remedy in flatufes; and is happily joined with rhubarb, and other medicines, in diarrhœas. It is obferved to have a foporific virtue, and to exert it too ftrongly if taken in immoderate quantities. It has a confiderable degree of aftringency; and given, after toafting before the fire till thoroughly dry and crumbly, it has been fometimes known alone to cure diarrhœas.

NUTRITION, in the animal-œconomy, is the repairing the continual lofs which the different parts of the body undergo. The motion of the parts of the body, the friction of thefe parts with each other, and efpecially the action of the air, would deftroy the body entirely, if the lofs was not repaired by a proper diet, containing nutritive juices; which being digefted in the ftomach, and afterwards converted into chyle, mix with the blood, and are diftributed through the whole body for its nutrition.

In young perfons, the nutritive juices not only ferve to repair the parts that are damaged, but alfo to increafe them, which is called *growth*.

In grown perfons, the cuticle is every-where conftantly defquamating, and again renewing: and in the fame manner the parts rubbed off, or otherwife feparated from the flefhy parts of the body, are foon fupplied with new flefh; a wound heals, and an emaciated perfon grows plump and fat.

Buffon, in order to account for nutrition, fuppofes the body of an animal or vegetable to be a kind of mould, in which the matter neceffary to its nutrition is modelled and affimilated to the whole. But (continues he) of what nature is this matter which an animal or vegetable affimilates to its own fubftance? What power is it that communicates to this matter the activity and motion neceffary to penetrate this mould? and, if fuch a force exift, would it not be by a fimilar force that the internal mould itfelf might be reproduced?

As to the firft queftion, he fuppofes that there exifts in nature an infinite number of living organical parts, and that all organized bodies confift of fuch organical parts; that their production cofts nature nothing, fince their exiftence is conftant and invariable; fo that the matter which the animal or vegetable affimilates to its fubftance, is an organical matter, of the fame nature with that of the animal or vegetable, which confequently may augment its volume without changing its form or altering the quality of the fubftance in the mould.

As to the fecond queftion: There exift (fays he) in nature certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the moft intimate parts, and penetrate them throughout, and which can never fall under the obfervation of our fenfes.

And, as to the third queftion, he anfwers, that the internal mould itfelf is reproduced, not only by a fimilar power, but it is plain that it is the very fame power that caufes the unfolding and reproduction thereof: for it is fufficient (proceeds he), that in an organized body that unfolds itfelf, there be fome part fimilar to the whole, in order that this part may one day become itfelf an organized body, altogether like that of which it is actually a part.

NUX PISTACHIA. See PISTACHIA.

NUX *Vomica*, a flat, compreffed, round fruit, about the breadth of a fhilling, brought from the Eaft Indies. It is found to be a certain poifon for dogs, cats, &c. and it is not to be doubted that it would alfo prove fatal to mankind. Its furface is not much corrugated; and its texture is firm like horn, and of a pale greyifh-brown colour.

NYCHTHEMERON, the natural day, or day and night, which together make 24 hours.

NYCTALOPIA. See MEDICINE, n° 456.

NYCTANTHES, ARABIAN JASMINE; a genus of the monogynia order, belonging to the diandria clafs of plants. There are five fpecies; the moft remarkable of which are, 1. The arbor triftis, or forrowful tree. This tree, or fhrub, the *pariatacu* of the Bramins, grows naturally in fandy places in India, particularly in the iflands of Ceylon and Java, where it is produced in great abundance, and attains the height of 18 or 20 feet. It rifes with a four-cornered ftem, bearing leaves that are oval, and taper to a point. They ftand oppofite, on fhort foot-ftalks; are of a fhining brownifh-green on the upper-fide, a more vivid green on the under, and of a tafte that is aftringent and fomewhat bitter. From the middle-rib, on the under-furface of the leaves, proceed on both fides a number of coftulæ, or fmaller ribs, which run nearly to the margin, and mark the furface with the impreffion of their arched furrows. The flowers, which are white, and highly odoriferous, having a fweet delectable fmell emulating the beft honey, confift of one petal deeply divided into eight parts, which are narrower towards the ftalk, and dilated towards the fummit. They ftand upon foot-ftalks, which emerge from the origin of the leaves; are rigid, obliquely

raifed

raifed towards the top, grow oppofite in pairs, and are divided into three fhort leffer branches, which each fupports five flowers placed clofe together, without partial foot-ftalks. The fruit is dry, capfular, membranaceous, and compreffed.

It is generally afferted of this plant, that the flowers open in the evening, and fall off the fucceeding day. Fabricius and Paludanus, however, reftrict the affertion, by affirming, from actual obfervation, that this effect is found to take place only in fuch flowers as are immediately under the influence of the folar rays. Grimmius remarks in his *Laboratorium Ceylonicum*, that the flowers of this tree afford a fragrant water, which is cordial, refrefhing, and frequently employed with fuccefs in inflammations of the eyes. The tube of the flower, when dried, has the fmell of faffron; and, being pounded and mixed with fanders-wood, is ufed by the natives of the Malabar coaft for imparting a grateful fragrancy to their bodies, which they rub or anoint with the mixture.

2. The fambac, noted, like the other fpecies, for the fragrancy of its flowers, is a native likewife of India; and is cultivated in our ftoves, where it generally rifes with a twining ftem, to the height of 18 or 20 feet. The leaves are oppofite, fimple, and entire; but in different parts of the plant affume different forms: the lower leaves being heart-fhaped and blunt; the upper, oval and fharp. The flowers are white, inexpreffibly fragrant, and generally appear with us in the warm fummer-months. Strong loam is its proper foil. There is a variety of this fpecies with a double flower, which is much larger and more fragrant than the former.

NYCTICORAX, in ornithology, the night-raven; a fpecies of ARDEA.

NYLAND, a province of Finland in Sweden, lying on the gulf of Finland, to the weft of the province of Carelia.

NYMPH, in mythology, an appellation given to certain inferior goddeffes, inhabiting the mountains, wood, waters, &c. faid to be the daughters of Oceanus and Tethys. All the univerfe was reprefented as full of thefe nymphs, who are diftinguifhed into feveral ranks or claffes. The general divifion of them is into celeftial and terreftrial; the former of which were called *uraniæ*, and were fuppofed to be intelligences that governed the heavenly bodies or fpheres. The terreftrial nymphs, called *epigeiæ*, prefided over the feveral parts of the inferior world; and were divided into thofe of the water, and thofe of the earth. The nymphs of the water were the *oceanitides*, or nymphs of the ocean; the *nereids*, the nymphs of the fea; the *naiads* and *ephydriades*, the nymphs of the fountains; and the *limniades*, or nymphs of the lakes. The nymphs of the earth were the *oreades*, or nymphs of the mountains; the *napææ*, nymphs of the meadows; and the *dryads* and *hamadryads*, who were nymphs of the forefts and groves. Befides thefe, we meet with nymphs who took their names from particular countries, rivers, &c. as the *cithæroniades*, fo called from mount Cithæron in Bœotia; the *dodonides*, from Dodona; *tiberiades*, from the Tiber, &c.—Goats were fometimes facrificed to the nymphs; but their conftant offerings were milk, oil, honey, and wine.

NYMPH, among naturalifts, that ftate of winged-infects between their living in the form of a worm, and their appearing in the winged or moft perfect ftate.

The eggs of infects are firft hatched into a kind of worms, or maggots; which afterwards pafs into the nymph-ftate, furrounded with fhells or cafes of their own fkins: fo that, in reality, thefe nymphs are only the embryo infects, wrapped up in this covering; from whence they at laft get loofe, though not without great difficulty.

During this nymph-ftate the creature lofes its motion. Swammerdam calls it *nympha aurelia*, or fimply *aurelia;* and others give it the name of *chryfalis*, a term of the like import. See the article CHRYSALIS.

NYMPHÆ, in anatomy, two membranaceous parts, fituated on each fide the rima. They are of a red colour, and cavernous ftructure, fomewhat refembling the wattles under a cock's throat. They are fometimes fmaller, fometimes larger; and are continuous to the præputium of the clitoris, and joined to the interior fide of the labia.

NYMPHÆA, the WATER-LILY; a genus of the monogynia order, belonging to the polyandria clafs of plants. There are four fpecies; of which the moft remarkable are, 1, 2. The lutea and alba, or yellow and white water-lilies; both of which are natives of Britain, growing in lakes and ditches. Linnæus tells us, that fwine are fond of the leaves and roots of the former; and that the fmoke of it will drive away crickets and blattæ, or cock-roaches, out of houfes.—The root of the fecond has an aftringent and bitter tafte, like thofe of moft aquatic plants that run deep into the mud. The Highlanders make a dye with it of a dark cheftnut colour. 3. In the Eaft and Weft Indies grows a fpecies of this plant, named *nelumbo* by the inhabitants of Ceylon. The leaves which reft upon the furface of the water, are fmooth, undivided, perfectly round, thick, target-fhaped, and about one foot and a half in diameter. The footftalk of the leaves is prickly; and inferted, not into their bafe, or margin, as in moft plants, but in the centre of the lower difk or furface. From this centre, upon the upper furface, iffue, like rays, a great number of large ribs, or nerves, which towards the circumference are divided and fubdivided into a fmall number of very minute parts. The flowers are large, flefh-coloured, and confift of numerous petals, difpofed, as in the other fpecies of water-lily, in two or more rows. The feed-veffel is fhaped like a top, being broad and circular above, narrow and almoft pointed below. It is divided into feveral diftinct cells, which form fo many large round holes upon the furface of the fruit; each containing a fingle feed.—With the flower of this plant, which is facred among the heathens, they adorn the altars of their temples: they paint their gods fitting upon it; and make ufe of fuch pictures to animate the minds of the pious on their death-bed, and to raife their affections to heaven. The ftalks, which are ufed as a pot-herb, are of a wonderful length. The root is very long, extends itfelf tranfverfely, is of the thicknefs of a man's arm, jointed and fibrous, with long intervals betwixt the joints. The fibres furround the joints in verticilli, or whirls.

NYMPHEUM, in antiquity, a public hall magnificently decorated, for entertainment, &c. and where thofe who wanted convenience at home held their marriageriage-feasts, whence the name.

NYON, a considerable town of Switzerland, in the canton of Bern, and capital of a bailiwick of the same name, with a castle. There are a great many Roman inscriptions here; and it is a trading place, seated in a good country, near the lake of Geneva. E. Long. 5. 10. N. Lat. 46. 24.

NYSLOT, a strong town of Russia, in Livonia, with a castle; seated on the river Narva, among large marshes. E. Long. 26. 55. N. Lat. 58. 46.

NYSSA, a genus of the order of dioecia, belonging to the polygamia class of plants. There is but one species, *viz.* The aquatica, or water-tupelo-tree. This has a large trunk, especially near the ground, and grows very tall. The leaves are broad, and irregularly notched. The flowers come out from the sides of the branches, on footstalks of three inches long, and are of a greenish colour. The grain of the wood is soft and spongy; but the roots much more so, approaching near to the consistence of cork; and are used for the purposes of cork in Carolina, where these trees are natives. They grow in wet places, and usually in the shallow parts of rivers.

O

O, The 14th letter and fourth vowel of our alphabet; pronounced as in the words *nose*, *rose*, &c.

The sound of this letter is often so soft as to require it double, and that chiefly in the middle of words; as *goose*, *reproof*, &c. And in some words this *oo* is pronounced like *u* short, as in *flood*, *blood*, &c.

As a numeral, O is sometimes is used for 11; and with a dash over it thus, $\bar{O}$, for 11,000.

In the notes of the ancients, O. CON. is read *opus conductum;* O. C. Q. *opera consilioque;* O. D. M. *operæ, donum, munus;* and O. LO. *opus locatum.*

In music, the O, or rather a circle, or double CO, is a note of time, called by us a *semi-breve;* and by the Italians, *circolo.* The O is also used as a mark of triple time, as being the most perfect of all figures. See Triple.

OAK, in botany. See Quercus.

Oak-*Leaves.* The uses of oak-bark in tanning, and in hot-beds, is generally known. For the latter of these purposes, however, oak-leaves are now found to answer equally well, or rather better. In the notes to Dr Hunter's edition to Evelyn's Treatise on Forest-trees, we find the following directions for their use by W. Speechly. The leaves are to be raked up as soon as possible after they fall from the trees. When raked into heaps, they should immediately be carried into some place near the hot-houses, where they may lie to couch. Mr Speechly says it was his custom to fence them round with charcoal hurdles, or any thing else, to keep them from being blown about the garden in windy weather. In this place they tread them well, and water them in case they happen to have been brought in dry. The heap is made six or seven feet thick, and covered over with old mats, or any thing else, to prevent the upper leaves from being blown away. In a few days the heap will come to a strong heat. For the first year or two in which he used these leaves, our author did not continue them in the heap longer than ten days or a fortnight: but by this method of management they settled so much when brought to the hot-house, that a supply was very soon required; and he afterwards found, that it was proper to let them remain five or six weeks in the heaps before they are brought to the hot-house. In getting them into the pine-pits, if they appear dry, they are to be watered, and again trodden down exceedingly well, in layers, till the pits are quite full. The whole is then covered with tan-bark, to the thickness of two inches, and well trodden down, till the surface becomes smooth and even. On this the pine-pots are to be placed in the manner they are to stand, beginning with the middle row first, and filling up the spaces between the pots with tan. In this manner we are to proceed to the next row, till the whole be finished; and this operation is performed in the same manner as when tan only is used. The leaves require no further trouble through the whole season; as they will retain a constant and regular heat for 12 months without stirring or turning; and our author informs us, that if he may judge from their appearance when taken out, (being always entire and perfect), it is probable they would continue their heat through a second year; but, as an annual supply of leaves is easily obtained, the experiment is hardly worth making. After this, the pines will have no occasion to be moved, but at stated times of their management, *viz.* at the shifting them in their pots, &c. when at each time a little fresh tan should be added to make up the deficiency arising from the settling of the beds; but this will be inconsiderable, as the leaves do not settle much after their long couching. During the first two years of our author's practice he did not use any tan, but plunged the pine-pots into the leaves, and just covered the surface of the beds, when finished, with a little saw-dust, to give it a neatness. This method, however, was attended with one inconvenience; for by the caking of the leaves they shrunk from the sides of the pots, whereby they became exposed to the air, and at the same time the heat of the beds was permitted to escape.

"Many powerful reasons, says Mr Speechly, may be given why oak-leaves are preferable to tanner's-bark.

"1. They always heat regularly; for during the whole time that I have used them, which is near seven years, I never once knew of their heating with violence; and this is so frequently the case with tan, that I affirm, and indeed it is well known to every person conversant in the management of the hot-house, that pines suffer more from this one circumstance, than all the other accidents put together, insects excepted.

When

When this accident happens near the time of their fruiting, the effect is soon seen in the fruit, which is exceedingly small and ill-shaped. Sometimes there will be little or no fruit at all; therefore gardeners who make use of tan only for their pines, should be most particularly careful to avoid an over-heat at that critical juncture,—the time of shewing the fruit.

"2. The heat of oak-leaves is constant; whereas tanner's bark generally turns cold in a very short time after its furious heat is gone off. This obliges the gardener to give it frequent turnings in order to promote its heating. These frequent turnings, not to mention the expence, are attended with the worst consequences; for by the continual moving of the pots backwards and forwards, the pines are exposed to the extremes of heat and cold, whereby their growth is considerably retarded; whereas, when leaves are used, the pines will have no occasion to be moved but at the times of potting, &c. The pines have one peculiar advantage in this undisturbed situation; their roots grow through the bottoms of the pots, and mat among the leaves in a surprising manner. From the vigour of the plants when in this situation, it is highly probable that the leaves, even in this state, afford them an uncommon and agreeable nourishment.

"3. There is a saving in point of expence; which is no inconsiderable object in places where tan cannot be had but from a great distance.

"4. The last ground of preference is, that decayed leaves make good manure; whereas rotten tan is experimentally found to be of no value. I have often tried it both on sand and clay, and on wet and dry land; and never could discover, in any of my experiments, that it deserved the name of a manure; whereas decayed leaves are the richest, and of all others the most proper manure for a garden. Leaves mixed with dung make excellent hot-beds; and I find that beds compounded in this manner, preserve their heat much longer than when made entirely with dung; and in both cases, the application of leaves will be a considerable saving of dung, which is a circumstance on many accounts agreeable."

Oak *Saw-dust* is now found to answer the purposes of tanning as well, at least, as the bark. See Tanning.

Oak *of Jerusalem*. See Chenopodium.

OAKAM, old ropes untwisted and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a town of Devonshire, which sends two members to parliament; situated in E. Long. 1. 47. N. Lat. 45. 4.

OAR, a long piece of timber, flat at one end, and round or square at the other, and which being applied to the side of a floating-vessel, serves to make it advance upon the water.

That part of the oar which is out of the vessel, and which enters into the water, is called the *blade*, or *wash*, *plat;* and that which is within-board is termed the *loom*, whose extremity being small enough to be grasped by the rowers, or persons managing the oars, is called the *handle*.

To push the boat or vessel forwards by means of this instrument, the rowers turn their backs forward, and, dipping the blade of the oar in the water, pull the handle forward so that the blade at the same time may move aft in the water: but since the blade cannot be so moved, without striking the water, this impulsion is the same, as if the water were to strike the blade from the stern towards the head: the vessel is therefore necessarily moved according to this direction. Hence it follows, that she will advance with the greater rapidity, by as much as the oar strikes the water more forcibly. Thus it is evident, that an oar acts upon the side of a boat or vessel like a lever of the second class, whose fulcrum is the station upon which the oar rests on the boat's gunnel. In large vessels, this station is usually called the *row-port;* but in lights and boats it is always termed the *row lock*.

OAT, in botany. See Avena.

OATH, is a solemn affirmation, in which the persons sworn invoke the Almighty to witness that their testimony is true; renouncing all claim to his mercy, and calling for vengeance, if it be false.

Coronation-Oath. See King.

OBADIAH, or the *Prophecy of* Obadiah, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Ebonites, who mocked and derided the children of Israel, as they passed into captivity, and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil amongst themselves; and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

OBELISK, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

Obelisks appear to be of very great antiquity, and to be first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Ramases king of Egypt, in the time of the Trojan war, which was 40 cubits high. Phius, another king of Egypt, raised one of 45 cubits: and Ptolemy Philadelphus, another of 88 cubits, in memory of Arsinoë. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on an horizontal dial, drawn on the pavement. They were called by the Egyptian priests the *fingers of the sun*, because they were made in Egypt also to serve as styles or gnomons to mark the hours on the ground. The Arabs still call them *Pharaoh's needles:* whence the Italians call them *aguglia*, and the French *aiguilles*.

OBJECT, in philosophy, something apprehended or presented to the mind by sensation or imagination. See Metaphysics.

Object-*Glass of a Telescope*, or *Microscope*, the glass placed at the end of the tube which is next the object. See Optics.

OBJECTION, something urged to overthrow a position, or a difficulty raised against an allegation or proposition of a person we are disputing withal.

OBJECTIVE, is used in the schools, in speaking of a thing which exists no otherwise than as an object known.

N.° 2.

A. Bell Sculp.t

known. The exiftence of fuch a thing is faid to be objective.

OBIT, (Lat.) fignifies a funeral folemnity, or office for the dead, moft commonly performed when the corpfe lies in the church uninterred: Alfo the anniverfary office, (2 Cro. 51 Dyer 313). The anniverfary of any perfon's death was called the *obit;* and to obferve fuch day with prayers and alms, or other commemoration, was the keeping of the obit. In religious houfes they had a regifter, wherein they entered the obits or obitual days of their founders and benefactors; which was thence termed the *obituary.* The tenure of obit or chantry lands is taken away and extinct by 1 Edw. VI. c. 14. and 15 Car. II. c. 9.

OBLATI, in church-hiftory, were fecular perfons, who devoted themfelves and their eftates to fome monaftery, into which they were admitted as a kind of lay-brothers. The form of their admiffion, was putting the bell-ropes of the church round their necks, as a mark of fervitude. They wore a religious habit, but different from that of the monks.

OBLIGATION, in general, denotes any act whereby a perfon becomes bound to another to do fomething; as to pay a fum of money, be furety, or the like.

Obligations are of three kinds, *viz.* natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligation, on civil authority alone, without any foundation in natural equity; and mixed obligations are thofe which, being founded on natural equity, are farther enforced by a civil authority.

In a legal fenfe, obligation fignifies a bond, wherein is contained a penalty, with a condition annexed for the payment of money, &c. The difference between it and a bill is, that the latter is generally without a penalty or condition, though it may be made obligatory: and obligations are fometimes by matter of record, as ftatutes and recognizances. See the article Bond.

Moral Obligation. See Morals, n° 36—40.

OBLIQUE, in geometry, fomething aflant, or that deviates from the perpendicular. Thus an oblique angle, is either an acute or obtufe one, *i. e.* any angle except a right one.

Oblique *Cafes*, in grammar, are all the cafes except the nominative. See Case.

Oblique *Line*, that which, falling on another line, makes oblique angles with it, *viz.* one acute, and the other obtufe.

Oblique *Planes*, in dialling, are thofe which decline from the zenith, or incline towards the horizon. See Dial.

Oblique *Sailing*, in navigation, is when a fhip fails upon fome rhumb between the four cardinal points, making an oblique angle with the meridian; in which cafe, fhe continually changes both latitude and longitude. See Navigation, §. 6.

OBLIQUUS, in anatomy, a name given to feveral mufcles, particularly in the head, eyes, and abdomen. See Anatomy, *Table of the Mufcles*.

OBLONG, in general, denotes a figure that is longer than broad: fuch is a parallellogram, ellipfis, &c.

OBOLUS, an ancient filver money of Athens, the fixth part of a drachma; worth fomewhat more than penny-farthing Sterling.—The word comes from the Greek ὀβολὸς, of ὀβελὸς, "fpit, or broach;" either becaufe it bore fuch an impreffion; or becaufe, according to Euftachius, it was in form thereof. But thofe now in the cabinets of the antiquaries are round.

Obolus, in medicine, is ufed for a weight of ten grains, or half a fcruple.

OBRECHT (Ulric), a learned German, born of a noble family at Strafburg in 1646, where he filled the chairs of civil law and hiftory with great diftinction. He was of the Proteftant religion; but when Lewis XIV. made himfelf mafter of Strafburg, and went there with his court, he was prevailed on to change; and accordingly abjured in 1684, and put his inftrument into the hands of Boffuet bifhop of Meaux. The next year the king nominated him to prefide in his name in the fenate of Strafburg, with the title of prætor royal, in imitation of the ancient Romans; from which time Mr Obrecht applied himfelf entirely to public affiairs. He was the editor, tranflator, and writer, of feveral learned works; and died in 1701.

OBREPTITIOUS, an appellation given to letters patent, or other inftruments, obtained of a fuperior by furprife, or by concealing from him the truth.

OBSCURE, fomething that is dark and reflects little light, or that is not clear and intelligible.

OBSECRATION, in rhetoric, a figure whereby the orator implores the affiftance of God or man.

OBSEQUENS (Julius), a Latin writer, conjectured to have lived before the emperor Honorius's reign. He made a collection of the prodigies which Livy related in his hiftory. There are feveral editions of thofe remains. Lycofthenes endeavoured to fupply what was wanting in the original.

OBSEQUIES, the fame with funeral folemnities. See Funeral.

OBSERVATION, among navigators, fignifies the taking the fun's or the ftars meridian altitude, in order thereby to find the latitude.

OBSERVATORY, a place deftined for obferving the heavenly bodies; being generally a building erected on fome eminence, covered with a terrace for making aftronomical obfervations.

The more celebrated obfervatories are, 1. The Greenwich obfervatory, built in 1676, by order of Charles II. at the folicitation of Sir Jonas Moore and Sir Chriftopher Wren; and furnifhed with the moft accurate inftruments, particularly a noble fextant of feven feet radius, with telefcopic fights.

2. The Paris obfervatory, built by the order of Louis XIV. in the Fauxbourg, St Jaques.

It is a very fingular, but withal a very magnificent building, the defign of Monfieur Perault: it is eighty feet high; and at top is a terrace.

The difference in longitude between this and the Greenwich obfervatory is 2° 20′ weft.

In it is a cave, or cellar, of 170 feet defcent, for experiments that are to be made far from the fun, &c. particularly fuch as relate to congelations, refrigerations, indurations, confervations, &c.

3. Tycho Brahe's obfervatory, which was in the little ifland Ween, or Scarlet Ifland, between the coafts of Schonen and Zealand, in the Baltic. It was erected and furnifhed with inftruments at his own expence,

Obſervatory pence, and called by him *Uraniburg*. Here he ſpent twenty years in obſerving the ſtars; the reſult is his catalogue.

4. Pekin obſervatory. Father Le Compte deſcribes a very magnificent obſervatory, erected and furniſhed by the late emperor of China, in his capital, at the interceſſion of ſome Jeſuit miſſionaries, principally Father Verbeiſt, whom he made his chief obſerver.—The inſtruments are exceedingly large; but the diviſion leſs accurate, and the contrivance in ſome reſpects leſs commodious, than that of the Europeans. The chief are, An armillary zodiacal ſphere of ſix feet diameter; an equinoctial ſphere of ſix feet diameter; an azimuthal horizon of ſix feet diameter; a large quadrant ſix feet radius; a ſextant eight feet radius; and a celeſtial globe ſix feet diameter.

5. Bramins obſervatory at Benares. Of this Sir Robert Barker gives the following account, Phil. Tranſ. Vol. LXVII. p. 598. "Benares in the Eaſt Indies, one of the principal ſeminaries of the Bramins or prieſts of the original Gentoos of Hindoſtan, continues ſtill to be the place of reſort of that ſect of people; and there are many public charities, hoſpitals, and pagodas, where ſome thouſands of them now reſide. Having frequently heard that the ancient Bramins had a knowledge of aſtronomy, and being confirmed in this by their information of an approaching eclipſe both of the ſun and moon, I made inquiry, when at that place in the year 1772, among the principal Bramins, to endeavour to get ſome information relative to the manner in which they were acquanted of an approaching eclipſe. The moſt intelligent that I could meet with, however, gave me but little ſatisfaction. I was told, that theſe matters were confined to a few, who were in poſſeſſion of certain books and records; ſome containing the myſteries of their religion; and others the tables of aſtronomical obſervations, written in the Skanſkirrit language, which few underſtood but themſelves: that they would take me to a place which had been conſtructed for the purpoſe of making ſuch obſervations as I was inquiring after, and from whence they ſuppoſed the learned Bramins made theirs. I was then conducted to an ancient building of ſtone, the lower part of which, in its preſent ſituation, was converted into a ſtable for horſes, and a receptacle for lumber; but, by the number of court-yards and apartments, it appeared that it muſt once have been an edifice for the uſe of ſome public body of people. We entered this building, and went up a ſtair-caſe to the top of a part of it, near to the river Ganges, that led to a large terrace, where, to my ſurpriſe and ſatisfaction, I ſaw a number of inſtruments yet remaining, in the greateſt preſervation, ſtupendouſly large, immoveable from the ſpot, and built of ſtone, ſome of them being upwards of 20 feet in height; and, although they are ſaid to have been erected 200 years ago, the graduations and diviſions on the ſeveral arcs appeared as well cut, and as accurately divided, as if they had been the performance of a modern artiſt. The execution in the conſtruction of theſe inſtruments exhibited a mathematical exactneſs in the fixing, bearing, fitting of the ſeveral parts, in the neceſſary and ſufficient ſupports to the very large ſtones that compoſed them, and in the joining and faſtening each into the other by means of lead and iron.

"The ſituation of the two large quadrants of the inſtrument marked A in the plate, whoſe radius is nine feet two inches, by their being at right angles with a gnomon at twenty-five degrees elevation, are thrown into ſuch an oblique ſituation as to render them the moſt difficult, not only to conſtruct of ſuch a magnitude, but to ſecure in their poſition for ſo long a period, and affords a ſtriking inſtance of the ability of the architect in their conſtruction: for, by the ſhadow of the gnomon thrown on the quadrants, they do not appear to have altered in the leaſt from their original poſition; and ſo true is the line of the gnomon, that, by applying the eye to a ſmall iron ring of an inch diameter at one end, the ſight is carried through three others of the ſame dimenſion, to the extremity at the other end, diſtant 38 feet 8 inches, without obſtruction; ſuch is the firmneſs and art with which this inſtrument has been executed. This performance is the more wonderful and extraordinary when compared with the works of the artificers of Hindoſtan at this day, who are not under the immediate direction of an European mechanic; but arts appear to have declined equally with ſcience in the eaſt.

Obſervatory

Plate CCV.

"Lieutenant-colonel Archibald Campbell, at that time chief engineer in the Eaſt India Company's ſervice at Bengal, made a perſpective drawing of the whole of the apparatus that could be brought within his eye at one view; but I lament he could not repreſent ſome very large quadrants, whoſe radii were about twenty feet, they being on the ſide from whence he took his drawing. Their deſcription however is, that they are exact quarters of circles of different radii, the largeſt of which I judged to be 20 feet, conſtructed very exactly on the ſides of ſtone-walls built perpendicular, and ſituated, I ſuppoſe, in the meridian of the place: a braſs pin is fixed at the centre or angle of the quadrant, from whence, the Bramin informed me, they ſtretched a wire to the circumference when an obſervation was to be made; from which it occurred to me, the obſerver muſt have moved his eye up or down the circumference, by means of a ladder or ſome ſuch contrivance, to raiſe and lower himſelf, until he had diſcovered the altitude of any of the heavenly bodies in their paſſage over the meridian, ſo expreſſed on the arcs of theſe quadrants: theſe arcs were very exactly divided into nine large ſections; each of which again into ten, making ninety leſſer diviſions or degrees; and thoſe alſo into twenty, expreſſing three minutes each, of about two-tenths of an inch aſunder; ſo that it is probable, they had ſome method of dividing even theſe into more minute diviſions at the time of obſervation.

"My time would only permit me to take down the particular dimenſions of the moſt capital inſtrument, or the greater equinoctial ſun-dial, repreſented by figure A, which appears to be an inſtrument to expreſs ſolar time by the ſhadow of a gnomon upon two quadrants, one ſituated to the eaſt, and the other to the weſt of it; and indeed the chief part of their inſtruments at this place appear to be conſtructed for the ſame purpoſe, except the quadrants, and a braſs inſtrument that will be deſcribed hereafter.

"Figure B is another inſtrument for the purpoſe of determining the exact hour of the day by the ſhadow

Observatory Obsidianus.

dow of a gnomon, which ftands perpendicular to and in the centre of a flat circular ftone, fupported in an oblique fituation by means of four upright ftones and a crofs-piece; fo that the fhadow of the gnomon, which is a perpendicular iron rod, is thrown upon the divifion of the circle defcribed on the face of the flat circular ftone.

"Figure C is a brafs circle, about two feet diameter, moving vertically upon two pivots between two ftone pillars, having an index or hand turning round horizontally on the centre of this circle, which is divided into 360 parts; but there are no counter divifions on the index to fubdivide thofe on the circle. This inftrument appears to be made for taking the angle of a ftar at fetting or rifing, or for taking the azimuth or amplitude of the fun at rifing or fetting.

"The ufe of the inftrument, figure D, I was at a lofs to account for. It confifts of two circular walls; the outer of which is about forty feet diameter, and eight feet high; the wall within about half that height, and appears intended for a place to ftand on to obferve the divifions on the upper circle of the outer wall, rather than for any other purpofe; and yet both circles are divided into 360 degrees, each degree being fubdivided into twenty leffer divifions, the fame as the quadrants. There is a door-way to pafs into the inner circle, and a pillar in the centre, of the fame height with the lower circle, having a hole in it, being the centre of both circles, and feems to be a focket for an iron rod to be placed perpendicular into it. The divifions on thefe, as well as all the other inftruments, will bear a nice examination with a pair of compaffes.

"Figure E is a fmaller equinoctial fun-dial, conftructed upon the fame principle as the large one A.

"I cannot quit this fubject without obferving, that the Bramins, without the affiftance of optical glaffes, had neverthelefs an advantage unexperienced by the obfervers of the more northern climates. The ferenity and clearnefs of the atmofphere in the night-time in the Eaft Indies, except at the feafons of changing the monfoons or periodical winds, is difficult to exprefs to thofe who have not feen it, becaufe we have nothing in comparifon to form our ideas upon: it is clear to perfection, a total quietude fubfifts, fcarcely a cloud to be feen, and the light of the heavens, by the numerous appearance of the ftars, affords a profpect both of wonder and contemplation.

"This obfervatory at Benares is faid to have been built by the order of the emperor Ackbar: for as this wife prince endeavoured to improve the arts, fo he wifhed alfo to recover the fciences of Hindoftan, and therefore directed that three fuch places fhould be erected; one at Delhi, another at Agra, and the third at Benares."

Edinburgh OBSERVATORY. See EDINBURGH.

OBSIDIANUS LAPIS, in the natural hiftory of the ancients, the name of a ftone which they have alfo defcribed under the name of the *Chian marble*. It is a very fmooth and hard marble, extremely difficult to cut, but capable of a fine polifh; and was ufed among the ancient Greeks for the purpofe of making reflecting mirrors. The later writers have fuppofed the name *obfidianus* to be derived from fomebody called *Obfidius*, who was the inventor of this ufe of it; but it feems only a falfe fpelling of the word *opfianus*, ἀπὸ τῆς ὄψεως, from feeing the images of things in it.

Obfidionalis ‖ Occupancy.

OBSIDIONALIS, an epithet applied by the Romans to a fort of crown. See the article CROWN.

OBSTETRICS, or the OBSTETRIC ART, the fame with MIDWIFERY.

OBSTRUCTION, in medicine, fuch an obturation of the veffels as prevents the circulation of the fluids, whether of the found and vital, or of the morbid and peccant kind, through them.

OBTURATOR, in anatomy. See ANATOMY, *Table of the Mufcles*.

OBTUSE, fignifies blunt, dull, &c. in oppofition to acute or fharp. Thus we fay, obtufe angle; obtufe angled triangle, &c.

OBY, or OB, a river of the Ruffian empire in Afia, which rifes in the defart of Ifchinfka, and, running north, joins the Irtis near Tobolfk; and, ftill keeping its name, continues its courfe north, and falls into a deep bay called *Obfkaya*, in about 63 degrees of latitude. The exact courfe of this river was unknown, till the country was furveyed by the Ruffians; who have given us good maps of it and of all Siberia. The Oby forms the boundary between Europe and Afia, and its courfe is upwards of 2000 miles in length.

OCCIDENT, in geography, the weftward quarter of the horizon; or that part of the horizon where the ecliptic, or the fun therein, defcends into the lower hemifphere; in contradiftinction to *orient*. Hence we ufe the word *occidental* for any thing belonging to the weft; as occidental bezoar, occidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the fkull.

OCCULT, fomething hidden, fecret, or invifible. The occult fciences are magic, necromancy, cabbala, &c.

OCCULT, in geometry, is ufed for a line that is fcarce perceivable, drawn with the point of the compaffes or a leaden pencil. Thefe lines are ufed in feveral operations, as the raifing of plans, defigns of building, pieces of perfpective, &c. They are to be effaced when the work is finifhed.

OCCULTATION, in aftronomy, the time a ftar or planet is hid from our fight, by the interpofition of the body of the moon or fome other planet.

OCCUPANCY, in law, is the taking poffeffion of thofe things which before belonged to nobody. This is the true ground and foundation of all PROPERTY, or of holding thofe things in feveralty, which by the law of nature, unqualified by that of fociety, were common to all mankind. But, when once it was agreed that every thing capable of ownerfhip fhould have an owner, natural reafon fuggefted, that he who could firft declare his intention of appropriating any thing to his own ufe, and, in confequence of fuch his intention, actually took it into poffeffion, fhould thereby gain the abfolute property of it; according to that rule of the law of nations, recognized by the laws of Rome, *quod nullius eft, id ratione naturali occupanti conceditur*. *Blackft. Comment.*

Occupancy. This right of occupancy, fo far as it concerns real property, hath been confined by the laws of England within a very narrow compafs; and was extended only to a fingle inftance; namely, where a man was tenant *pour autre vie*, or had an eftate granted to himfelf only (without mentioning his heirs) for the life of another man, and died during the life of *ceftuy que vie*, or him by whofe life it was holden: in this cafe, he that could firft enter on the land, might lawfully retain the poffeffion fo long as *ceftuy que vie* lived, by right of occupancy.

This feems to have been recurring to firft principles, and calling in the law of nature to afcertain the property of the land, when left without a legal owner, For it did not revert to the grantor; who had parted with all his intereft, fo long as *ceftuy que vie* lived: it did not efcheat to the lord of the fee; for all efcheats muft be of the abfolute entire fee, and not of any particular eftate carved out of it; much lefs of fo minute a remnant as this: it did not belong to the grantee; for he was dead: it did not defcend to his heirs; for there were no words of inheritance in the grant: nor could it veft in his executors; for no executors could fucceed to a freehold. Belonging therefore to nobody, like the *hæreditas jacens* of the Romans, the law left it open to be feifed and appropriated by the firft perfon that could enter upon it, during the life of *ceftuy que vie*, under the name of an occupant. But there was no right of occupancy allowed, where the king had the reverfion of the lands: for the reverfioner hath an equal right with any other man to enter upon the vacant poffeffion; and where the king's title and a fubject's interfere, the king's fhall always be preferred. Againft the king therefore there could be no prior occupant, becaufe *nullum tempus occurrit regi.* And, even in the cafe of a fubject, had the eftate *pour autre vie* been granted to a man *and his heirs* during the life of *ceftuy qui vie*, there the heir might, and ftill may, enter and hold poffeffion, and is called in law a *fpecial occupant;* as having a fpecial exclufive right, by the terms of the original grant, to enter upon and occupy this *hæreditas jacens*, during the refidue of the eftate granted: though fome have thought him fo called with no very great propriety; and that fuch eftate is rather a defcendible freehold. But the title of *common occupancy* is now reduced almoft to nothing by two ftatutes; the one, 29 Car. II. c. 3. which enacts, that where there is no fpecial occupant, in whom the eftate may veft, the tenant *pour autre vie* may devife it by will, or it fhall go to the executors and be affets in their hands for payment of debts: the other that of 14 Geo. II. c. 20. which enacts, that it fhall veft not only in the executors, but, in cafe the tenant dies inteftate, in the adminiftrators alfo; and go in courfe of a diftribution like a chattel intereft.

By thefe two ftatutes the title of *common occupancy* is utterly extinct and abolifhed: tho' that of *fpecial occupancy*, by the heir at law, continues to this day; fuch heir being held to fucceed to the anceftor's eftate, not by defcent, for then he muft take an eftate of inheritance, but as an occupant, fpecially marked out and appointed by the original grant. The doctrine of common occupancy may, however, be ufefully remembered on the following account, amongft others: That, as by the common law no occupancy could be of incorporeal hereditaments, as of rents, tithes, advowfons, commons, or the like, (becaufe, with refpect to them, there could be no actual entry made, or corporal feifin had; and therefore by the death of the grantee *pour autre vie* a grant of fuch hereditaments was entirely determined): fo now, it is apprehended, notwithftanding thofe ftatutes, fuch grant would be determined likewife; and the hereditaments could not be devifeable, nor veft in the executors, nor go in a courfe of diftribution. For the ftatutes muft not be conftrued fo as to create any new eftate, or to keep that alive which by the common law was determined, and thereby to defeat the grantor's reverfion; but merely to difpofe of an intereft in being, to which by law there was no owner, and which therefore was left open to the firft occupant. When there is a refidue left, the ftatutes give it to the executors, &c. inftead of the firft occupant; but they will not create a refidue, on purpofe to give it to the executors. They only mean to provide an appointed inftead of a cafual, a certain inftead of an uncertain, owner, of lands which before were nobody's; and thereby to fupply this *cafus omiffus*, and render the difpofition of the law in all refpects entirely uniform: this being the only inftance wherein a title to a real eftate could ever be acquired by occupancy.

For there can be no other cafe devifed, wherein there is not fome owner of the land appointed by the law. In the cafe of a fole corporation, as a parfon of a church, when he dies or refigns, though there be no *actual* owner of the land till a fucceffor be appointed, yet there is a *legal*, *potential* ownerfhip, fubfifting in contemplation of law; and when the fucceffor is appointed, his appointment fhall have a retrofpect and relation backwards, fo as to entitle him to all the profits from the inftant that the vacancy commenced. And, in all other inftances, when the tenant dies inteftate, and no other owner of the lands is to be found in the common courfe of defcents, there the law vefts an ownerfhip in the king, or in the fubordinate lord of the fee, by efcheat.

So alfo, in fome cafes, where the laws of other nations give a right by occupancy, as in lands newly created, by the rifing of an ifland in a river, or by the alluvion or dereliction of the fea; in thefe inftances, the law of England affigns them an immediate owner. For Bracton tells us, that if an ifland arife in the *middle* of a *river*, it belongs in common to thofe who have lands on each fide thereof; but if it be nearer to one bank than the other, it belongs only to him who is proprietor of the neareft fhore: which is agreeable to, and probably copied from, the civil law. Yet this feems only to be reafonable, where the foil of the river is equally divided between the owners of the oppofite fhores: for if the whole foil is the freehold of any one man, as it muft be whenever a feveral fifhery is claimed, there it feems juft (and fo is the ufual practice) that the iflets, or little iflands, arifing in any part of the river, fhall be the property of him who owneth the pifcary and the foil. However, in cafe a new ifland rife in the *fea*, though the civil law gives it to the firft occupant, yet our's gives it to the king. And as to lands gained from the fea; either by *alluvion*, by the wafhing up of fand and earth, fo as in time to make *terra firma;* or by *dereliction*, as when the fea fhrinks back below the ufual water-mark; in thefe these cases the law is held to be, that if this gain be by little and little, by small and imperceptible degrees, it shall go to the owner of the land adjoining. For *de minimis non curat lex:* and, besides, these owners being often losers by the breaking in of the sea, or at charges to keep it out, this possible gain is therefore a reciprocal consideration for such possible charge or loss. But if the alluvion or dereliction be sudden and considerable, in this case it belongs to the king: for, as the king is lord of the sea, and so owner of the soil while it is covered with water, it is but reasonable he should have the soil when the water has left it dry. So that the quantity of ground gained, and the time during which it is gained, are what make it either the king's or the subject's property. In the same manner, if a river, running between two lordships, by degrees gains upon the one, and thereby leaves the other dry; the owner who loses his ground thus imperceptibly has no remedy: but if the course of the river be changed by a sudden and violent flood, or other hasty means, and thereby a man loses his ground, he shall have what the river has left in any other place, as a recompence for this sudden loss. And this law of alluvions and derelictions, with regard to *rivers*, is nearly the same in the imperial law; from whence indeed those our determinations seem to have been drawn and adopted: but we ourselves, as islanders, have applied them to *marine* increases; and have given our sovereign the prerogative he enjoys, as well upon the particular reasons before-mentioned, as upon this other general ground of prerogative, which was formerly remarked, that whatever hath no other owner is vested by law in the king. See PREROGATIVE.

OCCUPANT, in law, the person that first seizes or gets possession of a thing.

OCCUPATION, in a legal sense, is taken for use or tenure; as in deeds it is frequently said, that such lands are, or were lately, in the tenure of occupation of such a person.—It is likewise used for a trade or mystery.

OCCUPIERS *of* WALLING, a term used in the salt-works for the persons who are the sworn officers that allot in particular places what quantity of salt is to be made, that the markets may not be overstocked, and see that all is carried fairly and equally between the lord and the tenant.

OCEAN, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands.

The ocean is distinguished into three grand divisions. 1. The Atlantic ocean, which divides Europe and Africa from America, which is generally about 3000 miles wide. 2. The Pacific ocean, or South-sea, which divides America from Asia, and is generally about 10,000 miles over. And, 3. The Indian ocean, which separates the East Indies from Africa; which is 3000 miles over. The other seas, which are called *oceans*, are only parts or branches of these, and usually receive their names from the countries they border upon.

For the saltness, tides, &c. of the ocean, see the articles SEA, TIDES, &c.

OCEANUS, in Pagan mythology, the son of Cælus and Terra, the husband of Thetis, and the father of the Rivers and Fountains. The ancients called him the *Father of all things*, imagining that he was produced by Humidity, which, according to Thales, was the first principle from which every thing was produced. Homer represents Juno visiting him at the remotest limits of the earth, and acknowledging him and Thetis as the parents of the gods. He was represented with a bull's head, as an emblem of the rage and bellowing of the ocean when agitated by a storm.

OCELLUS *the* LUCANIAN, an ancient Greek philosopher of the school of Pythagoras, who lived before Plato. His work περι τȣ Παντος, or "the Universe," is the only piece of his which is come down entire to us; and was written originally in the Dorci dialect, but was translated by another hand into the Attic. William Christian, and after him Lewis Nogarola, translated this work into Latin; and we have several editions of it, both in Greek and Latin.

OCHLOCRACY, that form of government wherein the populace have the chief administration of affairs.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water. Ochres are of various colours, as red, blue, yellow, brown, green, &c.

OCKLEY (Simon), a learned orientalist, was born at Exeter, in 1678, and educated at Queen's college, Cambridge, where he distinguished himself by his intense application to literature. At the usual time he took the degrees in arts, and that of bachelor in divinity; but marrying very young, was precluded from a fellowship in his college, and this occasioned his being afterwards involved in many difficulties. In 1705, he was presented to the vicarage of Swavesey in Cambridgeshire; and in 1711, he was chosen Arabic professor of the university; but afterwards had the misfortune to be confined for some time in Cambridge-castle for debt. The above preferments, however, he enjoyed till his death, which happened on the 9th of August 1720. He wrote, 1. *Introductio ad Linguas Orientales*. 2. The history of the present Jews throughout the world; translated from the Italian of Leo Modena, a Venetian rabbi. 3. The improvement of human reason, exhibited in the life of Hai Ebn Yokdhan, translated from the Arabic. 4. An account of South-west Barbary, containing what is most remarkable in the kingdoms of Fez and Morocco; written by a person who had been a slave there a considerable time, and translated from his manuscript. 5. The history of the Saracens, collected from the most authentic Arabic authors, in 2 vols 8vo. He was not only well skilled in the learned languages; but also in the modern, as French, Spanish, Italian, &c.

OCTAETARIDES, in chronology, denotes a cycle of eight years, at the end of which three entire lunar months were added. This cycle was used at Athens till Meton discovered the golden number.

OCTAGON, or OCTOGON, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a *regular octagon*, or one that may be inscribed in a circle.

OCTAGON, in fortification, denotes a place that has eight bastions. See FORTIFICATION.

OCTAHEDRON, or OCTAEDRON, in geometry, one

one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA (οκτω, "eight," and ανηρ, a "man, or husband,") the eighth class in Linnæus sexual system; consisting of plants with hermaphrodite flowers, which are furnished with eight stamina, or male organs of generation. See Botany, p. 1292.

OCTANT, or Octile, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45°, from each other.

OCTAPLA, in matters of sacred literature, denotes a polyglot bible, consisting of eight columns, and as many different versions of the sacred text; viz. the original Hebrew both in Hebrew and Greek characters, Greek versions, &c.

OCTATEUCH, an appellation given to the eight first books of the Old Testament.

OCTAVE, in music. See Interval.

OCTOBER, in chronology, the tenth month of the Julian year, consisting of 31 days; it obtained the name of *October*, from its being the eighth month in the kalendar of Romulus.

OCTOSTYLE, in the ancient architecture, is the face of an edifice adorned with eight columns.

OCULUS, the eye, in anatomy. See there, n° 406.

Oculus *Beli*, in natural history, one of the semi-pellucid gems, of a greyish white colour, variegated with yellow, and with a black central nucleus: it is of a roundish form, and its variegations very beautifully represent the pupil and iris of the eye; whence the name.

Oculus *Cati*. See Asteria.

Oculus *Mundi*, one of the semi-pellucid gems, of a whitish-grey colour, without any variegations.

OCYMUM, basil; a genus of the gynospermia order, belonging to the didynamia class of plants. There are eight species, all of them natives of warm climates, rising from six inches to two feet in height, and having a strong aromatic smell, resembling that of cloves. One of the species is used in the kitchen, particularly by the French cooks, who make great use of it in their soups and sauces. This rises about ten inches high, sending out branches by pairs opposite, from the bottom; the stalks and branches are four-cornered; the leaves are oval, spear-shaped, ending in acute points, and are indented on their edges; the whole plant is hairy, and has a strong scent of cloves too powerful for most persons, but to some it is very agreeable. These plants are propagated by seeds, and will thrive in this country in the open air, and will even ripen their seeds if placed in a stove or airy glass-case.

OCZAKOW, or Oczakoff, a town of Turky in Europe, and capital of a Sangiack of the same name, inhabited by Tartars. During a late war, here was a Turkish garrison of 20,000 men. However, it was taken by the Russians in 1737, and all those that resisted were put to the sword. The Russians themselves lost 18,000 men in the assault. The Turks returned the same year with 70,000 men to retake it; but were obliged to retire, after the loss of 20,000. In 1738, the Russians withdrew their garrison, and demolished the fortifications. It is seated on the river Bog, to the west of the Nieper, or rather where they both unite and fall into the Black Sea. It is 42 miles south-west of Bialagrod, and 190 north by east of Constantinople. E. Long. 30. 0. N. Lat. 46. 30.

ODA, in the Turkish seraglio, signifies a class, order, or chamber. The grand signior's pages are divided into five classes or chambers. The first, which is the lowest in dignity, is called the *great oda*, from the great number of persons that compose it: these are the juniors, who are taught to read, write, and speak the languages. The second is called the *little oda*, where, from the age of 14 or 15 years, till about 20, they are trained up to arms, and the study of all the polite learning the Turks are acquainted with. The third chamber, called *kilar oda*, consists of 200 pages, which, besides their other exercises, are under the command of the kilardgi-bachi, and serve in the pantry and fruitery. The fourth consists only of 24, who are under the command of the khazineda-bachi, and have charge of the treasure in the grand signior's apartment, which they never enter with cloaths that have pockets. The fifth is called *kas-oda*, or *privy-chamber;* and is composed of only 40 pages who attend in the prince's chamber. Every night eight of these pages keep guard in the grand signior's bed-chamber, while he sleeps: they take care that the light, which is constantly kept in the room, does not glare in his eyes, lest it should awake him; and if they find him disturbed with troublesome dreams, they cause him to be awaked by one of their agas.

Oda-*Bachi*, or *Oddobassi*, among the Turks, an officer equivalent to a serjeant or corporal among us.

ODE, in poetry, a song, or composition proper to be sung. See Poetry.

ODENSEE, a considerable town of Denmark, in the Isle of Funen, with a bishop's see. E. Long. 10. 27. N. Lat. 55. 28.

ODER, a river of Germany, which has its source near a town of the same name in Silesia, and on the confines of Moravia. It runs north through that province, and then into the Marche of Brandenburg and Pomerania, where it forms a large lake, afterwards falling into the Baltic Sea by three mouths; between which lie the islands Usedom and Wolin. It passes by several towns; as Ratibor, Oppelen, Breslau, Glogau, and Crossen, in Silesia; Francfort, Lebus, and Custrin, in Brandenburg; and Gartz, Stetin, Cammin, Wallin, Usedom, and Wolgast, in Pomerania.

ODEUM, in Grecian antiquity, a music-theatre, built by Pericles; the inside of which was filled with seats and ranges of pillars, and on the outside the roof descended shelving downwards from a point in the centre, with many bendings, in imitation of the king of Persia's pavilion. Here the musical prizes were contended for; and here also, according to Aristophanes, was a tribunal.

De Odio *et Atia*. See *False* Imprisonment.

The writ *de odio et atia* was anciently used to be directed to the sheriff, commanding him to inquire whether a prisoner charged with murder was committed upon just cause of suspicion, or merely *propter odium et atiam*, for hatred and ill-will; and if upon the inquisition due cause of suspicion did not then appear, then there issued another writ for the sheriff to admit him to bail. This writ, according to Bracton, ought not to be denied to any man; it being expressly ordered

to

to be made out *gratis*, without any denial, by *magna carta*, c. 26. and ſtatute Weſtm. 2. 13 Edw. I. c. 29. But the ſtatute of Gloceſter, 6 Edw. I. c. 9. reſtrained it in the caſe of killing by miſadventure or ſelf-defence, and the ſtatute 28 Edw. III. c. 9. aboliſhed it in all caſes whatſoever: but as the ſtat. 42 Ed. III. c. 1. repealed all ſtatutes then in being, contrary to the great charter, Sir Edward Coke is of opinion that the writ *de odio et atia* was thereby revived. See Habeas *Corpus*.

ODO (St), ſecond abbot of Clugni in France, was illuſtrious for learning and piety in the 10th century. The ſanctity of his life contributed greatly to enlarge the congregation of Clugni; and he was ſo eſteemed, that popes, biſhops, and ſecular princes, uſually choſe him the arbiter of their diſputes. He died about the year 942, and his works are printed in the Bibliotheque of Clugni.

Odo *Cantianus*, ſo called as being a native of Kent, in England, was a Benedictine monk in the 12th century, in which order his learning and eloquence raiſed him to the dignity of prior and abbot. Archbiſhop Becket was his friend, and his panegyric was made by John of Saliſbury. He compoſed Commentaries on the Pentateuch, and the Second Book of Kings; Moral Reflections on the Pſalms; treatiſes intitled, *De onere Philiſtim; De moribus Eccleſiaſticis; De vitiis et virtutibus Animæ*, &c.

ODONTALGIA, the toothach. See Medicine, n° 314. and p. 4869.

ODONTOIDE, in anatomy, an appellation given to the proceſs of the ſecond vertebra of the neck, from its reſemblance to a tooth.

ODOROUS, or Odoriferous, appellations given to whatever ſmells ſtrongly, whether they be fetid or agreeable; but chiefly to things whoſe ſmell is briſk and agreeable.

ODYSSEY, a celebrated epic poem of Homer, wherein are related the adventures of Ulyſſes in his return from the ſiege of Troy.

OECONOMICS, the art of managing the affairs of a family, or community; and hence the perſon who takes care of the revenues and other affairs of churches, monaſteries, and the like, is termed *œconomus*.

OECONOMY, denotes the prudent conduct, or diſcreet and frugal management, whether of a man's own eſtate, or that of another.

Animal Oeconomy, comprehends the various operations of nature in the generation, nutrition, and preſervation of animals †. The doctrine of the animal œconomy is nearly connected with phyſiology, which explains the ſeveral parts of the human body, their ſtructure, uſe, &c. See Anatomy and Medicine.

† See *Generation, Nutrition*, &c.

OECUMENICAL, ſignifies the ſame with *general* or *univerſal;* as, œcumenical council, biſhop, &c.

OEDEMA, or Phlegmatic Tumour, in medicine and ſurgery, a ſort of tumour attended with paleneſs and cold, yielding little reſiſtance, retaining the print of the finger when preſſed with it, and accompanied with little or no pain.

This tumour obtains no certain ſituation in any particular part of the body, ſince the head, eye-lids, hands, and ſometimes part, ſometimes the whole body, is afflicted with it. When the laſt mentioned is the caſe, the patient is ſaid to be troubled with a cachexy, leucophlegmatia, or dropſy. But if any particular part is more ſubject to this diſorder than another, it is certainly the feet, which are at that time called *ſwelled* or *œdematous feet*.

OEDIPUS, the unfortunate king of Thebes, whoſe hiſtory is partly fabulous, flouriſhed about 1266 B. C. It is ſaid he was given by his father to a ſhepherd, who was ordered to put him to death, in order to prevent the misfortunes with which he was threatened by an oracle. But the ſhepherd being unwilling to kill him with his own hands, tied him by the feet to a tree, that he might be devoured by wild beaſts. The infant was, however, found in this ſituation by another ſhepherd named *Phorbas*, who carried him to Polybus king of Corinth; where the queen, having no children, educated him with as much care as if he had been her ſon. When he was grown up, he was informed that he was not the ſon of Polybus: on which, by order of the oracle, he went to ſeek for his father in Phocis; but ſcarce was he arrived in that country, when he met his father on the road, and killed him without knowing him. A ſhort time after, having delivered the country from the monſter called the *Sphinx*, he married Jocaſta, without knowing that ſhe was his mother, and had four children by her; but afterwards being informed of his inceſt, he quitted the throne, and, thinking himſelf unworthy of the light, put out his eyes. Eteocles and Polynices, who were celebrated amongſt the Greeks, were born of this inceſtuous marriage.

OELAND, an iſland of Sweden, ſeated on the Baltic ſea, between the continent of Gothland and the iſle of Gothland, in between 56° and 57° of north latitude, and between 17° and 18° of eaſt longitude. It is about 60 miles in length, and 15 in breadth; having a wholeſome air, and a fertile ſoil, with riſing hills, and ſeveral caſtles. It has no town of any great note.

OENANTHE, water dropwort; a genus of the digynia order, belonging to the pentandria claſs of plants. There are five ſpecies; of which the moſt remarkable is the crocata, or hemlock dropwort, growing frequently on the banks of ditches, rivers, and lakes, in many parts of Britain. The roots and leaves of this plant are a terrible poiſon; ſeveral perſons have periſhed by eating it through miſtake, either for water-parſnips or for celery, which laſt it reſembles pretty much in its leaves. So exceedingly deleterious is this plant, that Mr Lightfoot tells us, he has heard the late Mr Chriſtopher d'Ehret, the celebrated botanic painter, ſay, that while he was drawing it, the ſmell or effluvia only rendered him ſo giddy, that he was ſeveral times obliged to quit the room, and walk out in the freſh air to recover himſelf; but recollecting at laſt what might be the probable cauſe of his repeated illneſs, he opened the door and windows of the room, and the free air then enabled him to finiſh his work without any more returns of the giddineſs. Mr Lightfoot informs us, that he has given a ſpoonful of the juice of this plant to a dog, but without any other effect than that of making him very ſick and ſtupid. In about an hour he recovered; and our author has ſeen a goat eat it with impunity. To ſuch of the human ſpecies as have unfortunately eat any part of this plant, a vomit is the

moſt

moſt approved remedy.

OENOPTÆ, in Grecian antiquity, a kind of cenſors at Athens, who regulated entertainments, and took care that none drank too much, nor too little.

OENOTHERA, TREE-PRIMROSE; a genus of the monogynia order, belonging to the octandria claſs of plants. There are ſeven ſpecies; the moſt remarkable of which are,

1. The biennis, or common biennial tree-primroſe. It hath a long, thick, deeply-ſtriking root; crowned with many large, oval, ſpear-ſhaped, plane, ſpreading leaves; upright, thick, firm, rough, hairy ſtems, riſing three or four feet high; garniſhed with long, narrow, lanceolate, cloſe-fitting leaves, irregularly; and at all the axillas, from the middle upwards, large bright-yellow flowers.

2. Octovalvis, or octovalved, ſmooth, biennial tree-primroſe, hath upright, firm, ſomewhat hairy ſtems, riſing a yard high; oblong, ſpear-ſhaped, pointed, plane, ſmooth leaves; and at the axillas large bright-yellow flowers.

3. The fruticoſa, or ſhrubby, narrow-leaved, perennial tree-primroſe, hath long thick roots; upright, under-ſhrubby like red ſtems, two or three feet high; ſpear-ſhaped, lightly-indented leaves; and at the axillas pedunculated cluſters of yellow flowers, ſucceeded by pedicellated, acute-angled capſules.

4. The pumila, or low perennial tree-primroſe, hath fibrous roots, crowned with many oval, ſpear-ſhaped, cloſe-fitting leaves; ſlender herbaceous ſtems 10 or 12 inches long; garniſhed with ſpear-ſhaped, blunt, ſmooth leaves, having very ſhort foot-ſtalks; and at the axillas ſmalliſh bright-yellow flowers, ſucceeded by acute-angled capſules.

All theſe plants flower very profuſely in June and July, coming out almoſt half the length of the ſtalks from the axillas; and as the ſtalk advances in ſtature, new flowers are produced, ſucceeding thoſe below; in which order the plants continue flowering from about midſummer till October: each flower is moderately large and conſpicuous, conſiſting of four plane petals, which with the calix forms a very long tube below, and ſpreading above, generally expand moſt towards the evening; and are ſucceeded by plenty of ſeed in autumn for propagation.

Theſe plants are exotics from America; but are all very hardy, proſper in any common ſoil and ſituation, and have been long in the Engliſh gardens, eſpecially the three firſt ſorts; but the œnothera biennis is the moſt commonly known.

The firſt and ſecond ſpecies are biennial, and the third and fourth are perennial in root.

They are proper to be employed as plants of ornament for embelliſhing the pleaſure-garden; they may be placed any-where, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds muſt be raiſed annually from ſeed, for they totally periſh after they have flowered. But the perennials, once raiſed, continue for years by the root.

The propagation of all the ſorts is by ſeed, and the perennials alſo by parting the roots.

OENOTRIA, an ancient name of Italy; ſo called from the *Oenotri*, (Virgil); inhabiting between Pæſtum and Tarentum, (Ovid). Originally Arcadians, (Dionyſius Halicarnaſſæus), who came under the conduct of Oenotrus ſon of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. Cato derives the name from *Oenotrus*, king of the Sabines and Etruſcans; but Varro from *Oenotrus*, king of the Latins; and Servius from the Greek name for wine, for which Italy was famous; of which opinion is Strabo.

OENOTRIDES (Strabo, Pliny), two ſmall iſlands in the Tuſcan ſea, over-againſt Velia, a town of Lucania, called *Pontia* and *Iſcia;* now *Penza* and *Iſchta*, on the coaſt of the Principato Citra, or to the weſt of Naples. So called from the *Oenotri*, an ancient people of Italy.

OESEL, an iſland of the Baltic ſea, at the entrance of the gulf of Livonia. It is about 70 miles in length, and 50 in breadth, and contains 10 pariſhes. It is defended by the fortreſſes of Airenſburg and Sonneburg. It is in between 22° and 24° of eaſt longitude, and between 58° and 59° of north latitude.

OESOPHAGUS, in anatomy, the GULA, or *Gullet*, is a membranaceous canal, reaching from the fauces to the ſtomach, and conveying into it the food taken in at the mouth. See ANATOMY, n° 353.

OESTRUS, in zoology, a genus of inſects belonging to the order of diptera. It has no mouth; but three punctures, without trunk or beak: Antennæ taper, proceeding from a lenticular joint. There are five ſpecies.

1. Bovis, the breeze or gad-fly. Thorax yellow, with a black tranſverſe line between the wings: Abdomen tawny, with fine black tranſverſe lines; laſt ſegment black: Wings white, with a brown tranſverſe line, and three brown ſpots. Size of the large blue fly. Depoſits its eggs under the ſkin on the backs of oxen, where the maggots are nouriſhed the whole winter till the month of June; and plague the cattle ſo all the ſummer, that they are obliged to fly for refuge into the water, and dare not quit it the whole day.

2. The hæmorrhoidalis. Body long, black, covered with tawny hair; middle of the thorax leſs hairy; wings immaculate; antennæ very ſhort: Length half an inch. Depoſits its eggs in the rectum of horſes, and occaſions great torment.

3. Ovis, the grey-fly. Spotted with black; front pale yellow; legs browniſh; wings with ſhort black veins: Length half an inch. Breeds in the frontal ſinus of ſheep; where the maggots, hatched from the eggs, lodge the whole winter, vellicating the internal membranes, and often bringing on death.

5. The naſalis. Body black; but the head, thorax, and abomen, covered with pale-red hair, except the firſt ſegment of the latter, which is covered with white hair; the wings immaculate. Breeds in the fauces of horſes, entering by their noſe.

5. The tarandi. Thorax yellow; with a black line between the wings, which are immaculate: abdomen tawny, laſt ſegment black. Infeſt the back of the rein-deer, ſo as greatly to retard the breed. The rein-deer of Lapland are obliged every year to fly to the

the Alpine mountains, to escape the pursuit of these insects: yet a fourth part of their number perish by them at two years old; the rest are emaciated, and have their skins spoiled.

OETA (Strabo, Ptolemy), a mountain of Thessaly, extending from Thermopylæ westward to the Sinus Ambracius, and in some measure cutting at right angles the mountainous country stretching out between Parnassus to the south, and Pindus to the north. At Thermopylæ it is very rough and high, rising and ending in sharp and steep rocks, affording a narrow passage between it and the sea from Thessaly to Locris, (Strabo): with two paths over it; the one above Trachis, very steep and high; the other through the country of the Ænianes, much easier and readier for travellers; by this it was that Leonidas was attacked in rear by the Persians, (Pausanias). Here Hercules laid himself on the funeral pile, (Silius Italicus, Ovid); the spot thence called *Pyra*, (Livy): who says, that the extreme mountains to the east are called *Oeta;* and hence the poets allege, that day, night, sun, and stars, arose from Oeta, (Seneca, Statius, Silius Italicus, Catullus, Virgil's *Culex.)* Circumstances which shew the height of this mountain.

OETING, a town of Germany, in Upper Bavaria, under the jurisdiction of Burkhausen. It is divided into the upper and the lower town, and seated on the river Inn, eight miles west of Burckhausen. E. Long. 12. 47. N. Lat. 48. 0. There is a great resort of pilgrims to the old chapel.

Oeting, or *Oetingen*, a town of Germany, in the circle of Suabia, and capital of a county of the same name, seated on the river Wirnitz. E. Long. 10. 45. N. Lat. 48. 52.

Oeting, a county of Germany, in the circle of Suabia, bounded on the north and east by Franconia; on the south by the duchy of Neuburg; and on the west by that of Wirtemberg. It is about 40 miles from east to west, and 20 from north to south.

OFFA's-dyke, an entrenchment cast up by Offa, a Saxon king, to defend England against the incursions of the Welch. It runs through Herefordshire, Shropshire, Montgomeryshire, Denbighshire, and Flintshire.

OFFANTO, a river of Italy, in the kingdom of Naples. It rises in the Appenine mountains, in the Farther Principato; and passing by Conza, and Monte Verde, it afterwards separates the Capitanata from the Basilicata and the Terra-di-Barri, and then it falls into the gulf of Venice, near Salpe.

OFFENCE, in law, an act committed against the law, or omitted where the law requires it.

OFFICE, a particular charge or trust, or a dignity attended with a public function. See Honour.—The word is primarily used in speaking of the offices of judicature and policy; as the office of secretary of state, the office of a sheriff, of a justice of peace, &c.

Office also signifies a place or apartment appointed for officers to attend in, in order to discharge their respective duties and employments; as the secretary's office, ordnance-office, excise-office, signet-office, paper-office, pipe-office, six-clerks office, &c.

Office, in architecture, denotes all the apartments appointed for the necessary occasions of a palace or great house; as kitchen, pantries, confectionaries, &c.

Office, in the canon-law, is used for a benefice that has no jurisdiction annexed to it.

Duty upon Offices *and Pensions*, a branch of the king's extraordinary perpetual revenue, consisting in a payment of 1s. in the pound (over and above all other duties) out of all salaries, fees, and perquisites, of offices and pensions payable by the crown. This highly-popular taxation was imposed by stat. 31 Geo. II. c. 22. and is under the direction of the commissioners of the land-tax.

OFFICER, a person possessed of a post or office. See the preceding article.

The great officers of the crown, or state, are, The lord high-steward, the lord high-chancellor, the lord high-treasurer, the lord-president of the council, the lord privy-seal, the lord-chamberlain, the lord high-constable, and the earl-marshal; each of which see under its proper article.

Non-commissioned Officers, are serjeant-majors, quarter-master serjeants, serjeants, corporals, drum and fife majors; who are nominated by their respective captains, and appointed by the commanding officers of regiments, and by them reduced without a court-martial.

Orderly non-commissioned Officers, are those who are orderly, or on duty for that week; who, on hearing the drum beat for orders, are to repair to the place appointed to receive them, and to take down in writing, in the orderly book, what is dictated by the adjutant, or serjeant-major: they are then immediately to shew these orders to the officers of the company, and afterwards warn the men for duty.

Flag Officers. See Flag *Officers*, and Admirals.

General Officers, are those whose command is not limited to a single company, troop, or regiment; but extends to a body of forces composed of several regiments: such are the general, lieutenant-general, major-general, and brigadier.

Officers *of the Household*. See the article Household.

Staff Officers, are such as, in the king's presence, bear a white staff, or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: such are the lord-steward, lord-chamberlain, lord-treasurer, &c.

The white staff is taken for a commission; and, at the king's death, each of these officers breaks his staff over the hearse made for the king's body, and by this means lays down his commission, and discharges all his inferior officers.

Subaltern Officers are all who administer justice in the name of subjects; as those who act under the earl-marshal, admiral, &c. In the army, the subaltern officers are the lieutenants, cornets, ensigns, serjeants, and corporals.

OFFICIAL, in the canon-law, an ecclesiastical judge, appointed by a bishop, chapter, abbot, &c. with charge of the spiritual jurisdiction of the diocese.

Official is also a deputy appointed by an archdeacon as his assistant, who sits as judge in the archdeacon's court.

OFFICINAL, in pharmacy, an appellation given to ſuch medicines, whether ſimple or compound, as are required to be conſtantly kept in the apothecaries ſhops. The *officinal ſimples* are appointed, among us, by the college of phyſicians; and the manner of making the compoſitions directed in their diſpenſatory. See PHARMACY.

OFFING, or OFFIN, in the ſea-language, that part of the ſea a good diſtance from ſhore, where there is deep water, and no need of a pilot to conduct the ſhip: thus, if a ſhip from ſhore be ſeen ſailing out to ſeaward, they ſay, *ſhe ſtands for the offing;* and if a ſhip, having the ſhore near her, have another a good way without her, or towards the ſea, they ſay, *that ſhip is in the offing.*

OFF-SETS, in gardening, are the young ſhoots that ſpring from the roots of plants; which being carefully ſeparated, and planted in a proper ſoil, ſerve to propagate the ſpecies.

OFF-SETS, in ſurveying, are perpendiculars let fall, and meaſuring from the ſtationary lines to the hedge, fence, or extremity of an incloſure.

OGEE, or O. G. in architecture, a moulding conſiſting of two members, the one concave, and the other convex; or of a round and hollow, like an S. See ARCHITECTURE.

OGILBY (John), an eminent writer, was born in or near Edinburgh, about the 17th of November 1600. His father having ſpent his eſtate, and being priſoner in the King's Bench for debt, could contribute but little to his education; however, he obtained ſome knowledge in the Latin grammar, and afterwards ſo much money as to procure his father's diſcharge from priſon, and to bind himſelf an apprentice to a dancing-maſter in London; when, by his dexterity in his profeſſion, and his complaiſant behaviour to his maſter's ſcholars, he obtained money to buy out the remainder of his time, and to ſet up for himſelf. But being afterwards appointed to dance in the duke of Buckingham's great maſk, he by a falſe ſtep ſtrained a vein in the inſide of his leg, which occaſioned his being ever after ſomewhat lame. When Thomas earl of Strafford was made lord lieutenant of Ireland, he was entertained as a dancing-maſter in his family, and made one of the earl's troop of guards; at which time he compoſed a humorous piece called the *Character of a Trooper.* He was ſoon after appointed maſter of the revels in Ireland, and built a theatre at Dublin. About the time of the concluſion of the war in England, he left Ireland, and, being ſhipwrecked, came to London in a neceſſitous condition; but ſoon after walked to Cambridge, where, being aſſiſted by ſeveral ſcholars, he became ſo complete a maſter of the Latin tongue, that in 1649 he publiſhed a tranſlation of Virgil. He ſoon after learned Greek; and in 1660 publiſhed in folio, a tranſlation of Homer's Iliad, with Annotations. About two years after, he went into Ireland, where he was made maſter of the revels by patent. He then built another theatre in Dublin, which coſt him about 1000 l. He publiſhed at London in folio, a tranſlation of Homer's Odyſſey, with Annotations; and afterwards wrote two heroic poems, intitled the *Epheſian Matron,* and the *Roman Slave.* He next compoſed the Carolics, an epic poem, in 12 books, in honour of king Charles I. but this was entirely loſt in the fire of London; when Mr Ogilby's houſe in White Fryars was burnt down, and his whole fortune, except to the value of five pounds, deſtroyed. He, however, ſoon procured his houſe to be re-built, ſet up a printing-office within it, was appointed his majeſty's coſmographer and geographic printer, and printed ſeveral great works, tranſlated or collected by himſelf and his aſſiſtants, particularly his Atlas. He died in 1676.

OGIVE, in architecture, an arch or branch of a Gothic vault; which, inſtead of being circular, paſſes diagonally from one angle to another, and forms a croſs with the other arches. The middle, where the ogives croſs each other, is called the *key;* being cut in form of a roſe, or a *cul de lampe.* The members or mouldings of the ogives are called *nerves, branches,* or *reins;* and the arches which ſeparate the ogives, *double arches.*

OGYGES, king of the Thebans, or, as others, of Ogygia and Actæ, afterwards called *Bœotia* and *Attica.* He is recorded to have been the firſt founder of Thebes and Eleuſin. The famous deluge happened in his time, in which ſome ſay he periſhed with all his ſubjects, 1796 B. C.

OGYGIA, (Homer), the iſland of Calypſo; placed by Pliny in the Sinus Scylaceus, in the Ionian ſea, oppoſite to the promontory Lacinium; by Mela in the ſtrait of Sicily, calling it *Ææe;* which others place at the promontory Circeium, and call it the iſland of *Circe.*

OGYGIA, the ancient name of Thebes in Bœotia; ſo called from Ogyges, an ancient king, under whom happened a great deluge, 1020 years before the firſt olympiad.

OHIO, a river of North America, called by the French the *Beautiful River,* has its ſource between the Allegany mountains and the lake Erie; and running ſouth-weſt through a moſt delightful country, as alſo receiving many ſmaller rivers in its paſſage, at length falls into the Miſſiſippi, in about 37 degrees of latitude. The French had ſeveral forts on and near it; but the whole country through which it flows was ceded by the peace of 1763 to the Britiſh.

O-HETEROA, one of the South Sea iſlands lately diſcovered, is ſituated in W. Long. 150. 47. S. Lat. 22. 27. It is neither fertile nor populous; nor has it an harbour or anchorage fit for ſhipping, and the diſpoſition of the people is hoſtile to ſuch as viſit them.

OIL, in natural hiſtory, an unctuous inflammable ſubſtance, drawn from ſeveral natural bodies, as animal and vegetable ſubſtances.

Animal oils are their fats, which are originally vegetable oils: all animal ſubſtances yield them, together with their volatile ſalts, in diſtillation.

Vegetable oils are obtained by expreſſion, infuſion, and diſtillation.

The oils by expreſſion are obtained from the ſeed, leaves, fruit, and bark of plants; thus, the ſeed of muſtard, and of the ſun-flower, almonds, nuts, beech-maſt, &c. afford a copious oil by expreſſion; and the leaves of roſemary, mint, rue, wormwood, thyme, ſage, &c. the berries of juniper, olives, Indian cloves, nutmeg, mace, &c. the barks of cinnamon, ſaſſafras, and clove, yield a conſiderable proportion of eſſential oil by diſtillation.

Oil.

The method of procuring oils by expreffion is very fimple: thus, if either fweet or bitter almonds, that are frefh, be pounded in a mortar, the oil may be forced out with a prefs, not heated: and in the fame manner fhould the oil be preffed from linfeed and muftard. The avoiding the ufe of heat in preparing thefe oils, intended for internal medicinal ufe, is of great importance, as heat gives them a very prejudicial rancidnefs.

This method holds of all thofe vegetable matters that contain a copious oil, in a loofe manner, or in certain cavities or receptacles; the fides whereof being broke, or fqueezed, makes them let go the oil they contain: and thus the zeft or oil of lemon-peel, orange-peel, citron-peel, &c. may be readily obtained by preffure, without the ufe of fire. But how far this method of obtaining oils may be applied to advantage, feems not hitherto confidered. It has been commonly applied to olives, almonds, linfeed, rape-feed, beech-maft, ben-nuts, walnuts, bay-berries, mace, nutmeg, &c. but not, that we know of, to juniper-berries, cafhew-nuts, Indian cloves, pine apples, and many other fubftances that might be enumerated, both of foreign and domeftic growth. It has, however, been of late fuccefsfully applied to muftard-feed, fo as to extract a curious gold-coloured oil, leaving a cake behind, fit for making the common table-muftard.

Certain dry matters, as well as moift ones, may be made to afford oils by expreffion, by grinding them into a meal, which being fufpended to receive the vapour of boiling water, will thus be moiftened fo as to afford an oil in the fame manner as almonds; and thus an oil may be procured from linfeed, hemp-feed, lettuce-feed, white-poppy feed, &c.

As to the treatment of oils obtained by expreffion, they fhould be fuffered to depurate themfelves by ftanding in a moderately cool place, to feparate from their water, and depofit their fæces; from both which they ought to be carefully freed. And if they are not thus rendered fufficiently pure, they may be wafhed well with frefh water, then thoroughly feparated from it again by the feparating-glafs, whereby they will be rendered bright and clear.

The next clafs of oils are thofe made by infufion, or decoction, wherein the virtues of fome herb or flower is drawn out in the oil; as the oils of rofes, chamæmile, hypericum, alder, &c. However, thefe require to be differently treated: thus, for the fcented flowers, particularly rofes, infolation does beft; becaufe much boiling would exhale their more fragrant parts: but oils impregnated with green herbs, as thofe of chamæmile and alder, require long boiling, before they receive the green colour defired. And, in general, no oils will bear to be boiled any longer than there remains fome aqueous humidity, without turning black.

There are many compound oils prepared in the fame manner, *viz.* by boiling and infolation, and then ftraining off the oil for ufe.

The fame contrivance has likewife its ufe in making effences for the fervice of the perfumer; not only where effential oils cannot be well obtained in fufficient quantities, but alfo where they are too dear. The effential oil of jeffamine-flowers, honey-fuckles, fweet-briar, damafk-rofes, lilies of the valley, &c. are either extremely dear, or fcarcely obtainable by diftillation; and, in fome of them, the odorous matter is fo fubtile, as almoft to be loft in the operation. But if thefe flowers be barely infused in fine oil of nuts, or oil of ben, drawn without heat, and kept in a cool place, their fubtile odorous matter will thus pafs into the oil, and richly impregnate it with their flavour. And thefe effences may be rendered ftill more perfect by ftraining off the oil at firft put on, and letting it ftand again, without heat, upon frefh flowers; repeating the operation twice or thrice.

Oils or fats may likewife be obtained, by boiling and expreffion, from certain animal-fubftances; for the membranes which contain the fat, being chopped fmall, and fet in a pan over the fire, become fit for the canvas bag, and, by preffure, afford a large quantity of fat; as we fee in the art of chandlery, which thus extracting the oily matter, leaves a cake behind, commonly called *graves*.

As to the effential oils of vegetables, they are obtained by diftillation with an alembic and a large refrigeratory. Water muft be added to the materials, in fufficient quantity to prevent their burning; and they fhould be macerated or digefted in that water, a little time before diftillation. The oil comes over with the water; and either fwims on the top, or finks to the bottom, according as it is fpecifically heavier or lighter than water.

This procefs is applicable to the diftilling of the effential oils from flowers, leaves, barks, roots, woods, gums, and balfams, with a flight alteration of circumftances, as by longer digeftion, brifker diftillation, &c. according to the tenacity and hardnefs of the fubject, the ponderofity of the oil, &c.

Effential oils may be divided into two claffes, according to their different fpecific gravities; fome floating upon water, and others readily finking to the bottom. Thus, the effential oils of cloves, cinnamon, and faffafras, readily fink; whereas thofe of lavender, marjoram, mint, &c. fwim in water: the lighteft of thefe effential oils is, perhaps, that of citron-peel, which even floats in fpirit of wine; and the heavieft feems to be oil of faffafras.

For obtaining the full quantity of the more ponderous oils from cinnamon, cloves, faffafras, &c. it is proper to reduce the fubjects to powder; to digeft this powder for fome days in a warm place, with thrice its quantity of foft river-water, made very faline by the addition of fea-falt, or fharp with oil of vitriol; to ufe the ftrained decoction, or liquor left behind in the ftill, inftead of common water, for frefh digeftion; to ufe for the fame purpofe the water of the fecond running, after being cleared of its oil; not to diftil too large a quantity of thefe fubjects at once; to leave a confiderable part of the ftill, or about one fourth, empty; to ufe a brifk fire, or a ftrong boiling heat, at the firft, but to flacken it afterwards; to have a low ftill-head, with a proper internal ledge and current leading to the nofe of the worm; and, finally, to cohobate the water, or pour back the liquor of the fecond running upon the matter in the ftill, repeating this once or twice.

The directions here laid down for obtaining the ponderous oils to advantage, are eafily transferred to the obtaining of the lighter; fo that we need not dwell particularly upon them.

Many of the effential oils being dear, it is a very common practice to adulterate or debafe them feveral ways, fo as to render them cheaper both to the feller and the buyer. Thefe feveral ways feem reducible to three general kinds, each of which has its proper method of detection, viz. 1. With expreffed oils. 2. With alcohol. And, 3. With cheaper effential oils.

If an effential oil be adulterated with an expreffed oil, it is eafy to difcover the fraud; by adding a little fpirit of wine to a few drops of the fufpected effential oil, and fhaking them together; for the fpirit will diffolve all the oil that is effential, or procured by diftillation, and leave all rhe expreffed oil that was mixed with it, untouched.

If an effential oil be adulterated with alcohol, or rectified fpirit of wine, it may be done in any proportion, up to that of an equal quantity, without being eafily difcoverable either by the fmell or tafte: the way to difcover this fraud, is to drop a few drops of the oil into a glafs of fair water; and if the oil be adultered with fpirit, the water will immediately turn milky, and, by continuing to fhake the glafs, the whole quantity of fpirit will be abforbed by the water, and leave the oil pure at top.

Finally, if an effential oil be adulterated by a cheaper effential oil, this is commonly done very artfully: the method is to put fir-wood, turpentine, or oil of turpentine, into the ftill, along with the herbs to be diftilled for their oil, fuch as rofemary, lavender, origanum, &c. and by this means, the oil of turpentine diftilled from thefe ingredients, comes over in great quantity, and intimately blended with the oil of the genuine ingredient. The oils thus adulterated always difcover themfelves in time, by their own flavour being overpowered by the turpentine-fmell: but the ready way to detect the fraud, is to drench a piece of rag, or paper, in the oil, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine-fcent behind.

The virtues of oils being the fame with thofe of the fubftances from whence they are obtained, may be learned under their feveral articles.

Method of Purifying Rancid OILS. See CHEMISTRY, n° 497.

OINTMENT, in pharmacy. See UNGUENT.

OKEHAM, the capital of Rutlandfhire, in England, feated in a rich and pleafant valley, called the *vale of Catmus*. It is pretty well built, has a good church, a free-fchool, and an hofpital. W. Long. 0. 45. N. Lat. 52. 40.

OKINGHAM, OCKINGHAM, or *Woxingham*, a large town of Berkfhire, in England, noted for the manufacture of filk ftockings. W. Long. 0. 50. N. Lat. 51. 26.

OLAUS MAGNUS, archbifhop of Upfal in Sweden, fucceeded his brother John Magnus in 1544. He appeared with great credit at the council of Trent in 1546, and fuffered much afterward for the Catholic religion. We have of his writing, A Hiftory of the Manners, Cuftoms, and Wars of the Northern Nations of Europe.

OLD-AGE. See LONGEVITY.

OLD-*Man of the Mountain*. See ASSASINS.

OLDCASTLE (Sir John), called the *Good Lord Cobham*, was born in the reign of Edward III. and was the firft author as well as the firft martyr among the Englifh nobility: he obtained his peerage by marrying the heirefs of that Lord Cobham who with fo much virtue and patriotifm oppofed the tyranny of Richard II. By his means the famous ftatute againft provifors was revived, and guarded againft by feverer penalties; he was one of the leaders of the reforming party; was at great expence in procuring and difperfing copies of Wickliffe's writings among the people, as well as by maintaining a number of his difciples as itinerant preachers. In the reign of Henry V. he was accufed of herefy; the growth of which was attributed to his influence. Being a domeftic in the king's court, the king delayed his profecution that he might reafon with him himfelf; but not being able to reclaim him to the church of Rome, he in great difpleafure refigned him to its cenfure He was apprehended and condemned for herefy; but efcaping from the tower, lay concealed for four years in Wales, until the rumour of a pretended confpiracy was raifed againft him, and a price fet upon his head: he was at laft feized, and executed in St Giles's Fields; being hung alive in chains upon a gallows, and burned by a fire placed underneath. He wrote "Twelve Conclufions, addreffed to the Parliament of England."

OLDENBURG (Henry), a learned German gentleman in the 17th century, was defcended from the noble family of his name, who were earls of the county of Oldenburg, in the north part of Weftphalia for many generations. He was born in the duchy of Bremen in the Lower Saxony; and during the long Englifh parliament in king Charles I's. time, was appointed conful for his countrymen, at London, after the ufupation of Cromwell: but being difcharged of that employ, he was made tutor to the lord Henry O'Bryan, an Irifh nobleman, whom he attended to the univerfity of Oxford, where he was admitted to ftudy in the Bodleian library in the beginning of the year 1656, when Cromwell was vice-chancellor. He was afterwards tutor to William lord Cavendifh, and was acquainted with Milton the poet. During his refidence at Oxford, he became alfo acquainted with the members of that fociety there, which gave birth to the royal fociety; and upon the foundation of this latter, he was elected fellow; and when the fociety found it neceffary to have two fecretaries, he was chofen affiftant-fecretary to Dr Wilkins. He applied himfelf with extraordinary diligence to the bufinefs of his office, and began the publication of the Philofophical Tranfactions with N° 1. in 1664. In order to difcharge this tafk with greater credit to himfelf and the fociety, he held a correfpondence with more than feventy learned perfons, and others, upon a vaft variety of fubjects, in different parts of the world. This fatigue would have been infupportable, had not he, as he told Dr Lifter, managed it fo as to make one letter anfwer another, and that, to be always frefh, he never read a letter before he had pen, ink and paper, ready to anfwer it forthwith; fo that the multitude of his letters cloyed him not, nor ever lay upon his hands. Among others, he was a conftant correfpondent of Mr Robert Boyle, with whom he had a very intimate friendfhip; and he tranflated feveral of that ingenious gentleman's works into Latin.

M.

Mr Oldenburg continued to publiſh the Tranſactions, as before, to N° xxxvi. June 25, 1677. After which the publication was diſcontinued till the January following, when it was again reſumed by his ſucceſſor in the ſecretary's office, Mr Nehemiah Grew, who carried it on till the end of February 1678. Our author dying at his houſe at Charleton, near Greenwich in Kent, in the month of Auguſt that year, was interred there.

OLDHAM (John), an eminent Engliſh poet in the 17th century, ſon of a non-conformiſt miniſter, was educated under his father, and then ſent to Edmund-hall in Oxford. He became uſher to the free-ſchool at Croyden in Surry; where he received a viſit from the earls of Rocheſter and Dorſet, Sir Charles Sedley, and other perſons of diſtinction, merely upon the reputation of ſome verſes which they had ſeen in manuſcript. He was tutor to ſeveral gentlemens ſons ſucceſſively; and having ſaved a ſmall ſum of money, came to London, and became a perfect votary to the bottle, being an agreeable companion. He was quickly found out here by the noblemen who had viſited him at Croydon, who brought him acquainted with Mr Dryden. He lived moſtly with the earl of Kingſton at Holme-Pierpoint in Nottinghamſhire, where he died of the ſmall-pox in 1683, in the 30th year of his age. His acquaintance with learned authors appears by his ſatires againſt the Jeſuits, in which there is as much learning as wit diſcovered. Mr Dryden eſteemed him highly. His works are printed in 2 vols 12mo. They chiefly conſiſt of ſatires, odes, tranſlations, paraphraſes of Horace and other authors, elegiac verſes, imitations, parodies, familiar epiſtles, &c.

OLDMIXON (John) was deſcended from an ancient family in Somerſetſhire: he was a violent party-writer and malevolent critc, who would ſcarcely have been remembered, if Pope, in reſentment of his abuſe, had not condemned him to immortality in his Dunciad. His party-writings procured him a place in the revenue at Liverpool, where he died at an advanced age in the year 1745. Beſides his fugitive temporary pieces, he wrote a hiſtory of the Stuarts in folio; a critical hiſtory of England, 2 vols 8vo; a volume of poems, ſome dramatic pieces, &c.; none of them worthy of notice, his principal talent being that of falſifying hiſtory.

OLD-WIFE, or *Wraſſe*, See LABRUS.

OLD-WIFE *Fiſh*. See BALISTES.

OLEA, the OLIVE-TREE; a genus of the monogynia order, belonging to the diandria claſs of plants.

There are two ſpecies, 1. The Europea, or common olive-tree, riſes with upright ſolid ſtems, branching numerouſly on every ſide, 20 or 30 feet high; ſpear-ſhaped, ſtiff, oppoſite leaves, two or three inches long, and half an inch or more broad; and at the axillas ſmall cluſters of white flowers, ſucceeded by oval fruit.

This ſpecies is the principal ſort cultivated for its fruit; the varieties of which are numerous, varying in ſize, colour, and quality.

It is a native of the ſouthern warm parts of Europe, and is cultivated in great quantities in the ſouth of France, Italy, and Portugal, for the fruit to make the olive-oil, which is in ſo great repute, and is tranſported to all parts. to the great advantage of thoſe countries where the trees grow in the open ground: the green fruit is alſo in much eſteem for pickling, of which we may ſee plenty in the ſhops.

2. The capenſis, or cape box-leaved olive, riſes with ſhrubby ſtems, branching numerouſly from the bottom, ſix or ſeven feet high; ſmall, oval, thick, ſtiff, ſhining leaves; and at the axillas ſmall cluſters of whitiſh flowers; ſucceeded by ſmall fruit of inferior value.

Theſe plants in this country muſt be kept principally in pots for moving to ſhelter of a green-houſe in winter; for they are too render to proſper well in the open ground here: though ſometimes they are planted againſt a warm ſouth wall, and ſheltered occaſionally from froſt in winter, by mulching the roots, and matting their tops; whereby they may be preſerved, and will ſometimes produce fruit for pickling: a very ſevere winter, however, often kills or greatly injures their young branches; therefore let the principal part be potted in rich earth, and placed among the green-houſe ſhrubs, and managed as others of that kind.

Theſe trees are often ſent over from Italy to the Italian warehouſes in London, along with orange-trees, &c. where pretty large plants may be purchaſed reaſonably, which ſhould be managed as directed for orange-trees that are imported from the ſame country. See CITRUS.

Their propagation here is commonly by layers.

The laying is performed on the young branches in ſpring. Give plenty of water all ſummer, and they will ſometimes be rooted fit for potting-off by autumn; but ſometimes they require two ſummers to be rooted effectually: when, however, they are properly rooted take them off early in autumn, and pot them ſeparately, give water, and place them in the ſhade till they have taken freſh root; and in October remove them into the green-houſe, &c.

Thoſe you intend to plant in the open ground, as before ſuggeſted, ſhould be kept in pots; in order to have occaſional ſhelter of a garden-frame two or three years, till they have acquired ſome ſize, and are hardened to the full air; then tranſplant them into a warm border againſt a wall: mulch their roots in winter, and mat their tops in froſty weather.

Olives have an acrid, bitter, extremely diſagreeable taſte: pickled (as we receive them from abroad) they prove leſs diſagreeable. The Lucca olives, which are ſmaller than the others, have the weakeſt taſte; the Spaniſh, or larger, the ſtrongeſt; the Provence, which are of a middling ſize, are generally the moſt eſteemed.

The oil obtained from this fruit has no particular taſte or ſmell, and does not greatly differ in quality from oil of almonds. Authors make mention of two ſorts of this oil, one expreſſed from the olives when fully ripe, which is our common oil olive; the other, before it has grown ripe; this is called *oleum immaturum*, and *omphacinum*. Nothing is met with in the ſhops under this name; and Lemery affirms, that there is no ſuch oil, unripe olives yielding only a viſcid juice to the preſs. From the ripe fruit, two or three ſorts are obtained, differing in degree of purity: the pureſt runs by light preſſure; the remaining magma, heated and preſ-

ſed

fed more ftrongly, yields an inferior fort, with fome dregs at the bottom, called *amurca*. All thefe oils contain a confiderable quantity of aqueous moifture, and a mucilaginous fubftance, which fubject them to run into a putrid ftate: to prevent this, the preparers add fome fea-falt, which, imbibing the aqueous and mucilaginous parts, finks with them to the bottom; by this means the oil becomes more homogene, and confequently lefs fufceptible of alteration. In its paffage to us, fome of the falt, thrown up from the bottom by the fhaking of the veffel, is fometimes mixed with and detained in the oil, which, in our colder climate, becomes too thick to fuffer it freely to fubfide; and hence the oil is fometimes met with of a manifeftly faline tafte. Oil- olive is ufed in the fimple balfam of fulphur, Locatelli's balfam, and feveral ointments. It is oftener employed in this laft intention than the other expreffed oils, but more rarely for internal medicinal purpofes.

OLEAGINOUS, fomething that partakes of the nature of oil, or out of which oil may be expreffed.

OLECRANUM, or OLECRANON, in anatomy, the protuberance of the ulna, which prevents the joint of the elbow from being bent back beyond a certain length. See ANATOMY, n° 50.

OLEARIUS (Adam), minifter to the duke of Holftein, and fecretary to the embaffy fent in 1633 to the great duke of Mufcovy and to the king of Perfia. He fpent fix years in this employment; and, on his return, publifhed a relation of his journeys, with maps and figures, at Slefwic 1656, in folio. He wrote an *Abridgement of the chronicles of Holftein from* 1448 *to* 1663: and was appointed librarian to the duke of Holftein, in which capacity he probably died. He has the character of an able mathematician, an adept of mufic, and a good orientalift, efpecially in the Perfian language.

OLEARIUS (Godfrey), fon of Godfrey Olearius, D. D. fuperintendant of Halle in Saxony, was born there in 1639. He became profeffor of Greek at Leipfic; and fhewed his abilities in that language by 52 exercitations on the dominical epiftles, and upon thofe parts of the epiftles in the New Teftament which are read in the public exercifes, and which among the Lutherans are the fubject of part of their fermons. He difcharged the moft important pofts in the univerfity, and among other dignities was ten times rector of it. His learning and induftry were difplayed in 106 theological difputations, 61 in philofophy, fome programmas upon difficult points, feveral fpeeches and theological counfels; which make two thick volumes: befide his *Moral Theology*, his *Introduction to Theology*, which treats of cafes of confcience, and his *Hermeneutica Sacra*. He lived to a good old age, dying in 1713. His eldeft fon of his own name, was a man of genius and learning, a profeffor in the fame univerfity, who publifhed feveral works, but died young of a confumption before his father.

OLERON, an ifland of France, on the coaft of Aunis and Saintonge, about five miles from the continent. It is 12 miles in length, and five in breadth; and is very fertile, containing about 12,000 inhabitants, who are excellent feamen. It is defended by a caftle, which is well fortified; and there is a lighthoufe placed here for the direction of fhips. It is 14 miles fouth-eaft of Rochelle. W. Long. 1. 26. N. Lat. 46. 10.

Sea-Laws of OLERON, certain laws relative to maritime affairs, made in the time of Richard I. when he was at the ifland of Oleron. Thefe laws, being accounted the moft excellent fea-laws in the world, are recorded in the black book of the admiralty. See *Selden's Mare Claufum.*

OLFACTORY-NERVES. See ANATOMY, n°400.

OLIBANUM, (FRANKINCENSE), in pharmacy, a dry refinous fubftance, brought to us in detached pieces, or drops, as it were, like thofe of maftic; but larger, and of a lefs pure and pellucid texture. This drug has received many different appellations, according to its different appearances: the fingle tears are called fimply *olibanum*, or *thus;* when two are joined together, they have been called *thus mafculum*, and when very large, *thus fœmininum:* fometimes four or five, about the bignefs of filberds, are found adhering to a piece of the bark of the tree which they exfuded from; thefe have been named *thus corticofum:* the finer powder which rubs off from the tears in the carriage, *mica thuris;* and the coarfer powder, *manna thuris*. This drug is not however in any of its ftates which is now called *thus* or *frankincenfe* in the fhops. See the article THUS.

Olibanum confifts of about equal parts of a gummy and refinous fubftance; the firft foluble in water, the other in rectified fpirit. With regard to its virtues, abundance have been attributed to it, particularly in diforders of the head and breaft, in hæmoptoes, and in alvine and uterine fluxes: but its real effects in thefe cafes are far from anfwering the promifes of the recommenders. Riverius is faid to have had large experience of the good effects of this drug in pleurifies, efpecially epidemic ones: he directs a fcooped apple to be filled with a dram of olibanum, then covered and roafted under the afhes; this is to be taken for a dofe, three ounces of carduus water after it, and the patient covered up warm in bed; in a fhort time, he fays, either a plentiful fweat, or a gentle diarrhœa, enfues, which carry off the difeafe. Geoffroy informs us, that he has frequently made ufe of this medicine after venefection, with good fuccefs; but acknowledges that it has fometimes failed.

OLIGÆDRA, in natural hiftory, the name of a genus of cryftals compofed of very few planes, as the name expreffes. The bodies of this clafs are cryftals of the imperfect kind; being compofed of columns affixed irregularly to fome folid body at one end, and the other terminated by a pyramid: but the column and pyramid being both pentangular, the whole confifts only of ten planes, and not, as the common kind, of 12.

OLIGARCHY, a form of government, wherein the adminiftration of affairs is confined to a few hands.

OLISIPO, (Pliny, Antonine, Infcriptions); a town of Lufitania, fituate on the north fide of the frith of the Tagus; of fuch antiquity, that Solinus thought it was built by Ulyffes: and Mela, probably to favour this opinion, writes, according the common copies, *Ulyffipo;* both of them perhaps deceived by the fimilarity of found. It was a municipium, with the furname *Felicitas Julia*, a privilege granted by the munificence

nificence of Auguftus, (Infcriptions, Pliny.) Now *Lifbon*, capital of Portugal, fituate on the north bank of the Tagus, diftant about ten miles from its mouth.

OLIO, in cookery, denotes a favoury difh compofed of a great variety of ingredients, chiefly ufed by the Spaniards.

OLIVE, in botany. See OLEA.

Plate CCI. fig. 3. OLIVE-*Prefs*. In order to obtain the olive oil, the olives are firft bruifed in a rough trough, under a millftone, rolling perpendicularly over them; and when fufficiently mafhed, put into the maye, or trough, *m*, of an olive-prefs, where *a a* are the upright beams, or cheeks; *b*, the female, and *c*, the male fcrew; *f*, the board on which the fcrew preffes; *g*, a cubical piece of wood, called a *block; b*, the peel, a circular board, to be put under the block. By turning the fcrew, all the liquor is preffed out of the mafhed olives, and is called *virgin-oil;* after which, hot water being poured upon the remainder in the prefs, a coarfer oil is obtained. Olive-oil keeps only about a year, after which it degenerates.

OLIVE-*Colour*, a yellow mingled with black.

OLIVER (Ifaac), an excellent Englifh painter, born in 1556; eminent both for hiftory and portraits. Several fine miniatures of this mafter are to be feen in the collections of our nobility and gentry; fome of them portraits of himfelf. As he was a very good defigner, his drawings are finifhed to an extraordinary degree of perfection; many being copies after Parmegiano. Rubens and Vandyck painted James I. after a miniature of Oliver's, which is a fufficient teftimony of his merit. He died in 1617.

OLIVER (Peter), the fon and difciple of Ifaac Oliver, was born in 1601. He arrived at a degree of perfection in miniature portraits confeffedly fuperior to his father, or any of his cotemporaries; as he did not confine his fubjects to a head only. In the collections of Charles I. and James II. there were 13 hiftorical fubjects painted by this Oliver; of which feven are ftill preferved in the clofet of queen Caroline at Kenfington: and a capital painting of his wife is in the poffeffion of the duchefs of Portland. He died in 1660.

OLIVET, or *Mount of* OLIVES, (anc. geog.), a mount which lay a little without Jerufalem, on the eaft fide (Zechar. xiv.); feparated from it by a deep valley called *Kedron*, (Jofephus), or the valley of Jehofaphat; diftant about eight furlongs or a mile from Jerufalem, (Luke); five furlongs, (Jofephus); which may be underftood of the nearer part of the mount.

OLMUTZ, a town of Germany, in Moravia, with a bifhop's fee, and a famous univerfity. The public buildings are very handfome, particularly the Jefuits college. It is a populous, trading, and very ftrong place; and yet it was taken, with the whole garrifon, by the king of Pruffia in 1741. In July 1758, he befieged it again; and when he had almoft taken the place, he was obliged to raife the fiege, to go and meet the Ruffian army. It is feated on the river Morave. E. Long. 17. 35. N. Lat. 49. 30.

OLYMPIA, (anc. geog.), with the furname *Pifatis*, (Strabo); fo called from the territory of Pifa in Elis; defcribed by Strabo, "as the temple of Jupiter Olympius, before which ftands a grove of wild olive-trees, in which is the ftadium, or foot-courfe, fo called, becaufe the eighth part of a mile; and by which the Alpheus, coming down from Arcadia, runs." A temple and fhrine highly ennobled by gymnaftic exercifes; and diftinguifhed by a peculiar degree of veneration, and ftill more fo by the ftatue of Jupiter, the work of Phidias, (Mela): fituated between Offa and Olympius, mountains cognominal with thofe of Theffally, diftant 12 miles from Pylos; famous for games called the *Olympian*, celebrated the beginning of each fifth year, by which Greece computed time, (Pliny;) a period of four years complete being called an *Olympiad*. Olympia was anciently called *Pifa*, or Pifa ftood in its neighbourhood; and there Jupiter Olympius was worfhipped. Hiftorians take no notice of Pifa, though poets do, but only of Olympia: which is thought to have arifen, if it had ever any habitations, (fo as to become a town or village, befides the temple and place of exercife,) from the ruins of Pifa; deftroyed by the Eleans, according to Paufanias; who adds, that not a veftige either of the houfes or walls was to be feen, but a plantation of vines on the fpot where it ftood. Again, Olympia and Pifa are faid to have ftood on different fpots, but in each other's adjacency. The public edifices of Olympia were the temple of Jupiter, the gymnafium, the portico, the dwellings of the Athletæ, the ftadium or raifed caufeway, the Hippodromus or chariot-courfe, the barrier and goal. *Olympiacus*, (Virgil;) *Olympicus*, (Horace;) the epithets. Now called *Longinico*, in the Morea: E. Long. 22. 0. N. Lat. 37. 30.

OLYMPIAD, the fpace of four years, whereby the Greeks reckoned time.

OLYMPIC GAMES, were folemn games among the ancient Greeks, fo called from Olympian Jupiter, to whom they were dedicated; and by fome faid to be firft inftituted by Jupiter, after his victory over the fons of Titan; others afcribe their inftitution to Hercules, not the fon of Alcmena, but one of much greater antiquity; others to Pelops; and others to Hercules the fon of Alcmena. Thefe games were fo confiderable, that the Greeks made them their epocha, diftinguifhing their years by the return of the Olympic games.

The care and management of the Olympics belonged for the moft part to the Eleans; who, on that account, enjoyed their poffeffions without moleftation or fear of war or violence. They appointed a certain number of judges, who were to take care that thofe who offered themfelves as competitors fhould perform their preparatory exercifes; and thefe judges, during the folemnity, fat naked, having before them a crown of victory, formed of wild olive, which was prefented to whomfoever they adjudged it. Thofe who were conquerors were called *Olympionices*, and were loaded with honours by their countrymen. At thefe games women were not allowed to be prefent; and if any woman was found, during the folemnity, to have paffed the river Alpheus, fhe was to be thrown headlong from a rock.

OLYMPUS, the name of feveral mountains; one bounding Bithynia on the fouth. Another in the ifland of Cyprus, on whofe top was a temple of Venus, which women were not permitted either to enter or to fee, (Strabo.) A third Olympus of Galatia, (Livy.) A fourth, of Lycia, with a noble cognominal town,

near

near the fea-coaft, (Strabo, Cicero); extinct in Pliny's time, there remaining only a citadel: the town was deftroyed by P. Servilius Ifauricus, (Florus); having been the retreat of pirates. From this mountain there was an extenfive profpect of Lycia, Pamphylia, and Pifidia, (Strabo.) A fifth Olympus of Myfia, (Ptolemy); thence furnamed *Olympena*, anciently *Minor;* one of the higheft mountains, and furnamed *Myfius*, (Theophraftus); fituate on the Propontis, and thence extending more inland. A fixth, on the north of Theffaly, or on the confines of Macedonia; famous for the fable of the giants, (Virgil, Horace, Seneca); reckoned the higheft in the whole world, and to exceed the flight of birds, (Apuleius); which is the reafon of its being called *heaven*, than which nothing is higher: the ferenity and calmnefs which reign there are celebrated by Homer, Lucan, and Claudian.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five perfons, but generally by three. When three play at this game, nine cards are dealt to each party; the whole ombre pack being only 40; becaufe the eights, nines, and tens are thrown out of the pack. There are two forts of counters for ftakes, the greater and the leffer; the laft having the fame proportion to the other, as a penny to a fhilling: of the greater counters each man ftakes one for the game; and one of the leffer for paffing, for the hand when eldeft, and for every card taken in. As to the order and value of the cards, the ace of fpades, called *fpadillo*, is always the higheft trump, in whatfoever fuit the trump be; the *manille*, or black-duce, is the fecond; and the *bafto*, or ace of clubs, is always the third: the next in order is the king, the queen, the knave, the feven, the fix, the five, four, and three. Of the black there are 11 trumps; of the red, 12. The leaft fmall cards of the red are always the beft, and the moft of the black; except the duce and red feven, both of which are called the *manilles*, and are always fecond when the red is a trump. The red ace, when a trump, enters into the fourth place, and is called *punto*, otherwife it is only called an *ace*. The three principal cards are called *matadores;* which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of a fmall trump, the perfon may renounce trumps, and play any other card; and when thefe are all in the fame hand, the others pay three of the greater counters a-piece; and with thefe three for a foundation, he may count as many matadores as he has cards in an uninterrupted feries of trumps; for all which the others are to pay one counter a-piece. He who hath the firft hand is called *ombre*, and has his choice of playing the game, of naming the trump, and of taking in as many and as few cards as he pleafes; and after him the fecond, &c. But if he does not name the trump before he look on the cards he has taken in, any other may prevent him, by naming what trump he pleafes. He that has the firft hand, fhould neither take in, nor play, unlefs he has at leaft three fure tricks in his hand: for, as he wins the game who wins moft tricks, he that can win five of the nine has a fure game; which is alfo the cafe if he wins four, and can fo divide the tricks as that one perfon may win two, and the other three.

If a perfon plays without difcarding or changing any cards, this is called *playing fans prendre;* and if another wins more tricks than he, he is faid to win codille. The over-fights in the courfe of the game, are called *beafts*. And if the ombre wins all the nine tricks, it is called *winning the vole*.

In ombre by five, which many, on account of its not requiring fo clofe an attention, prefer to that by three, only eight cards a-piece are dealt; and five tricks muft be won, otherwife the ombre is beafted. Here, the perfon who undertakes the game, after naming the trump, calls a king to his affiftance; upon which the perfon in whofe hand the king is, without difcovering himfelf, is to affift him as a partner, and to fhare his fate. If, between both, they can make five tricks, the ombre wins two counters, and the auxiliary king only one; but when the counters are even, they divide them equally. If the ombre venture the game without calling in any king, this too is called *playing fans prendre;* in which cafe other four are all againft him, and he muft win five tricks alone, or be beafted. The reft is much the fame as by three.

Ombre *de foleil*, "Shadow of the fun," in heraldry, is when the fun is borne in armory, fo as that the eyes, nofe, and mouth, which at other times are reprefented, do not appear; and the colouring is thin, fo that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called *Spoletto* and *Perugia*.

OMBRO, or Lombro, a town of Italy, in the duchy of Tufcany, and territory of the Siennois, fituated near the Tufcan fea, a little fouth of the lake of Caftiglione, 45 miles fouth-weft of Sienna.

OMELET, or Amlet, a kind of pancake or fricaffee of eggs, with other ingredients, very ufual in Spain and France. It may be made as follows: the eggs being beaten, are to be feafoned with falt and pepper, and then fried in butter made boiling hot; this done, gravy is to be poured on, and the whole ftewed with chives and parfley fhred fmall: when one fide is fried enough, it is to be turned on the other.

OMEN, a certain accident and cafual occurrence, that was thought to prefage either good or evil. There were three forts of omens among the ancients: one was of things internal, or thofe which affected the perfons themfelves; the fecond, of things external, that only appeared to men, but did not make any impreffion on them; the third were ominous words. Of the firft fort were thofe fudden confternations, called *panic fears*, that feized upon men without any vifible caufe, and were therefore imputed to the demons, efpecially the god Pan: of thefe panics there is frequent mention in hiftory. The fecond fort of omens were of fuch things as appeared to men, but were not contained in their own bodies: of thefe there were feveral forts; the beginning of things were thought to contain fomething ominous; it was thought a direful omen, when any thing unufual befel the temples, altars, or ftatues of the gods: under the head of external omens are to be placed thofe which offered themfelves in the way; fuch were the meeting of an eunuch, a black, a bitch with whelps, a fnake lying in the road, &c. Words were ominous, and, as they were good or bad, were believed to prefage accordingly

ingly.

OMENTUM, or Epiloon, the *Cawl*, in anatomy, a membranaceous part, usually furnished with a large quantity of fat; being placed under the peritonæum, and immediately above the intestines. See Anatomy, n° 351.

OMBROMETER, a machine to measure the quantity of rain that falls. We have the description and sign of one in Phil. Transf. n° 473. p. 12. It consists of a tin funnel, whose surface is an inch square, with a flat board, and a glass tube set into the middle of it in a groove. The rise of the water in the tube, whose capacity at different times must be measured and marked, shews the quantity of rain that has fallen.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, sirnamed *Omophagos*, *i. e.* eater of raw-flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they counterfeited madness; what was peculiar to it, was, that the worshippers used to eat the entrails of goats, raw and bloody, in imitation of the god, who was supposed to do the same thing.

OMPHALMO-mesenteric, in anatomy. All fœtuses are wrapped up in at least two coats or membranes; most of them have a third, called *allantoides*, or *urinary*.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, viz. a vein and an artery, called *omphalo-mesenterics*, because passing along the string to the navel, and terminating in the mesentery.

ON, (anc. geog.), a town of Egypt towards Arabia, to the south-east of Babylon, and of the eastern branch of the Nile. The prophet Jeremiah calls it the house or town of the sun, in the land of Egypt. The high-priest Onias built a temple here, held in great esteem by the Hellenists.

ONANIA, or Onanism, terms lately framed to denote the crime of self-pollution, mentioned in scripture to have been committed by Onan, and punished in him with death.

This practice, however common, hath among all nations been reckoned a very great crime. In scripture, besides the instance of Onan abovementioned, we find self-polluters termed *effeminate*, *unclean*, *filthy*, and *abominable*. Even the heathens, who had not the advantage of revelation, were of the same opinion, as appears from the following lines of Martial.

Hoc nihil esse putes! scelus est; mihi crede, sed ingens
Quantum vix animo concipis ipse tuo.

You think 'tis nothing! 'tis a crime, believe!
A crime so great you scarcely can conceive.

Dr Tissot has published a treatise on the pernicious effects of this shameful practice, which appears to be no less baneful to the mind than to the body. He begins with observing, that, by the continual waste of the human body, aliments are required for our support. These aliments, however, require certain preparations in the body itself; and when by any means we become so altered that these preparations cannot be effected, the best aliments then prove insufficient for the support of the body. Of all the causes by which this morbid alteration is brought on, none is more common than too copious evacuations; and of all evacuations, that of the semen is the most pernicious when carried to excess. It is also to be observed, that though excess in natural venery is productive of very dangerous disorders, yet an equal evacuation by self-pollution, which is an unnatural way, is productive of others still more to be dreaded. The consequences enumerated by Dr Tissot are as follow.

1. All the intellectual faculties are weakened; the memory fails; the ideas are confused, and the patient sometimes even falls into a slight degree of insanity. They are continually under a kind of inward restlessness, and feel a constant anguish. They are subject to giddiness; all the senses, especially those of seeing and hearing, grow weaker and weaker, and they are subject to frightful dreams.

2. The strength entirely fails, and the growth in young persons is considerably checked. Some are afflicted with almost continual watching, and others dose almost perpetually. Almost all of them become hypochondriacs or hysteric, and are afflicted with all the evils which attend these disorders. Some have been known to spit calcareous matter; and others are afflicted with coughs, slow fevers, and consumptions.

3. The patients are affected with the most acute pains in different parts of the body, as the head, breast, stomach, and intestines; while some complain of an obtuse sensation of pain all over the body, on the slightest impression.

4. There are not only to be seen pimples on the face, which are one of the most common symptoms; but even blotches, or suppurative pustules, appear on the face, nose, breast, and thighs; and sometimes fleshy excrescences arise on the forehead.

5. The organs of generation are also affected; and the semen is evacuated on the slightest irritation, even that of going to stool. Numbers are afflicted with an habitual gonorrhœa, which entirely destroys the vigour of the constitution, and the matter of it resembles a fetid sanies. Others are affected with painful priapisms, dysuries, stranguries, and heat of urine, with painful tumours in the testicles, penis, bladder, and spermatic cord.

6. The functions of the intestines are sometimes totally destroyed; and some patients complain of costiveness, others of diarrhœa, piles, and the running of a fœtid matter from the fundament.

With regard to the cure, the first step is to leave off those practices which have occasioned the disease: which our author asserts is no easy matter; as, according to him, the soul itself becomes polluted, and can dwell on no other idea; or if she does, the irritability of the parts of generation themselves quickly recal ideas of the same kind. This irritability is no doubt much more to be dreaded than any pollution the soul can have received; and by removing it, there will be no occasion for exhortations to discontinue the practice. The principal means for diminishing this irritability are, in the first place, to avoid all stimulating, acrid, and spiced meats. A low diet, however, is improper, because it would further reduce the body already too much emaciated. The food should therefore be nutritive, but plain, and should consist of flesh rather roasted than boiled, rich broths, &c. It is certain, however, that as thefe foods contribute to reftore the ftrength of the body, the ftimulus on the organs of generation will be proportionably increafed, by the femen which is conftantly fecreted, and which will now be in larger quantity than even in healthy perfons, owing to the great evacuations of it which have preceded. Some part of the femen is gradually abforbed by the lymphatics; in confequence of which, the remainder becomes thick, acrid, and very ftimulating. To remedy this, exercife is to be ufed, and that not only for pleafure, but till it is attended with a very confiderable degree of fatigue. The fleep alfo muft be no more than is barely fufficient to repair the fatigues occafioned by the exercife, or other employment; for an excefs in fleep is as bad as idlenefs or ftimulating foods. Excefs in wine or intoxicating liquors is alfo to be avoided; or rather fuch liquors ought never to be tafted, unlefs as a medicine to reftore the exhaufted fpirits: and to all this ought to be joined the Peruvian bark, which hath this admirable property, that, with little or no ftimulus, it reftores the tone of the fyftem, and invigorates the body in a manner incredible to thofe who have not obferved its effects. If thefe directions are followed, the patient may almoft certainly expect a recovery, provided any degree of vital ftrength remains; and thofe who defire a life of celibacy on a moral account, will find them much more effectual than all the vows of chaftity they can make.

ONCA, or Ounce, in zoology. See Felis.

ONEGA, a river and lake of the Ruffian empire, between Mufcovite Carelia, the territory of Cargapol, and Swedifh Carelia. It is 100 miles in length and 40 in breadth, having a communication with the lake Ladoga, and confequently with Peterfburgh. The river has its fource in Cargapol, and gives its name to a country full of woods.

ONEGLIA, a fea-port town of Italy, in the territory of Genoa, with the title of a principality; but it belongs to the king of Sardinia, as well as the province, which abounds in olive-trees, fruit and wine. It has often been taken and retaken in the wars of Italy; which is no wonder, as it is an open place. The French and Spaniards had poffeffion of it in 1744, but were driven out by the Piedmontefe; however, they returned next winter, and again made themfelves mafters of it. E. Long. 8. 1. N. Lat. 43. 55.

ONEIROCRITICA, the art of interpreting dreams; or a method of foretelling future events by means of dreams. See Dream, Divination, &c.—The word is formed from the Greek ονειρος, "dream," and κριτικη, of κρισις, "judgment."—Some call it *oneirocritica;* and derive it from ονειρος, and κρατεω, "I poffefs, I command."

It appears from feveral paffages of fcripture, that there was, under the Jewifh difpenfation, fuch a thing as foretelling future events by dreams; but then there was a particular gift, or revelation, required for that purpofe.

Hence it has been inferred, that dreams are really fignificative, and do forebode fomething to come; and all that is wanting among us is the *oneirocritica*, or the art of knowing what: yet it is the opinion of many, that dreams are mere chimeras; bearing, indeed, fome relation to what has paffed, but none to what is to come.—As to the cafe of Jofeph, it was poffible for God, who knew all things, to difcover to him what was in the womb of fate; and to introduce that, he might take the occafion of a dream.

ONEIROCRITICS, a title given to interpreters of dreams, or thofe who judge of events from the circumftances of dreams.

There is no great regard to be had to thofe Greek books called *oneirocritics;* nor do we know why the patriarch of Conftantinople, and others, fhould amufe themfelves with writing on fo pitiful a fubject.

Rigault has given us a collection of the Greek and Latin works of this kind; one attributed to Aftrampfichus; another to Nicephorus, patriarch of Conftantinople; to which are added the treatifes of Artemidorus and Achmet.—But the books themfelves are little elfe than reveries; a kind of waking dreams, to explain and account for fleeping ones.

The fecret of oneirocriticifm, according to them all, confifts in the relation fuppofed to be between the dream, and the thing fignified: but they are far from keeping to the relations of agreement and fimilitude; and frequently have recourfe to others of diffimilitude, and contrariety.

ONESIÆ thermæ, (Strabo;) who calls them *excellent baths*, and *falutary waters*, at the foot of the Pyrenees in Aquitania. Near the river Aturus ftands at this day the town Bagneres, famous for its waters, which appear to be the *Onefiæ* of Strabo; fituate in the county of Bigorre in Gafcony, near the river Adour.

ONIÆ oppidum and *Templum*, (Jofephus); fo called from Onias, the high-prieft of the Jews in Egypt; who built a temple in imitation of that at Jerufalem, by permiffion of the king of Egypt, on the fpot where ftood the temple of Diana Agreftis in Leontopolis: it was encompaffed with a brick wall, and had a large tower like that at Jerufalem, (Jofephus:) it was the metropolis of the Nomos Heliopolites, (Ptolemy;) becaufe in Strabo's time Heliopolis was fallen to decay.

ONGLEE, in heraldry, an appellation given to the talons or claws of beafts or birds, when borne of a different colour from that of the body of the animal.

ONION. See Cepa.—Onions, leeks, and garlic, are all of the fame genus; and in their recent ftate are are acrid, but harmlefs to the human body. When, by age or climate, this acrimony is too great, we do not ufe them as food. In Spain, the garlic being equally mild with the onion is ufed as common food. By the ordinary culinary preparation their acrimony is diffipated, and a remarkably mild fubftance remains, promifing much nutriment, which thofe who can digeft them raw will certainly obtain. Though fometimes fhunned as food, yet they are on that account ufed in medicine, uniting the two qualities of pectorals, viz. on the account of their acrimony, being in their recent ftate expectorant; in their boiled ftate, on account of their mucilage, demulcent, provided the quantity taken be fufficient. Some of late, in this country, have found in leeks a fomniferous quality; but this is not yet confirmed by a fufficient number of experiments.—Befides the three abovementioned, there are several others belonging to the same tribe, which we use as condiment; but only the leek and onion as diet. In its recent state, the onion is the most acrid; in its boiled state, the leek retains its acrimony most tenaciously. On account of this, and some difference of texture, the onion is more easily digested, and more universally used, than the leek; being more easily broke down, and more generally agreeable.

ONISCUS, in zoology, a genus of insects belonging to the order of aptera. It has 14 legs, bristly feelers, and an oval body. There are 15 species; of which the most remarkable are, 1. The entomon, or sea wood-louse, is white; eyes black; convex above, beneath flat, margin acute: Antennæ 4: Four hind pair of legs largest, hairy. Body of 7 segments. Length $1\frac{1}{2}$ line. Found on the coast. It accompanies the herring, and is an enemy well known to our fishermen: these insects will frequently eat up a whole fish while it hangs in the net.—2. Asellus, millepes, or wood-louse, is oval; the tail obtuse, with 2 undivided bristles: Various as to colour: Length, 5 lines. Their use in medicine is well known.

ONKELOS, surnamed the *Proselyte*, a famous rabbi of the first century, and the author of the Chaldee Targum on the Pentateuch. He flourished in the time of Jesus Christ, according to the Jewish writers; who all agree, that he was, at least in some part of his life, cotemporary with Jonathan Ben Uzziel, author of the second Targum upon the prophets. Dean Prideaux thinks he was the elder of the two, for several reasons: the chief of which is the purity of the style in his Targum, therein coming nearest to that part of Daniel and Ezra which is in Chaldee, and is the truest standard of that language, and consequently is the most ancient; since that language, as well as others, was in a constant flux, and continued deviating in every age from the original: nor does there seem to be any reason why Jonathan Ben Uzziel, when he understood his Targum, should pass over the law, and begin with the prophets, but that he found Onkelos had done this work before him, and with a success which he could not exceed.

Azaries, the author of a book, intitled *Meor Enaim*, or the *Light of the Eyes*, tells us, that Onkelos was a proselyte in the time of Hillel and Samnai, and lived to see Jonathan Ben Uzziel one of the prime scholars of Hillel. These three doctors flourished 12 years before Christ, according to the chronology of Gauz; who adds, that Onkelos was cotemporary with Gamaliel the elder, St Paul's master, who was the grandson of Hillel, who lived 28 years after Christ, and did not die till 18 years before the destruction of Jerusalem. However, the same Gauz, by his calculation, places Onkelos 100 years after Christ; and to adjust his opinion with that of Azarias, extends the life of Onkelos to a great length. The Talmudists tell us that he assisted at the funeral of Gamaliel, and was at a prodigious expence to make it most magnificent. Dean Prideaux observes, that the Targum of Onkelos is rather a version than a paraphrase; since it renders the Hebrew text word for word, and for the most part accurately and exactly, and is by much the best of all this sort: and therefore it has always been held in esteem among the Jews, much above all the other Targums; and being set to the same musical notes with the Hebrew text, it is thereby made capable of being read in the same tone with it in their public assemblies. From the excellency and accuracy and Onkelos's Targum, the dean also concludes him to have been a native Jew, since, without being bred up from his birth in the Jewish religion and learning, and long exercised in all the rites and doctrines thereof, and being also thoroughly skilled in both the Hebrew and Chaldee languages, as far as a native Jew could be, he can scarce be thought thoroughly adequate to that work which he performed; and that the representing him as a proselyte, seems to have proceeded from the error of taking him to have been the same with Akilas, or Aquila, of Pontus, author of the Greek Targum or version of the prophets and Hagiographia, who was indeed a Jewish proselyte.

ONKOTOMY, in surgery, the opening of a tumour or abscess. See SURGERY.

ONOMANCY, or rather ONOMAMANCY, a branch of divination, which foretells the good or bad fortune of a man, from the letters in his name. See the article DIVINATION.

From much the same principle the young Romans toasted their mistresses as often as there were letters in their names: hence Martial says,

Nævia sex cyathis, septem Justina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to resemble the sound made by the things signified; as the buzz of bees, the cackling of hens, &c.

ONOSANDER, a Greek author and Platonic philosopher, who wrote Commentaries on Plato's politics, which are lost: but his name is particularly famous for a treatise intitled Λογος Στρατηγικος, "Of the duty and virtues of the general of an army;" which has been translated into Latin, Italian, Spanish, and French. The time when he lived is not precisely known; but is imagined to be in the reign of the emperor Claudius.

ONTARIO, a lake of North America, in the country of the Iroquois, 180 miles in length and 60 in breadth. There are many rivers that run into it; and from it the great river St Lawrence proceeds. It communicates with lake Erie by a river 33 miles in length, in which is the remarkable cataract of NIAGARA.

ONTOLOGY. See METAPHYSICS, n° 1.

ONUPHRIUS PANVINUS, a learned Italian, of the order of hermits of St Augustine, was born of a noble family at Verona, in 1529; and, being trained to literature, became so indefatigable in his studies, that he spent whole days and nights in reading the ancients: which made Manutius style him *Helluo Antiquitatis*. His first performance was A Chronicle of Popes and Cardinals, which was printed without his knowledge at Venice in 1557; and some time after, more correctly by himself. He afterwards continued Platina's Lives of the Popes, from Sextus IV. to Pius V. and subjoined annotations to the lives Platina had written. He also wrote four pieces upon Roman Antiquities, which are printed in Grævius's Collection. He died in his 39th year, in 1568.

ONYCOMANCY, or, as some write it, ONYMANCY; a kind of divination by means of the nails of the fingers.——The word is formed from the Greek ονυξ, "nail," and μαντεια, "divination."

The ancient practice was to rub the nails of a youth with oil and foot, or wax; and to hold up the nails thus fmeared againft the fun.—Upon them were fuppofed to appear figures or characters, which fhewed the thing required.

ONYX, in natural hiftory, one of the femipellucid gems, with varioufly coloured zones, but none red; being compofed of cryftal, debafed by a fmall admixture of earth; and made up either of a number of flat plates, or of a feries of coats furrounding a central nucleus, and feparated from each other by veins of a different colour, refembling zones or belts.

We have four fpecies of this gem. 1. A bluifh-white one, with broad white zones. 2. A very pure onyx, with fnow-white veins. 3. The jafponyx, or horny-onyx, with green zones. 4. The brown onyx, with bluifh-white zones.

The ancients attributed wonderful properties to the onyx, and imagined that if worn on the finger it acted as a cardiac; they have alfo recommended it as an aftringent: but at prefent no regard is paid to it.

The word in the Greek language fignifies *nail;* the poets making this ftone to have been formed by the Parcæ, from a piece of Venus's nails, cut off by Cupid with one of his arrows.

OOST, a kiln for drying hops after they are picked from the ftalks.

OPACITY, in philofophy, a quality of bodies which renders them impervious to the rays of light.

OPAL, in natural hiftory, a fpecies of the chroaftaces genus of gems.

The opal is a gem of a very peculiar kind, and has been efteemed by many in all ages of very great value; though at prefent it is of lefs value, in proportion to its fize, than any of the finer gems. It is fofter than any other of the fine gems, and is difficult to polifh to any degree of nicety. It is found of various fhapes and fizes; its moft frequent bignefs is between that of a pea and a horfe-bean; but it is found as fmall as the head of a large pin, and has been feen of the fize of a large walnut. Its figure is very various and uncertain, but it is never found in a cryftalliform or columnar ftate; its moft ufual fhape is an irregular oblong one, convex above, flatted at bottom, and dented with various finuofities at its fides. It is often found among the loofe earth of mountains, fometimes on the fhores of rivers, and not unfrequently bedded in the coarfer kinds of jafper. It is found in Egypt, Arabia, fome parts of the Eaft Indies, and in many parts of Europe: thofe of Europe are principally from Bohemia, and are of a greenifh or greyifh colour; the colour of the other opals much refembles the fineft mother of pearl, its bafis feeming a bluifh or greyifh white, but with a property of reflecting all the colours of the rainbow, as turned differently to the light.

OPALIA, in antiquity, feafts celebrated at Rome in honour of the goddefs Ops. Varro fays they were held on the 19th of December, which was one of the days of the faturnalia: thefe two feafts were celebrated in the fame month, becaufe Saturn and Ops were hufband and wife: the vows offered to the goddefs were made fitting on the ground.

OPERA, a dramatic compofition fet to mufic, and fung on the ftage, accompanied with mufical inftruments, and enriched with magnificent dreffes, machines, and other decorations. See Poetry, ch. ii. and Music, n° 26.

OPERATION, in general, the act of exerting or exercifing fome power or faculty, upon which an effect follows.

Operation, in furgery and medicine, denotes a methodical action of the hand on the human body, in order to re-eftablifh health.

OPHIDIUM, a genus of fifhes belonging to the order of apodes. The head is fomewhat naked; the teeth are in the jaws, palate, and fauces; there are feven rays in the gill-membranes; and the body is fhaped like a fword. There are two fpecies.

OPHIOGLOSSUM, adder's-tongue; a genus of the order of filices, belonging to the cryptogamia clafs of plants. There are feven fpecies; of which the only remarkable one is the vulgatum, or common adder's-tongue, which is a native of feveral places of Britain, growing in meadows and moift paftures. The country-people make an ointment of the frefh leaves, and ufe it as a vulnerary to green wounds; which is a very ancient application, recommended by Matthiolus, Tragus, and others.

OPHIOMANCY, in antiquity, the art of making predictions from ferpents. Thus Calchas, on feeing a ferpent devour eight fparrows with their dam, foretold the duration of the fiege of Troy: and the feven coils of a ferpent that was feen on Anchifes's tomb, were interpreted to mean the feven years that Æneas wandered from place to place before he arrived at Latium.

OPHIORHIZA, in botany, a genus of the monogynia order, belonging to the pentandria clafs of plants. There are two fpecies; the moft remarkable of which is the Afiaticum, or true lignum colubrinum. The root of this is known in the Eaft Indies to be a fpecific againft the poifon of that moft dreadful animal called the *hooded ferpent*. There is a treatife in *Amœn. Acad.* tom. iv. upon this fubject, wherein the author Joh. And. Darelius undertakes, from the defcription of fuch authors as had feen it upon the fpot, to afcertain the plant from which the genuine root is taken. It appears in this account, that it had puzzled the European phyficians; and what had been fold in the fhops for it, is the root of a very different plant, and of a poifonous nature.

The true root is called *mungus*, for the following reafon.—There is a kind of weafel in the Eaft Indies, called *mungutia* by the natives, *mungo* by the Portuguefe, and *muncas* by the Dutch. This animal purfues the hooded ferpent, as the cat does the moufe with us. As foon as this ferpent appears, the weafel attacks him; and if fhe chances to be bit by him, fhe immediately runs to find a certain vegetable, upon eating which fhe returns, and renews the fight.—The Indians are of opinion that this plant is the mungos.

That celebrated traveller Kempfer, who kept one of thefe weafels tame, that eat with him, lived with him, and was his companion wherever he went, fays he faw one of thefe battles between her and the ferpent, but could not certainly find out what root the weafel looked out for. But whether the weafel firft difcovered this antidote or not, it is an infallible remedy

remedy against the bite of the hooded serpent. And this he undertakes to ascertain.

OPHITES, in natural history, a sort of variegated marble, of a dusky-green ground, sprinkled with spots of a lighter green, otherwise called *serpentine*. See the article MARBLE.

OPHITES, in church-history, Christian heretics, so called both from the veneration they had for the serpent that tempted Eve, and the worship they paid to a real serpent: they pretended that the serpent was Jesus Christ, and that he taught men the knowledge of good and evil. They distinguished between *Jesus* and *Christ:* Jesus, they said, was born of the Virgin, but Christ came down from heaven to be united with him; Jesus was crucified, but Christ had left him to return to heaven. They distinguished the God of the Jews, whom they termed *Jaldabaoth*, from the supreme God: to the former they ascribed the body, to the latter the soul of men. They had a live serpent, which they kept in a kind of cage; at certain times they opened the cage-door, and called the serpent: the animal came out, and, mounting upon the table, twined itself about some loaves of bread; this bread they broke and distributed it to the company, who all kissed the serpent: this they called their *Eucharist*.

OPHIR, a country mentioned in scripture, from which Solomon had great quantities of gold brought home in ships which he sent out for that purpose; but where to fix its situation is the great difficulty, authors running into various opinions on that head. Some have gone to the West, others to the East Indies, and the eastern coasts of Africa, in search of it. The generality place Ophir in the East Indies: but where there, is the question; many taking it for Taphrobana, now supposed to be Ceylon; others for Pegu, or for Sumatra; or for the Aurea Chersonesus, now Malacca: unless *Aurea Chersonesus* be, as many think, an appellative common to all countries producing gold. Kircher takes the term *Ophir* to be of Egyptian original, and to denote a great part of India: and, to obviate difficulties, perhaps it is best to take *Ophir* for India at large, without confining it to any particular country, not excluding even China and the Japanese islands.

OPHRYS, TWYBLADE; a genus of the diandria order, belonging to the gynandria class of plants. The species are numerous; but the most remarkable are the following.

1. The ovata, oval-leaved ophrys, or common twyblade, hath a bulbous, fibrated root; crowned by two oval, broad, obtuse, veined, opposite leaves; an erect, succulent, green stalk, six or eight inches high, naked above, and terminated by a loose spike of greenish flowers, having the lip of the nectarium bifid. The flowers of this species resemble the figure of gnats. 2. The spiralis, spiral orchis, or triple ladies-tresses, hath bulbous, oblong, aggregated roots; crowned by a cluster of oval, pointed, ribbed leaves; erect simple stalks, half a foot high; terminated by long spikes of white odoriferous flowers, hanging to one side, having the lip of the nectarium entire, and crenated. 3. The nidus-avis, or bird's-nest, hath a bulbose, fibrated, clustered root; upright, thick, succulent stalks, a foot high, sheathed by the leaves, and terminated by loose spikes of pale-brown flowers; having the lip of the nectarium bifid. 4. The anthropophora, man-shaped ophrys, or man-orchis, hath a roundish bulbose root, crowned with three or four oblong leaves; upright thick stalks, rising a foot and a half high; adorned with narrow leaves, and terminated by loose spikes of greenish flowers, representing the figure of a naked man; the lip of the nectarium linear tripartite, with the middle segment longest and bifid. There is a variety with brownish flowers tinged with green. 5. The insectifera, or insect-orchis, hath two roundish bulbous roots, crowned with oblong leaves; erect leafy stalks, from six to 10 or 12 inches high, terminated by spikes of insect-shaped greenish flowers, having the lip of the nectarium almost five-lobed. This wonderful species exhibit flowers in different varieties, that represent singular figures of flies, bees, and other insects; and are of different colours in the varieties. 6. The monorchis, or musky ophrys, hath a roundish bulbose root; crowned with three or four oblong leaves; an erect naked stalk, six inches high; terminated by a loose spike of yellowish, musky-scented flowers.

All these six species of ophrys flower in summer, at different times in different sorts, from May until July; and in most of the sorts exhibit a singularly curious appearance. The plants are all perennial in root, which are of the bulbous fleshy kind, from which the flower-stalks rise annually in spring, and decay in autumn; at which period is the proper time for removing the roots from one place to another. They all grow wild in Britain, &c.; are residents of woods, bogs, marshy grounds, sterile pastures, chalky soils, and the like places, where they flourish and display their singular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured some plants at the proper season, and planted them in soils and situations somewhat similar to that where they naturally grow, the roots will abide for several years, and flower annually.

As to their propagation, it may be tried by seed in a shady border, as soon as it is ripe; likewise by off-sets from the root, though they multiply sparingly in gardens: however, roots of some standing may be examined at the proper season, and any off-sets separated and planted in the proper places.

OPHTHALMOSCOPY, a branch of physiognomy, which deduces the knowledge of a man's temper and manner from the appearance of his eyes.

OPHTHALMIA, in medicine, an inflammation of the membranes which invest the eye; especially of the adnata, or albugineous coat. See MEDICINE, n° 283.

OPIATES, medicines of a thicker consistence than a syrup, prepared with opium scarcely fluid. They consist of various ingredients, made up with honey or syrup; and are to be used for a long time either for purgative, alterative, or corroborative intentions.

The word *opiate* is also used, in general, for any medicine given with an intention to procure sleep, whether in the form of electuaries, drops, or pills.

OPITS, or OPITIUS (Martin), a celebrated German poet, born at Breslaw in 1507. He acquired great fame by his Latin, and more by his German poems; and, retiring to Dantzic, wrote a history of the ancient

ancient Daci: he died of the plague in 1639.

OPITS (Henry), a learned Lutheran divine, born at Altenburg in Misnia in 1642. He was professor of theology and of the oriental languages at Kiel, where he acquired great reputation by a variety of excellent works concerning oriental literature and Hebrew antiquities. He died in 1712.

OPIUM, in the materia medica, is an inspissated juice, partly of the resinous and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry; but, in general, easily receives an impression from the finger: its colour is a brownish yellow, so very dark and dusky that at first it appears black: it has a dead and faint smell, and its taste is very bitter and acrid. It is to be chosen moderately firm, and not too soft; its smell and taste should be very strong, and care is to be taken that there be no dirty or stony matter in it.

Opium is the juice of the papaver album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which on being stuck into the head makes at once five long cuts in it; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and put up in a vessel which he carries fastened to his girdle; at the same time that this opium is collected, the opposite side of the poppy-head is wounded, and the opium collected from it the next day. They distinguish, however, the produce of the first wounds from that of the succeeding ones; for the first juice afforded by the plant is greatly superior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it a long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the consistence of pitch; and then work it up with their hands, and form it into cakes or rolls for sale.

Opium at present is in great esteem, and is one of the most valuable of all the simple medicines. Applied externally, it is emollient, relaxing, and discutient, and greatly promotes suppuration: if long kept upon the skin, it takes off the hair, and always occasions an itching in it; sometimes is exulcerates it, and raises little blisters, if applied to a tender part. Sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the sutures of the skull; for it has been known to have the most terrible effects in this application, and even to bring on death itself. Opium, taken internally, removes melancholy, eases pain, and disposes to sleep; in many cases removes hæmorrhages, and provokes sweating. A moderate dose is commonly under a grain; though, according to the circumstances, two grains, or even three, may be within the limits of this denomination: but custom will make people bear a dram or more; though in this case nature is vitiated, and nothing is to be hence judged in regard to others. If given dissolved, it operates in half an hour; if in a solid form, as in pills, or the like, it is sometimes an hour and a half. Its first effect, in this case, is the making the patient cheerful, as if he had drank moderately of wine, and at the same time bold and above the fear of danger; for which reason the Turks always take it when they are going to battle. A very immoderate dose brings on a sort of drunkenness, much like that occasioned by an immoderate quantity of strong liquors; cheerfulness and loud laughter at first, than a relaxation of the limbs, a loss of memory, and lightheadedness; then vertigoes, dimness of the eyes, with a laxity of the cornea and a dilatation of the pupils, a slowness of the the pulse, redness of face, relaxation of the under-jaws, swelling of the lips, difficulty of breathing, painful erection of the penis, convulsions, cold sweat, and finally death. Those who escape are usually relieved by a great number of stools, or profuse sweats.

OPOBALSAMUM, in the materia medica. Opobalsam, or balm of Gilead; a resinous juice, obtained from an evergreen tree, or shrub, growing spontaneously in Arabia. The best sort, which naturally exsudes from the plant, is scarce known to Europe; and the inferior kinds, said to be extracted by lightly boiling the leaves and branches in water, are very rarely seen among us. The true opobalsam, according to Alpinus, is at first turbid and white; of a very strong pungent smell, like that of turpentine, but much sweeter; and of a bitter, acrid, astringent taste; upon being kept for some times it becomes thin, limpid, light, of a greenish hue; then of a gold yellow; and at length of the colour of honey: after this it grows thick like turpentine, and loses much of its fragrance. This balsam is of great esteem in the eastern countries, both as a medicine, and as an odoriferous unguent and cosmetic. Its great scarcity has prevented its coming into use among us; in the mithridate and theriaca, which it is directed as an ingredient in, the London college allows the expressed oil of nutmegs as a succedaneum to it.

OPOPANAX, in the materia medica, is a gum resin of a tolerably firm texture, usually brought to us in loose granules or drops, and sometimes in large masses, formed of a number of these connected by a quantity of matter of the same kind; but these are usually loaded with extraneous matter, and are greatly inferior to the pure loose kind. The drops or granules of the fine opopanax, are on the outside of a brownish red colour, and of a dusky yellowish or whitish colour within: they are of a somewhat unctuous appearance, smooth on the surface; and are to be chosen in clear pieces, of a strong smell and acrid taste.

Opopanax is attenuating and discutient, and is gently purgative; it dispels flatulencies, and is good in asthmas, in inveterate coughs, and in disorders of the head and nerves. It also promotes the menses, and is good against all obstructions of the viscera.

OPOSSUM, in zoology. See DIDELPHIS.

OPPIANUS, a poet and grammarian of Anazarba in Cilicia, in the second century. He composed a poem of hunting, and another of fishing, for which Antoninus Caracalla gave him as many golden crowns as their were verses in his poems; they were called hence *Oppian's golden verses*. He died in the 30th year of his age.

OPPILATION, in medicine, the act of obstructing or stopping up the passages of the body, by redundant

dundant or peccant humours. This word is chiefly uſed for obſtructions in the lower belly.

OPTATIVE mood, in grammar, that which ſerves to expreſs an ardent deſire or wiſh for ſomething.

In moſt languages, except the Greek, the optative is only expreſſed by prefixing to the ſubjunctive an adverb of wiſhing; as *utinam*, in Latin; *plut a Dieu*, in French; and *would to God*, in Engliſh.

OPTIC angle, the angle which the optic axes of both eyes make with one another, as they tend to meet at ſome diſtance before the eyes.

Optic *Axis*, the axis of the eye, or a line going through the middle of the pupil, and the centre of the eye.

OPTICS;

THAT ſcience which treats of element of the light, and the various phenomena of viſion.

HISTORY.

§ 1. *Diſcoveries concerning the Light.*

These are enumerated under the article Light ſo fully, that there is little room for any further addition here. The nature of that ſubtile element is indeed very little known as yet, notwithſtanding all the endeavours of philoſophers; and whatever ſide is taken with regard to it, whether we ſuppoſe it to conſiſt of an infinity of ſmall particles propagated by a repulſive power from the luminous body, or whether we ſuppoſe it to conſiſt in the vibrations of a ſubtile fluid, there are prodigious difficulties, almoſt, if not totally inſuperable, which will attend the explanation of its phenomena. In many parts of this work the identity of light and of the electric fluid is aſſerted: this, however, doth not in the leaſt interfere with the phenomena of optics; all of which are guided by the ſame invariable laws, whether we ſuppoſe light to be a vibration of that fluid, or any thing elſe. We ſhall therefore proceed to,

1 Great difficulties attend the explanation of the phenomena of light.

§ 2. *Diſcoveries concerning the Refraction of Light.*

2 Refraction known to the ancients.

We find that the ancients, though they made very few optical experiments, nevertheleſs knew, that when light paſſed through mediums of different denſities, it did not move forward in a ſtraight line, but was bent, or *refracted*, out of its courſe. This was probably ſuggeſted to them by the appearance of a ſtraight ſtick partly immerſed in water: and we find many queſtions concerning this and other optical appearances in Ariſtotle; to which, however, his anſwers are inſignificant. Archimedes is even ſaid to have written a treatiſe concerning the appearance of a ring or circle under water, and therefore could not have been ignorant of the common phenomena of refraction. But the ancients were not only acquainted with theſe more ordinary appearances of refraction, but knew alſo the production of colours by refracted light. Seneca ſays, that if the light of the ſun ſhines through an angular piece of glaſs, it will ſhew all the colours of the rainbow. Theſe colours, however, he ſays are falſe, ſuch as are ſeen in a pigeon's neck when it changes its poſition; and of the ſame nature he ſays is a ſpeculum, which, without having any colour of its own, aſſumes that of any other body. It appears alſo, that the ancients were not unacquainted with the magnifying power of glaſs globes filled with water, though they do not ſeem to have known any thing of the reaſon of this power; and the ancient engravers are ſuppoſed to have made uſe of a glaſs globe filled with water to magnify their figures, and thereby to work to more advantage. That the power of tranſparent bodies of a ſpherical form in magnifying or burning was not wholly unknown to the ancients, is farther probable from certain gems preſerved in the cabinets of the curious, which are ſuppoſed to have belonged to the Druids. They are made of rock-cryſtal of various forms, amongſt which are found ſome that are lenticular and others that are ſpherical: and though they are not ſufficiently wrought to perform their office as well as they might have done if they had been more judiciouſly executed, yet it is hardly poſſible that their effect, in magnifying at leaſt, could have eſcaped the notice of thoſe who had often occaſion to handle them; if indeed, in the ſpherical or lenticular form, they were not purpoſely intended for the purpoſes of burning. One of theſe, of the ſpherical kind, of about an inch and a half diameter, is preſerved among the foſſils given to the univerſity of Cambridge by Dr Woodward.

3 And the magnifying power of glaſs-globes.

4 Refraction firſt treated of by Ptolemy.

The firſt treatiſe of any note written on the ſubject of optics, was by the celebrated aſtronomer Claudius Ptolomæus, who lived about the middle of the ſecond century. The treatiſe is loſt; but from the accounts of others we find that he treated of aſtronomical refractions. Though refraction in general had been obſerved very early, it is poſſible that it might not have occurred to any philoſophers much before his time, that the light of the ſun, moon, and ſtars muſt undergo a ſimilar refraction, in conſequence of falling obliquely upon the groſs atmoſphere that ſurrounds the earth; and that they muſt, by that means, be turned out of their rectilinear courſe, ſo as to cauſe thoſe luminaries to appear higher in the heavens than they would otherwiſe do. The firſt aſtronomers were not aware that the intervals between ſtars appear leſs near the horizon than in the meridian; and, on this account, they muſt have been much embarraſſed in their obſervations. But it is evident that Ptolemy was aware of this circumſtance, by the caution that he gives to allow ſomething for it, upon every recourſe to ancient obſervations.

2 His hypotheſis concerning the horizontal ſun and moon.

This philoſopher alſo advances a very ſenſible hypotheſis to account for the remarkably greater apparent ſize of the ſun and moon when ſeen near the horizon. The mind, he ſays, judges of the ſize of objects by means of a pre-conceived idea of their diſtance from us: and this diſtance is fancied to be greater when a number of objects are interpoſed between the eye and the body we are viewing; which is the caſe when we ſee the heavenly bodies near the horizon. In his Almageſt, however, he aſcribes this appearance to a refraction

fraction of the rays by vapours, which actually enlarge the angle under which the luminaries appear; juſt as the angle is enlarged by which an object is ſeen from under water.

6 Diſcoveries of Alhazen.

In the 12th century, the nature of refraction was largely conſidered by Alhazen an Arabian writer; in ſo much that, having made experiments upon it at the common ſurface between air and water, air and glaſs, water and glaſs or cryſtal; and, being prepoſſeſſed with the ancient opinion of cryſtalline orbs in the regions above the atmoſphere, he even ſuſpected a refraction there alſo, and fancied he could prove it by aſtronomical obſervations. This author deduces from hence ſeveral properties of atmoſpherical refraction, as that it increaſes the altitudes of all objects in the heavens; and he firſt advanced, that the ſtars are ſometimes ſeen above the horizon by means of refraction, when they are really below it. This obſervation was confirmed by Vitellio, B. Waltherus, and eſpecially by the excellent obſervations of Tycho Brahe. Alhazen obſerved, that refraction contracts the diameters and diſtances of the heavenly bodies, and that it is the cauſe of the twinkling of the ſtars. But we do not find that either he, or his follower Vitellio, knew any thing of its juſt quantity. Indeed it is too ſmall to be determined except by very accurate inſtruments, and therefore we hear little more of it till about the year 1500; at which time great attention was paid to it by Bernard Walther, Mæſtlin, and others, but chiefly by Tycho Brahe.

Alhazen ſuppoſed that the refraction of the atmoſphere did not depend upon the vapours in it, as was probably the opinion of philoſophers before his time, but on the different tranſparency; by which, as Montucla conjectures, he meant the denſity of the groſs air contiguous to the earth, and the ether or ſubtile air that lies beyond it. In examining the effects of refraction, he endeavours to prove that it is ſo far from being the cauſe of the heavenly bodies appearing larger near the horizon, that it would make them appear leſs; two ſtars, he ſays, appearing nearer together in the horizon, than near the meridian. This phenomenon he ranks among optical deceptions. We judge of diſtance, he ſays, by comparing the angle under which objects appear, with their ſuppoſed diſtance; ſo that if theſe angles be nearly equal, and the diſtance of one object be conceived greater than that of the other, it will be imagined to be larger. And the ſky near the horizon he ſays is always imagined to be further from us than any other part of the concave ſurface. Roger Bacon aſcribes this account of the horizontal moon to Ptolemy; and as ſuch it is examined, and objected to by B. Porta.

In the writings of this philoſopher we find the firſt diſtinct account of the magnifying power of glaſſes; and it is not improbable, that what he wrote upon this ſubject gave riſe to that moſt uſeful invention of ſpectacles. For he ſays, that if an object be applied cloſe to the baſe of the larger ſegment of a ſphere of glaſs, it will appear magnified. He alſo treats of the appearance of an object through a globe, and ſays that he was the firſt who obſerved the refraction of rays into it.

7 Of Vitellio.

In 1270, Vitellio, a native of Poland, publiſhed a treatiſe of optics, containing all that was valuable in Alhazen, and digeſted in a much more intelligible and methodical manner. He obſerves, that light is always loſt by refraction, in conſequence of which the objects ſeen by refracted light always appear leſs luminous; but he does not pretend to eſtimate the quantity of this loſs. He reduced into a table the reſult of his experiments on the refractive powers of air, water, and glaſs, correſponding to different angles of incidence. In his account of the horizontal moon he agrees exactly with Alhazen; obſerving, that in the horizon ſhe ſeems to touch the earth, and appears much more diſtant from us than in the zenith, on account of the intermediate ſpace containing a greater variety of objects upon the viſible ſurface of the earth. He aſcribes the twinkling of the ſtars to the motion of the air in which the light is refracted; and to illuſtrate this hypotheſis, he obſerves, that they twinkle ſtill more when viewed in water put in motion. He alſo ſhews, that refraction is neceſſary as well as reflection, to form the rainbow; becauſe the body which the rays fall upon is a tranſparent ſubſtance, at the ſurface of which one part of the light is always reflected and another refracted. But he ſeems to conſider refraction as ſerving only to condenſe the light, and thereby enabling it to make a ſtronger impreſſion upon the eye. This writer alſo makes ſome ingenious attempts to explain refraction, or to aſcertain the law of it. He alſo conſiders the foci of glaſs ſpheres, and the apparent ſize of objects ſeen through them; though upon theſe ſubjects he is not at all exact. It is ſufficient indeed to ſhew the ſtate of knowledge, or rather of ignorance, at that time, to obſerve, that both Vitellio, and his maſter Alhazen, endeavour to account for objects appearing larger when they are ſeen under water by the circular figure of its ſurface; ſince, being fluid, it conforms to the figure of the earth.

8 Of Roger Bacon.

Cotemporary with Vitellio was Roger Bacon, a man of very extenſive genius, and who wrote upon almoſt every branch of ſcience; yet he does not ſeem to have made any conſiderable advances beyond what Alhazen had done before him. Even ſome of the wildeſt and moſt abſurd of the opinions of the ancients have had the ſanction of his authority. He does not heſitate to aſſent to an opinion adopted by many of the ancients, and indeed by moſt philoſophers till his time, that viſual rays proceed from the eye; giving this reaſon for it, that every thing in nature is qualified to diſcharge its proper functions by its own powers, in the ſame manner as the ſun and other celeſtial bodies. In his *Specula Mathematica*, he added ſome obſervations on the refraction of the light of the ſtars; the apparent ſize of objects; the extraordinary ſize of the ſun and moon in the horizon: but in all this he is not very exact, and advances but little. In his *Opus Majus* he demonſtrates, that if a tranſparent body interpoſed between the eye and an object, be convex towards the eye, the object will appear magnified. This obſervation, however, he certainly had from Alhazen; the only difference between them is, that Bacon prefers the ſmaller ſegment of a ſphere, and Alhazen the larger, in which the latter certainly was right.

9 Of Maurolycus.

From this time, to that of the revival of learning in Europe, we have no farther treatiſe on the ſubject of refraction, or indeed on any other part of optics. One of the firſt who diſtinguiſhed himſelf in this way was, Maurolycus teacher of mathematics at Meſſina. In a treatiſe treatife, *De Lumine et Uumbra*, publifhed in 1575, he demonftrates that the cryftalline humour of the eye is a lens that collects the rays of light iffuing from the objects, and throws them upon the retina where is the focus of each pencil. From this principle he difcovered the reafon why fome people were fhort-fighted and others long-fighted; and why the former are relieved by concave, and the others by convex, glaffes.

10 Difcoveries of B. Porta.

About the fame time that Maurolycus made fuch advances towards the difcovery of the nature of vifion, Joannes Baptifta Porta of Naples difcovered the *camera obfcura*, which throws ftill more light on the fame fubject. His houfe was conftantly reforted to by all the ingenious perfons at Naples, whom he formed into what he called *an academy of fecrets*; each member being obliged to contribute fomething that was not generally known, and might be ufeful. By this means he was furnifhed with materials for his *Magia Naturalis*, which contains his account of the *camera obfcura*, and the firft edition of which was publifhed, as he informs us, when he was not quite 15 years old. He alfo gave the firft hint of the magic lantern; which Kircher afterwards followed and improved. His experiments with the *camera obfcura* convinced him, that vifion is performed by the intromiffion of fomething into the eye, and not by vifual rays proceeding from the eye as had been formerly imagined; and he was the firft who fully fatisfied himfelf and others upon this fubject. Indeed the refemblance between experiments with the *camera obfcura* and the manner in which vifion is performed in the eye, was too ftriking to efcape the obfervation of a lefs ingenious perfon. But when he fays that the eye is a *camera obfcura*, and the pupil the hole in the window-fhutter, he was fo far miftaken as to fuppofe that it was the cryftalline humour that correfponds to the wall which receives the images; nor was it difcovered till the year 1604, that this office is performed by the retina. He makes a variety of juft obfervations concerning vifion; and particularly explains feveral cafes in which we imagine things to be without the eye, when the appearances are occafioned by fome affection of the eye itfelf, or fome motion within the eye. He obferves alfo, that, in certain circumftances, vifion will be affifted by convex or concave glaffes; and he feems alfo to have made fome fmall advances towards the difcovery of telefcopes. He takes notice, that a round and flat furface plunged into water, will appear hollow as well as magnified to an eye perpendicularly over it; and he very well explains by a figure, the manner in which it is done.

11 The law of refraction difcovered.

All this time, however, the great problem concerning the meafuring of refractions had remained unfolved. Alhazen and Vitellio, indeed, had attempted it; but failed, by attempting to meafure the angle itfelf, inftead of its fine. At laft, however, it was difcovered by Snellius, profeffor of mathematics at Leyden. This philofopher, however, did not perfectly underftand his own difcovery, nor did he live to publifh any account of it himfelf. It was afterwards explained by profeffor Hortenfius both publicly and privately, before it appeared in the writings of Defcartes, who publifhed it under a different form, without making any acknowledgement of his obligations to Snellius, whofe papers Huygens affures us, from his own knowledge, Defcartes had feen.

12 Opinions of Defcartes and Leibnitz on this fubject.

It does not appear that, before Defcartes, any perfon attempted to explain the caufe of refraction; which he undertook to do by the refolution of forces, on the principles of mechanics. In confequence of this, he was obliged to fuppofe that light paffes with more eafe through a denfe medium, than through a rare one. The truth of this explanation was firft queftioned by M. Fermat, counfellor to the parliament of Thouloufe, and an able mathematician. He afferted, contrary to the opinion of Defcartes, that light fuffers more refiftance in water than air, and more in glafs than in water; and he maintained, that the refiftance of different mediums with refpect to light is in proportion to their denfities. M. Leibnitz adopted the fame general idea; and thefe gentlemen argued upon the fubject in the following manner.

Nature, fay they, accomplifhes her ends by the fhorteft methods. Light therefore ought to pafs from one point to another, either by the fhorteft road, or that in which the leaft time is required. But it is plain that the line in which light paffes, when it falls obliquely upon a denfer medium, is not the moft direct or the fhorteft; fo that it muft be that in which the leaft time is fpent. And whereas it is demoftrable, that light falling obliquely upon a denfer medium (in order to take up the leaft time poffible in paffing from a point in one medium to a point in the other) muft be refracted in fuch a manner, that the fines of the angles of incidence and refraction muft be to one another, as the different facilities with which light is tranfmitted in thofe mediums; it follows, that fince light approaches the perpendicular when it paffes obliquely from air into water, fo that the fine of the angle of refraction is lefs than that of the angle of incidence, the facility with which water fuffers light to pafs through it is lefs than that of the air; fo that light meets with more refiftance in water than air.

13 Difcoveries concerning the refraction of different fubftances.

Arguments of this kind could not give fatisfaction; and a little time fhewed the fallacy of the hypothefis. At a meeting of the Royal Society, Aug. 31. 1664. an experiment for meafuring the refraction of common water was made with a new inftrument which they had prepared for that purpofe; and, the angle of incidence being 40 degrees, that of refraction was found to be 30. About this time alfo we find the firft mention of mediums not refracting the light in an exact proportion to their denfities. For Mr Boyle, in a letter to Mr Oldenburgh, dated Nov. 3. 1664, obferves, that in fpirit-of-wine, the proportion of the fines of the angles of incidence to the fines of the angles of refraction was nearly the fame, viz. as 4 to 3; and that, as fpirit-of-wine occafions a greater refraction than common water, fo oil of turpentine, which is lighter than fpirit-of-wine, produces not only a greater refraction than common water, but a much greater than falt water. And at a meeting held Nov. 9. the fame year, Dr Hooke (who had been ordered to profecute the experiment) brought in an account of one that he had made with pure and clear fallad oil, which was found to have produced a much greater refraction than any liquor which he had then tried; the angle of refraction that anfwered to an angle of incidence of 30° being found no lefs than 40° 30′, and the angle of refraction that anfwered to an angle of incidence of 20° being 29° 47′.—M. de la Hire alfo made

made several experiments to ascertain the refractive power of oil with respect to that of water and air, and found the sine of the angle of incidence to that of refraction to be as 60 to 42; which, he observes, is a little nearer to that of glass than to that of water, though oil is much lighter than water, and glass much heavier.

The members of the Royal Society finding that the refraction of salt water exceeded that of fresh, pursued the experiment farther with solutions of vitriol, saltpetre, and alum, in water; when they found the refraction of the solution of vitriol and saltpetre a little more, but that of alum a little less, than common water.

Dr Hooke made an experiment before the Royal Society, Feb. 11. 1663, which clearly proves that ice refracts the light less than water; which he took to be a good argument that the lightness of ice, which causes it to swim in water, is not caused only by the small bubbles which are visible in it, but that it arises from the uniform constitution or general texture of the whole mass. M. de la Hire also took a good deal of pains to determine whether, as was then the common opinion, the refractive power of ice and water were the same; and he found, as Dr Hooke had done before, that ice refracts less than water.

By a most accurate and elaborate experiment made in the year 1698, in which a ray of light was transmitted through a Torricellian vacuum, Mr Lowthorp found, that the refractive power of air is to that of water as 36 to 34,400. He concludes his account of the experiment with observing, that the refractive power of bodies is not proportioned to the density, at least not to the gravity, of the refracting medium. For the refractive power of glass to that of water, is as 55 to 34, whereas its gravity is as 87 to 34; that is, the squares of their refractive powers are very nearly as their respective gravities. And there are some fluids, which, though they are lighter than water, yet have a greater power of refraction. Thus the refractive power of spirit-of-wine, according to Dr Hooke's experiment, is to that of water as 36 to 33, and its gravity reciprocally as 33 to 36, or 36½. But the refractive powers of air and water seem to observe the simple proportion of their gravities directly. And if this should be confirmed by succeeding experiments, it is probable, he says, that the refractive powers of the atmosphere are every-where, and at all heights above the earth, proportioned to its density and expansion: and then it would be no difficult matter to trace the light through it, so as to terminate the shadow of the earth; and, together with proper expedients for measuring the quantity of light illuminating an opaque body, to examine at what distances the moon must be from the earth to suffer eclipses of the observed durations.

Cassini the younger happened to be present when Mr Lowthorp made the abovementioned experiment before the Royal Society; and upon his return home, having made a report of it to the members of the Royal Academy of Sciences, those gentlemen endeavoured to repeat the experiment in 1700; but they did not succeed.—For, as they said, beams of light passed through the vacuum without suffering any refraction. The Royal society being informed of this, were desirous that it might be put past dispute, by repeated and well-attested trials; and ordered Mr Hauksbee to make an instrument for the purpose, by the direction of Dr Halley. It consisted of a strong brass prism, two sides of which had sockets to receive two plane glasses, whereby the air in the prism might either be exhausted or condensed. The prism had also a mercurial gage fixed to it, to discover the density of the contained air; and was contrived to turn upon its axis, in order to make the refractions equal on each side when it was fixed to the end of a telescope. The refracting angle was near 64°; and the length of the telescope was about 10 feet, having a fine hair in its focus. The event of this accurate experiment was as follows:

Having chosen a proper and very distinct erect object, whose distance was 2588 feet, June 15. O. S. 1708, in the morning, the barometer being then at 29. 7½, and the thermometer at 60, they first exhausted the prism, and then applying it to the telescope, the horizontal hair in the focus covered a mark on the object distinctly seen through the vacuum, the two glasses being equally inclined to the visual ray. Then admitting the air into the prism, the object was seen to rise above the hair gradually as the air entered, and in the end the hair was observed to hide a mark 10¼ inches below the former mark. This they often repeated, and with the same success.

After this they applied the condensing engine to the prism; and having forced in another atmosphere, so that the density of the included air was double to to that of the outward, they again placed it before the telescope, and, letting out the air, the object which before seemed to rise, appeared gradually to descend, and the hair at length rested on an object higher than before by the same interval of 10¼ inches. This experiment they likewise frequently repeated, without any variation in the event.

They then forced in another atmosphere; and upon discharging the condensed air, the object was seen near 21 inches lower than before.

Now the radius in this case being 2588 feet, 10¼ inches will subtend an angle of one minute and 8 seconds, and the angle of incidence of the visual ray being 32 degrees (because the angle of the glass planes was 64) it follows from the known laws of refraction, that as the sine of 39° is to that of 31°, 59′, 26″, differing from 32° by 34″ the half of 1′, 8″; so is the sine of any other incidence, to the sine of its angle of refraction; and so is radius, or 1000000, to 999736; which, therefore, is the proportion between the sine of incidence *in vacuo* and the sine of refraction from thence into common air.

14 Refractive power of the air determined.

It appears, by these experiments, that the refractive power of the air is proportionable to its density. And since the density of the atmosphere is as its weight directly, and its heat inversely, the ratio of its density, at any given time, may be had by comparing the heights of the barometer and thermometer; and thence he concludes that this will also be the ratio of the refraction of the air. But Dr Smith observes, that, before we can depend upon the accuracy of this conclusion, we ought to examine whether heat and cold alone may not alter the refractive power of air, while its density continues the same. This, he says, may

may be tried, by heating the condenſed or rarified air, ſhut up in the priſm, juſt before it is fixed to the teleſcope, and by obſerving whether the hair in its focus will continue to cover the ſame mark all the while that the air is cooling.

The French academicians, being informed of the reſult of the above-mentioned experiment, employed M. Deliſle the younger to repeat their former experiment with more care; and he preſently found, that their operators had never made any vacuum at all, there being chinks in their inſtrument, through which the air had inſinuated itſelf. He therefore annexed a gage to his inſtrument, by which means he was ſure of his vacuum; and then the reſult of the experiment was the ſame with that in England. The refraction was always in proportion to the denſity of the air, excepting when the mercury was very low, and conſequently the air very rare; in which caſe the whole quantity being very ſmall, he could not perceive much difference in them. Comparing, however, the refractive power of the atmoſphere, obſerved at Paris, with the reſult of his experiment, he found, that the beſt vacuum he could make was far ſhort of that of the etherial regions above the atmoſphere.

Dr Hooke firſt ſuggeſted the thought of making allowance for the effect of the refraction of light, in paſſing from the higher and rarer, to the lower and denſer regions of the atmoſphere, in the computed height of mountains. To this he aſcribes the different opinions of authors concerning the height of ſeveral very high hills. He could not account for the appearance of the Pike of Tenerif, and ſeveral very high mountains, at ſo great a diſtance as that at which they are actually ſeen, but upon the ſuppoſition of the curvature of the viſual ray, that is made by its paſſing obliquely through a medium of ſuch different denſity, from the top of them to the eye, very far diſtant in the horizon. All calculations of the height of mountains that are made upon the ſuppoſition that the rays of light come from the tops of them, to our eyes, in ſtraight lines, muſt, he ſays, be very erroneous.

Dr Hooke gives a very good account of the twinkling of the ſtars; aſcribing it to the irregular and unequal refraction of the rays of light, which is alſo the reaſon why the limbs of the ſun, moon, and planets appear to wave or dance. And that there is ſuch an unequal diſtribution of the parts of the atmoſphere, he ſays, is manifeſt from the different degrees of heat and cold in the air. This, he ſays, will be evident by looking upon diſtant objects, over a piece of hot glaſs, which cannot be ſuppoſed to throw out any kind of exhalation from itſelf, as well as through aſcending ſteams of water.

15
Colours diſcovered to ariſe from refraction.

About this time Grimaldi firſt obſerved that the coloured image of the ſun refracted through a priſm is always oblong, and that colours proceed from refraction.—The way in which firſt he diſcovered this was by Vitellio's experiment above-mentioned, in which a piece of white paper placed at the bottom of a glaſs veſſel filled with water, and expoſed to the light of the ſun, appears coloured. However, he obſerved, that in caſe the two ſurfaces of the refracting medium were exactly parallel to each other, no colours were produced. But of the true cauſe of thoſe colours, viz. the different refrangibility of the rays of light, he had not the leaſt ſuſpicion. This diſcovery was reſerved for Sir Iſaac Newton, and which occurred to him in the year 1666. At that time he was buſied in grinding optic glaſſes, and procured a triangular glaſs priſm to ſatisfy himſelf concerning the phenomena of colours. While he amuſed himſelf with this, the oblong figure of the coloured ſpectrum firſt ſtruck him. He was ſurpriſed at the great diſproportion betwixt its length and breadth; the former being about five times the meaſure of the latter. He could hardly think that any difference in the thickneſs of the glaſs, or in the compoſition of it, could have ſuch an influence on the light. However, without concluding any thing *à priori*, he proceeded to examine the effects of theſe circumſtances, and particularly tried what would be the conſequence of tranſmitting the light through parts of the glaſs that were of different thickneſſes, or through holes in the window-ſhutter of different ſizes; or by ſetting the priſm on the outſide of the ſhutter, that the light might paſs through it, and be refracted before it was terminated by the hole.

16
Different refrangibility of the rays of light diſcovered by Sir Iſaac Newton.

He then ſuſpected that theſe colours might ariſe from the light being dilated by ſome unevenneſs in the glaſs, or ſome other accidental irregularity; and to try this, he took another priſm, like the former, and placed it in ſuch a manner, as that the light, paſſing through them both, might be refracted contrary ways, and ſo to be returned by the latter into the ſame courſe from which he had been diverted by the former. In this manner he thought that the regular effects of the firſt priſm would be deſtroyed by the ſecond; but that the irregular ones would be augmented by the multiplicity of refractions. The event was, that the light, which by the firſt priſm was diffuſed into an oblong form, was by the ſecond reduced into a circular one, with as much regularity as if it had not paſſed through either of them.

At laſt, after various experiments and conjectures, he hit upon what he calls the *experimentum crucis*, and which completed this great diſcovery. He took two boards, and placed one of them cloſe behind the priſm at the window, ſo that the light might paſs through a ſmall hole made in it for the purpoſe, and fall on the other board, which he placed at the diſtance of about 12 feet; having firſt made a ſmall hole in it alſo, for ſome of that incident light to paſs through. He then placed another priſm behind the ſecond board, ſo that the light which was tranſmitted through both the boards might paſs through that alſo, and be again refracted before it arrived at the wall. This being done, he took the firſt priſm in his hand, and turned it about its axis, ſo much as to make the ſeveral parts of the image, caſt on the ſecond board, ſucceſſively to paſs through the hole in it, that he might obſerve to what places on the wall the ſecond priſm would refract them; and he ſaw, by the change of thoſe places, that the light tending to that end of the image towards which the refraction of the firſt priſm was made, did, in the ſecond priſm, ſuffer a refraction conſiderably greater than the light which tended to the other end. This true cauſe, therefore, of the length of that image was diſcovered to be no other, than that light is not ſimilar, or homogeneal; but that it it consists of rays, some of which are more refrangible than others: so that, without any difference in their incidence on the same medium, some of them shall be more refracted than others; and therefore, that, according to their particular degrees of refrangibility, they will be transmitted through the prism to different parts of the opposite wall.

Since it appears from these experiments that different rays of light have different degrees of refrangibility, it necessarily follows, that the rules laid down by preceding philosophers concerning the refractive power of water, glass, &c. must be limited to the middle kind of rays. Sir Isaac, however, proves that the sine of the incidence of every kind of light, considered apart, is to its sine of refraction in a given ratio. This he deduces, both by experiment, and also geometrically, from the supposition that bodies refract the light by acting upon its rays in lines perpendicular to their surfaces.

17 Mr Dollond's discovery of the method of correcting the faults in refracting telescopes.

The most important discovery with regard to refraction since the time of Sir Isaac Newton is that of Mr Dollond, who found out a method of curing the faults of refracting telescopes arising from the different refrangibility of the rays, and which had been generally thought impossible to be removed.—Notwithstanding the great discovery of Sir Isaac Newton concerning the different refrangibility of the rays of light, he had no idea but that they were all affected in the same proportion by every medium, so that the refrangibility of the extreme rays might be determined if that of the mean ones was given. From this it would follow, as Mr Dollond observes, that equal and contrary refractions must not only destroy each other, but that the divergency of the colours from one refraction would likewise be corrected by the other, and there could be no possibility of producing any such thing as refraction which would not be affected by the different refrangibility of light; or, in other words, that however a ray of light might be refracted backwards and forwards by different mediums, as water, glass, &c. provided it was so done, that the emergent ray should be parallel to the incident one, it would ever after be white; and consequently, if it should come out inclined to the incident, it would diverge, and ever after be coloured; and from this it was natural to infer, that all spherical object-glasses of telescopes must be equally affected by the different refrangibility of light, in proportion to their apertures, of whatever materials they may be formed.

For this reason, Sir Isaac Newton, and all other philosophers and opticians, had despaired of bringing refracting telescopes to any great degree of perfection, without making them of an immoderate and very inconvenient length. They therefore applied themselves chiefly to the improvement of the reflecting telescope; and the business of refraction was dropped till about the year 1747, when M. Euler, improving upon a hint of Sir Isaac Newton's, formed a scheme of making object-glasses of two materials, of different refractive powers; hoping, that by this difference, the refractions would balance one another, and thereby prevent the dispersion of the rays that is occasioned by the difference of refrangibility. These object-glasses were composed of two lenses of glass with water between them. This memoir of M. Euler excited the attention of Mr Dollond. He carefully went over all M. Euler's calculations, substituting for his hypothetical laws of refraction, those which had been actually ascertained by the experiments of Newton; and found, that, after this necessary substitution, it followed from M. Euler's own principles, that there could be no union of the foci of all kinds of colours, but in a lens infinitely large.

M. Euler did not pretend to controvert the experiments of Newton: but he said, that they were not contrary to his hypothesis, but in so small a degree as might be neglected; and asserted, that, if they were admitted in all their extent, it would be impossible to correct the difference of refrangibility occasioned by the transmission of the rays from one medium into another of different density; a correction which he thought was very possible, since he supposed it to be actually effected in the structure of the eye, which he thought was made to consist of different mediums for that very purpose. To this kind of reasoning Mr Dollond made no reply, but by appealing to the experiments of Newton, and the great circumspection with which it was known that he conducted all his inquiries.

In this state of the controversy, the friends of M. Clairaut engaged him to attend to it; and it appeared to him, that, since the experiments of Newton cited by Mr Dollond could not be questioned, the speculations of M. Euler were more ingenious than useful.

The same paper of M. Euler was also particularly noticed by M. Klingenstierna of Sweden, who gave a considerable degree of attention to the subject, and discovered, that, from Newton's own principles, the result of the 8th experiment of the second book of his Optics could not answer his description of it.

He found, he says, that when light goes out of air through several contiguous refracting mediums, as through water and glass, and thence goes out again into air, whether the refracting surfaces be parallel or inclined to one another, that light, as often as by contrary refractions it is so corrected as to emerge in lines parallel to those in which it was incident, continues ever after to be white; but if the emergent rays be inclined to the incident, the whiteness of the emerging light will, by degrees, in passing on from the place of emergence, become tinged at its edges with colours. This he tried by refracting light with prisms of glass, placed within a prismatic vessel of water.

By theorems deduced from this experiment he infers, that the refractions of the rays of every sort, made out of any medium into air, are known by having the refraction of the rays of any one sort; and also that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

On the contrary, the Swedish philosopher observes, that, in this experiment, the rays of light, after passing through the water and the glass, though they come out parallel to the incident rays, will be coloured; but that the smaller the glass prism is, the near will the result of it approach to Newton's description.

This paper of M. Klingenstierna, being communicated to Mr Dollond by M. Mallet, made him entertain

tain doubts concerning Newton's report, and determined him to have recourfe to experiment.

He therefore cemented together two plates of parallel glafs at their edges, fo as to form a prifmatic veffel, when ftopped at the ends or bafes; and the edge being turned downwards, he placed in it a glafs prifm, with one of its edges upwards, and filled up the vacancy with clear water; fo that the refraction of the prifm was contrived to be contrary to that of the water, in order that a ray of light, tranfmitted through both thefe refracting mediums, might be affected by the difference only between the two refractions. As he found the water to refract more or lefs than the glafs prifm, he diminifhed or increafed the angle between the glafs plates, till he found the two contrary refractions to be equal; which he difcovered by viewing an object thro' this double prifm. For when it appeared neither raifed or depreffed, he was fatisfied that the refractions were equal, and that the emergent rays were parallel to the incident.

Now, according to the prevailing opinion, he obferves, that the object fhould have appeared thro' this double prifm in its natural colour; for if the difference of refrangibility had been in all refpects equal in the two equal refractions, they would have rectified each other. But this experiment fully proved the fallacy of the received opinion, by fhewing the divergency of the light by the glafs prifm, to be almoft double of that by the water; for the image of the object, though not at all refracted, was yet as much infected with prifmatic colours, as if it had been feen thro' a glafs wedge only, whofe refracting angle was near 30 degrees.

This experiment is the very fame with that of Sir Ifaac Newton's above-mentioned, notwithftanding the refult was fo remarkably different: but Mr Dollond affures us, that he ufed all poffible precaution and care in his procefs; and he kept his apparatus by him, that he might evince the truth of what he wrote, whenever he fhould be properly required to do it.

He plainly faw, however, that if the refracting angle of the water veffel could have admitted of a fufficient increafe, the divergency of the coloured rays would have been greatly diminifhed, or entirely rectified; and that there would have been a very great refraction without colour, as he had already produced a great difcolouring without refraction: but the inconveniency of fo large an angle, as that of the prifmatic veffel muft have been, to bring the light to an equal divergency with that of the glafs prifm whofe angle was about 60 degrees, made it neceffary to try fome experiments of the fame kind with fmaller angles.

Accordingly, he got a wedge of plate glafs, the angle of which was only nine degrees; and ufing it in the fame circumftances, he increafed the angle of the water wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glafs; that is, till the image of the object, though confiderably refracted by the excefs of the refraction of the water, appeared neverthelefs quite free from any colours proceeding from the different refrangibility of the light; and, as near as he could then meafure, the refraction by the water was about $\frac{3}{4}$ of that by the glafs. He acknowledges, indeed, that he was not very exact in taking the meafures, becaufe his bufinefs was not at that time to determine the exact proportions, fo much as to fhew that the divergency of the colours, by different fubftances, was by no means in proportion to the refractions, and that there was a poffibility of refraction without any divergency of the light at all.

As thefe experiments clearly proved, that different fubftances made the light to diverge very differently in proportion to their general refractive power, Mr Dollond began to fufpect that fuch variety might poffibly be found in different kinds of glafs, efpecially as experience had already fhewn that fome of the kinds made much better object-glaffes in the ufual way than others; and as no fatisfactory caufe had been affigned for fuch difference, he thought there was great reafon to prefume that it might be owing to the different divergency of the light in the fame refractions.

His next bufinefs, therefore, was to grind wedges of different kinds of glafs, and apply them together; fo that the refractions might be made in contrary directions, in order to difcover, as in the above-mentioned experiments, whether the refraction and the divergency of the colours would vanifh together. But a confiderable time elapfed before he could fet about that work: for tho' he was determined to try it at his leifure, for fatisfying his own curiofity, he did not expect to meet with a difference fufficient to give room for any great improvement of telefcopes, fo that it was not till the latter end of the year 1757 that he undertook it; but his firft trials convinced him that the bufinefs deferved his utmoft attention and application.

He difcovered a difference far beyond his hopes in the refractive qualities of different kinds of glafs, with refpect to the divergency of colours. The yellow or ftraw-coloured foreign fort, commonly called *Venice glafs*, and the *Englifh crown glafs*, proved to be very nearly alike in that refpect; though, in general, the crown glafs feemed to make the light diverge the lefs of the two. The common Englifh plate-glafs made the light diverge more; and the white cryftal, or Englifh flint-glafs, moft of all.

It was now his bufinefs to examine the particular qualities of every kind of glafs that he could come at, not to amufe himfelf with conjectures about the caufe of this difference, but to fix upon two forts in which it fhould be the greateft; and he foon found thefe to be the crown glafs, and the white flint glafs. He therefore ground one wedge of white flint, of about 25 degrees; and another of crown glafs, of about 29 degrees; which refracted very nearly alike, but their power of making the colours diverge was very different. He then ground feveral others of crown glafs to different angles, till he got one which was equal, with refpect to the divergency of the light, to that in the white flint-glafs: for when they were put together, fo as to refract in contrary directions, the refracted light was entirely free from colours. Then meafuring the refraction of each wedge with thefe different angles, he found that of the white glafs to be to that of the crown glafs, nearly as two to three: and this proportion held very nearly in all fmall angles; fo that any two wedges made in this proportion, and applied

plied together, so as to refract in a contrary direction, would refract the light without any dispersion of the rays.

In a letter to M. Klingenstierna, quoted by M. Clairaut, Mr Dollond says, that the sine of incidence in crown glass is to that of its general refraction as 1 to 1.53, and in flint glass as 1 to 1.583.

To apply this knowledge to practice, Mr Dollond went to work upon the object-glasses of telescopes; not doubting but that, upon the same principles on which a refracted colourless ray was produced by prisms, it might be done by lenses also, made of similar materials. And he succeeded, by considering, that, in order to make two spherical glasses that should refract the light in contrary directions, the one must be concave and the other convex; and as the rays are to converge to a real focus, the excess of refraction must evidently be in the convex lens. Also, as the convex glass is to refract the most, it appeared from his experiments, that it must be made of crown glass, and the concave of white flint glass. Farther, as the refractions of spherical glasses are in an inverse ratio of their focal distances, it follows, that the focal distances of the two glasses shall be inversely as the ratios of the refractions of the wedges; for being thus proportioned, every ray of light that passes thro' this combined glass, at whatever distance it may pass from its axis, will constantly be refracted, by the difference between two contrary refractions, in the proportion required; and therefore the different refrangibility of the light will be entirely removed.

Notwithstanding our author had these clear grounds in theory and experiment to go upon, he found that he had many difficulties to struggle with when he came to reduce them into actual practice; but with great patience and address, he at length got into a ready method of making telescopes upon these new principles.

His principal difficulties arose from the following circumstances. In the first place, the focal distances, as well as the particular surfaces, must be very nicely proportioned to the densities or refracting powers of the glasses, which are very apt to vary in the same sort of glass made at different times. Secondly, The centres of the two glasses must be placed truly in the common axis of the telescope, otherwise the desired effect will be in a great measure destroyed. Add to these, that there are four surfaces to be wrought perfectly spherical; and any person, he says, but moderately practised in optical operations, will allow, that there must be the greatest accuracy throughout the whole work. At length, however, after numerous trials, and a resolute perseverance, he was able to construct refracting telescopes, with such apertures and magnifying powers, under limited lengths, as, in the opinion of the best judges, far exceeded any thing that had been produced before, representing objects with great distinctness, and in their true colours.

It was objected to Mr Dollond's discovery, that the small dispersion of the rays in crown glass is only apparent, owing to the opacity of that kind of glass which does not transmit the fainter coloured rays in a sufficient quantity; but this objection is particularly considered, and answered by M. Beguelin.

As Mr Dollond did not explain the methods which he took in the choice of different spheres proper to destroy the effect of the different refrangibility of the rays of light, and gave no hint that he himself had any rule to direct himself in it; and as the calculation of the dispersion of the rays, in so complicated an affair, is very delicate; M. Clairaut, who had given a good deal of attention to this subject, from the beginning of the controversy, endeavoured to make out a complete theory of it.

Without some assistance of this kind, it is impossible, says this author, to construct telescopes of equal goodness with those of Mr Dollond, except by a servile imitation of his; which, however, on many accounts, would be very unlikely to answer. Besides, Mr Dollond only gave his proportions in general, and pretty near the truth; whereas the greatest possible precision is necessary. Also the best of Mr Dollond's telescopes were far short of the Newtonian ones (A); whereas it might be expected that they should exceed them, if the foci of all the coloured rays could be as perfectly united after refraction thro' glass, as after reflexion from a mirror; since there is more light lost in the latter case than in the former.

With a view, therefore, to assist the artist, he endeavoured to ascertain the refractive power of different kinds of glass, and also their property of separating the rays of light, by the following exact methods. He made use of two prisms placed close to one another, as Mr Dollond had done: but, instead of looking thro' them, he placed them in a darkened room; and when the image of the sun, transmitted thro' them, was perfectly white, he concluded that the different refrangibility of the rays was corrected.

In order to ascertain with more ease the true angles that prisms ought to have to destroy the effect of the difference of refrangibility, he constructed one which had one of its surfaces cylindrical, with several degrees of amplitude. By this means, without changing his prisms, he had the choice of an infinity of angles; among which, by examining the point of the curve surface, which, receiving the solar ray, gave a white image, he could easily find the true one.

He also ascertained the proportion in which different kinds of glass separated the rays of light, by measuring, with proper precautions, the oblong image of the sun, made by transmitting a beam of light thro' them. In making these experiments, he hit upon an easy method of convincing any person of the greater refractive power of English flint-glass above the common French glass, both with respect to the mean refraction, and the different refrangibility of the colours; for having taken two prisms, of these two kinds of glass, but equal in all other respects, and placed them so that they received, at the same time, two rays of the sun, with the same degree of incidence, he saw, that, of the two images, that which was produced by the English flint-glass was a little higher upon the wall than the other, and longer by more than one half.

M. Clairaut was assisted in these experiments by M. De Tournieres, and the results agreed with Mr Dollond's

(A) This assertion of M. Clairaut might be true at the time that it was made, but it is by no means so at present.

lond's in general; but whereas Mr Dollond had made the difperfion of the rays in glafs and in water to be as five to four (acknowledging, however, that he did not pretend to do it with exactnefs) thefe gentlemen, who took more pains, and ufed more precautions, found it to be as three to two. For the theorems and problems deduced by M. Clairaut from thefe new principles of optics, with a view to the perfection of telefcopes, we muft refer the reader to *Mem. Acad. Par.* 1756, 1757.

The labours of M. Clairaut were fucceeded by thofe of M. D'Alembert, which feem to have given the makers of thefe achromatic telefcopes all the aid that calculations can afford them. This excellent mathematician has likewife propofed a variety of new conftructions of thefe telefcopes, the advantages and difadvantages of which he diftinctly notes; at the fame time that he points out feveral methods of correcting the errors to which they are liable: as by placing the object-glaffes, in fome cafes, at a fmall diftance from one another, and fometimes by ufing eye-glaffes of different refractive powers; which is an expedient that feems not to have occurred to any perfon before him. He even fhews, that telefcopes may be made to advantage, confifting of only one object-glafs, and an eye-glafs of a different refractive power. Some of his conftructions have two or more eye-glaffes of different kinds of glafs. This fubject he confidered at large in one of the volumes of his *Opufcules Mathematiques*. We have alfo three memoirs of M. D'Alembert upon this fubject, among thofe of the French Academy; one in the year 1764, another in 1765, and a third in 1767.

At the conclufion of his fecond memoir he fays, that he does not doubt, but, by the different methods he propofes, achromatic telefcopes may be made to far greater degrees of perfection than any that have been feen hitherto, and even fuch as is hardly credible: And tho' the crown glafs, by its greenifh colour, may abforb fome part of the red or violet rays, which, however, is not found to be the cafe in fact; that objection cannot be made to the common French glafs, which is white, and which on this account he thinks muft be preferable to the Englifh crown glafs.

Nothwithftanding Meffrs Clairaut and D'Alembert feemed to have exhaufted the bufinefs of calculation on the fubject of Mr Dollond's telefcopes, no ufe could be made of their labours by foreign artifts. For ftill the telefcopes made in England, according to no exact rule, as foreigners fuppofed, were greatly fuperior to any that could be made elfe where, though under the immediate direction of thofe able calculators. For this M. Beguelin affigned feveral reafons. Among others, he thought that their geometrical theorems were too general, and their calculations too complicated, for the ufe of workmen. He alfo thought, that in confequence of neglecting fmall quantities, which thefe calculators profeffedly did, in order to make their algebraical expreffions more commodious, their conclufions were not fufficiently exact. But what he thought to be of the moft confequence, was the want of an exact method of meafuring the refractive and difperfing powers of the different kinds of glafs; and for want of this, the greateft precifion in calculation was altogether ufelefs.

Thefe confiderations induced this gentleman to take another view of this fubject; but ftill he could not reconcile the actual effect of Mr Dolland's telefcopes with his own conclufions: fo that he imagined, either that he had not the true refraction and difperfion of the two kinds of glafs given him; or elfe, that the aberration which ftill remained after his calculations, muft have been deftroyed by fome irregularity in the furfaces of the lenfes. He finds feveral errors in the calculations both of M. D'Alembert and Clairaut, and concludes with expreffing his defign to purfue this fubject much farther.

M. Euler, who firft gave occafion to this inquiry, which terminated fo happily for the advancement of fcience, being perfuaded both by his reafoning and calculations, that Mr Dollond had difcovered no new principle in optics, and yet not being able to controvert Mr Short's teftimony in favour of the goodnefs of his telefcopes, concluded that this extraordinary effect was owing, in part, to the crown glafs not tranfmitting all the red light, which would otherwife have come to a different focus, and have diftorted the image; but principally to his happening to hit on a juft curvature of his glafs, which he did not doubt would have produced the fame effect if his lenfes had all been made of the fame kind of glafs. In another place he imagines that the goodnefs of Mr Dollond's telefcope might be owing to the eye-glafs. If my theory, fays he, be true, this difagreeable confequence follows, that Mr Dollond's object-glaffes cannot be exempt from the difperfion of colours: yet a regard to fo refpectable a teftimony embarraffes me extremely, it being as difficult to queftion fuch exprefs authority, as to abandon a theory which appears me perfectly well founded, and to embrace an opinion, which is as contrary to all the eftablifhed laws of nature, as it is ftrange and feemingly abfurd. He even appeals to experiments made in a darkened room; in which, he fays, he is confident that Mr Dollond's object-glaffes would appear to have the fame defects that others are fubject to.

No doubting, however, but that Mr Dollond, either by chance, or otherwife, had made fome confiderable improvement in the conftruction of telefcopes, by the combination of glaffes; he abandoned his former project, in which he had recourfe to different mediums, and confined his attention to the correction of the errors which arife from the curvature of lenfes. But while he was proceeding, as he imagined, upon the true principles of optics, of which, however, he made but little ufe, he could not help expreffing his furprife that Mr Dollond fhould have been led to fo important a difcovery by reafoning in a manner quite contrary to the nature of things. At length, however, Mr Euler was convinced of the reality and importance of Mr Dollond's difcoveries; and very frankly acknowledges, that he fhould, perhaps, never have been brought to affent to it, had not his friend M. Clairaut affured him that the experiments of the Englifh optician might be depended upon. However, the experiments of M. Zeiher of Peterfburgh gave him the moft complete fatisfaction with refpect to this new law of refraction.

This gentleman demonftrated, that it is the lead in the compofition of glafs that gives it this remarkable property,

property, that while the refraction of the mean rays is nearly the same, that of the extremes differs considerably. And, by increasing the quantity of lead in the mixture, he produced a kind of glass, which occasioned a much greater separation of the extreme rays than the flint-glass which Mr Dollond had made use of. By this evidence M. Euler owns that he was compelled to renounce the principle which, before this time, had been considered as incontestible, *viz.* that the dispersion of the extreme rays depends upon the refraction of the mean; and that the former varies with the quality of the glass, while the latter is not affected by it.

From these new principles M. Euler deduces theorems concerning the combination of the lenses, and, in a manner similar to M. Clairaut and D'Alembert, points out methods of constructing achromatic telescopes.

18 Different compositions of glass for the purpose of correcting the faults of refracting telescopes.

While he was employed upon this subject, he informs us, that he received a letter from M. Zeiher, dated Petersburgh 30th of January 1764, in which he gives him a particular account of the success of his experiments on the composition of glass; and that, having mixed minium and sand in different proportions, the result of the mean refraction and the dispersion of the rays varied according to the following table.

Proportion of minium to flint.	Mean refraction from air into glass.	Dispersion of the rays in comparison of crown-glass.
I. — 3 : 1	2028 : 1000	4800 : 1000
II. — 2 : 1	1830 : 1000	3550 : 1080
III. — 1 : 1	1787 : 1000	3259 : 1000
IV. — $\frac{3}{4}$: 1	1732 : 1000	2207 : 1000
V. — $\frac{1}{2}$: 1	1724 : 1000	1800 : 1000
VI. — $\frac{1}{4}$: 1	1664 : 1000	1354 : 1000

By this table it is evident, that a greater quantity of lead not only occasions a greater dispersion of the rays, but also considerably increases the mean refraction. The first of these kinds of glass, which contains three times as much minium as flint, will appear very extraordinary; since, hitherto, no transparent substance has been known, whose refractive power exceded the ratio of two to one, and that the dispersion occasioned by this glass is almost five times as great at that of crown glass, which could not be believed by those who entertained any doubt concerning the same property in flint glass, the effect of which is three times as great as crown glass. One may observe, however, in these kinds of glass, something of a proportion between the mean refraction and the dispersion of rays, which may enable us to reconcile these surprising effects with other principles already known,

Here, however, M. Euler announces to us another discovery of the same M. Zeiher, no less surprising than the former, and which disconcerted all his schemes for reconciling the above-mentioned phenomena. As the six kinds of glass mentioned in the above table were composed of nothing but minium and flint, M. Zeiher happened to think of mixing alkaline salts with them, in order to give the glass a consistence more proper for dioptric uses; when he was much surprised to find this mixture greatly diminished the mean refraction, almost without making any change in the dispersion. After many trials, he at length obtained a kind of glass greatly superior to the flint-glass of Mr Dollond, with respect to the construction of telescopes; since it occasioned three times as great a dispersion of the rays as the common glass, at the same time that the mean refraction was only as 1.61 to 1.

M. Euler also gives particular instructions how to find both the mean and extreme refractive power of different kinds of glass; and particularly advises to make use of prisms with very large refracting angles, not less than 70°.

Notwithstanding it evidently appeared, we may say, to almost all philosophers, that Mr Dollond had made a real discovery of something not comprehended in the optical principles of Sir Isaac Newton, it did not appear so to Mr Murdoch. Upon this occasion, he interposed in the defence, as he imagined, of Sir Isaac Newton; maintaining, that Mr Dollond's positions, which, he says, he knows not by what mishap have been deemed paradoxes in Sir Isaac's theory of light, are really the necessary consequences of it. He also endeavours to shew that Sir Isaac might not be mistaken in his account of the experiment above-mentioned. But, admitting all that he advances in this part of his defence, Newton must have made use of a prism with a much smaller refracting angle than, from his own account of his experiments, we have any reason to believe that he ever did make use of.

The fact probably was, that Sir Isaac deceived himself in this case, by attending to what he imagined to be the clear consequence of his other experiments; and though the light he saw was certainly tinged with colours, and he must have seen it to be so, yet he might imagine that this circumstance arose from some imperfection in his prisms, or in the disposition of them, which he did not think it worth his while to examine. It is also observable, that Sir Isaac is not so particular in his description of his prisms, and other parts of his apparatus, in his account of this experiment, as he generally is in other cases; and therefore, probably, wrote his account of it from his memory only. In reality, it is no reflection upon Sir Isaac Newton, who did so much, to say that he was mistaken in this particular case, and that he did not make the discovery that Mr Dollond did; though it be great praise to Mr Dollond, and all those persons who contributed to this discovery, that they ventured to call in question the authority of so great a man.

19 Of the refraction of the atmosphere.

We shall conclude the history of the discoveries concerning refraction, with some account of the refractions of the atmosphere.—Tables of this have been calculated by Mr Lambert with a view to correct the inaccuracies of geometrical observations of the altitudes of mountains. The observations of Mr Lambert, however, go upon the supposition that the refractive power of the atmosphere is invariable: But this is by no means the case; and therefore his rules must be considered as true for the mean state of the air only.

A most remarkable variety in the refractive power of the atmosphere was observed by Dr Nettleton, near Halifax in Yorkshire, which demonstrates how little we can depend upon the calculated heights of mountains, when the observations are made with an instrument, and the refractive power of the air is to be allowed

Bramin's OBSERVATORY. Plate CCV.

lowed for. Being desirous to learn, by observation, how far the mercury would descend in the barometer at any given elevation, (for which there is the best opportunity in that hilly country), he proposed to take the height of some of their highest hills; but when he attempted it, he found his observation so much disturbed by refraction, that he could come to no certainty. Having measured one hill of a considerable height, in a clear day, and observed the mercury at the bottom and at the top, he found, according to that estimation, that about 90 feet, or more, were required to make the mercury fall $\frac{1}{10}$ of an inch; but afterwards, repeating the experiment on a cloudy day, when the air was rather gross and hazy, he found the small angles so much increased by refraction as to make the hill much higher than before. He afterwards frequently made observations at his own house, by pointing a quadrant to the tops of some neighbouring hills, and observed that they would appear higher in the morning before sun-rise, and also late in the evening, than at noon in a clear day, by several minutes. In one case the elevations of the same hill differed more than 30 minutes. From this he infers, that observations made on very high hills, especially when viewed at a distance, and under small angles, as they generally are, are probably uncertain, and not much to be depended upon.

M. Euler considered with great accuracy the refractive power of the atmosphere, as affected by different degrees of heat and elasticity, in which he shews, that its refractive power, to a considerable distance from the zenith, is sufficiently near the proportion of the tangent of that distance, and that the law of refraction follows the direct ratio of the height of the barometer, and the inverse ratio of the difference marked by the thermometer; but when stars are in the horizon, the changes are in a ratio somewhat greater than this, more especially on account of the variation in the heat.

20 Mr Michell's opinion concerning the twinkling of the stars.

The cause of the twinkling of the stars is now generally acknowledged to be the unequal refraction of light, in consequence of inequalities and undulations in the atmosphere.

Mr Michell supposes that the arrival of fewer or more rays at one time, especially from the smaller or the more remote fixed stars, may make such an unequal impression upon the eye, as may, at least, have some share in producing this effect; since it may be supposed, that even a single particle of light is sufficient to make a sensible impression upon the organs of sight; so that very few particles arriving at the eye in a second of time, perhaps no more than three or four, may be sufficient to make an object constantly visible. For though the impression may be considered as momentary, yet the perception occasioned by it is of some duration. Hence, he says, it is not improbable that the number of the particles of light which enter the eye in a second of time, even from Sirius himself, (the light of which does not exceed that of the smallest visible fixed star, in a greater proportion than that of about 1000 to 1), may not exceed 3000 or 4000, and from stars of the second magnitude they may, therefore, probably not exceed 100. Now the apparent increase and diminution of the light which we observe in the twinkling of the stars, seems to be repeated at not very unequal intervals, perhaps about four or five times in a second. He therefore thought it reasonable to suppose, that the inequalities which will naturally arise from the chance of the rays coming sometimes a little denser, and sometimes a little rarer, in so small a number of them, as must fall upon the eye in the fourth or fifth part of a second, may be sufficient to account for this appearance. An addition of two or three particles of light, or perhaps a single one, upon 20, especially if there should be an equal deficiency out of the next 20, would, he supposed, be very sensible, as he thought was probable from the very great difference in the appearance of stars, the light of which does not differ so much as is commonly imagined. The light of the middlemost star in the tail of the great bear does not, he thinks, exceed the light of the very small star that is next to it in a greater proportion than that of about 16 or 20 to 1; and M. Bouger found, that a difference in the light of objects of one part in 66 was sufficiently distinguishable.

It will perhaps, he says, be objected, that the rays coming from Sirius are too numerous to admit of a sufficient inequality arising from the common effect of chance, so frequently as would be necessary to produce this effect, whatever might happen with respect to the smaller stars; but he observes, that, till we know what inequality is necessary to produce this effect, we can only guess at it one way or the other.

Since these observations were published, Mr Michell has entertained some suspicion that the unequal density of light does not contribute to this effect in so great a degree as he had imagined, especially in consequence of observing that even Venus does sometimes twinkle. This he once observed her to do remarkably when she was about 6 degrees high, though Jupiter, which was then about 16 degrees high, and was sensibly less luminous, did not twinkle at all. If, notwithstanding the great number of rays which, no doubt, come to the eye from such a surface as this planet presents, its appearance be liable to be affected in this manner, it must be owing to such undulations in the atmosphere, as will probably render the effect of every other cause altogether insensible. The conjecture, however, has so much probability in it, that it well deserved to be recited.

21 Mr Muschenbroek's opinion.

M. Muschenbroek suspects, that the twinkling of the stars arises from some affection of the eye, as well as the state of the atmosphere. For he says, that in Holland, when the weather is frosty, and the sky very clear, the stars twinkle most manifestly to the naked eye, though not in telescopes; and since he does not suppose that there is any great exhalation, or dancing of the vapour at that time, he questions whether the vivacity of the light affecting the eye may not be concerned in the phenomenon.

But this philosopher might very easily have satisfied himself with respect to this hypothesis, by looking at the stars near the zenith, when the light traverses but a small part of the atmosphere, and therefore might be expected to affect the eye the most sensibly. For he would not have perceived them to twinkle near so much, as they do nearer the horizon, when much more of their light is intercepted by the atmosphere.

Some astronomers have lately endeavoured to explain the twinkling of the fixed stars by the extreme minuteness of their apparent diameter; so that they

they suppose the sight of them is intercepted by every mote that floats in the air. But Mr Michell observes, that no object can hide a star from us that is not large enough to exceed the apparent diameter of the star, by the diameter of the pupil of the eye; so that if a star was a mathematical point, the interposing object must still be equal in size to the pupil of the eye: nay, it must be large enough to hide the star from both eyes at the same time.

Besides a variation in the quantity of light, a momentary change of colour has likewise been observed in some of the fixed stars. Mr Melville says, that when one looks stedfastly at Sirius, or any bright star not much elevated above the horizon, its colour seems not to be constantly white, but appears tinctured, at every twinkling, with red and blue. This observation Mr Melville puts among his queries, with respect to which he could not entirely satisfy himself; and he observes, that the separation of the colours by the refractive power of the atmosphere is, probably, too small to be perceived. But the supposition of Mr Michell above-mentioned will pretty well account for this circumstance, though it may be thought inadequate to the former case. For the red and blue rays being much fewer than those of the intermediate colours, and therefore much more liable to inequalities, from the common effect of chance, a small excess or defect in either of them will make a very sensible difference in the colour of the stars.

§ 3. *Discoveries concerning the Reflection of Light.*

22 Account of the discoveries of the ancients.

However much the ancients might have been mistaken with regard to the nature of light, we find that they were acquainted with two very important observations concerning it; viz. that light is propagated in right lines, and that the angle of incidence is equal to the angle of reflection. Who it was that first made these important observations is not known. But indeed, important as they are, and the foundation of a great part of even the present system of optics, it is possible that, if he were known, he might not be allowed to have any share of merit, at least for the *former* of them; the fact is so very obvious, and so easily ascertained. As to the latter, that *the angle of incidence is equal to the angle of reflection* it was probably first discovered by observing a ray of the sun reflected from the surface of water, or some other polished body; or from observing the images of objects reflected by such surfaces. If philosophers attended to this phenomenon at all, they could not but take notice, that, if the ray fell nearly perpendicular upon such a surface, it was reflected near the perpendicular; and if it fell obliquely, it was reflected obliquely: and if they thought of applying any kind of measures to these angles, however coarse and imperfect, they could not but see that there was sufficient reason to assert their equality. At the same time they could not but know that the incident and reflected rays were both in the same plane.

Aristotle was sensible that it is the reflection of light from the atmosphere which prevents total darkness after the sun sets, and in places where he doth not shine in the day-time. He was also of opinion, that rainbows, halos, and mock suns, were all occasioned by the reflection of the sunbeams in different circumstances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he says, is not single, as in a mirror; for each drop of rain is too small to reflect a visible image, but the conjunction of all the images is visible.

23 Euclid's treatise of optics.

Without inquiring any farther into the nature of light or vision, the ancient geometricians contented themselves with deducing a system of optics from the two observations mentioned above, viz. the rectilinear progress of light, and the equality of the angles of incidence and reflection. The treatise of optics which has been ascribed to Euclid is employed about determining the aparent size and figure of objects, from the angle under which they appear, or which the extremities of them subtend at the eye, and apparent place of the image of an object reflected from a polished mirror; which he fixes at the place where the reflected ray meets a perpendicular to the mirror drawn through the object. But this work is so imperfect, and so inaccurately drawn up, that it is not generally thought to be the production of that great geometrician.

24 Of the burning-glasses of the ancients.

It appears from a circumstance in the history of Socrates, that the effects of burning-glasses had also been observed by the ancients; and it is probable that the Romans had a method of lighting their sacred fire by means of a concave speculum. It seems indeed to have been known pretty early, that there is an increase of heat in the place where the rays of light meet, when they are reflected from a concave mirror. The burning power of concave mirrors is taken notice of by Euclid in the second book of the treatise above-mentioned. If we give but a small degree of credit to what some ancient historians are said to have written concerning the exploits of Archimedes, we shall be induced to think that he made great use of this principle, in constructing some very powerful burning-mirrors; but nothing being said of other persons making use of his inventions, the whole account is very doubtful. It is allowed, however, that this eminent geometrician did write a treatise on the subject of burning-mirrors, though it be not now extant.

B. Porta supposes that the burning-mirrors of the ancients were of metal, in the form of a section of a parabola. It follows from the properties of this curve, that all the rays which fall upon it, parallel to its axis, will meet in the same point at the focus. Consequently, if the vertex of the parabola be cut off, as in fig. 1. it will make a convenient burning-mirror. Plate CCVI
In some drawings of this instrument frustum is so small, as to look like a ring. With an instrument of this kind, it is thought, that the Romans lighted their sacred fire. Some have also thought that this was the form of the mirror with which Archimedes burnt the Roman fleet; using either a lens, to throw the rays parallel, when they had been brought to a focus; or applying a smaller parabolic mirror for this purpose, as is represented fig. 2. But Dechales shows, that it is impossible to convey any rays in a direction parallel to one another, except those that come from the same point in the sun's disk.

25 Of seeing images in the air.

All this time, however, the nature of reflection was very far from being understood. Even lord Bacon, who

who made much greater advances in natural philosophy than his predecessors, and who pointed out the true method of improving it, was so far deceived with regard to the nature of reflection and refraction, that he supposed it possible to see the image reflected from a looking-glass, without seeing the glass itself; and to this purpose he quotes a story of friar Bacon, who is reported to have apparently walked in the air between two steeples, and which was thought to have been effected by reflection from glasses while he walked upon the ground.

The whole business of seeing images in the air may be traced up to Vitellio; and what he said upon the subject seems to have passed from writer to writer, with considerable additions, to the time of lord Bacon. What Vitellio endeavours to shew is, that it is possible, by means of a cylindrical convex speculum, to see the images of objects in the air, out of the speculum, when the objects themselves cannot be seen. But, if his description of the apparatus requisite for this experiment be attended to, it will be seen that the eye was to be directed towards the speculum, which was placed within a room, while both the object and the spectator were without it. But though he recommends this observation to the diligent study of his readers, he has not described it in such a manner as is very intelligible; and, indeed, it is certain, that no such effect can be produced by a convex mirror. If he himself did make any trial with the apparatus that he describes for this purpose, he must have been under some deception with respect to it.

B. Porta says, that this effect may be produced by a plane mirror only; and that an ingenious person may succeed in it: but his more particular description of a method to produce this extraordinary appearance is by a plane mirror and a concave one combined.

Kircher also speaks of the possibility of exhibiting these pendulous images, and supposes that they are reflected from the dense air; and the most perfect and pleasing deception depending upon the images in the air is one of which this writer gives a particular account in his *Ars Magna Lucis et Umbræ*, p. 783. In this case the image is placed at the bottom of a hollow polished cylinder, by which means it appears like a real solid substance, suspended within the mouth of the vessel. In this manner, he says, he once exhibited a representation of the ascension of Christ; when the images were so perfect, that the spectators could not be persuaded, but by attempting to handle them, that they were not real substances.

Among other amusing things that were either invented or improved by Kircher, was the method of throwing the appearance of letters, and other forms of things, into a darkened room from without, by means of a lens and a plane mirror. The figures or letters were written upon the face of the mirror, and inverted; and the focus of the lens was contrived to fall upon the screen or wall that received their images. In this manner, he says, that with the light of the sun he could throw a plain and distinct image 500 feet.

26 Discoveries of Kepler and Gregory.

It was Kepler who first discovered the true reason of the apparent places of objects seen by reflecting mirrors, as it depends upon the angle which the rays of light, issuing from the extreme part of an object, make with one another after such reflections. In plane mirrors these rays are reflected with the same degree of inclination to one another that they had before their incidence; but he shews that this inclination is changed in convex and concave mirrors.

27 Of Mr Boyle.

Mr Boyle made some curious observations concerning the reflecting powers of differently coloured substances. Many learned men, he says, imagined that snow affects the eyes, not by a *borrowed*, but by a *native* light; but having placed a quantity of snow in a room from which all foreign light was excluded, neither he nor any body else was able to perceive it. To try whether white bodies reflect more light than others, he held a sheet of white paper in a sun-beam admitted into a darkened room; and observed that it reflected much more light than a paper of any other colour, a considerable part of the room being enlightened by it. Farther, to shew that white bodies reflect the rays outwards, he adds, that common burning-glasses will not of a long time burn or discolour white paper. When he was a boy, he says, and took great pleasure in making experiments with these glasses, he was much surprised at this remarkable circumstance; and it set him very early upon guessing at the nature of whiteness, especially as he observed that the image of the sun was not so well defined upon white paper as upon black; and as, when he put ink upon the paper, the moisture would be quickly dried up, and the paper, which he could not burn before, would presently take fire. He also found, that, by exposing his hand to the sun, with a thin black glove upon it, it would be suddenly and more considerably heated, than if he held his naked hand to the rays, or put on a glove of thin white leather.

To prove that black is the reverse of white, with respect to its property of reflecting the rays of the sun, he procured a large piece of black marble; and having got it ground into the form of a large spherical concave speculum, he found that the image of the sun reflected from it was far from offending or dazzling his eyes, as it would have done from another speculum; and tho' this was large, he could not in a long time set a piece of wood on fire with it; tho' a far less speculum, of the same form, and of a more reflecting substance, would presently have made it flame.

To satisfy himself still farther with respect to this subject, he took a broad and large tile; and having made one half of its surface white and the other black, he exposed it to the summer sun. And having let it lie there some time, he found, that while the whited part remained cool, the part that was black was grown very hot. For his farther satisfaction, he sometimes left part of the tile of its native red; and, after exposing the whole to the sun, observed that this part grew hotter than the white, but was not so hot as the black part. He also observes, that rooms hung with black are not only darker than they would otherwise be, but warmer too; and he knew several persons, who found great inconvenience from rooms hung with black. As another proof of his hypothesis, he informs, that a virtuoso, of unsuspected credit, acquainting him, that, in a hot climate, he had seen eggs well roasted in a short time, by first blacking the shells, and then exposing them to the sun.

28 Of the infusion of lignum nephriticum.

We have already taken notice of the remarkable property of lignum nephriticum first observed by Kircher.

cher. However, all his obfervations with regard to it fell very fhort of Mr Boyle. He defcribes this lignum nephriticum to be a whitifh kind of wood, that was brought from Mexico, which the natives call *coatl* or *tlapazatli*, and which had been thought to tinge water of a green colour only; but he fays that he found it to communicate all kinds of colours. If, fays he, an infufion of this wood be put into a glafs globe, and expofed to a ftrong light, it will be as colourlefs as pure water; but if it be carried into a place a little fhaded, it will be a moft beautiful green. In a place ftill more fhaded, it will incline to red; and in a very fhady place, or in an opaque veffel, it will be green again.

A cup of this remarkable wood was fent to Kircher by the procurator of his fociety at Mexico, and was prefented by him to the emperor as a great curiofity. It is called *lignum nephriticum*, becaufe the infufion of it was imagined to be of fervice in difeafes of the kidneys and bladder, and the natives of the country where it grows do make ufe of it for that purpofe.

Mr Boyle corrected feveral of the hafty obfervations of Kircher concerning the colours that appear in the infufion of lignum nephriticum, and he diverfified the experiments with it in a very pleafing manner. He firft diftinctly noted the two very different colours which this remarkable tincture exhibits, by tranfmitted and reflected light. If, fays he, it be held directly between the light and the eye, it will appear tinged (excepting the very top of it, where a fky-coloured circle fometimes appears) almoft of a golden colour, except the infufion be too ftrong; in which cafe it will be dark or reddifh, and requires to be diluted with water. But if it be held from the light, fo that the eye be between the light and the phial, it will appear of a deep lovely blue colour; as will alfo the drops, if any lie on the outfide of the glafs.

When a little of this tincture was poured upon a fheet of white paper, and placed in a window where the fun could fhine upon it, he obferved, that if he turned his back upon the fun, the fhadow of his pen, or any fuch flender fubftance, projected upon the liquor, would not be all dark, like other fhadows; but that part of it would be curioufly coloured, the edge of it next the body being almoft of a lively golden colour, and the more remote part blue. Thefe, and other experiments of a fimilar nature, many of his friends, he fays, beheld with wonder; and he remembered an excellent oculift, who accidentally meeting with a phial full of this liquor, and being unacquainted with this remarkable property of it, imagined, after he had viewed it a long time, that fome new and ftrange diftemper had feized his eyes: and Mr Boyle himfelf acknowledges, that the oddnefs of the phenomenon made him very defirous to find out the caufe of it; and his inquiries were not altogether unfuccefsful.

Obferving that this tincture, if it were too deep, was not tinged in fo beautiful a manner, and that the impregnating virtue of the wood did, by being frequently infufed in frefh water, gradually decay, he conjectured that the tincture contained much of the effential falt of the wood; and to try whether the fubtle parts, on which the colour depended, were volatile enough to be diftilled, without diffolving their texture, he applied fome of it to the gentle heat of a lamp-furnace; but he found all that came over was as limpid and colourlefs as rock water, while that which remained behind was of fo deep a blue, that it was only in a very ftrong light that it appeared of any colour.

Sufpecting that the tinging particles abounded with falts, whofe texture, and the colour thence arifing, would probably be altered by acids, he poured into a fmall quantity of it a very little fpirit of vinegar, and found that the blue colour immediately vanifhed, while the golden one remained, on which ever fide it was viewed with refpect to the light.

Upon this he imagined, that as the acid falts of the vinegar had been able to deprive the liquor of its blue colour, a fulphureous falt, which is of a contrary nature, would deftroy their effects; and having placed himfelf betwixt the window and the phial, and let fall into the fame liquor a few drops of oil of tartar *per deliquium*, he found that it was immediately reftored to its former blue colour, and exhibited all the fame phenomena which it had done at the firft.

Having fometimes brought a round long-necked phial, filled with this tincture, into a darkened room, into which a beam of the fun was admitted by a fmall aperture; and holding the phial fometimes near the fun-beams, and fometimes partly in them and partly out of them, changing alfo the pofition of the glafs, and viewing it from feveral parts of the room, it exhibited a much greater variety of colours than it did in an enlightened room. Befides the ufual colours, it was red in fome places, and green in others, and within were intermediate colours produced by the different degrees and odd mixtures of light and fhade.

It was not only in this tincture of lignum nephriticum that Mr Boyle obferved the difference between reflected and tranfmitted light. He obferved it even in gold, tho' no perfon explained the caufe of thefe effects before Sir Ifaac Newton. He took a piece of leaf-gold, and holding it betwixt his eye and the light, obferved that it did not appear of a golden colour, but of a greenifh blue. He alfo obferved the fame change of colour by candle-light; but the experiment did not fucceed with a leaf of filver.

The conftitution of the atmofphere and of the fea, we fhall find, by obfervations made in later periods, to be fimilar to that of this infufion; for the blue rays, and others of a faint colour, do not penetrate fo far into them as the red, and others of a ftronger colour: but what this conftitution is, which is common to them all, deferves to be inquired into. For almoft all other tinctures, and this of lignum nephriticum too, after fome change made in it by Mr Boyle, as well as all other femi-tranfparent coloured fubftances, as glafs, appear of the fame hue in all pofitions of the eye. To increafe or diminifh the quantity makes no difference, but to make the colour deeper or more dilute. 29

Mr Boyle's account of the colours of thin plates.

The firft diftinct account of the colours exhibited by thin plates of various fubftances, are met with among the obfervations of Mr Boyle. To fhew the chemifts that colours may be made to appear or vanifh, where there is no acceffion or change either of the fulphureous, the faline, or the mercurial principle of bodies, he obferves, that all chemical effential oils, as as alſo good ſpirit of wine, being ſhaken till they riſe in bubbles, appear of various colours; which immediately vaniſh when the bubbles burſt, ſo that a colourleſs liquor may be immediately made to exhibit a variety of colours, and loſe them in a moment, without any change in its eſſential principles. He then mentions the colours that appear in bubbles of ſoap and water, and alſo in turpentine. He ſometimes got glaſs blown ſo thin as to exhibit ſimilar colours; and obſerves, that a feather, of a proper ſhape and ſize, and alſo a black ribbon, held at a proper diſtance, between his eye and the ſun, ſhewed a variety of little rainbows, as he calls them, with very vivid colours, none of which were conſtantly to be ſeen in the ſame objects.

30
Dr Hooke's account of theſe colours.

Much more pains were taken with this ſubject, and a much greater number of obſervations reſpecting it were made, by Dr Hooke. As he loved to give ſurpriſe by his diſcoveries, he promiſed, at a meeting of the ſociety on the 7th of March 1672, to exhibit, at their next meeting, ſomething which had neither reflection nor refraction, and yet was diaphanous. Accordingly, at the time appointed, he produced the famous coloured bubble of ſoap and water, of which ſuch admirable uſe was afterwards made by Sir Iſaac Newton, but which Dr Hooke and his cotemporaries ſeem to have overlooked in Mr Boyle's treatiſe on colours, tho' it was publiſhed nine years before. It is no wonder that ſo curious an appearance excited the attention of that inquiſitive body, and that they ſhould deſire him to bring an account of it in writing at their next meeting.

By the help of a ſmall glaſs-pipe, there were blown ſeveral ſmall bubbles, out of a mixture of ſoap and water; where it was obſervable, that, at firſt, they appeared white and clear; but that, after ſome time, the film of water growing thinner, there appeared upon it all the colours of the rainbow: Firſt a pale yellow; then orange, red, purple, blue, green, &c. with the ſame ſeries of colours repeated; in which it was farther obſervable, that the firſt and laſt ſeries were very faint, and that the middlemoſt order or ſeries was very bright. After theſe colours had paſſed over the changes above mentioned, the film of the bubble began to appear white again; and preſently, in ſeveral parts of this ſecond white film, there appeared ſeveral holes, which by degrees grew very big, ſeveral of them running into one another. After reciting other obſervations, which are not of much conſequence, he ſays it is ſtrange, that tho' both the encompaſſing and encompaſſed air have ſurfaces, yet he could not obſerve that they afforded either reflection or refraction, which all the other parts of the encompaſſed air did. This experiment, he ſays, at firſt ſight, may appear very trivial, yet, as to the finding out the nature and cauſe of reflection, refraction, colours, congruity and incongruity, and ſeveral other properties of bodies, he looked upon it as one of the moſt inſtructive. And he promiſed to conſider it more afterwards; but we do not find that ever he did; nor indeed is it to be much regretted, as we ſhall ſoon find this buſineſs in better hands. He adds, that that which gives one colour by reflection, gives another by trajection; not much unlike the tincture of lignum nephriticum.

Dr Hooke was the firſt to obſerve, if not to deſcribe, the beautiful colours that appear in thin plates of muſcovy glaſs. Theſe, he ſays, are very beautiful to the naked eye, but much more when they are viewed with a microſcope. With this inſtrument he could perceive that theſe colours were ranged in rings ſurrounding the white ſpecks or flaws in this thin ſubſtance, that the order of the colours was the very ſame as in the rainbow, and that they were often repeated ten times. But the colours, he ſays, were diſpoſed as in the outer bow, and not the inner. Some of them alſo were much brighter than others, and ſome of them very much broader. He alſo obſerved, that if there was a place where the colours were very broad, and conſpicuous to the naked eye, they might be made, by preſſing the place with the finger, to change places, and move from one part to another. Laſtly, he obſerved, that if great care be uſed, this ſubſtance may be ſplit into plates of $\frac{1}{8}$ or $\frac{1}{6}$ of an inch in diameter, each of which will appear thro' a microſcope to be uniformly adorned with ſome one vivid colour, and that theſe plates will be found upon examination to be of the ſame thickneſs throughout.

As a fact ſimilar to this, but obſerved previous to it, we ſhall here mention that Lord Brereton, at a meeting of the Royal Society in 1666, produced ſome pieces of glaſs taken out of a window of a church, both on the north and on the ſouth ſide of it; obſerving, that they were all eaten in by the air, but that the piece taken from the ſouth ſide had ſome colours like thoſe of the rainbow upon it, which the others on the north ſide had not. This phenomenon has been frequently obſerved ſince, and in other circumſtances. It is not to doubted, but that in all theſe caſes, the glaſs is divided into thin plates, which exhibit colours, upon the ſame principle with thoſe which Dr Hooke obſerved in the bubble of ſoap and water, and in the thin plate of air, which we ſhall find more fully explained by Sir Iſaac Newton. With care the thin plates of the glaſs may be ſeparated, and the theory verified.

31
Why the ſtars are viſible by day at the bottom of a well.

An obſervation made by Otto Guericke, well explains the reaſon why ſtars are viſible at the bottom of a deep well. It is, ſays he, becauſe the light that proceeds from them is not overpowered by the rays of the ſun, which are loſt in the number of reflections which they muſt undergo in the pit, ſo that they can never reach the eye of a ſpectator at the bottom of it.

But of all thoſe who have given their attention to this ſubject of the reflection of light, none ſeems to have given ſuch ſatisfaction as M. Bouguer, and next to thoſe of Sir Iſaac Newton, his labours ſeem to have been the moſt ſucceſsful. The object of his curious and elaborate experiments was to meaſure the degrees of light, whether emitted, reflected, or refracted, by different bodies. They were originally occaſioned by an article of M. Mairan's in the Memoirs of the French academy for 1721, in which the proportion of the light of the ſun at the two ſolſtices were ſuppoſed to be known, and his laudable attempt to verify what had been before taken for granted, ſuggeſted a variety of new experiments, and opened to him and to the world a new field of optical knowledge. His firſt production upon this ſubject was a treatiſe intitled *Eſſai d'Optique*, which was received with general approbation. Afterwards,

wards, giving more attention to this fubject, he formed an idea of a much larger work, to which many more experiments were neceffary: but he was prevented, by a variety of interruptions, from executing his defign fo foon as he had propofed; and he had hardly completed it at the time of his death, in 1758; fo that we are obliged to his friend M. de la Caille for the care of the publication. At length, however, it was printed at Paris, in 1760, under the title of *Traite d' Optique*.

32 Difcoveries of M. Bouguer.

At the entrance upon this treatife, we are induced to form the moft pleafing expectations from our author's experiments, by his account of the variety, the fingular accuracy, and circumfpection, with which he made them; whereby he muft, to all appearance, have guarded againft every avenue to error, and particularly againft thofe objections to which the few attempts that had been made, of a fimilar nature, before him had been liable. In order to compare different degrees of light, he always contrived to place the bodies from which it proceeded, or other bodies illuminated by them, in fuch a manner as that he could view them diftinctly at the fame time; and he either varied the diftances of thefe bodies, or modified their light in fome other way, till he could perceive no difference between them. Then, confidering their different diftances, or the other circumftances by which their light was affected, he calculated the proportion which they would have borne to each other at the fame diftance, or in the fame circumftances.

Plate CCVI fig. 3.

To afcertain the quantity of light loft by reflection, he placed the mirror, or reflecting furface, B, on which the experiment was to be made, truly upright; and having taken two tablets, of precifely the fame colour, or of an equal degree of whitenefs, he placed them exactly parallel to one another at E and D, and threw light upon them by means of a lamp or candle, P, placed in a right line between them. He then placed himfelf fo that, with his eye at A, he could fee the tablet E, and the image of the tablet D, reflected from the mirror B, at the fame time; making them, as it were, to touch one another. He then moved the candle along the line ED, fo as to throw more or lefs light upon either of them, till he could perceive no difference in the ftrength of the light that came to his eye from them. After this, he had nothing more to do than to meafure the diftances EP and DP; for the fquares of thofe diftances expreffed the degree in which the reflection of the mirror diminifhed the quantity of light. It is evident, that if the mirror reflected all the rays it received, the candle P muft have been placed at C, at an equal diftance from each of the tablets, in order to make them appear equally illuminated; but becaufe much of the light is loft in reflection, they can only be made to appear equally bright by placing the candle nearer the tablet D, which is feen by reflection only.

Fig. 4.

To find how much light is loft by oblique reflection, he took two equally polifhed plates, D and E, and caufed them to be enlightened by the candle P; and while one of them, D, was feen at A, by reflection from B, placed in a pofition oblique to the eye, the other, E, was fo placed, as to appear contiguous to it; and removing the plate E, till the light which it reflected was no ftronger than that which came from the image D, feen by reflection at B, he eftimated the quantity of light that was loft by this oblique reflection, by the fquares of the diftances of the two objects from the candle.

It need fcarcely be added, that, in thefe experiments all foreign light was excluded, that his eye was fhaded, and that every other precaution was obferved in order to make his conclufions unqueftionable.

Fig. 5.

In order to afcertain the quantity of light loft by reflection with the greateft exactnefs, M. Bouguer introduced two beams of light into a darkened room, as by the apertures P and Q; which he had fo contrived, that he could place them higher or lower, and enlarge or contract them at pleafure; and the reflecting furface (as that of a fluid contained in a veffel) was placed horizontally at O, from whence the light coming thro' the hole P, was reflected to R, upon the fcreen GH, where it was compared with another beam of light that fell upon S, through the hole Q; which he made fo much lefs than P, as that the fpaces S and R were equally illuminated; and by the proportion that the apertures P and Q bore to each other, he calculated what quantity of light was loft by the reflection at O.

It is neceffary, he obferves, that the two beams of light PO and QS (which he ufually made 7 or 8 feet long) fhould be exactly parallel, that they might come from two points of the fky equally elevated above the horizon, and having precifely the fame intenfity of light. It was alfo neceffary that the hole Q fhould be a little higher than P, in order that the two images fhould be at the fame height, and near one another. It is no lefs neceffary, he fays, that the fcreen GH be exactly vertical, in order that the direct and reflected beams may fall upon it with the fame inclination; fince, otherwife, though the two lights were perfectly equal, they would not illuminate the fcreen equally. This difpofition, he fays, ferves to anfwer another important condition in thefe experiments; for the direct ray QS muft be of the fame length with the fum of the incident and reflected rays, PO and OR, in order that the quantity of light introduced into the room may be fenfibly proportional to the fizes of the apertures.

We fhall now proceed to recite the refult of the experiments which he made to meafure the quantity of light that is loft by reflection in a great variety of circumftances; but we fhall introduce them by the recital of fome which were made previous to them on the diminution of light by reflection, and the tranfmiffion of it to confiderable diftances through the air, by M. Buffon, at the time that he was conftructing his machine to burn at great diftances, mentioned under the article BURNING-*Glafs*.

33 Of Mr Buffon.

Receiving the light of the fun in a dark place, and comparing it with the fame light of the fun reflected by a mirror, he found, that at fmall diftances, as four or five feet, about one half was loft by reflection; as he judged by throwing two reflected beams upon the fame place, and comparing them with a beam of direct light; for then the intenfity of them both feemed to be the fame.

Having received the light at greater diftances, as at 100, 200, and 300 feet, he could hardly perceive that it loft any of its intenfity by being tranfmitted through fuch a fpace of air.

He afterwards made the fame experiments with candles, in the following manner: He placed himfelf oppofite

oppofite to a looking-glafs, with a book in his hand, in a room perfectly dark; and having one candle lighted in the next room, at the diftance of about 40 feet, he had it brought nearer to him by degrees, till he was juft able to diftinguifh the letters of the book, which was then 24 feet from the candle. He then received the light of the candle, reflected by the looking-glafs, upon his book, carefully excluding all the light that was reflected from any thing elfe; and he found that the diftance of the book from the candle, including the diftance from the book to the looking-glafs (which was only half a foot) was in all 15 feet. He repeated the experiment feveral times, and always with nearly the fame refult; and therefore concluded, that the quantity of direct light is to that of reflected as 576 to 225; fo that the light of five candles reflected from a plane mirror is about equal to that of two candles.

From thefe experiments it appeared, that more light was loft by reflection of the candles than of the fun, which M. Buffon thought was owing to this circumftance, that the light iffuing from the candle diverges, and therefore falls more obliquely upon the mirror than the light of the fun, the rays of which are nearly parallel.

Thefe experiments and obfervations of M. Buffon are curious; though it will be feen that they fall far fhort of thofe of M. Bouguer, both in extent and accuracy. We fhall begin with thofe which he made to afcertain the difference in the quantity of light reflected by glafs and polifhed metal.

34 Mr Bouguer's difcoveries concerning the reflection of glafs and polifhed metal.

Ufing a fmooth piece of glafs one line in thicknefs, he found, that when it was placed at an angle 15 degrees with the incident rays, it reflected 628 parts of 1000 which fell upon it; at the fame time that a metallic mirror, which he tried in the fame circumftances, reflected only 561 of them. At a lefs angle of incidence much more light was reflected; fo that at an angle of three degrees the glafs reflected 700 parts, and the metal fomething lefs, as in the former cafe.

Trying the reflection of bodies that were not polifhed, he found that a piece of white plafter, placed at an angle of 75°, with the incident rays, reflected $\frac{1}{119}$ part of the light is received from a candle, nine inches from it. White paper, in the fame circumftances, reflected in the fame proportion; but at the diftance of three inches, they both reflected 150 parts of 1000 that were incident.

Proceeding to make farther obfervations on the fubject of reflected light, he premifes the two following theorems, which he demonftrates geometrically. 1. When the luminous body is at an infinite diftance, and its light is received by a globe, the furface of which has a perfect polifh, and abforbs no light, it reflects the light equally in all directions, provided it be received at a confiderable diftance. He only excepts the place where the fhadow of the globe falls; but this, he fays, is no more than a fingle point, with refpect to the immenfity of the fpherical furface which receives its light.

2. The quantity of light reflected in one certain direction will always be exactly the fame, whether it be reflected by a very great number of fmall polifhed hemifpheres, by a lefs number of larger hemifpheres, or by a fingle hemifphere, provided they occupy the fame bafe, or cover the fame ground-plan.

The ufe he propofes to make of thefe theorems is to affift him in diftinguifhing whether the light reflected from bodies be owing to the extinction of it within them, or whether the roughnefs or eminences which cover them have not the fame effect with the fmall polifhed hemifpheres above-mentioned.

He begins with obferving, that, of the light reflected from Mercury, $\frac{1}{4}$ at leaft is loft, and that probably no fubftances reflect more than this. The rays were received at an angle of $11\frac{1}{2}$ degrees of incidence, that is meafured from the furface of the reflecting body, and not from the perpendicular, which, he fays, is what we are from this place to underftand whenever he mentions the angle of incidence.

35 Great differences in the reflective power of fubftances according to the angle of incidence.

The moft ftriking obfervations which he made with refpect to this fubject, are thofe which relate to the very great difference in the quantity of light reflected at different angles of incidence. In general, he fays, that reflection is ftronger at fmall angles of incidence, and weaker at large ones. The difference is exceffive when the rays ftrike the furface of tranfparent fubftances, with different degrees of obliquity; but it is almoft as great in fome opaque fubftances, and it was always more or lefs fo in every thing that he tried. He found the greateft inequality in black marble; in which he was aftonifhed to find, that, with an angle of 3° 35′ of incidence, though not perfectly polifhed, yet it reflected almoft as well as quick-filver. Of 1000 rays which it received, it returned 600; but when the angle of incidence was 14 degrees, it reflected only 156; when it was 30, it reflected 51; and when it was 80, it reflected only 23.

Similar experiments made with metallic mirrors always gave the differences much lefs confiderable. The greateft was hardly ever an eighth or a ninth part of it, but they were always in the fame way.

The great difference between the quantity of light reflected from the furface of water, at different angles of incidence, is truly furprifing; but our author obferves, that this difference was greater when the fmalleft inclinations were compared with thofe which were near to a right angle. He fometimes fufpected that, at very fmall angles of incidence, the reflection from water was even greater than from quick-filver. All things confidered, he thought it was not quite fo great, though it was very difficult to determine the precife difference between them. In very fmall angles, he fays, that water reflects nearly $\frac{3}{4}$ of the direct light.

There is no perfon, he fays, but has fometimes felt the force of this ftrong reflection from water, when he has been walking in ftill weather on the brink of a lake oppofite to the fun. In this cafe, the reflected light is $\frac{1}{3}$, $\frac{1}{2}$, or fometimes a greater proportion of the light that comes directly from the fun, which is an addition to the direct rays of the fun that cannot fail to be very fenfible. The direct light of the fun diminifhes gradually as it approaches the horizon, while the reflected light at the fame time grows ftronger: fo that there is a certain elevation of the fun, in which the united force of the direct and reflected light will be the greateft poffible, and this he fays is 12 or 13 degrees.

On the other hand, the light reflected from water at great angles of incidence is extremely fmall. Our author was affured, that, when the light was perpendicular, it reflected no more than the 37th part that quick-

quickſilver does in the ſame circumſtances; for it did not appear, from all his obſervations, that water reflects more than the 60th, or rather the 55th, part of perpendicular light. When the angle of incidence was 50 degrees, the light reflected from the ſurface of water was about the 32d part of that which mercury reflected; and as the reflection from water increaſes with the diminution of the angle of incidence, it was twice as ſtrong in proportion at 39 degrees; for it was then the 16th part of the quantity that mercury reflected.

In order to procure a common ſtandard by which to meaſure the proportion of light reflected from various fluid ſubſtances, he pitched upon water as the moſt commodious; and partly by obſervation, and partly by calculation, which he always found to agree with his obſervations, he drew up the following table of the quantity of light reflected from the ſurface of water, at different angles with the ſurface.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
½	721	17 ½	178
1	692	20	145
1 ½	669	25	97
2	639	30	65
2 ½	614	40	34
5	501	50	22
7 ½	409	60	19
10	333	70	18
12 ½	271	80	18
15	211	90	18

In the ſame manner, he drew up the following table, of the quantity of light reflected from the looking-glaſs not quickſilvered.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
2 ½	584	30	112
5	543	40	57
7 ½	474	50	34
10	412	60	27
12 ½	356	70	25
15	299	80	25
20	222	90	25
25	157		

Pouring a quantity of water into a veſſel containing quickſilver, it is evident that there will be two images of any objects ſeen by reflection from them, one at the ſurface of the water, and the other at that of the quickſilver. In the largeſt angles of incidence, the image at the ſurface of the water will diſappear, which will happen when it is about a 60th or an 80th part leſs luminous than the image at the ſurface of the quickſilver. Depreſſing the eye, the image on the water will grow ſtronger, and that on the quickſilver weaker in proportion; till at laſt, the latter will be incomparably weaker than the former, and at an angle of about 10 degrees they will be equally luminous. According to the table, $\frac{333}{1000}$ of the incident rays are reflected from the water at this angle of 10 degrees. At the ſurface of the mercury, they were reduced to 500; and of theſe, part being reflected back upon it from the under ſurface of the water, only 333 remained to make the image from the mercury.

36 Reflection of images by the air.

It has been obſerved by ſeveral perſons, particularly by Mr Edwards, (ſee Phil. Tranſ. vol. 53. p. 229.) that there is a remarkably ſtrong reflection into water, with reſpect to rays iſſuing from the water; and perſons under water have ſeen images of things in the water in a manner peculiarly diſtinct and beautiful: but this fact had not been obſerved with a ſufficient degree of attention, till it came into M. Bouguer's way to do it, and he acknowledges it to be very remarkable. In this caſe, he ſays, that from the ſmalleſt angles of incidence, to a certain number of degrees, the greateſt part of the rays are reflected, perhaps in as great a proportion as at the ſurface of metallic mirrors, or of quickſilver; while the other part, which does not eſcape into the air, is extinguiſhed or abſorbed; ſo that the ſurface of the tranſparent body appears opaque on the inſide. If the angle of incidence be increaſed only a few degrees, the ſtrong reflection ceaſes altogether, a great number of rays eſcape into the air, and very few are abſorbed or extinguiſhed. In poportion as the angle of incidence is farther increaſed, the quantity of the light reflected becomes leſs and leſs; and when it is near 90 degrees, almoſt all the rays eſcape out of the tranſparent body, its ſurface loſing almoſt all its power of reflection, and becoming almoſt as tranſparent as it is in other caſes, or when the light falls upon it from without.

37 Extinction of the rays of light at the ſurfaces of tranſparent bodies.

This property belonging to the ſurfaces of tranſparent bodies, of abſorbing or extinguiſhing the rays of light, is truly remarkable, and, as there is reaſon to believe, had not been noticed by any perſon before M. Bouguer. It had been conjectured by Sir Iſaac Newton, that rays of light become extinct only by impinging upon the ſolid part of bodies; but theſe obſervations of M. Bouguer ſhew that the fact is quite otherwiſe; and that this effect is to be attributed, not to the ſolid parts of bodies, which are certainly more numerous in a long tract of water than juſt in the paſſage out of water into air, but to ſome power lodged at the ſurfaces of bodies only, and therefore probably the ſame with that which reflects, refracts, and inflects the light.

38 Strong reflection by a priſm.

One of the above-mentioned obſervations, *viz.* all the light being reflected at certain angles of incidence from air into denſer ſubſtances, had frequently been obſerved, eſpecially in glaſs priſms; ſo that Newton made uſe of one of them inſtead of a reflecting mirror, in the conſtruction of his teleſcope. If a beam of light fall upon the air from within theſe priſms, at an angle of 10, 20, or 30 degrees, the effect will be nearly the ſame as at the ſurface of quickſilver, a fourth or a third of the rays being extinguiſhed, and $\frac{2}{3}$ or $\frac{3}{4}$ths reflected. This property retains its full force as far as an incidence of 49° 49′, (ſuppoſing the proportion of the ſines of refraction to be 31 and 20 for the mean refrangible rays); but if the angle of incidence be increaſed but one degree, the quantity of light reflected inwards decreaſes ſuddenly, and a great part of the rays eſcape out of the glaſs, ſo that the ſurface becomes ſuddenly tranſparent.

All tranſparent bodies have the ſame property, with this difference, that the angle of incidence at which the ſtrong ftrong reflection ceafes, and at which the light which is not reflected is extinguifhed, is greater in fome than in others. In water this angle is about 41° 32′; and in every medium it depends fo much on the invariable proportion of the fine of the angle of refraction to the fine of the angle of incidence, that this law alone is fufficient to determine all the phenomena of this new circumftance, at leaft as to this accidental opacity of the furface.

When our author proceeded to meafure the quantity of light reflected by thefe internal furfaces at great angles of incidence, he found many difficulties, efpecially on account of the many alterations which the light underwent before it came to his eye: but at length, ufing a plate of cryftal, he found, that, at an angle of 75 degrees, this internal reflection diminifhed the light 27 or 28 times; and as the external reflection at the fame angle diminifhed the light only 26 times, it follows that the internal reflection is a little ftronger than the other.

Repeating thefe experiments with the fame and different pieces of cryftal, he fometimes found the two reflections to be equally ftrong; but, in general, the internal was the ftronger. Alfo, the image reflected internally was always a little redder than an object which was feen directly through the plate of cryftal.

39 Of the quantity of light reflected by different fubftances.

Refuming his obfervations on the diminution of light, occafioned by the reflection of opaque bodies obliquely fituated, he compared it with the appearances of fimilar fubftances which reflected the light perpendicularly. Ufing pieces of filver made very white, he found, that, when one of them was placed at an angle of 75 degrees with refpect to the light, it reflected only 640 parts out of 1000. He then varied the angle, and alfo ufed white plafter and fine Dutch paper, and drew up the following table of the proportion of the light reflected from each of thofe fubftances at certain angles.

INTENSITY of LIGHT reflected from

Angles of incidence.	Silver.	Plafter.	Dutch Paper.
90	1000	1000	1000
75	802	762	971
60	640	640	743
45	455	529	507
30	319	352	332
15	209	194	203

Suppofing the afperities of opaque bodies to confift of very fmall planes, it appears from thefe obfervations, that there are fewer of them in thefe bodies which reflect the light at fmall angles of incidence than at greater; and our author fays, that the cafe was nearly the fame with refpect to all the opaque bodies that he tried. None of them had their roughnefs equivalent to fmall hemifpheres, which would have difperfed the light equally in all directions; and, from the *data* in the preceding table, he deduces mathematically the number of the little planes that compofe thofe furfaces, and that are inclined to the general furface at the angles above-mentioned, fuppofing that the whole furface contains 1000 of them that are parallel to itfelf, fo as to reflect the light perpendicularly, when the luminous body is fituated at right angles with refpect to it. His conclufions reduced to a table, corresponding to the preceding, are as follows:

Inclinations of the fmall furfaces with refpect to the large one.	The diftribution of the fmall planes that conftitute the afperities of the opaque furface in the		
	Silver.	Plafter.	Paper.
0	1000	1000	1000
15	777	736	937
30	554	554	545
45	333	374	358
60	161	176	166
75	53	50	52

Thefe variations in the number of little planes, or furfaces, he expreffes in the form of a curve; and afterwards he fhews, geometrically, what would be the effect, if the bodies were enlightened in one direction, and viewed in another; upon which fubject he has feveral curious theorems and problems: as, the pofition of the eye being given, to find the angle at which the luminous body muft be placed, in order to its reflecting the moft light; or, the fituation of the luminous body being given, to find a proper fituation for the eye, in order to fee it the moft enlightened, &c. But it would carry us too far into geometry to follow him through all thefe difquifitions.

40 Obfervations concerning the planets, &c.

Since the planets, as this accurate obferver takes notice, are more luminous at their edges than at their centres, he concludes, from the abovementioned principles, that the bodies which form them are conftituted in a manner different from ours; particularly that their opaque furfaces confift of fmall planes, more of which are inclined to the general furface than they are in terreftrial fubftances; and that there are in them an infinity of points, which have exactly the fame fplendour.

Our philofopher and geometrician next proceeds to afcertain the quantity of furface occupied by the fmall planes of each particular inclination, from confidering the quantity of light reflected by each, allowing thofe that have a greater inclination to the common furface to take up proportionably lefs fpace than thofe which are parallel to it. And comparing the quantity of light that would be reflected by fmall planes thus difpofed, with the quantity of light that was actually reflected by the three fubftances abovementioned, he found, that plafter, notwithftanding its extreme whitenefs, abforbs much light; for that, of 1000 rays that fall upon it, of which 166 or 167 ought to be reflected at an angle of 77 degrees, only 67 are in fact returned; fo that 100 out of 167 were extinguifhed, that is, about three-fifths.

With refpect to the planets, our author concludes, that of 300,000 rays which the moon receives, 172,000 are abforbed, or perhaps 204,100.

41 Of the furfaces of bodies.

Having confidered the furfaces of bodies as confifting of planes only, he thus explains himfelf.—Each fmall furface, feparately taken, is extremely irregular, and fome of them are really concave, and others convex; but, in reducing them to a middle ftate, they are to be confidered as planes. Neverthelefs he confiders them

them as planes only with respect to the reception of the rays; for as they are almost all curves, and as, besides this, many of those whose situation is different from others contribute to the same effect, the rays always issue from an actual or imaginary focus, and after reflection always diverge from one another.

If it be asked what becomes of those rays that are reflected from one asperity to another, he shews that very few of the rays can be in those circumstances; since they must fall upon planes which have more than 45 degrees of obliquity to the surface, of which there are very few in natural bodies. These rays must also fall at the bottom of those planes, and must meet with other planes similarly situated to receive them; and considering the great irregularity of the surfaces of opaque bodies, it may be concluded that very few of the rays are thus reflected upon the body itself; and that the little that is so reflected is probably lost to the spectators, being extinguished in the body.

42
Mr Melville's observations on the manner in which bodies are heated by light.

We are obliged to Mr Melville for some ingenious observations on the manner in which bodies are heated by light. He observes, that, as each colorific particle of an opaque body must be somewhat moved by the reaction of the particles of light, when it is reflected backwards and forwards between the same particles, it is manifest that they must likewise be agitated with a vibratory motion, and the time of a vibration will be equal to that which light takes up in moving from one particle of a body to another adjoining. This distance, in the most solid opaque bodies, cannot be supposed greater than $\frac{1}{12500}$th of an inch, which space a particle of light describes in the $\frac{1}{125000000000000}$th of a second. With so rapid a motion, therefore, may the internal parts of bodies be agitated by the influence of light, as to perform 125,000,000,000,000 vibrations, or more, in a second of time.

The arrival of different particles of light at the surface of the same colorific particle, in the same or different rays, may disturb the regularity of its vibrations, but will evidently increase their frequency, or raise still smaller vibrations among the parts which compose those particles; by which means the intestine motion will become more subtle, and more thoroughly diffused. If the quantity of light admitted into the body be increased, the vibrations of the particles must likewise increase in magnitude and velocity, till at last they may be so violent, as to make all the component particles dash one another to pieces by their mutual collision; in which case, the colour and texture of the body must be destroyed.

Since there is no reflection of light but at the surface of a medium, the same person observes, that the greatest quantity of rays, though crowded into the smallest space, will not of themselves produce any heat. From hence it follows, that the portion of air which lies in the focus of the most potent speculum, is not at all affected by the passage of light through it, but continues of the same temperature with the ambient air; though any opaque body, or even any transparent body denser than air, when put in the same place, would be intensely heated in an instant.

This consequence, evidently flowing from the plainest and most certain principles, not seeming to have been rightly understood by many philosophers; and even the silence of most physical writers concerning this paradoxical truth making it probable that they were unacquainted with it, he thought it worth his while to say something in explication of it. He observes, that the easiest way to be satisfied of the matter experimentally is, to hold a hair, or a piece of down, immediately above the focus of a lens or speculum, or to blow a stream of smoke from a pipe horizontally over it; for if the air in the focus were hotter than the surrounding fluid, it would continually ascend upon account of its rarefaction, and thereby sensibly agitate those slender bodies. Or a lens may be so placed as to form its focus within a body of water, or some other transparent substance, the heat of which may be examined from time to time with a thermometer; but care must be taken, in this experiment, to hold the lens as near as possible to the transparent body, lest the rays, by falling closer than ordinary on its surface, should warm it more than the common sunbeams.

To apply these observations to the explication of natural phenomena, he observes, that the atmosphere is not much warmed by the passage of the sun's light through it, but chiefly by its contact with the heated surface of the globe. This, he thought, furnished one very simple and plausible reason why it is coldest in all climates on the tops of very high mountains; namely, because they are removed to the greatest distance from the general surface of the earth. For it is well known, that a fluid heated by its contact with a solid body, decreases in heat in some inverse proportion to the distance from the body. He himself found, by repeated trials, that the heat of water in deep lakes decreases regularly from the surface downwards. But to have this question fully determined, the temperature of the air in the valley and on the mountain-top must be observed every hour, both night and day, and carefully compared together.

From this doctrine he thinks it reasonable to suppose, that the heat produced by a given number of rays, in an opaque body of a given magnitude, must be greater when the rays are more inclined to one another, than when they are less so; for the direction of the vibrations raised by the action of the light, whether in the colorific particles, or those of an inferior order, will more interfere with one another; from whence the intestine shocks and collisions must increase. Besides this, the colorific particles of opaque bodies being disposed in various situations, perhaps, upon the whole, the rays will fall more directly on each, the more they are inclined to one another. Is not this, says he, the reason of what has been remarked by philosophers, that the heat of the sun's light, collected into a cone, increases in approaching the focus in a much higher proportion than according to its density? That the difference of the angle in which the rays fall on any particle of a given magnitude, placed at different distances from the focus, is but small, is no proof that the phenomenon cannot be ascribed to it; since we know not in what high proportion one or both the circumstances now mentioned may operate. However, that it proceeds not from any unknown action of the rays upon one another, as has been insinuated, is evident from this, that each particular ray, after passing through the focus, preserves its own colour and its own direction, in the same manner

manner as if it were alone.

43 Abbé Nollet's experiments with burning-glaffes.

The attempts of the Abbé Nollet to fire inflammable fubftances by the power of the folar rays collected in the foci of burning mirrors, have a near relation to the prefent fubject. Confidering the great power of burning mirrors and lenfes, efpecially thofe of late conftruction, it will appear furprifing that this celebrated experimental philofopher fhould not be able to fire any liquid fubftance. But though he made the trial with all the care imaginable on the 19th of February 1757, he was not able to do it either with fpirit-of-wine, olive-oil, oil-of-turpentine, or æther; and though he could fire fulphur, yet he could not fucceed with Spanifh-wax, rofin, black pitch, or fuet. He both threw the focus of thefe mirrors upon the fubftances themfelves, and alfo upon the fumes that rofe from them; but all the effect was, that the liquor boiled, and was difperfed in vapour or very fmall drops, but would not take fire. When linen-rags, and other folid fubftances, were moiftened with any of thefe inflammable liquids, they would not take fire till the liquid was difperfed in a copious fume; fo that rags thus prepared were longer in burning than thofe that were dry.

44 M. Beaume's experiments.

M. Beaume, who affifted M. Nollet in fome of thefe experiments, obferved farther, that the fame fubftances which were eafily fired by the flame of burning bodies, could not be fet on fire by the contact of the hotteft bodies that did not actually flame. Neither æther nor fpirit-of-wine could be fired with a hot coal, or even red-hot iron, unlefs they were of a white heat. From thefe experiments our author concludes, that, fuppofing the electric matter to be the fame thing with fire or light, it muft fire fpirit-of-wine by means of fome other principle. The members of the academy Del Cimento had attempted to fire feveral of thefe fubftances, though without fuccefs; but this was fo early in the hiftory of philofophy, that nobody feems to have concluded, that, becaufe they failed in this attempt, the thing could not be done. However, the Abbé informs us, that he read an account of his experiments to the Royal Academy at Paris feveral years before he attended to what had been done by the Italian philofophers.

45 Bodies which feem to touch one another are not actually in contact.

By the help of optical principles, and efpecially obfervations on the reflection of light, Mr Melville difcovered that bodies which feem to touch one another are not always in actual contact. "It is common (fays he) to admire the volubility and luftre of drops of rain that lie on the leaves of colewort, and fome other vegetables;" but no philofopher, as far as he knew, had put himfelf to the trouble of explaining this curious phenomenon. Upon infpecting them narrowly, he found that the luftre of the drop is produced by a copious reflection of light from the flattened part of its furface contiguous to the plant. He obferved farther, that, when the drop rolls along a part which has been wetted, it immediately lofes all its luftre, the green plant being then feen clearly through it; whereas, in the other cafe, it is hardly to be difcerned.

From thefe two obfervations put together, he concluded, that the drop does not really touch the plant, when it has the mercurial appearance, but is fufpended in the air at fome diftance from it by the force of a repulfive power. For there could not be any copious reflection of white light from its under-furface, unlefs there were a real interval between it and the furface of the plant.

If that furface were perfectly fmooth, the under-furface of the drop would be fo likewife, and would therefore fhew an image of the illuminating body by reflection, like a piece of polifhed filver; but as it is confiderably rough and unequal, the under-furface becomes rough likewife, and fo, by reflecting the light copioufly in different directions, affumes the refplendent white colour of unpolifhed filver.

It being thus proved by an optical argument, that the drop is not really in contact with the plant which fupports it, it may eafily be conceived whence its volubility arifes, and why it leaves no moifture where it rolls.

46 Two curious mifcellaneous obfervations.

Before we conclude the hiftory of the obfervations concerning the reflection of light, we muft not omit to take notice of two curious mifcellaneous ones. Baron Alexander Funk, vifiting fome filver-mines in Sweden, obferved that, in a clear day, it was as dark as pitch under-ground in the eye of a pit, at 60 or 70 fathoms deep; whereas, in a cloudy or rainy day, he could even fee to read at 106 fathoms deep. Inquiring of the miners, he was informed that this is always the cafe; and, reflecting upon it, he imagined that it arofe from this circumftance, that when the atmofphere is full of clouds, light is reflected from them into the pit in all directions, and that thereby a confiderable proportion of the rays are reflected perpendicularly upon the earth; whereas, when the atmofphere is clear, there are no opaque bodies to reflect the light in this manner, at leaft in a fufficient quantity; and rays from the fun itfelf can never fall perpendicularly in that country. The other was that of the ingenious Mr Grey, who makes fuch a figure in the hiftory of electricity. This gentleman took a piece of ftiff brown paper, and pricking a fmall hole in it, he held it at a little diftance before him; when, applying a needle to his eye, he was furprifed to fee the point of it inverted. The nearer the needle was to the hole, the more it was magnified, but the lefs diftinct; and if it was fo held, as that its image was near the edge of the hole, its point feemed crooked. From thefe appearances he concluded, that thefe fmall holes, or fomething in them, produce the effects of concave fpeculums; and from this circumftance he took the liberty to call them *aërial fpeculums*.

§ 4. *Difcoveries concerning the Inflection of Light.*

This property of light was not difcovered till about the middle of the laft century. The perfon who firft made the difcovery was Father Grimaldi; at leaft he firft publifhed an account of it in his treatife *De lumine, coloribus, et iride*, printed in 1666. Dr Hooke, however, laid claim to the fame difcovery, though he did not publifh his obfervations till fix years after Grimaldi; having probably never feen his performance.

47 Dr Hooke's difcoveries.

Dr Hooke having made his room completely dark, admitted into it a beam of the fun's light by a very fmall hole in a brafs plate fixed in the window-fhutter. This beam fpreading itfelf, formed a cone, the apex of which was in the hole, and the bafe was on a paper, so placed, as to receive it at some distance. In this image of the sun, thus painted on the paper, he observed, that the middle was much brighter than the edges, and that there was a kind of dark penumbra about it, of about a 16th part of the diameter of the circle; which penumbra, he says, must be ascribed to a property of light, which he promised to explain.— Having observed this at the distance of about two inches from the former, he let in another cone of light; and receiving the bases of them, at such a distance from the holes as that the circles intersected each other, he observed that there was not only a penumbra, or darker ring, encompassing the lighter circle, but a manifest dark line, or circle, which appeared even where the limb of the one interfered with that of the other. This appearance is distinctly represented, fig. 6.

Plate CCVI

Comparing the diameter of this base with its distance from the hole, he found it to be by no means the same as it would have been if it had been formed by straight lines drawn from the extremities of the sun's disk, but varied with the size of the holes, and the distance of the paper.

Struck with this appearance, he proceeded to make farther experiments concerning the nature of light thus transmitted. To give a just idea of which, he held an opaque body BB, fig. 7, so as to intercept the light that entered at a hole in the window-shutter O, and was received on the screen AP. In these circumstances, he observed, that the shadow of the opaque body (which was a round piece of wood, not bright or polished) was all over somewhat enlightened, but more especially towards the edge. Some persons who were present, imagining that this light within the shadow might be produced by some kind of reflection from the side of this opaque body, on account of its roundness; and others supposing it might proceed from some reflection from the sides of the hole in the piece of brass through which the light was admitted into the room; to obviate both these objections, he admitted the light through a hole burnt in a piece of pasteboard, and intercepted it with a razor which had a very sharp edge; but still the appearances were the very same as before: so that, upon the whole, he concluded that they were occasioned by a new property of light, different from any that had been observed by preceding writers.

He farther diversified this experiment, by placing the razor so as to divide the cone of light into two parts, the hole in the shutter remaining as before, and placing the paper so as that none of the enlightened part of the circle fell upon it, but only the shadow of the razor; and, to his great surprise, he observed what he calls a *very brisk and visible radiation* striking down upon the paper, of the same breadth with the diameter of the lucid circle; and this radiation always struck perpendicularly from the line of shadow, and, like the tail of a comet, extended more than 10 times, and probably more than 100 times the breadth of the remaining part of the circle: nay, as far as he could find, by many trials, the light from the edge struck downwards into the shadow very near to a quadrant, though the greater were the deflections of this new light from the direct radiations of the cone, the more faint they were.

Observing this appearance with more attention, he found, wherever there was a part of the interposed body higher than the rest, that, opposite to it, the radiation of light into the shadow was brighter, as in the figure; and wherever there was a notch or gap in it, there would be a dark stroke in the half-enlightened shadow. From all these appearances, he concluded that they were to be ascribed to a new property of light, whereby it is deflected from straight lines, contrary to what had been before asserted by optical writers.

It does not appear, however, that our philosopher ever prosecuted this experiment to any purpose; as all that we find of his on the subject of light, after this time, are some crude thoughts which he read at a meeting of the Royal Society, on the 18th of March 1675; which, however, as they are only short hints, we shall copy.

They consist of eight articles; and, as he thought, contained an account of several properties of light, that had not been noticed before. There is a deflection of light, differing both from reflection and refraction, and seeming to depend on the unequal density of the constituent parts of the ray, whereby the light is dispersed from the place of condensation, and rarified, or gradually diverged into a quadrant. 2. This deflection is made towards the superficies of the opaque body perpendicularly. 3. Those parts of the diverged radiations which are deflected by the greatest angle from the straight or direct radiations are the faintest, and those that are deflected by the least angles are the strongest. 4. Rays cutting each other in one common foramen do not make the angles at the vertex equal. 5. Colours may be made without refraction. 6. The diameter of the sun cannot be truly taken with common sights. 7. The same rays of light, falling upon the same point of an object, will turn into all sorts of colours, by the various inclination of the object. 8. Colours begin to appear when two pulses of light are blended so well, and so near together, that the sense takes them for one.

43 Grimaldi's discoveries.

We shall now proceed to the discoveries of Father Grimaldi. Having introduced a ray of light, through a very small hole, AB, fig. 8. into a darkened room, he observed that the light was diffused in the form of a cone, the base of which was CD; and that if any opaque body, FE, was placed in this cone of light, at a considerable distance from the hole, and the shadow was received upon a piece of white paper, the boundaries of it were not confined within GH, or the penumbra IL, occasioned by the light proceeding from different parts of the aperture, and of the disk of the sun, but extended to MN; at which he was very much surprised, suspecting, and finding by calculation, that it was considerably broader than it could have been made by rays passing in right lines by the edges of the object.

But the most remarkable circumstance in this appearance was, that upon the lucid part of the base, CM and ND, streaks of coloured light were plainly distinguished, each being terminated by blue on the side next to the shadow, and by red on the other; and though these coloured streaks depended, in some measure, on the size of the aperture AB, because they could not be made to appear if it was large, yet he

A. Bell sculp.

he found that they were not limited either by it, or by the diameter of the ſun's diſk.

He farther obſerved, that theſe coloured ſtreaks were not all of the ſame breadth, but grew narrower as they receded from the ſhadow, and were each of them broader the farther the ſhadow was received from the opaque body, and alſo the more obliquely the paper on which they were received was held with reſpect to it. He never obſerved more than three of theſe ſtreaks.

To give a clearer idea of theſe coloured ſtreaks, he drew the repreſentation of them, exhibited in fig. 9. in which NMO repreſents the broadeſt and moſt luminous ſtreak, next to the dark ſhadow X. In the ſpace in which M is placed there was no diſtinction of colour, but the ſpace NN was blue, and the ſpace OO, on the other ſide of it, was red. The ſecond ſtreak, QPR, was narrower than the former; and of the three parts of which it conſiſted, the ſpace P had no particular colour, but QQ was a faint blue, and RR a faint red. The third ſtreak, TSV, was exactly ſimilar to the two others, but narrower than either of them, and the colours ſtill fainter.

Theſe coloured ſtreaks he obſerved to lie parallel to the ſhadow of the opaque body; but when it was of an angular form, they did not make the ſame acute angles, but were bent into a curve, the outermoſt being rounder than thoſe that were next the ſhadow, as is repreſented in fig. 10. If it was an inward angle, as DCH, the coloured ſtreaks, parallel to each other of the two ſides, croſſed without obliterating one another; only the colours were thereby rendered either more intenſe, or mixed.

The light that formed theſe coloured ſtreaks, the reader will perceive, muſt have been bent from the body; but this attentive obſerver has likewiſe given an account of other appearances, which muſt have been produced by the light bending towards the body. For within the ſhadow itſelf he ſometimes perceived coloured ſtreaks, ſimilar to thoſe above-mentioned on the outſide of the ſhadow. Sometimes he ſaw more of them, and ſometimes fewer: but for this purpoſe a very ſtrong light was requiſite, and the opaque body was obliged to be long, and of a moderate breadth; which, he ſays, is eaſily found by experience. A hair, for inſtance, or a fine needle, did not anſwer ſo well as a thin and narrow plate; and the ſtreaks were moſt diſtinguiſhable when the ſhadow was taken at the greateſt diſtance; but then the light grew fainter in the ſame proportion.

The number of theſe ſtreaks within the ſhadow was greater in proportion to the breadth of the plate. They were at leaſt two, and ſometimes four, if a thicker rod were made uſe of. But, with the ſame plate or rod, more or fewer ſtreaks appeared, in proportion to the diſtance at which the ſhadow was received; but they were broader when they were few, and narrower when there were more of them; and they were all much more diſtinct when the paper was held obliquely.

Theſe coloured ſtreaks within the ſhadow, like thoſe on the outſide of it, were bent in an arch, round the acute angles of the ſhadow, as they are repreſented in fig. 11. At this angle alſo, as at D, other ſhorter lucid ſtreaks were viſible, bent in the form of a plume, as they are drawn betwixt D and C, each bending round and meeting again in D. Theſe angular ſtreaks appeared, though the plate or rod was not wholly immerſed in the beam of light, but the angle of it only; and there were more or fewer in number, in proportion to the breadth of the rod or plate. If the plate or rod was very thin, the coloured ſtreaks within the ſhadow might be ſeen to bend round from the oppoſite ſides, and meet one another, as at B. A only repreſents a ſection of the figure, and not a proper termination of the ſhadow, and the ſtreaks within each ſide of it. The coloured ſtreaks without the ſhadow, he alſo obſerves, bend round it in the ſame manner.

Our author acknowledges, that he omits ſeveral obſervations of leſs conſequence, which cannot but occur to any perſon who ſhall make the experiment; and he ſays, that he was not able to give a perfectly clear idea of what he has attempted to deſcribe, nor does he think it in the power of words to do it.

In order to obtain the more ſatisfactory proof that rays of light do not always proceed in ſtraight lines, but really bend, in paſſing by the edges of bodies, he diverſified the firſt of the above-mentioned experiments in the following manner. He admitted a beam of light, by a very ſmall aperture, into a darkened room, as before; and, at a great diſtance from it, he fixed a plate EF, fig. 12. with a ſmall aperture, GH, which admitted only a part of the beam of light, and found, that when the light tranſmitted through this plate, was received at ſome diſtance, upon a white paper, the baſe IK was conſiderably larger than it could poſſibly have been made by rays iſſuing in the ſtraight lines through the two apertures, as the other ſtraight lines drawn cloſe to their edges plainly demonſtrate.

That thoſe who chooſe to repeat theſe experiments may not be diſappointed in their expectations from them, our author gives the following more particular inſtructions. The ſun's light muſt be very intenſe, and the apertures through which it is tranſmitted very narrow, particularly the firſt, CD, and the white paper, IK, on which it is received, muſt be at a conſiderable diſtance from the hole GH; otherwiſe it will not much exceed NO, which would be the breadth of the beam of light proceeding in ſtraight lines. He generally made the aperture CD $\frac{4}{100}$ or $\frac{5}{100}$ part of an ancient Roman foot, and the ſecond aperture, GH, $\frac{25}{100}$ or $\frac{30}{100}$; and the diſtances DG and GN were, at leaſt, 12 ſuch feet. The obſervation was made in the ſummer-time, when the atmoſphere was free from all vapours, and about mid-day.

F. Grimaldi alſo made the ſame experiment that has been recited from Dr Hooke, in which two beams of light, entering a darkened room by two ſmall apertures near to one another, projected cones of light, which, at a certain diſtance, in part coincided; and he particularly obſerved that the dark boundaries of each of them were viſible within the lucid ground of the other.

49 Obſervation of Dechales.

To theſe diſcoveries of Grimaldi, we ſhall ſubjoin an additional obſervation of Dechales; who took notice, that if ſmall ſcratches be made in any piece of poliſhed metal, and it be expoſed to the beams of the ſun in a darkened room, it will reflect the rays ſtreaked with colours in the direction of the ſcratches;

ches; as will appear if the reflected light be received upon a piece of white paper. That these colours are not produced by refraction, he says, is manifest; for that, if the scratches be made upon glass, the effect will be the same; and in this case, if the light had been refracted at the surface of the glass, it would have been transmitted through it. From these, and many other observations, he concludes that colour does not depend upon the refraction of light only, nor upon a variety of other circumstances, which he particularly enumerates, and the effects of which he discusses, but upon the intensity of the light only.

50 Of M. De la Hire.

We shall here give an account of a phenomenon of vision observed by M. De la Hire, because the subject of this section, viz. the *inflection of light*, seems to supply the true solution of it, though the author himself thought otherwise. It is observable, he says, that when we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions, to a considerable distance, like the tails of comets. This appearance exercised the sagacity of Descartes and Rohault, as well as of our author; but all three seem to have been mistaken with respect to it. Descartes ascribed this effect to certain wrinkles in the surface of the humours of the eye. Rohault says, that when the eye-lids are nearly closed, the edges of them act like convex lenses. But our author says, that the moisture on the surface of the eye, adhering partly to the eye itself, and partly to the edge of the eye-lid, makes a concave mirror, and so disperses the rays at their entrance into the eye. But the true reason seems to be, that the light passing among the eye-lashes, in this situation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions. The two former of these opinions are particularly stated and objected to by our author.

51 Sir Isaac Newton's discoveries.

The experiments of Father Grimaldi and Dr Hooke were not only repeated with the greatest care by Sir Isaac Newton, but carried much farther than they had thought of. So little use had been made of Grimaldi's observations, that all philosophers before Newton had ascribed the broad shadows, and even the fringes of light which he described, to the ordinary refraction of the air; but we shall see them placed in a very different point of view by our author.

He made in a piece of lead a small hole with a pin, the breadth of which was the 42d part of an inch, Through this hole he let into his darkened chamber a beam of the sun's light; and found, that the shadows of hairs, and other slender substances placed in it, were considerably broader than they would have been, if the rays of light had passed by those bodies in right lines. He therefore concluded, that they must have passed as they are represented in fig. 1. in which X represents a section of the hair, and AD, BE, &c. rays of light passing by at different distances, and then falling upon the wall GQ. Since, when the paper which receives the rays is at a great distance from the hair, the shadow is broad, it must follow, as he observes, that the hair acts upon the rays of light at some considerable distance from it, the action being strongest on those rays which are at the least distance, and growing weaker and weaker on those which are farther off, as is represented in this figure; and from hence it came to pass, that the shadow of the hair is much broader in proportion to the distance of the paper from the hair when it is nearer than when it is at a great distance.

Plate CCVII.

He found, that it was not material whether the hair was surrounded with air, or with any other pellucid substance; for he wetted a polished plate of glass, and laid the hair in the water upon the glass, and then laying another polished plate of glass upon it, so that the water might fill up the space between the glasses, and holding them in the beam of light, he found the shadow at the same distances was as big as before. Also the shadows of scratches made in polished plates of glass, and the veins in the glass, cast the like broad shadows; so that this breadth of shadow must proceed from some other cause than the refraction of the air.

The shadows of all bodies, metals, stones, glass, wood, horn, ice, &c. in this light were bordered with three parallel fringes, or bands of coloured light, of which that which was contiguous to the shadow was the broadest and most luminous, while that which was the most remote was the narrowest, and so faint as not easily to be visible. It was difficult to distinguish these colours, unless when the light fell very obliquely upon a smooth paper, or some other smooth white body, so as to make them appear much broader than they would otherwise have done; but in these circumstances the colours were plainly visible, and in the following order. The first or innermost fringe was violet, and deep blue next the shadow, light blue, green, and yellow in the middle, and red without. The second fringe was almost contiguous to the first, and the third to the second; and both were blue within, and yellow and red without; but their colours were very faint, especially those of the third. The colours, therefore, proceeded in the following order from the shadow; violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The shadows made by scratches and bubbles in polished plates of glass were bordered with the like fringes of coloured light.

He also observes, that by looking on the sun thro' a feather, or black ribbon, held close to the eye, several rainbows will appear, the shadows which the fibres or threads cast on the retina being bordered with the like fringes of colours.

Measuring these fringes and their intervals with the greatest accuracy, he found the former to be in the progression of the numbers 1, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{5}}$, and their intervals to be in the same progression with them, that is, the fringes and their intervals together to be in continual progression of the numbers 1, $\sqrt{\frac{1}{2}}$, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{4}}$, $\sqrt{\frac{1}{4}}$, or thereabouts. And these proportions held the same very nearly at all distances from the hair, the dark intervals of the fringes being as broad in proportion to the breadth the fringes at their first appearance as afterwards, at great distances from the hair, though not so dark and distinct.

In the next observation of our author, we find a very remarkable and curious appearance, which we should hardly have expected from the circumstances, though it is pretty similar to one that was noticed by Dr Hooke. The sun shining into his darkened chamber, through a hole ¼ of an inch broad, he placed, at the distance of two or three feet from the hole, a sheet of pasteboard,

board, black on both ſides; and in the middle of it he had made a hole about $\frac{1}{4}$ of an inch ſquare, for the light to paſs through; and behind the hole he faſtened to the paſteboard the blade of a ſharp knife, to intercept ſome part of the light which paſſed thro' the hole. The planes of the paſteboard and blade of the knife were parallel to one another, and perpendicular to the rays; and when they were ſo placed that none of the light fell on the paſteboard, but all of it paſſed through the hole to the knife, and there part of it fell upon the blade of the knife, and part of it paſſed by its edge, he let that part of the light which paſſed by fall on a white paper, 2 or 3 feet beyond the knife, and there ſaw two ſtreams of faint light ſhoot out both ways from the beam of light into the ſhadow, like the tails of comets. But becauſe the ſun's direct light, by its brightneſs upon the paper, obſcured theſe faint ſtreams, ſo that he could ſcarce ſee them, he made a little hole in the midſt of the paper for that light to paſs through and fall on a black cloth behind it; and then he ſaw the two ſtreams plainly. They were like one another, and pretty nearly equal in length, breadth, and quantity of light. Their light, at that end which was next to the ſun's direct light, was pretty ſtrong for the ſpace of about $\frac{1}{4}$ of an inch, or $\frac{1}{2}$ of an inch, and decreaſed gradually till it became inſenſible.

The whole length of either of theſe ſtreams, meaſured upon the paper, at the diſtance of 3 feet from the knife, was about 6 or 8 inches; ſo that it ſubtended an angle, at the edge of the knife, of about 10 or 12, or at moſt 14 degrees. Yet ſometimes he thought he ſaw it ſhoot 3 or 4 degrees farther; but with a light ſo very faint, that he could hardly perceive it. This light he ſuſpected might, in part at leaſt, ariſe from ſome other cauſe than the two ſtreams. For, placing his eye in that light, beyond the end of that ſtream which was behind the knife, and looking towards the knife, he could ſee a line of light upon its edge; and that not only when his eye was in the line of the ſtreams, but alſo when it was out of that line, either towards the point of the knife, or towards the handle. This line of light appeared contiguous to the edge of the knife, and was narrower than the light of the innermoſt fringe, and narroweſt when his eye was fartheſt from the direct light; and therefore ſeemed to paſs between the light of that fringe and the edge of the knife; and that which paſſed neareſt the edge ſeemed to be moſt bent, though not all of it.

He then placed another knife by the former, ſo that their edges might be parallel, and look towards one another, and that the beam of light might fall upon both the knives, and ſome part of it paſs between their edges. In this ſituation he obſerved, that when the diſtance of their edges was about the 400th part of an inch, the ſtream divided in the middle, and left a ſhadow between the two parts. This ſhadow was ſo black and dark, that all the light which paſſed between the knives ſeemed to be bent and turned aſide to the one hand or the other; and as the knives ſtill approached one another, the ſhadow grew broader, and the ſtreams ſhorter, next to it, till, upon the contact of the knives, all the light vaniſhed.

From this experiment our author concludes, that the light which is leaſt bent, and which goes to the inward ends of the ſtreams, paſſes by the edges of the knives at the greateſt diſtance; and this diſtance, when the ſhadow began to appear between the ſtreams, was about the 800th part of an inch; and the light which paſſed by the edges of the knives at diſtances ſtill leſs and leſs, was more and more faint, and went to thoſe parts of the ſtreams which were farther from the direct light; becauſe, when the knives approached one another till they touched, thoſe parts of the ſtreams vaniſhed laſt which were fartheſt from the direct light.

In the experiment of one knife only, the coloured fringes did not appear; but, on account of the breadth of the hole in the window, became ſo broad as to run into one another, and, by joining, to make one continual light in the beginning of the ſtreams; but in the laſt experiment, as the knives approached one another, a little before the ſhadow appeared between the two ſtreams, the fringes began to appear on the inner ends of the ſtreams, on either ſide of the direct light, three on one ſide, made by the edge of one knife, and three on the other ſide, made by the edge of the other knife. They were the moſt diſtinct when the knives were placed at the greateſt diſtance from the hole in the window, and became ſtill more diſtinct by making the hole leſs; ſo that he could ſometimes ſee a faint trace of a 4th fringe, beyond the three abovementioned; and as the knives approached one another, the fringes grew more diſtinct and larger, till they vaniſhed; the outermoſt vaniſhing firſt, and the innermoſt laſt. After they were all vaniſhed, and the line of light which was in the middle between them was grown very broad, extending itſelf on both ſides into the ſtreams of light deſcribed before, the above-mentioned ſhadow began to appear in the middle of this line, and to divide it along the middle into two lines of light, and increaſed till all the light vaniſhed. This enlargement of the fringes was ſo great, that the rays which went to the innermoſt fringe ſeemed to be bent about 20 times more when the fringe was ready to vaniſh, than when one of the knives was taken away.

From both theſe experiments compared together, our author concluded, that the light of the firſt fringe paſſed by the edge of the knife at a diſtance greater than the 800th part of an inch, that the light of the ſecond fringe paſſed by the edge of the knife at a greater diſtance than the light of the firſt fringe, and that of the third at a greater diſtance than that of the ſecond; and that the light of which the ſtreams abovementioned conſiſted, paſſed by the edges of the knives at leſs diſtances than that of any of the fringes.

He then got the edges of two knives ground truly ſtraight, and pricking their points into a board, ſo that their edges might look towards one another, and meeting near their points, contain a rectilinear angle, he faſtened their handles together, to make the angle invariable. The diſtance of the edges of the knives from one another, at the diſtance of 4 inches from the angular point, where the edges of the knives met, was the 8th part of an inch, ſo that the angle contained by their edges was about 1° 54′. The knives being thus fixed together, he placed them in a beam of the ſun's light let into his darkened chamber, thro' a hole the 42d part of an inch wide, at the diſtance of 10 or 13 feet from the hole; and he let the light which paſſed between their edges fall very obliquely on a ſmooth

ſmooth white ruler, at the diſtance of $\frac{1}{2}$ inch, or an inch, from the knives; and there he ſaw the fringes made by the two edges of the knives run along the edges of the ſhadows of the knives, in lines parallel to thoſe edges, without growing ſenſibly broader, till they meet in angles equal to the angle contained by the edges of the knives; and where they met and joined they ended, without croſſing one another. But if the ruler was held at a much greater diſtance from the knives, the fringes, where they were farther from the place of their meeting, were a little narrower, and they became ſomething broader as they approached nearer to one another, and after they met they croſſed one another, and then became much broader than before.

From theſe obſervations he concluded, that the diſtances at which the light compoſing the fringes paſſed by the knives were not increaſed or altered by the approach of the knives, but that the angles in which the rays were there bent were much increaſed by that approach, and that the knife which was neareſt to any ray determined which way the ray ſhould be bent, but that the other knife increaſed the bending.

When the rays fell very obliquely upon the ruler, at the diſtance of a third part of an inch from the knives, the dark line between the firſt and ſecond fringe of the ſhadow of one knife, and the dark line between the firſt and ſecond fringe of the ſhadow of the other knife, met one another, at the diſtance of the fifth part of an inch from the end of the light which paſſed between the knives, where their edges met one another; ſo that the diſtance of the edges of the knives, at the meeting of the dark lines, was the 160th part of an inch; and one half of that light paſſed by the edge of one knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of that knife; while the other half paſſed by the edge of the other knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of the other knife. But if the paper was held at a diſtance from the knives greater than the third part of an inch, the dark lines above-mentioned met at a greater diſtance than the fifth part of an inch from the end of the light which paſſed between the knives, at the meeting of their edges; ſo that the light which fell upon the paper where thoſe dark lines met paſſed between the knives, where their edges were farther diſtant than the 160th part of an inch. For at another time, when the two knives were 8 feet and 5 inches from the little hole in the window, the light which fell upon the paper where the above-mentioned dark lines met paſſed between the knives, where the diſtance between their edges was, as in the following table, at the diſtances from the paper there noted.

Diſtances of the paper from the knives in inches.	Diſtances between the edges of the knives in milleſimal parts of an inch.
$1\frac{1}{2}$	0,012
$3\frac{1}{3}$	0,020
$8\frac{3}{5}$	0,034
32	0,057
96	0,081
131	0,087

From theſe obſervations he concluded, that the light which makes the fringes upon the paper is not the ſame light at all diſtances of the paper from the knives; but that, when the paper is held near the knives, the fringes are made by light which paſſes by the edges of the knives at a leſs diſtance, and is more bent than when the paper is held at a greater diſtance from the knives.

When the fringes of the ſhadows of the knives fell perpendicularly upon the paper, at a great diſtance from the knives, they were in the form of hyperbolas, their dimenſions being as follows. Let CA, CB, repreſent lines drawn upon the paper, parallel to the edges of the knives; and between which all the light would fall if it ſuffered no inflection. DE is a right line drawn through C, making the angles ACD, BCE, equal to one another, and terminating all the light which falls upon the paper, from the point where the edges of the knives meet. Then *eis*, *fkt*, and *glv*, will be three hyperbolical lines, repreſenting the boundaries of the ſhadow of one of the knives, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Alſo *xip*, *ykq*, and *zlr*, will be three other hyperbolical lines, repreſenting the boundaries of the ſhadow of the other knife, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Theſe three hyperbolas are ſimilar, and equal to the former three, and croſs them in the points *i*, *k*, and *l*; ſo that the ſhadows of the knives are terminated, and diſtinguiſhed from the firſt luminous fringes, by the lines *eis* and *xip*, till the meeting and croſſing of the fringes; and then thoſe lines croſs the fringes in the form of dark lines terminating the firſt luminous fringes on the inſide, and diſtinguiſhing them from another light, which begins to appear at *i*, and illuminates all the triangular ſpace *i* DE*s*, comprehended by theſe dark lines and the right line DE. Of theſe hyperbolas one aſymptote is the line DE, and the other aſymptotes are parallel to the lines CA and CB.

Plate CCVII. fig. 2.

The ſun ſhining into his darkened room through the ſmall hole mentioned above, he placed at the hole a priſm to refract the light, and to form on the oppoſite wall the coloured image of the ſun; and he found, that the ſhadows of all bodies held in the coloured light between the priſm and the wall, were bordered with fringes of the colour of that light in which they were held; and comparing the fringes made in the ſeveral coloured lights, he found, that thoſe made in the red light were the largeſt, thoſe made in the violet were the leaſt, and thoſe made in the green were of a middle bigneſs. For the fringes with which the ſhadow of a man's hair were bordered, being meaſured croſs the ſhadow, at the diſtance of ſix inches from the hair, the diſtance between the middle and moſt luminous part of the firſt or innermoſt fringe on one ſide of the ſhadow, and that of the like fringe on the other ſide of the ſhadow, was, in the full red light $\frac{1}{37\frac{1}{2}}$ of an inch, and in the full violet $\frac{1}{46}$. The like diſtance between the middle and moſt luminous parts of the ſecond fringes, on either ſide of the ſhadow, was in the full red light $\frac{1}{22}$, and the violet $\frac{1}{27}$ of an inch; and theſe diſtances of the fringes held the ſame pro-

portion

portion at all diftances from the hair, without any fenfible variation.

From thefe obfervations it was evident, that the rays which made the fringes in the red light, paffed by the hair at a greater diftance than thofe which made the like fringes in the violet; fo that the hair, in caufing thefe fringes, acted alike upon the red light or leaft refrangible rays at a greater diftance, and upon the violet or moft refrangible rays at a lefs diftance; and thereby occafioned fringes of different fizes, without any change in the colour of any fort of light.

It may therefore be concluded, that when the hair in the firft obfervation was held in the white beam of the fun's light, and caft a fhadow which was bordered with three fringes of coloured light, thofe colours arofe not from any new modifications impreffed upon the rays of light by the hair, but only from the various inflections whereby the feveral forts of rays were feparated from one another, which before feparation, by the mixture of all their colours, compofed the white beam of the fun's light; but, when feparated, compofed lights of the feveral colours which they are originally difpofed to exhibit.

52 Maraldi's difcoveries. The perfon whofe name we find firft upon the lift of thofe who purfued any experiments fimilar to thofe of Newton on inflected light is M. Maraldi; whofe obfervations chiefly refpect the inflection of light towards other bodies, whereby their fhadows are partially illuminated; and many of the circumftances which he noticed relating to it are well worthy of our attention, as the reader will be convinced from the following account of them.

53 Experiments concerning the fhadows of cylinders. He expofed in the light of the fun a cylinder of wood three feet long, and 6½ lines in diameter; when its fhadow, being received upon a paper held clofe to it, was every where equally black and well defined, and continued to be fo to the diftance of 23 inches from it. At a greater diftance the fhadow appeared to be of two different denfities; for the two extremities of the fhadow, in the direction of the length of the cylinder, were terminated by two dark ftrokes, a little more than a line in breadth. Within thefe dark lines there was a faint light, equally difperfed through the fhadow, which formed an uniform penumbra, much lighter than the dark ftrokes at the extremity, or than the fhadow received near the cylinder. This appearance is reprefented in Plate CCVII. fig. 3.

As the cylinder was removed to a greater diftance from the paper, the two black lines continued to be nearly of the fame breadth, and the fame degree of obfcurity; but the penumbra in the middle grew lighter, and its breadth diminifhed, fo that the two dark lines at the extremity of the fhadow approached one another, till, at the diftance of 60 inches, they coincided, and the penumbra in the middle entirely vanifhed. At a ftill greater diftance a faint penumbra was vifible, but it was ill defined, and grew broader as the cylinder was removed farther off, but was fenfible at a very great diftance.

Befides the black and dark fhadow, which the cylinder formed near the opaque body, a narrow and faint penumbra was feen on the outfide of the dark fhadow. And on the outfide of this there was a tract more ftrongly illuminated than the reft of the paper.

The breadth of the external penumbra increafed with the diftance of the fhadow from the cylinder, and the breadth of the tract of light on the outfide of it was alfo enlarged; but its fplendor diminifhed with the diftance.

He repeated thefe experiments with three other cylinders of different dimenfions; and from them all he inferred, that every opaque cylindrical body, expofed to the light of the fun, makes a fhadow which is black and dark to the diftance of 38 to 45 diameters of the cylinder which forms it; and that, at a greater diftance, the middle part begins to be illuminated in the manner defcribed above.

In explaining thefe appearances, our author fuppofes that the light which diluted the middle part of the fhadow was occafioned by the inflection of the rays, which, bending inwards on their near approach to the body, did at a certain diftance enlighten all the fhadow, except the edges, which was left undifturbed. At the fame time other rays were deflected from the body, and formed a ftrong light on the outfide of the fhadow, and which might at the fame time contribute to dilute the outer fhadow, though he fuppofed that penumbra to be occafioned principally by that part of the paper not being enlightened, except by a part of the fun's difk only, according to the known principles of optics.

The fame experiments he made with globes of feveral diameters; but he found, that, whereas the fhadows of the cylinders did not difappear but at the diftance of 41 of their diameters, thofe of the globes were not vifible beyond 15 of their diameters; which he thought was owing to the light being inflected on every fide of a globe, and confequently in fuch a quantity as to difperfe the fhadows fooner than in the cafe of the cylinders. 54 Concerning thofe of globes.

In all thefe cafes the penumbra occafioned by the inflected light, began to be vifible at a lefs diftance from the body in the ftronger light of the fun than in a weaker, on account of the greater quantity of rays inflected in thofe circumftances.

Confidering the analogy between thefe experiments and the phenomena of an eclipfe of the moon, immerfed in the fhadow of the earth, he imagined, that part of the light by which fhe is then vifible is inflected light, and not that which is refracted by the atmofphere; though this may be fo copious as to efface feveral of the above-mentioned appearances, occafioned by inflected light only. But this gentleman fhould have confidered, that as no light is inflected but what paffes exceedingly near to any body, perhaps fo near as the diftance of $\frac{1}{40}$ part of an inch, this caufe muft be altogether inadequate to the effect. 55 His miftake concerning the moon.

Being fenfible that the above-mentioned phenomena of the fhadows were caufed by inflected light, he was induced to give more particular attention to this remarkable property; and in order to it to repeat the experiments of Grimaldi and Sir Ifaac Newton in a darkened room. In doing this, he prefently obferved, that, befides the enlarged fhadow of a hair, a fine needle, &c. the bright gleam of light that bordered it, and the three coloured rings next to this enlightened part, when the fhadow was at a confiderable diftance from the hair, the dark central fhadow was divided in the middle by a mixture of light; and that it was not of the fame denfity, except when it was very near the hair.

This new appearance will be feen to be exactly fimilar to what our philofopher had obferved with refpect to the fhadows in the open day-light above-mentioned; but the following obfervations, which he made with fome variation of his apparatus, are much more curious and ftriking, though they arife from the fame caufe.

Having placed a briftle, which is thicker than a common hair, in the rays of the fun, admitted into a dark chamber by a fmall hole, at the diftance of nine feet from the hole, it made a fhadow, which, being received at five or fix feet from the object, he obferved to confift of feveral ftreaks of light and fhade. The middle part was a faint fhadow, or rather a kind of penumbra, bordered by a darker fhadow, and after that by a narrower penumbra, next to which was a light ftreak broader than the dark part, and next to the ftreak of light the red, violet, and blue colours were feen as in the fhadow of the hair.

In the fame manner he placed, in the fame rays of the fun, feveral needles of different fizes; but the appearances were fo exceedingly various, tho' fufficiently fingular, that he does not recite them particularly, but choofes rather to give, at fome length, the obfervations he made on the fhadows of two plates, as by that means he could better explain the phenomena of the round bodies.

56 Experiments concerning the fhadows of metalline plates.

He expofed in the rays of the fun, admitted by a fmall hole into a dark chamber, a plate that was two inches long, and a little more than half a line broad. This plate being fixed perpendicularly to the rays, at the diftance of nine feet from the hole, a faint light was feen uniformly difperfed over the fhadow, when it was received perpendicularly to it, and very near. The fhadow of the fame plate being received at the diftance of two feet and a half, was divided into four very narrow black ftreaks, feparated by fmall lighter intervals equal to them. The boundaries of this fhadow on each fide had a penumbra, which was terminated by a very ftrong light, next to which were the coloured ftreaks of red, violet, and blue, as before. This is reprefented in Plate CCVII. fig. 4.

The fhadow of the fame plate at $4\frac{1}{2}$ feet diftance from it, was divided into two black ftreaks only, the two outermoft having difappeared, as in fig. 5.; but thefe two black ftreaks which remained were broader than before, and feparated by a lighter fhade, twice as broad as one of the former black ftreaks, when the fhadow was taken at $2\frac{1}{2}$ feet. This penumbra in the middle had a tinge of red. After the two black ftreaks there appeared a pretty ftrong penumbra, terminated by the two ftreaks of light, which were now broad and fplendid, after which followed the coloured ftreaks.

A fecond plate, two inches long and a line broad, being placed like the former, 14 feet from the hole by which the rays of the fun were admitted, its fhadow being received perpendicularly very near the plate, was illuminated by a faint light, equally difperfed, as in the the cafe of the preceding plate. But being received at the diftance of 13 feet from the plate, fix fmall black ftreaks began to be vifible, as in fig. 6. At 17 feet from the plate, the black ftreaks were broader, more diftinct, and more feparated from the ftreaks that were lefs dark. At 42 feet from the plate, only two black ftreaks were feen in the middle of the penumbra, as in fig. 7. This middle penumbra between the two black ftreaks was tinged with red. Next to the black ftreaks there always appeared the ftreaks of light, which were broad, and the coloured ftreaks next to them.

Receiving the fhadow of the fame plate at the diftance of 72 feet, the appearances were the fame as in the former fituation, except that the two black ftreaks were broader, and the interval between them, occupied by the penumbra, was broader alfo, and tinged with a deeper red.

In the fame rays of the fun he placed different plates, and larger than the former, one of them a line and a half, another two lines, another three lines broad, &c. but receiving their fhadows upon paper, he could not perceive in them thofe ftreaks of faint light which he had obferved in the fhadows of the fmall plates, though he received thefe fhadows at the diftance of 56 feet. Nothing was feen but a weak light, equally diffufed, as in the fhadows of the two fmalleft plates, received very near them. But had his dark chamber been large enough, he did not doubt, but that, at a proper diftance, there would have been the fame appearances in the fhadows of the larger plates as in thofe of the fmalleft. For the fame reafon, he fuppofed, that, if the fhadows of the fmall needles could have been diftinctly viewed very near thofe bodies, the different ftreaks of light and fhade would have been as vifible in them as in thofe of the fmall plates; and indeed he did obferve the fame appearances in the fhadows of needles of a middling fize.

The ftreaks of light in thefe fhadows our author afcribed to the rays of light which are inflected at different diftances from the bodies; and he imagined that their croffing one another was fufficient to account for the variations obfervable in them at different diftances.

The extraordinary fize of the fhadows of thefe fmall fubftances M. Maraldi thought to be occafioned by the fhadow from the enlightened part of the fky, added to that which was made by the light of the fun, and alfo to a vortex occafioned by the circulation of the inflected light behind the object; but our readers will probably not think it neceffary for us either to produce all his reafons for this hypothefis, or to enter into a refutation of them.

Our author having made the preceding experiments upon fingle long fubftances, had the curiofity to place two of them fo as to crofs one another in a beam of the fun's light. The fhadows of two hairs placed in this manner, and received at fome diftance from them, appeared to be painted reciprocally one upon the other, fo that the obfcure part of one of them was vifible upon the obfcure part of the other. The ftreaks of light alfo croffed one another, and the coloured ftreaks did the fame.

Having placed a needle and a hair croffing one another, their fhadows, at the fame diftance, exhibited the fame appearances as the fhadows of the two hairs, though the fhadow of the needle was the ftronger.

He alfo placed in the rays of the fun a briftle and a plate of iron a line thick, fo that they croffed one another

another obliquely; and when their fhadows were received at the fame diftance, the light and dark ftreaks of the fhadow of the briftle were vifible fo far as the middle of the fhadow of the plate on the fide of the acute angle, but not on the fide of the obtufe angle, whether the briftle or the plate were placed next to the rays. The plate made a fhadow fufficiently dark, divided into fix black ftreaks; and thefe were again divided by as many light ones equal to them; and yet all the ftreaks belonging to the fhadow of the briftles were vifible upon it, as in fig. 8. To explain this appearance, he fuppofed that the rays of the fun glid a little along the briftle, fo as to enlighten part of that which is behind the plate. But this feems to be an arbitrary and improbable fuppofition.

Our philofopher did not fail to expofe feveral fmall globes in the light of the fun in his dark chamber, and to compare their fhadows with thofe of the long fubftances, as he had done in the day-light, and the appearances were ftill fimilar. It was particularly evident, that there was much more light in the fhadows of the globes than in thofe of the cylinders, not only when they were both of an equal diameter, but when that of the globe was larger than that of the cylinder, and the fhadows of both the bodies were received at the fame diftance. He alfo obferved, that he could perceive no difference of light in the fhadows of the plates which were a little more than one line broad, though they were received at the diftance of 72 feet; but he could eafily fee a difference of fhades in thofe of the globes, taken at the fame diftance, tho' they were $2\frac{1}{4}$ lines in diameter.

In order to explain the colours at the edges of thefe fhadows, he contrived to throw fome of the fhadows upon others; and the following obfervations, though they did not enable him to accomplifh what he intended, are curious and worth reciting.

57 Experiments with a mixture of coloured fhadows.

Having thrown feveral of the fimilar colours upon one another, and thereby produced a tinge more lively than before, he threw the gleam of light, which always intervened between the colours and the darker part of the fhadow, upon different parts of other fhadows; and obferved, that, when it fell upon the exterior penumbra made by another needle, it produced a beautiful fky-blue colour, almoft like that which was produced by two blue colours thrown together. When the fame gleam of light fell upon the deeper fhadow in the middle, it produced a red colour; which feemed to prove, that the reddifh colour in the middle of feveral of the fhadows might come from the little light inflected into that place. But here our author feems to have been mifled by fome falfe hypothefis concerning colours.

He placed two plates of iron, each three or four lines broad, very near one another, but with a very fmall interval between them; and having placed them in the rays of the fun, and received their fhadows at the diftance of 15 or 20 feet from them, he faw no light between them but a continued fhadow, in the middle of which were fome ftreaks of a lively purple, parallel to one another, and feparated by other black ftreaks; but between them there were other ftreaks, both of a very faint green, and alfo of a pale yellow. He alfo informs us, that M. Delifle had obferved colours in the ftreaks of light and fhade, which are obfervable in fhadows taken near the bodies.

58 M. Mairan's obfervations.

Among thofe who followed Sir Ifaac Newton in his obfervations on the inflection of light, we alfo find the ingenious M. Mairan: but, without attempting the difcovery of new facts, he only endeavoured to explain the old ones, by the hypothefis of an atmofphere furrounding all bodies; and confequently making two reflections and refractions of the light that impinges upon them, one at the furface of the atmofphere, and the other at that of the body itfelf. This atmofphere he fuppofed to be of a variable denfity and refractive power, like the air.

59 Difcoveries of M. Du Tour.

M. Mairan was fucceeded by M. Du Tour, who thought the variable atmofphere fuperfluous, and imagined that he could account for all the phenomena by the help of an atmofphere of an uniform denfity, and of a lefs refractive power than the air furrounding all bodies. But what we are moft obliged to this gentleman for is, not his ingenious *hypothefis*, but the beautiful variety with which he has exhibited the *experiments*, which will render it much eafier for any perfon to inveftigate the true caufes of them.

Before M. Du Tour gave his attention to this fubject, only three fringes had been obferved in the colours produced by the inflection of light; but he was accidentally led to obferve a greater number of them, and hit upon the following ingenious method of making them all appear very diftinct.

Plate CCVII.

He took a circular board ABED (fig. 9.), 13 inches in diameter, the furface of which was black, except at the edge, where there was a ring of white paper about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A flip of parchment three inches broad, and difpofed in the form of a hoop, was faftened round the board, and pierced at the point E with a fquare hole, each fide being four or five lines, in order to introduce a ray of the fun's light. Laftly, in the centre of the board C, and perpendicular to it, he fixed a pin about $\frac{1}{2}$ of a line in diameter.

This hoop being fo difpofed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and paffing parallel to the plane of the board, projected the image of the fun and the fhadow of the pin at A. In thefe circumftances he obferved,

1. That quite round the concave furface of this hoop, there were a multitude of coloured ftreaks; but that the fpace m A n, of about 18 degrees, the middle of which was occupied by the image of the fun, was covered with a faint light only.

2. The order of the colours in thefe ftreaks was generally fuch that the moft refrangible rays were the neareft to the incident ray ECA; fo that, beginning from the point A, the violet was the firft, and the red the laft colour in each of the ftreaks. In fome of them, however, the colours were difpofed in a contrary order.

3. The image of the fun, projected on each fide of the point A, was divided by the fhadow of the pin, which was bordered by two luminous ftreaks.

4. The coloured ſtreaks were narrower in ſome parts of the hoop than others, and generally decreaſed in breadth in receding from the point A.

5. Among theſe coloured ſtreaks, there were ſometimes others which were white, a line or a line and an half in breadth, which were always bordered on both ſides by a ſtreak of orange colour, at leaſt when the light of the ſun was intenſe, and the chamber ſufficiently dark.

From this experiment he thought it was evident, that the rays which paſſed beyond the pin were not the only ones that were decompoſed, for that thoſe which are reflected back from the pin were decompoſed alſo; from which he concluded, that they muſt have undergone ſome refraction. He alſo thought that thoſe which went beyond the pin ſuffered a reflection, ſo that they were all affected in a ſimilar manner.

In order to account for theſe facts, our author deſcribes the progreſs of a ray of light through an uniform atmoſphere, which he ſuppoſes to ſurround the pin; and ſhews, that the differently refrangible rays will be ſeparated at their emergence from it: but he refers to ſome experiments and obſervations in a future memoir, to demonſtrate that all the coloured ſtreaks are produced by rays that are both reflected and refracted.

Plate CCVII. 60 Account of Du Tour's hypotheſis.

To give ſome idea of his hypotheſis, he ſhews that the ray *a b*, fig. 10. after being refracted at *b*, reflected at *r* and *u*, and again refracted at *s* and *t*, will be divided into its proper colours; the leaſt refrangible or the red rays iſſuing at *x*, and the moſt refrangible or violet at *y*; which agrees with his obſervations. Thoſe ſtreaks in which the colours appear in a contrary order he thinks are to be aſcribed to inequalities in the ſurface of the pin. This might eaſily have been aſcertained by turning the pin round, in which caſe theſe differently-coloured ſtreaks would have changed their places.

If any perſon ſhould chooſe to repeat theſe experiments, he obſerves that it requires that the ſky be very clear and free from vapours, in order to exhibit the colours with the greateſt diſtinctneſs; ſince even the vapours that are imperceptible, will diminiſh the luſtre of the colours on every part of the hoop, and even efface ſome of them, eſpecially thoſe which are on that in which the beam of light enters, as at E, where the colours are always fainter than in any other place, and indeed can never be diſtinguiſhed except when the hole E is confined by black ſubſtances, ſo as to intercept a part of the light that might reach the pin; and unleſs alſo thoſe rays which go beyond the pin to form the image of the ſun at A be ſtopped, ſo that no rays are viſible except thoſe that are reflected towards the hole, and which make the faint ſtreaks.

The coloured ſtreaks that are next the ſhadow of the pin, he ſhews, are formed by thoſe rays which, entering the atmoſphere, do not fall upon the pin; and, without any reflection, are only refracted at their entering and leaving the atmoſphere, as at *b* and *r u*, fig. 11. In this caſe, the red or leaſt refrangible rays will iſſue at *r*, and the violet at *u*.

To diſtinguiſh the rays which fell upon the hoop in any particular direction, from thoſe that came in any other, he made an opening in the hoop, as at P, by which means he could, with advantage, and at any diſtance from the centre, obſerve thoſe rays unmixed with any other.

To account for the coloured ſtreaks being larger next the ſhadow of the pin, and growing narrower to the place where the light was admitted, he ſhews, by fig. 12. that the rays *a b* are farther ſeparated by both the refractions than the rays *c d*.

Sometimes our author obſerved, that the broader ſtreaks were not diſpoſed in this regular order; but then he found, that, by turning the pin, they changed their places, ſo that this circumſtance muſt have been an irregularity depending upon the accidental ſurface of the pin.

The white ſtreaks intermixed with the coloured ones he aſcribes to ſmall cavities in the ſurface of the pin, or ſome other foreign circumſtance; for they alſo changed their places when the pin was made to turn upon its axis.

Other obſervations of our author ſeem to prove that the refracting atmoſpheres ſurrounding all kinds of bodies are of the ſame ſize; for when he placed a great variety of ſubſtances, and of different ſizes alſo, he always found the coloured ſtreaks of the ſame dimenſions.

M. Du Tour obſerves that his hypotheſis contradicts an obſervation of Sir Iſaac Newton, that thoſe rays which paſs the neareſt to any body are the moſt inflected; but he thinks that Newton's obſervations were not ſufficiently accurate. Beſides, he obſerves, that Newton only ſaid that *he thought it to be ſo*, without aſſerting it poſitively.

Since the rays which formed theſe coloured ſtreaks are but little diverted out of their way, our author infers that this atmoſphere is of ſmall extent, and that its refractive power is not much leſs than that of air.

Expoſing two pieces of paper in the beam of light, ſo that part of it paſſed between two planes formed by them, M. Du Tour obſerved, that the edges of this light, received upon paper, were bordered with two orange-coloured ſtreaks, which Newton had not taken notice of in any of his experiments. To account for them, he ſuppoſes, that in fig. 13. the more refrangible of the rays which enter at *b* are ſo refracted, that they do not reach the ſurface of the body itſelf at R; ſo that the red and orange-coloured light may be reflected from thence in the direction *d* M, where the orange-coloured ſtreaks will be formed; and, for the ſame reaſon, another ſtreak of orange will be formed at *m*, by the rays which enter the atmoſphere on the other ſide of the chink. In a ſimilar manner he accounts for the orange-coloured fringes at the borders of the white ſtreaks, in the experiment of the hoop.

The blue rays, which are not reflected at R, he ſuppoſes paſs on to I, and that of theſe rays the blue tinge obſervable in the ſhadows of ſome bodies are formed.

61 Objects ſometimes magnified by the inflection of light.

M. Le Cat has well explained a phenomenon of viſion depending upon the inflection of light, which ſhews, that, in ſome caſes, objects appear magnified by this means. Looking at a diſtant ſteeple, when a wire, of a leſs diameter than the pupil of his eye, was held pretty near to it, and drawing it ſeveral times betwixt

betwixt his eye and that object, he was furprifed to find, that, every time the wire paffed before his pupil, the fteeple feemed to change its place, and fome hills beyond the fteeple feemed to have the fame motion, juft as if a lens had been drawn betwixt his eye and them.

Examining this appearance more attentively, he found that there was a pofition of the wire, but very difficult to keep, in which the fteeple feemed not to have any motion, when the wire was paffed before his eye; and in this cafe the fteeple appeared lefs diftinctly, and feemed to be magnified. Thefe effects being fimilar to thofe of a lens, he attended to them more particularly; and placed his eye in fuch a manner, with refpect to the fteeple, that the rays of light by which he faw it muft come very clofe to the edge of a window, where he had placed himfelf to make his obfervations. Then paffing the wire once more before his eye, he obferved, that, when it was in the vifual axis, the fteeple appeared nearer to the window, on whichever fide the wire was made to approach. He repeated this experiment, and conftantly with the fame refult, the object being always magnified, and nearly doubled, by this means.

This phenomenon is eafily explained by fig. 14. in which B reprefents the eye, A the fteeple, and C the diameter of the wire. The black lines exprefs the cone of light by which the natural image of the fteeple A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, ftopped and turned out of its courfe by the wire, but alfo more diftant rays inflected by the wire, and thereby thrown more converging into the pupil; juft as would have been the effect of the interpofition of a lens between the eye and the object. The refult of this experiment was the fame, whatever fubftances he made ufe of in the place of the wire, provided they were of the fame diameter.

62 Mifcellaneous obfervations.

This difcovery, depending upon the inflection of the rays of light, led him to feveral others depending upon the fame principle. Thus he magnified fmall objects, as the head of a pin, by looking at them through a fmall hole in a card; fo that the rays which formed the image muft neceffarily pafs fo near the circumference of the hole, as to be attracted by it. He alfo obferved, that, by bringing his finger near the cone of light, which tranfmitted to him the image of any object well infulated, as a red coal in the midft of cinders, or a black coal in the midft of the fire, the object feemed to ftretch itfelf towards his finger, as it approached, and to follow it to a certain diftance when it was withdrawn. He thought it was owing to the fame caufe, that the clouds which pafs over the face of the fun occafion various motions in the fhadow of bodies; and when thefe clouds are interrupted in different places, thofe fhadows feems to dance, which is particularly vifible in the fhadows made by the leads in glafs-windows. It was to the fame inflection of light that he afcribed, in part, the prifmatic colours which he faw by the means of a very fine pin, placed near to his eye, and on which he made the light of a candle to fall obliquely.

§ 5. *Difcoveries concerning Vifion.*

63 Difcoveries of Maurolycus, Kepler, &c. concerning vifion.

Maurolycus was the firft who fhewed the true theory of vifion, by demonftrating that the cryftalline humour of the eye is a lens which collects the light iffuing from external objects, and throws them upon the retina, where is the focus of each pencil. He did not, however, find out, that, by means of this refraction of the rays, an image of every vifible object was formed upon the retina, though this feems hardly to have been a ftep beyond the difcovery he had already made. Montucla conjectures, that he was prevented from coming to this difficulty of accounting for the upright appearance of objects, as this image is always inverted. This difcovery was made by Kepler; but he, too, was much difficulted with the inverted pofition of the image. The rectification of thefe images, he fays, is the bufinefs of the mind; which, when it perceives an impreffion on the lower part of the retina, confiders it as made by rays proceeding from the higher parts of objects; tracing the rays back to the pupil, where they crofs one another. But this hypothefis can fcarcely be deemed fatisfactory.—Kepler did not pretend to account for the manner in which the mind perceives the images upon the retina, and very much blames Vitellio for attempting prematurely to determine a queftion of this nature, and which indeed, he fays, does not belong to optics. He accounts, however, though not in a fatisfactory manner, for the power we have of feeing diftinctly at different diftances.

64 Difcoveries of Scheiner.

The difcovery concerning vifion was completed by Scheiner. For, in cutting away the coats of the back part of the eyes of fheep and oxen, and prefenting feveral objects before them, within the ufual diftance of vifion, he faw their images diftinctly and beautifully painted upon the retina. He did the fame thing with the human eye, and exhibited this curious experiment at Rome in 1625. He takes particular notice of the refemblance between the eye and the camera obfcura, and explains a variety of methods to make the images of objects erect. As to the images of objects being inverted in the eye, he acquiefces in the reafon given for it by Kepler. He knew that the pupil of the eye is enlarged in order to view remote objects, and that it is contracted while we are viewing thofe that are near; and this he proved by experiment, and illuftrated by figures.

Scheiner alfo took a good deal of pains to afcertain the denfity and refractive power of all the humours of the eye by comparing their magnifying power with that of water or glafs in the fame form and circumftances. The refult of his inquiries was, that the aqueous humour doth not differ much from water in this refpect, nor the cryftalline from glafs; and that the vitreous humour is a medium between both. He alfo very accurately and minutely traces the progrefs of the rays of light through all the humours of the eye, and after difcuffing every poffible hypothefis concerning the proper feat of vifion, he demonftrates that it is in the retina, and fhews that this was the opinion of Alhazen, Vitellio, Kepler, and all the moft eminent philofophers. He produces many reafons of his own for this hypothefis; anfwers a great number of objections to it; and, by a variety of arguments, refutes the opinion of former times, that the feat of vifion is in the cryftalline.

Defcartes makes a good number of obfervations on the

65 Discoveries of Descartes. the phenomena of vision. He explains satisfactorily the natural methods of judging of the magnitudes, situations and distances, of objects by the direction of the optic axes; comparing it to a blind man's judging of the size and distance of an object, by feeling at it with two sticks of a known length, when the hands in which he holds them are at a known distance from each other. He also observes, that having been accustomed to judge of the situation of objects by their images falling on a particular part of the eye; if by any distortion of the eye they fall on a different place, we are apt to mistake their situation, or imagine one object to be two; as, till we become accustomed to it, we imagine one stick to be two, when it is placed between two contiguous fingers laid across one another. But he observes, that all the methods we have of judging of the distances of objects are very uncertain, and extend but to narrow limits. The direction of the optic axes, he says, will not serve us beyond 15 or 20 feet, and the change of form of the crystalline not more than three or four feet. For he imagined that the eye conforms itself to the view of near or distant objects by a change in the curvature of the crystalline, which he supposed to be a muscle, the tendons of it being the processus ciliares. In another place, he says, that the change in the conformation of the eye is of no use to us for the purpose of judging of distances beyond four or five feet, and the angle of the optic axes not more than 100 or 200 feet. For this reason, he says, that the sun and moon are conceived to be much more nearly of the same size than they are in reality. White and luminous objects, he says, appear larger than others, and also the parts contiguous to those on which the rays actually impinge; and for the same reason, if the objects be small, and placed at a great distance, they will always appear round, the figure of the angles disappearing. The description of the eye itself, the various modes of vision and optical deceptions to which we are liable, belong properly to the succeeding part of this treatise.

§ 6. *Of Optical Instruments, and Discoveries concerning them.*

66 Invention of spectacles. So little were the ancients acquainted with the science of Optics, that they seem to have have had no instruments of the optical kind, excepting the glass globes and speculums formerly mentioned, which they used in some cases for magnifying and burning. Alhazen, as we have seen, gave the first hint of the invention of spectacles, and it is probable that they were found out soon after his time. From the writings of Alhazen and the observations and experiments of Bacon together, it is not improbable that some monks gradually hit upon the construction of spectacles; to which Bacon's lesser segment, notwithstanding his mistake concerning it, was a nearer approach than Alhazen's larger one. Whoever they were that pursued the discoveries of Bacon, they probably observed, that a very small convex glass, when held at a greater distance from the book, would magnify the letters more than when it was placed close to them, in which position only Bacon seems to have used it. In the next place, they might try whether two of these small segments of a sphere placed together, or a glass convex on both sides, would not magnify more than one of them. They would then find, that two of these glasses, one for each eye, would answer the purpose of reading better than one; and lastly they might find, that different degrees of convexity suited different persons.

It is certain that spectacles were well known in the 13th century, and not long before. It is said that Alexander Spina, a native of Pisa, who died in 1313, and who was very ingenious in executing whatever he saw or heard of as having been done by others, happened to see a pair of spectacles in the hands of a person who would not explain them to him; but that he succeeded in making a pair for himself, and immediately made the construction public, for the good of others. It is also inscribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died 1317, that he was the inventor of spectacles.

The use of concave glasses, to help those persons who are short-sighted, was, probably, a discovery that did not follow long after that of convex ones, for the relief of those whose sight is defective in the contrary extreme, though we find no trace of this improvement. Whoever made this discovery, it was probably the result of nothing more than a random experiment. Perhaps a person who was short-sighted, finding that convex glasses did him more harm than good, had the curiosity to make trial of a contrary curvature of the glass. 67 Of concave glasses.

From this time, though both convex and concave lenses were sufficiently common, yet no attempt was made to form a telescope by a combination of them, till the end of the 16th century. Descartes considers James Metius, a person who was no mathematician, though his father and brother had applied to those sciences, as the first constructor of a telescope; and says, that as he was amusing himself with making mirrors and burning-glasses, he casually thought of looking thro' two of his lenses at a time; and that happening to take one that was convex and another that was concave, and happening also to hit upon a pretty good adjustment of them, he found, that, by looking thro' them, distant objects appeared very large and distinct. In fact, without knowing it, he had made a telescope. 68 Descartes's account of the invention of telescopes.

Other persons say, that this great discovery was first made by John Lippersheim, a maker of spectacles at Middleburgh, or rather by his children; who, like, Metius, were diverting themselves with looking thro' two glasses at a time, and placing them at different distances from one another. But Borellus, the author of a book intitled, *De vero telescopii inventore*, gives this honour to Zacharias Joannides, i. e. Jansen, another maker of spectacles at the same place, who made the first telescope in 1590; and it seems now to be the general opinion, that this account of Borellus is the most probable. 69 Other accounts.

Indeed, Borellus's account of the discovery of telescopes is so circumstantial, and so well authenticated, that it does not seem possible to call it in question. It is not true, he says, that this great discovery was made by a person who was no philosopher: for Zacharias Jansen was a diligent inquirer into nature; and being engaged in these pursuits, he was trying what uses could be made of lenses for those purposes, when he 70 Borellus's account probably the true one.

he fortunately hit upon the conſtruction.

This ingenious mechanic, or rather philoſopher, had no ſooner found the arrangement of glaſſes that produced the effect he deſired, than he incloſed them in a tube, and ran with his inſtrument to prince Maurice; who immediately conceiving that it might be of uſe to him in his wars, deſired the author to keep it a ſecret. But this, though attempted for ſome time, was found to be impoſſible; and ſeveral perſons in that city immediately applied themſelves to the making and ſelling of teleſcopes. One of the moſt diſtinguiſhed of theſe was Hans Laprey, called *Lipperſheim* by Sirturus. By him ſome perſon in Holland being very early ſupplied with a teleſcope, he paſſed with many for the inventor; but both Metius above-mentioned, and Cornelius Drebell of Alcmar, in Holland, applied to the

71 The firſt teleſcope an exceedingly good one.

inventor himſelf in 1620; as alſo did Galileo, and many others. The firſt teleſcope made by Janſen did not exceed 15 or 16 inches in length; but Sirturus, who ſays that he had ſeen it, and made uſe of it, thought it the beſt that he had ever examined.

Janſen, having a philoſophical turn, preſently applied his inſtrument to ſuch purpoſes as he had in view when he hit upon the conſtruction. Directing it towards celeſtial objects, he diſtinctly viewed the ſpots on the ſurface of the moon; and diſcovered many new ſtars, particularly ſeven pretty conſiderable ones in the great bear. His ſon Joannes Zachariæ, noted the lucid circle near the limb of the moon, from whence ſeveral bright rays ſeem to dart in different directions; and he ſays, that the full moon viewed through this inſtrument, did not appear flat, but was evidently ſpherical, the middle part being prominent. Jupiter alſo, he ſays, appeared round, and rather ſpherical; and ſometimes he perceived two, ſometimes three, and at the moſt four ſmall ſtars, a little above or below him; and as far as he could obſerve, they performed revolutions round him; but this, he ſays, he leaves to the conſideration of aſtronomers. This, it is probable, was the firſt obſervation of the ſatellites of Jupiter, tho' the perſon who made it was not aware of the importance of his diſcovery.

72 Honour of the invention claimed by Fontana.

One Francis Fontana, an Italian, alſo claims the invention; but as he did not pretend to have made it before the year 1608, and as it is well known that the inſtruments were made and ſold in Holland ſome time before, his pretenſions to a ſecond diſcovery are not much regarded.

73 A teleſcope made by Galileo without ſeeing one.

There are ſome, who ſay that Galileo was the inventor of teleſcopes; but he himſelf acknowledges, that he firſt heard of the inſtrument from a German; but he ſays, that being informed of nothing more than the effects of it, firſt by common report, and a few days after by a French nobleman, J. Badovere, at Paris, he himſelf diſcovered the conſtruction, by conſidering the nature of refraction: and thus he had much more real merit than the inventor himſelf.

The account of what Galileo actually did in this buſineſs, is ſo circumſtantially related by the author of his life, prefixed to the quarto edition of his works, printed at Venice in 1744, and it contains ſo many particulars, which cannot but be pleaſing to every perſon who is intereſted in the hiſtory of teleſcopes, that we ſhall abridge a part of it, intermixing circumſtances collected from other accounts.

About April or May, in 1609, it was reported at Venice, where Galileo (who was profeſſor of mathematics in the univerſity of Padua) then happened to be, that a Dutchman had preſented to Count Maurice of Naſſau, a certain optical inſtrument, by means of which, diſtant objects appeared as if they were near; but no farther account of the diſcovery had reached that place, tho' this was near 20 years after the firſt diſcovery. Struck, however, with this account, Galileo inſtantly returned to Padua, conſidering what kind of an inſtrument this muſt be. The night following, the conſtruction occurred to him; and the day after, putting the parts of the inſtrument together, as he had previouſly conceived of it, and, notwithſtanding the imperfection of the glaſſes that he could then procure, the effect anſwered his expectations, as he preſently acquainted his friends at Venice; to which place, he ſix days afterwards carried another and a better inſtrument that he had made, and where, from ſeveral eminences, he ſhewed to ſome of the principal ſenators of that republic a variety of diſtant objects, to their very great aſtoniſhment. When he had made farther improvements in the inſtrument, he, with his uſual generoſity and frankneſs in communicating his diſcoveries, made a preſent of one of them to the Doge, Leonardo Donati, and at the ſame time to all the ſenate of Venice; giving along with the inſtrument, a written paper, in which he explained the ſtructure and wonderful uſes that might be made of it both by land and at ſea. In return for ſo noble an entertainment, the republic, on the 25th of Auguſt, in the ſame year, more than tripled his ſalary as profeſſor.

74 Account of his diſcoveries.

Our philoſopher, having amuſed himſelf for ſome time with the view of terreſtrial objects, at length directed his tube towards the heavens; and, obſerving the moon, he found, that the ſurface of it was diverſified with hills and valleys, like the earth. He found that the *via lactea* and *nebulæ* conſiſted of a collection of fixed ſtars, which, on account either of their vaſt diſtance, or extreme ſmallneſs, were inviſible to the naked eye. He alſo diſcovered innumerable fixed ſtars diſperſed over the face of the heavens, which had been unknown to all the ancients; and examining Jupiter, with a better inſtrument than any he had made before, he found that he was accompanied by four ſtars, which, in certain fixed periods, performed revolutions round him, and which, in honour of the houſe of Medici, he called *Medicean planets*.

This diſcovery he made in January 1610, new ſtyle; and continuing his obſervations the whole of February following, in the beginning of March next he publiſhed an account of all his diſcoveries, in his *Nuncius Sidereus*, printed at Venice, and dedicated to Coſimo, great duke of Tuſcany, who, by a letter which he wrote to him on the 10th of July 1610, invited him to quit Padua, and aſſigned him an ample ſtipend, as primate and extraordinary profeſſor at Piſa, but without any obligation to read lectures, or to reſide.

The extraordinary diſcoveries contained in the Nuncius Sidereus, which was immediately reprinted both in Germany and France, was the cauſe of much ſpeculation and debate among the philoſophers and aſtronomer's of that time; many of whom could not be brought

brought to give any credit to Galileo's account, while others endeavoured to decry his discoveries as being nothing more than fictions or illusions. Some could not be prevailed upon even to look through a telescope; so devoted were they to the system of Aristotle, and so averse to admit any other source of knowledge besides his writings. When it was found to be in vain to oppose the evidence of sense, some did not scruple to assert that the invention was taken from Aristotle; and producing a passage from his writings, in which he attempts to give a reason why stars are seen in the day-time from the bottom of a deep well, said, that the well corresponded to the tube of the telescope, and that the vapours which arose from it gave the hint of putting glasses into it; and lastly, that in both cases the sight is strengthened by the transmission of the rays through a thick and dark medium. Galileo himself tells this story with a great deal of humour; comparing such men to alchymists, who imagine that the art of making gold was known to the ancients, but lay concealed under the fables of the poets.

In the beginning of July of the same year, 1610, Galileo being still at Padua, and getting an imperfect view of Saturn's ring, imagined that that planet consisted of three parts; and therefore, in the account which he gave of this discovery to his friends, he calls it *planetam tergeminum*.

Whilst he was still at Padua, which must have been either in the same month of July, or the beginning of August following, he observed some spots on the face of the sun: but, contrary to his usual custom, he did not choose, at that time, to publish his discovery; partly for fear of incurring more of the hatred of many obstinate peripatetics; and partly, in order to make more exact observations on this remarkable phenomenon, and to form some conjecture concerning the probable cause of it. He therefore contented himself with communicating his observations to some of his friends at Padua and Venice, among whom we find the name of father Paul. This delay, however, was the cause of this discovery being contested with him by the famous Scheiner, who likewise made the same observation in Oct. 1611, and we suppose had anticipated Galileo in the publication of it.

About the end of August, Galileo left Padua and went to Florence; and in November following he was satisfied, that, from the September preceding, Venus had been continually increasing in bulk, and that she changed her phases like the moon. About the end of March 1611, Galileo went to Rome, where he gratified the cardinals, and all the principal nobility, with a view of the new wonders he had discovered in the heavens, and among others the solar spots.

75 Named *Lynceus* from them.

From these discoveries Galileo obtained the name of *Lynceus*, who was famous in antiquity for the acuteness of his sight; and moreover, the marquis of Monticelli instituted an academy, with the title of *De' Lincei*, and made him a member of it. Twenty-nine years Galileo enjoyed the use of his telescope, continually enriching astronomy with his observations: but by too close an application to that instrument, and the detriment he received from the nocturnal air, his eyes grew gradually weaker, till in 1639 he became totally blind; a calamity which, however, neither broke his spirits, nor interrupted the course of his studies.

The first telescope that Galileo constructed magnified only three times: but presently after, he made another which magnified 18 times: and afterwards, with great trouble and expence, he constructed one that magnified 33 times; and with this it was that he discovered the satellites of Jupiter, and the spots of the sun. 76 Account of his telescopes.

Notwithstanding Galileo must be allowed to have considerable merit with respect to telescopes, it was neither that of the person who first hit upon the construction, nor that of him who thoroughly explained the *rationale* of the instrument. This important service to science was performed by John Kepler, whose name is famous on many accounts in the annals of philosophy, and especially by his discovery of the great law of motion respecting the heavenly bodies; which is, that the squares of their periodical times are as the cubes of their distances from the body about which they revolve; a proposition which, however, was not demonstrated before Sir Isaac Newton. Kepler was astronomer to several of the emperors of Germany; he was the associate of the celebrated astronomer Tycho Brahe, and the master of Descartes. 77 The rationale of the instrument first discovered by Kepler.

Kepler made several discoveries relating to the nature of vision; and not only explained the rationale of the telescope which he found in use, but also pointed out methods of constructing others of superior powers and more commodious application.

It was Kepler who first gave a clear explication of the effects of lenses, in making the rays of a pencil of light converge or diverge. He shewed, that a plano-convex lens makes rays that were parallel to its axis, to meet at the distance of the diameter of the sphere of convexity; but that if both sides of the lens be equally convex, the rays will have their focus at the distance of the radius of the circle, corresponding to that degree of convexity. But he did not investigate any rule for the foci of lenses unequally convex. He only says, in general, that they will fall somewhere in the medium, between the foci belonging to the two different degrees of convexity. It is to Cavallieri that we owe this investigation. He laid down this rule: As the sum of both the diameters is to one of them, so is the other to the distance of the focus. All these rules concerning convex lenses are applicable to those that are concave; with this difference, that the focus is on the contrary side of the glass, as will be particularly shewn in the second part of this treatise.

The principal effects of telescopes depend upon these plain maxims, *viz.* That objects appear larger in proportion to the angles which they subtend at the eye; and the effect is the same whether the pencils of rays, by which objects are visible to us, come directly from the objects themselves, or from any place nearer to the eye, where they may have been united so as to form an image of the object; because they issue again from those points where there is no real substance, in certain directions, in the same manner as they did from the corresponding points in the objects themselves. 78 General reason of the effects of telescopes.

In fact, therefore, all that is effected by a telescope is, first to make such an image of a distant object, by means of a lens or mirror; and then to give the eye some assistance for viewing that image as near as possible; so that the angle which it shall subtend at the eye, may be very large compared with the angle which the

the object itself would subtend in the same situation. This is done by means of an eye-glass, which so refracts the pencils of rays, as that they may afterwards be brought to their several foci by the natural humours of the eye. But if the eye was so formed as to be able to see the image with sufficient distinctness at the same distance without any eye-glass, it would appear to him as much magnified as it does to another person who makes use of a glass for that purpose, though he would not in all cases have so large a field of view.

If, instead of an eye-glass, an object, or the image of an object, be looked at thro' a small hole in a thin plate or piece of paper, held close to the eye, it may be viewed very near to the eye, and, at the same distance, the apparent magnitude of the object will be the same in both cases. For if the hole be so small as to admit but a single ray from every distinct point of the object, these rays will fall upon the retina in as many other distinct points, and make a distinct image. They are only pencils or cones of rays, which have a sensible base, as the breadth of the pupil, that are capable, by their spreading on the retina, of producing an indistinct image. As very few rays, however, can be admitted through a small hole, there will seldom be light sufficient to view any object to advantage in this manner.

If no image be actually formed by the foci of the pencils without the eye, yet if, by the help of any eye-glass, the pencils of rays shall enter the pupil, just as they would have done from any place without the eye, the visual angle will be the same as if an image had actually been formed in that place. Objects will not appear inverted through this telescope, because the pencils which form the images of them, only cross one another once, *viz.* at the object-glass, as in natural vision they do in the pupil of the eye.

79 Galilean telescope more difficult of construction than others.

Such is the telescope that was first discovered and used by philosophers; and it is remarkable that it should be of a much more difficult construction than some other kinds that have been invented since. The great inconvenience attending it is, that the field of view is exceedingly small. For since the pencils of rays enter the eye very much diverging from one another, but few of them can be intercepted by the pupil; and this inconvenience increases with the magnifying power of the telescope; so that philosophers at this day cannot help wondering, that it was possible, with such an instrument, for Galileo and others to have made the discoveries they did. It must have required incredible patience and address. No other telescope, however, than this, was so much as thought of for many years after the discovery. Descartes, who wrote 30 years after, mentions no other as actually constructed, though Kepler had suggested some.

80 Telescopes improved by Kepler.

It is to this great man that we are indebted for the construction of what we now call the *astronomical telescope*, being the best adapted for the purpose of viewing the heavenly bodies. The *rationale* of this instrument is explained, and the advantages of it are clearly pointed out, by this philosopher, in his Catoptrics; but, what is very surprising, he never actually reduced his excellent theory into practice. Montucla conjectures, that the reason why he did not make trial of his new construction was, his not being aware of the great increase of the field of view; so that being engaged in other pursuits, he might not think it of much consequence to take any pains about the construction of an instrument, which could do little more than answer the same purpose with those of which he was already possessed. He must also have foreseen, that the length of this telescope must have been greater in proportion to its magnifying power; so that it might appear to him to be upon the whole not quite so good a construction as the former.

81 His method first put in practice by Scheiner.

It was not long, however, before Kepler's new scheme of a telescope was executed; and the first person who actually made an instrument of this construction, was Father Scheiner, who has given a description of it in his *Rosa Ursina*, published in 1630. If, says he, you insert two similar lenses (that is, both convex) in a tube, and place your eye at a convenient distance, you will see all terrestrial objects inverted, indeed, but magnified and very distinct, with a considerable extent of view. He afterwards subjoins an account of a telescope of a different construction, with two convex eye-glasses, which again reverses the images, and makes them appear in their natural position. This disposition of the lenses had also been pointed out by Kepler, but had not been reduced to practice by him, any more than the former. This construction, however, answered the end but very imperfectly; and Father Rheita presently after hit upon a better construction, using three eye-glasses instead of two. This got the name of the *terrestrial telescope*, being chiefly used for terrestrial objects.

The first and last of these constructions are those which are now in common use. The proportion in which the first telescope magnifies, is as the focal length of the object-glass to that of the eye-glass.—The only difference between the Galilean telescope and the other is, that the pencils by which the extremities of any object are seen in this case, enter the eye diverging; whereas, in the other, they enter it converging; but if the sphere of concavity in the eye-glass of the Galilean telescope be equal to the sphere of convexity in the eye-glass of another telescope, their magnifying power will be the same. The concave eye-glass, however, being placed between the object-glass and its focus, the Galilean telescope will be shorter than the other, by twice the focal length of the eye-glass. Consequently, if the length of the telescopes be the same, the Galilean will have the greater magnifying power.

82 Vision most distinct in the Galilean telescopes.

Vision is also more distinct in these telescopes; owing perhaps, in part, to there being no intermediate image between the eye and the object. Besides, the eye-glass being very thin in the centre, the rays will be less liable to be distorted by irregularities in the substance of the glass. Whatever be the cause, we can sometimes see Jupiter's satellites very clearly in a Galilean telescope not more than twenty inches or two feet long; when one of four or five feet, of the common sort, will hardly make them visible.

83 Binocular telescope.

The same Father Rheita, to whom we are indebted for the useful construction of a telescope for land-objects, invented a binocular telescope, which Father Cherubin, of Orleans, endeavoured to bring into use afterwards. It consists of two telescopes fastened together, and made to point to the same object. When this instrument is well fixed, the object appears larger, and nearer to the eye, when it is seen through both the

the telescopes, than through one of them only, tho' they have the very same magnifying power. But this is only an illusion, occasioned by the stronger impression that two equal images, equally illuminated, make upon the eye. This advantage, however, is counterbalanced by the inconvenience attending the use of it.

84 Telescopes of Campani and Divini.

The first who distinguished themselves in grinding telescopic glasses were two Italians, Eustachio Divini at Rome, and Campani at Bologna, whose fame was much supperior to that of Divini, or that of any other person of his time; though Divini himself pretended, that, in all the trials that were made with their glasses, his, of a great focal distance, performed better than those of Campani, and that his rival was not willing to try them fairly, viz. with equal eye-glasses. It is generally supposed, however, that Campani realy excelled Divini, both in the goodness and the focal length of his object-glasses. It was with telescopes made by Campani that Cassini discovered the nearest satellites of Saturn. They were made by the express order of Lewis XIV. and were of 86, 100, and 136 Parisian feet focal length.

Campani sold his lenses for a great price, and took every possible method to keep his art of making them a secret. His laboratory was inaccessible to all the world, till after his death; when it was purchased by Pope Benedict XIV. who made a present of it to the academy called the *Institute*, established in that city; and by the account which M. Fougeroux has given of what he could discover from it, we learn, that (except a machine, which M. Campani constructed, to work the basons on which he ground his glasses) the goodness of his lenses depended upon the clearness of his glass, his Venetian tripoli, the paper with which he polished his glasses, and his great skill and address as a workman. It was also the general opinion at Bologna, that he owed a great part of his reputation to the secrecy and air of mystery which he affected; and that he made a great number of object-glasses which he rejected, shewing only those that were very good. He made few lenses of a very great focal distance; and having the misfortune to break one of 141 feet in two pieces, he took incredible pains to join the two parts together, which he did at length effectually, so that it was used as if it had been entire; but it is not probable that he would have taken so much pains about it, if, as he pretended, he could very easily have made another as good.

Sir Paul Neille, Dr Hooke says, made telescopes of 36 feet, pretty good, and one of 50, but not of proportional goodness. Afterwards Mr Reive first, and then Mr Cox, who were the most celebrated in England as grinders of optic glasses, made some good ones of 50 and 60 feet focal distance, and Mr Cox made one of 100; but how good, Dr Hooke could not assert.

Borelli, also, in France made object-glasses of a great focal length, one of which he presented to the royal society; but we do not find any particular account of their goodness.

85 Extraordinary object-glass made by Mr Auzout.

With respect to the focal length of telescopes, these and all others were far exceeded by M. Auzout, who made one object-glass of 600 feet focus; but he was never able to manage it, so as to make any use of it. Hartsocker is even said to have made some of a still greater focal length; but this ingenious mechanic, finding it impossible to make use of object-glasses, the focal distance of which was much less than this, when they were inclosed in a tube, contrived a method of using them without a tube, by fixing them at the top of a tree, a high wall, or the roof of a house.

86 Telescopes used without tubes.

Mr Huygens, who was also an excellent mechanic, made considerable improvements in the method of using an object-glass without a tube. He placed it at the top of a very long pole, having previously inclosed it in a short tube, which was made to turn in all directions, by means of a ball and socket. The axis of this tube he could command with a fine silken string, so as to bring it into a line with the axis of another short tube, which he held in his hand, and which contained the eye-glass. In this method he could make use of object-glasses of the greatest magnifying power, at whatever altitude his object was, and even in the zenith, provided his pole was as long as his telescope; and, to adapt it to the view of objects of different altitudes, he had a contrivance, by which he could raise or depress a stage that supported his object-glass at pleasure.

M. De la Hire made some improvement in this method of managing the object-glass, fixing it in the centre of a board, and not in a tube; but as it is not probable that this method will ever be made use of, since the discovery of both reflecting and achromatic telescopes, which are now brought to great perfection, and have even micrometers adapted to them, we shall not describe this apparatus minutely; but shall only gave a drawing of M. Huygens's pole, which, with a very short explanation, will be sufficient for the purpose. In fig. 1. *a* represents a pulley, by the help of which a stage *c*, *d*, *e*, *f*, (that supports the object-glass, *k*, and the apparatus belonging to it) may be raised higher or lower at pleasure, the whole being counterpoised by the weight *h*, fastened to a string *g*. *n*, Is a weight, by means of which the centre of gravity of the apparatus belonging to the object-glass is kept in the ball and socket, so that it may be easily managed by the string *l*, *u*, and its axis brought into a line with the eye-glass at *a*. When it was very dark, M. Huygens was obliged to make his object-glass visible by a lantern, *y*, so constructed as to throw the rays of light in a parallel direction up to it.

Plate CCVIII.

The recollection of the incredible pains which philosophers of the last age took in making observations, and the great expences they were obliged to be at for that purpose, should make us sensible of the obligations we are under to such men as Gregory, Newton, and Dollond, who have enabled us to get clearer and more satisfactory views of the remote parts of our system, with much less labour and expence; and should likewise make us more diligent and solicitous to derive all the advantages we possibly can from such capital improvements.

87 Why dioptric telescopes must be made so long.

The reason why it is necessary to make the common dioptric telescopes so very long, is, that the length of them must be increased in no less a proportion than the duplicate of the increase of their magnifying power; so that, in order to magnify twice as much as before, with the same light and distinctness, the telescope must be lengthened four times; and to

88 Of the apertures of refracting teleſcopes.

to magnify thrice as much, nine times; and ſo on.

Before we mention the *reflecting teleſcope*, it muſt be obſerved, that M. Auzout, in a paper delivered to the Royal Society, obſerved, that the apertures which the object-glaſſes of refracting teleſcopes can bear with diſtinctneſs, are in about a ſub-duplicate proportion to their lengths; and upon this ſuppoſition he drew up a table of the apertures proper for object-glaſſes of a great variety of focal lengths, from 4 inches to 400 feet. Upon this occaſion, however, Dr Hooke obſerved, that the ſame glaſs will bear a greater or leſs aperture, according to the leſs or greater light of the object. If, for inſtance, he was viewing the ſun, or Venus, or any of the fixed ſtars, he uſed ſmaller apertures: but if he wanted to view the moon by daylight; or Saturn, Jupiter, or Mars, by night; he uſed a larger aperture.

But the merit of all theſe improvements was in a manner cancelled by the diſcovery of the much more commodious *reflecting teleſcope*. For a refracting teleſcope, even of 1000 feet focus, ſuppoſing it poſſible to be made uſe of, could not be made to magnify with diſtinctneſs more than 1000 times; whereas a reflecting teleſcope, not exceeding 9 or 10 feet, will magnify 1200 times.

89 Hiſtory of the reflecting teleſcope.

"It muſt be acknowledged, (ſays Dr Smith in his *Complete Syſtem of Optics*), that Mr James Gregory of Aberdeen was the firſt inventor of the reflecting teleſcope; but his conſtruction is quite different from Sir Iſaac Newton's, and not nearly ſo advantageous."

But, according to Dr Pringle, Merſennus was the man who entertained the firſt thought of a reflector. A teleſcope with ſpecula he certainly propoſed to the celebrated Deſcartes many years before Gregory's invention, though indeed in a manner ſo very unſatisfactory, that Deſcartes, who had given particular attention to the improvement of the teleſcope, was ſo far from approving the propoſal, that he endeavoured to convince Merſennus of its fallacy (A). Dr Smith, it appears, had never peruſed the two letters of Deſcartes to Merſennus which briefly touch on that ſubject.

Again, as to his aſſertion, that Gregory's conſtruction was not nearly ſo advantageous as Newton's, it may be accounted for from his having ſet it down early in the compoſition of his work, and forgetting to qualify it afterwards, when, before the publication, he had received pretty ſure information to the contrary. Or perhaps he was influenced by the example of Dr Bradley, who had been a moſt ſucceſsful obſerver, and yet had always preferred the Newtonian teleſcope to the other. But we muſt certainly adjudge the ſuperiority to the latter, as that is now, and has been for ſeveral years paſt, the only inſtrument of the kind in requeſt.

Gregory, a young man of an uncommon genius, was led to the invention, in ſeeking to correct two imperfections of the common teleſcope: the firſt was its too great length, which made it leſs manageable; the ſecond, the incorrectneſs of the image. Mathematicians had demonſtrated, that a pencil of rays could not be collected in a ſingle point by a ſpherical lens; and alſo, that the image tranſmitted by ſuch a lens would be in ſome degree incurvated. Theſe inconveniences he believed would be obviated by ſubſtituting for the object-glaſs a metallic ſpeculum, of a parabolic figure, to receive the image, and to reflect it towards a ſmall ſpeculum of the ſame metal: this again was to return the image to an eye-glaſs placed behind the great ſpeculum, which for that purpoſe was to be perforated in its centre. This conſtruction he publiſhed in 1663, in his *Optica Promota*. But as Gregory, as he himſelf declares, was endowed with no mechanical dexterity, nor could find any workman capable of realizing his invention, after ſome fruitleſs attempts in that way he was obliged to give up the purſuit: and probably, had not ſome new diſcoveries been made in light and colours, a reflecting teleſcope would never more have been thought of, conſidering the difficulty of the execution, and the ſmall advantages that could accrue from it, deducible from the principles of optics that were then known.

But Newton, whoſe happy genius for experimental knowledge was equal to that for geometry, happily interpoſed, and ſaved this noble invention from well-nigh periſhing in its infant-ſtate. He likewiſe at an early period of life had applied himſelf to the improvement of the teleſcope; but imagining that Gregory's ſpecula were neither very neceſſary, nor likely to be executed, he began with proſecuting the views of Deſcartes, who aimed at making a more perfect image of an object, by grinding lenſes, not to the figure of a ſphere, but to that of one of the conic ſections. Now, whilſt he was thus employed, three years after Gregory's publication, he happened to take to the examination of the colours formed by a priſm, and having by the means of that ſimple inſtrument diſcovered the different refrangibility of the rays of light, he then perceived that the errors of teleſcopes, ariſing from that cauſe alone, were ſome hundred times greater than ſuch as were occaſioned by the ſpherical figure of lenſes. This circumſtance, forced, as it were, Newton to fall into Gregory's track, and to turn his thoughts to reflectors. "The different refrangibility of the rays of light (ſays he, in a letter to Mr Oldenburg, ſecretary to the Royal Society, dated in Feb. 1672), made me take reflections into conſideration; and finding them regular, ſo that the angle of reflection of all ſorts of rays was equal to the angle of incidence, I underſtood, that by their mediation optic inſtruments might be brought to any degree of perfection imaginable, providing a reflecting ſubſtance could be found which would poliſh as finely as glaſs, and reflect as much light as glaſs tranſmits, and the art of communicating to it a parabolic figure be alſo obtained. Amidſt theſe thoughts I was forced from Cambribge by the intervening plague, and it was more than two years before I proceeded further."

It appears, then, that if Newton was not the firſt inventor of the reflecting teleſcope, he was the main and effectual inventor. By the force of his admirable genius, he fell upon this new property of light; and thereby found, that all lenſes, of whatever figure, would be affected more or leſs with ſuch priſmatic aberrations of

(A) *Lettres de Deſcartes, tome* ii. printed at Paris in 1657, lett. 29. and 32. See this point diſcuſſed by two learned and candid authors, M. le Roi in the *Encyclopedie*, under the article *Teleſcope*, and M. Montecula in *Hiſt. des Mathem. tome* ii. p. 644.

of the rays as would be an insuperable obstacle to the perfection of a dioptric telescope.

It was towards the end of 1668, or in the beginning of the following year, when Newton, being thus obliged to have recourse to reflectors, and not relying on any artificer for making his specula, set about the work himself, and early in the year 1672 completed two small reflecting telescopes. In these he ground the great speculum into a spherical concave; not but that he approved of the parabolic form proposed by Gregory, though he found himself unable to accomplish it. In the letter that accompanied one of these instruments which he presented to the Society, he writes, "that though he then despaired of performing that work (to wit, the parabolic figure of the great speculum) by geometrical rules, yet he doubted not but that the thing might in some measure be accomplished by mechanical devices."

Not less did the difficulty appear to find a metallic substance that would be of a proper hardness, have the fewest pores, and receive the smoothest polish: a difficulty in truth which he deemed almost unsurmountable, when he considered, that every irregularity in a reflecting surface would make the rays of light stray five or six times more out of their due course, than the like irregularities in a refracting one. In another letter, written soon after, he tells the secretary, "that he was very sensible that metal reflects less light than glass transmits; but as he had found some metallic substances to be more strongly reflective than others, to polish better, and to be freer from tarnishing than others, so he hoped that there might in time be found out some substances much freer from these inconveniences than any yet known." Newton therefore laboured till he found a composition that answered in some degree, and left it to those who should come after him to find a better, and presented a reflecting telescope to the Royal Society; from whom he received such thanks as were due to so curious and valuable a present. And Huygens, one of the greatest geniuses of the age, and himself a distinguished improver of the refractor, no sooner was informed by Mr Oldenburg of the discovery, than he wrote in answer, "that it was an admirable telescope; and that Mr Newton had well considered the advantage which a concave speculum had above convex glasses in collecting the parallel rays, which according to his own calculation was very great: Hence that Mr Newton could give a far greater aperture to that speculum than to an object-glass of the same distance of focus, and consequently much more magnify in his way than by an ordinary telescope: Besides, that by the reflector he avoided an inconvenience inseparable from object-glasses, which was the obliquity of both their surfaces, which vitiated the refraction of the rays that pass towards the sides of the glass, and did more hurt than men were aware of: Again, that by the mere reflection of the metalline speculum there were not so many rays lost as in glasses, which reflected a considerable quantity by each of their surfaces, and besides intercepted many of them by the obscurity of their matter: That the main business would be, to find a matter for this speculum that would bear as good and even a polish as glass. Lastly, he believed that Mr Newton had not been without considering the advantage which a parabolic speculum would have over a spherical one in this construction; but had despaired, as he himself had done, of working other surfaces than spherical ones with due exactness." Huygens was not satisfied with thus expressing to the society his high approbation of the late invention; but drew up a favourable account of the new telescope, which he caused to be published in the *Journal des Scavans* for the year 1672, and by that channel it was soon known over Europe.

But how excellent soever the contrivance was; how well soever supported and announced to the public; yet whether it was that the artists were deterred by the difficulty and labour of the work, or that the discoveries even of a Newton were not to be exempted from the general fatality attending great and useful inventions, *the making a slow and vexatious progress to the authors*; the fact is, that, excepting an unsuccessful attempt which the society made, by employing an artificer to imitate the Newtonian construction, but upon a larger scale, and a disguised Gregorian telescope, set up by Cassegrain abroad as a rival to Newton's, and that in theory only (for it never was put in execution by the author), no reflector was heard of for nearly half a century after. But when that period was elapsed, a reflecting telescope was at last produced to the world of the Newtonian construction by Dr Hadley, which the author had the satisfaction to find executed in such a manner as left no room to fear that the invention would any longer continue in obscurity.

This memorable event was owing to the genius, dexterity, and application, of Mr Hadley the inventor of the reflecting quadrant, another most valuable instrument. The two telescopes which Newton had made were but six inches long, were held in the hand for viewing objects, and in power were compared to a six-feet refractor; whereas Hadley's was above five feet long, was provided with a well-contrived apparatus far managing it, and equalled in performance the famous aerial telescope of Huygens of 123 feet in length. Excepting as to the manner of making the specula, we have, in the transactions of 1723, a complete description, with a figure, of this telescope, together with that of the machine for moving it; but, by a strange omission, Newton's name is not once mentioned in that paper, so that any person not acquainted with the history of the invention, and reading that account only, might be apt to conclude that Hadley had been the sole contriver of it.

The same celebrated artist, after finishing two telescopes of the Newtonian construction, accomplished a third in the Gregorian way; but, it would seem, less successfully, by Dr Smith's declaring so strongly in favour of the other. Mr Hadley spared no pains to instruct Mr Molyneux and the reverend Dr Bradley; and when those gentlemen had made a sufficient proficiency in the art, being desirous that these telescopes should become more public, they liberally communicated to some of the principal instrument-makers of London the knowledge they had acquired from him. Now such scholars, as it is easy to imagine, soon advanced beyond their masters, and completed reflectors by other and better methods than what had been taught them.

Cer-

Certain it is, at leaſt, that Mr James Short, as early as the year 1734, had ſignalized himſelf at Edinburgh by his work of this kind. Mr Maclaurin wrote that year to Dr Jurin, "that Mr Short, who had begun with making glaſs ſpecula, was then applying himſelf to improve the metallic; and that, by taking care of the figure, he was enabled to give them larger apertures than others had done; and that upon the whole they ſurpaſſed in perfection all that he had ſeen of other workmen." He added, "that Mr Short's teleſcopes were all of the Gregorian conſtruction; and that he had much improved that excellent invention." This character of excellence Mr Short maintained to the laſt; and with the more facility, as he had been well grounded both in the geometrical and philoſophical principles of optics, and upon the whole was a moſt intelligent perſon in whatever related to his profeſſion. It was ſuppoſed he had fallen upon a method of giving the parabolic figure to his great ſpeculum; a point of perfection that Gregory and Newton had wiſhed for, but deſpaired of attaining; and that Hadley had never, as far as we know, attempted, either in his Newtonian or Gregorian teleſcope. Mr Short indeed ſaid he had acquired that faculty, but never would tell by what peculiar means he effected it; ſo that the ſecret of working that configuration, whatever it was, as far as it then appeared, died with that ingenious artiſt. Mr Mudge, however, hath lately realized the expectation of Sir Iſaac Newton, who, above 100 years ago, preſaged that the public would one day poſſeſs a parabolic ſpeculum, not accompliſhed by mathematical rules, but by mechanical devices.

This was a *deſideratum*, but it was not the only want ſupplied by this gentleman: he has taught us likewiſe a better compoſition of metals for the ſpecula, how to grind them better, and how to give them a finer poliſh; and this laſt part, (namely, the poliſh), he remarks, was the moſt difficult and eſſential of the whole operation. "In a word, (ſays Sir John Pringle), I am of opinion, there is no optician in this great city (which hath been ſo long and ſo juſtly renowned for ingenious and dextrous makers of every kind of mathematical inſtruments) ſo partial to his own abilities as not to acknowledge, that, however ſome parts of the mechanical proceſs now diſcloſed might have been known before by individuals of the profeſſion, yet that Mr Mudge hath opened to them all ſome new and important lights, and upon the whole hath greatly improved the art of making reflecting teleſcopes."

90
Account of Mr Dollond's improvements

The greateſt improvement in *refracting* teleſcopes is that of Mr Dollond, of which an account has already been given in a preceding ſection, wherein his diſcoveries in the ſcience of Optics were explained. But, beſides the obligation we are under to him for correcting the abberration of the rays of light in the focus of object-glaſſes, ariſing from their different refrangibility, he made another conſiderable improvement in teleſcopes, viz. by correcting, in a great meaſure, both this kind of aberration, and alſo that which ariſes from the ſpherical form of lenſes, by an expedient of a very different nature; viz. increaſing the number of eye-glaſſes.

If any perſon, ſays he, would have the viſual angle of a teleſcope to contain 20 degrees, the extreme pencils of the field muſt be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glaſs, will cauſe an aberration from the figure, in proportion to the cube of that angle; but if two glaſſes are ſo proportioned and ſituated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and therefore, the aberration being in proportion to the cube of half the angle taken twice over, will be but a fourth part of that which is in proportion to the cube of the whole angle; becauſe twice the cube of 1 is but $\frac{1}{4}$ of the cube of 2; ſo the aberration from the figure, where two eye-glaſſes are rightly proportioned, is but a fourth of what it muſt unavoidably be where the whole is performed by a ſingle eye-glaſs. By the ſame way of reaſoning, when the refraction is divided between three glaſſes, the aberration will be found to be but the ninth part of what would be produced from a ſingle glaſs; becauſe three times the cube of 1 is but one-ninth of the cube of 3. Whence it appears, that by increaſing the number of eye-glaſſes, the indiſtinctneſs which is obſerved near the borders of the field of a teleſcope may be very much diminiſhed, though not entirely taken away.

The method of correcting the errors ariſing from the different refrangibility of light is of a different conſideration from the former. For, whereas the errors from the figure can only be diminiſhed in a certain proportion according to the number of glaſſes, in this they may be entirely corrected by the addition of only one glaſs; as we find in the aſtronomical teleſcope, that two eye-glaſſes, rightly proportioned, will cauſe the edges of objects to appear free from colours, quite to the borders of the field. Alſo in the day-teleſcope, where no more than two eye-glaſſes are abſolutely neceſſary for erecting the object, we find, that by the addition of a third, rightly ſituated, the colours, which would otherwiſe make the image confuſed, are entirely removed. This, however, is to be underſtood with ſome limitation: for though the different colours into which the extreme pencils muſt neceſſarily be divided by the edges of the eye-glaſſes, may in this manner be brought to the eye in a direction parallel to each other, ſo as, by the humours of the eye, to be made to converge to a point on the retina; yet, if the glaſſes exceed a certain length, the colours may be ſpread too wide, to be capable of being admitted thro' the pupil or aperture of the eye; which is the reaſon, that in long teleſcopes, conſtructed in the common manner, with three eye-glaſſes, the field is always very much contracted.

Theſe conſiderations firſt ſet Mr Dollond on contriving how to enlarge the field, by increaſing the number of eye-glaſſes without any hindrance to the diſtinctneſs or brightneſs of the image; and though others had been about the ſame work before, yet, obſerving that ſome five-glaſs teleſcopes which were then made would admit of farther improvement, he endeavoured to conſtruct one with the ſame number of glaſſes in a better manner; which ſo far anſwered his expectations, as to be allowed by the beſt judges to be a conſiderable improvement on the former.

Encouraged by this ſucceſs, he reſolved to try if he could

could not make ſome farther enlargement of the field, by the addition of another glaſs, and by placing and proportioning the glaſſes in ſuch a manner as to correct the aberrations as much as poſſible, without any detriment to the diſtinctneſs; and at laſt he obtained as large a field as is convenient or neceſſary, and that even in the longeſt teleſcopes that can be made.

Theſe teleſcopes with ſix glaſſes having been well received, and ſome of them being gone into foreign parts, it ſeemed a proper time to the author to ſettle the date of his invention; on which account he drew up a letter, which he addreſſed to Mr Short, and which was read at the Royal Society, March 1, 1753.

91 Mr Smith's propoſal to ſhorten teleſcopes.

Various other attempts were made about this time to ſhorten and otherwiſe improve teleſcopes. Among theſe we muſt juſt mention that of Mr Caleb Smith, who, after giving much attention to the ſubject, thought that he had found it poſſible to rectify the errors which ariſe from the different degrees of refrangibility, on the principle that the ſines of refraction, or rays differently refrangible, are to one another in a given proportion, when their ſines of incidence are equal; and the method which he propoſed for this purpoſe was to make the ſpeculums of glaſs inſtead of metal, the two ſurfaces having different degrees of concavity. But we do not find that his ſcheme was ever executed; nor is it probable, for reaſons which have been mentioned, that any advantage could be made of it.

92 Equatorial teleſcope, or portable obſervatory

To Mr Short we are indebted for the excellent contrivance of an equatorial teleſcope, or, as he likewiſe called it, a *portable obſervatory;* for with it pretty accurate obſervations may be made with very little trouble, by thoſe who have no building adapted to the purpoſe. The inſtrument conſiſts of an ingenious piece of machinery, by the help of which a teleſcope mounted upon it may be directed to any degree of right aſcenſion or declination, ſo that the place of any of the heavenly bodies being known, they may be found without any trouble, even in the day-time. Alſo, being made to turn parallel to the equator, any object is eaſily kept in view, or recovered, without moving the eye from its ſituation. By this inſtrument, Mr Short informs us, that moſt of the ſtars of the firſt and ſecond magnitude have been ſeen even at mid-day, and the ſun ſhining bright; as alſo Mercury, Venus, and Jupiter. Saturn and Mars are not ſo eaſy to be ſeen, on account of the faintneſs of their light, except when the ſun is but a few hours above the horizon. This particular effect depends upon the teleſcope excluding almoſt all the light, except what comes from the object itſelf, and which might otherwiſe efface the impreſſion made by its weaker light upon the eye. Any teleſcope of the ſame magnifying power would have the ſame effect, could we be ſure of pointing it right. For the ſame reaſon, alſo, it is that ſtars are viſible in the day-time from the bottom of a deep pit.

93 How to obſerve the ſtars in the day-time.

In order to enable us to ſee the fixed ſtars in the day-time, it is neceſſary to exclude the extraneous light as much as poſſible. For this reaſon the greater magnifying power of any teleſcope is uſed, the more eaſily a fixed ſtar will be diſtinguiſhed in the day-time; the light of the ſtar remaining the ſame in all magnifying powers of the ſame teleſcope, but the ground upon which it is ſeen becoming darker by increaſing the magnifying power; and the viſibility of a ſtar depends very much upon the difference between its own light and that of the ground upon which it is ſeen. A fixed ſtar will be very nearly equally viſible with teleſcopes of very different apertures, provided the magnifying power remains the ſame.

If a comet, or any other heavenly body, be viewed through this equatorial teleſcope, properly rectified, it is ſeen immediately by the help of the ſame machinery what is its true place in the heavens. Other aſtronomical problems may alſo be ſolved by it, with great eaſe and certainty. But a particular deſcription of its conſtruction and uſes, will be afterwards given.

94 Mr Epinus's propoſal for bending the tubes of teleſcopes.

M. Æpinus propoſes to bend the tubes of long teleſcopes at right angles, fixing a plane mirror in the angle, in order to make them more commodious for viewing objects near the zenith of the obſerver; and he gives particular inſtructions how to make them in this form, eſpecially when they are furniſhed with micrometers. We are alſo informed that a little plane ſpeculum is ſometimes placed betwixt the laſt eye-glaſs and the eye in the reflecting teleſcopes, at an angle of 45°, for the ſame purpoſe.

95 Hiſtory of microſcopes

The invention of Microscopes was not much later than that of teleſcopes; and, according to Borellus, whoſe account we do not find to have been called in queſtion by any perſon, we are indebted for them to the ſame author, at leaſt to Z. Janſen, in conjunction with his ſon; and for this latter favour we may, perhaps, be conſidered as under more obligation to them than for the former, the microſcope having more various and extenſive uſes, with reſpect to philoſophy, than the teleſcope. In our ideas, however, it appears ſomething greater, and more extraordinary, to be able to ſee objects too diſtant to be perceived by the naked eye, than thoſe that are too near to be ſeen by us; and therefore there is more of the ſublime in the teleſcope than the microſcope. Theſe two inſtruments, though different in their application, are notwithſtanding very ſimilar; as both of them aſſiſt us in the diſcovery of objects that we muſt otherwiſe have remained unacquainted with, by enlarging the angle which they ſubtend at the eye.

The Janſens, however, have not always enjoyed, undiſturbed, that ſhare of reputation to which they ſeem to be intitled, with reſpect either to the teleſcope or the microſcope. The diſcovery of the latter, in particular, has generally been conſidered as more uncertain than that of the former. All that many writers ſay we can depend upon is, that microſcopes were firſt uſed in Germany about the year 1621. Others ſay poſitively, that this inſtrument was the contrivance of Cornelius Drebell, no philoſopher, but a man of curioſity and ingenuity, who alſo invented the thermometer.

According to Borellus, Zacharias Janſen and his ſon preſented the firſt microſcopes they had conſtructed to prince Maurice, and Albert archduke of Auſtria. William Borell, who gives this account in a letter to his brother Peter, ſays, that when he was ambaſſador in England, in 1619, Cornelius Drebell, with whom he was intimately acquainted, ſhewed him a microſcope, which he ſaid was the ſame the archduke had given him, and had been made by Janſen himſelf.

This

This inftrument was not fo fhort as they are generally made at prefent, but was fix feet long, confifting of a tube of gilt copper, an inch in diameter, fupported by three brafs pillars in the fhape of dolphins, on a bafe of ebony, on which the fmall objects were placed.

96 Microfcope made by Janfen.

This telefcope was evidently a compound one, or rather fomething betwixt a telefcope and a microfcope, what we fhould now, perhaps, choofe to call a *megalafcope;* fo that it is poffible that fingle microfcopes might have been known, and in ufe, fome time before: but perhaps nobody thought of giving that name to fingle lenfes; though, from the firft ufe of lenfes, they could not but have been ufed for the purpofe of magnifying fmall objects. In this fenfe we have feen, that even the ancients were in poffeffion of microfcopes; and it appears from Jamblicus and Plutarch, quoted by Dr Rogers, that they gave fuch inftruments as they ufed for this purpofe the name of *dioptra*. As fpectacles were certainly in ufe long before the invention of telefcopes, one can hardly help concluding, that lenfes muft have been made fmaller, and more convex, for the purpofe of magnifying of minute objects; efpecially as the application of this kind of microfcope was nearly the fame with that of a fpectacle glafs, both of them being held clofe to the eye. At what time lenfes were made fo fmall as we now generally ufe them for magnifying in fingle microfcopes, we have not found. But as this muft neceffarily have been done gradually, the only proper object of inquiry is the invention of the double, or compound microfcope; and this is clearly given, by the evidence of Borellus above-mentioned, to Zacharias Janfen, the inventor of the telefcope, or his fon.

The invention of compound microfcopes is claimed by the fame Fontana who claimed the difcovery of telefcopes; and though he did not publifh any account of this improvement till the year 1646 (nothwithftanding he pretended to have made the difcovery in 1618), Montucla, not having attended perhaps to the teftimony of Borellus, is willing to allow his claim, as he thought there was no other perfon who feemed to have any better right to it.

97 By Divini.

Euftachio Divini made microfcopes with two common object-glaffes, and two plano-convex eye-glaffes joined together on their convex fides fo as to meet in a point. The tube in which they were inclofed was as big as a man's leg, and the eye-glaffes almoft as broad as the palm of a man's hand. Mr Oldenburg, fecretary to the royal fociety, received an account of this inftrument from Rome, and read it at one of their meetings, Auguft 6, 1668.

98 By Hartfocker.

It was in this period that Hartfocker improved fingle microfcopes, by ufing fmall globules of glafs, made by melting them in the flame of a candle, inftead of the lenfes which had before been made ufe of for that purpofe. By this means he firft difcovered the *animalcula in femine mafculino*, which gave rife to a new fyftem of generation. A microfcope of this kind, confifting of a globule of $\frac{1}{10}$ of an inch in diameter, M. Huygens demonftrated to magnify 100 times; and fince it is eafy to make them of lefs than half a line in diameter, they may be made to magnify 300 times. Were it not for the difficulty of applying objects to thefe magnifiers, the want of light, and the fmall field of diftinct vifion, they would certainly have been the moft perfect of all microfcopes.

99 By Leeuwenhoek.

But no man diftinguifhed himfelf fo much by microfcopical difcoveries as the famous M. Leeuenhoek, though he ufed only fingle lenfes with fhort foci, preferring diftinctnefs of vifion to a large magnifying power.

M. Leeuwenhoek's microfcopes were all fingle ones, each of them confifting of a fmall double convex-glafs, fet in a focket between two filver plates rivetted together, and pierced with a fmall hole; and the object was placed on the point of a needle, fo contrived, as to be placed at any diftance from the lens. If the objects were folid, he faftened them with glue; and if they were fluid, or on other accounts required to be fpread upon glafs, he placed them on a fmall piece of Mufcovy talc, or glafs blown very thin; which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could fix to the fame microfcopes.

The greateft part of his mifcrofcopes M. Leeuwenhoek bequeathed to the royal fociety. They were contained in a fmall Indian cabinet, in the drawers of which were 13 little boxes, or cafes, in each of which were two microfcopes, neatly fitted up in filver; and both the glafs and the apparatus were made with his own hands.

The glafs of all thefe lenfes is exceedingly clear, but none of them magnifies fo much as thofe globules which are frequently ufed in other microfcopes; but Mr Folkes, who examined them, thought that they fhewed objects with much greater diftinctnefs, which M. Leeuwenhoek principally valued. His difcoveries, however, are to be afcribed not fo much to the goodnefs of his glaffes, as to his great judgment, acquired by long experience, in ufing them. He alfo particularly excelled in his manner of preparing objects for being viewed to the moft advantage.

Mr Baker, who alfo examined M. Leeuwenhoek's microfcopes, and made a report concerning them to the royal fociety, found that the greateft magnifier among them enlarged the diameter of an object about 160 times, but that all the reft fell much fhort of that power; fo he concluded that M. Leeuenhoek muft have had other microfcopes of a much greater magnifying power for many of his difcoveries. And it appears, he fays, by many circumftances, that he had fuch microfcopes.

It appears from M. Leeuwenhoek's writings, that he was not unacquainted with the method of viewing opaque objects by means of a fmall concave reflecting mirror, which was afterwards improved by M. Lieberkhun. For, after defcribing his apparatus for viewing eels in glafs tubes, he adds, that he had an inftrument to which he fcrewed a microfcope fet in brafs, upon which microfcope he faftened a little difh of brafs, probably that his eye might be thereby affifted to fee objects better; for he fays he had filed the brafs which was round his microfcope as bright as he could, that the light, while he was viewing objects, might be reflected from it as much as poffible. This microfcope, with its difh, (of which an exact copy, taken from the picture in his works, may be feen, Plate CCVIII. fig. 2.) feems fo like our opaque microfcope, with its filver fpeculum, that it may well be fuppofed to have given the hint to the ingenious invenventor of it, provided he ever attended to it.

100 Wilfon's microfcope. In 1702, Mr Wilfon made feveral ingenious improvements in the method of ufing fingle magnifiers, for the purpofe of viewing tranfparent objects; and they have been fo generally approved, that hardly any other method is made ufe of at this day. The capital advantage attending this microfcope confifts in its being furnifhed with a pretty large lens, to throw light upon the objects, and alfo with a fine fcrew and fpring, to bring them nearer, or remove them farther from the magnifier at pleafure. This microfcope is alfo a neceffary part of the folar microfcope, invented afterwards.

101 Adams's method of making globules for large magnifiers. In 1710, Mr Adams gave to the Royal Society the following account of his method of making fmall globules for large magnifiers. He took a piece of fine window-glafs, and cut it with a diamond into as many lengths as he thought proper, not exceeding $\frac{1}{8}$ of an inch in breadth; then, holding one of them between the fore-finger and thumb of each hand over a very fine flame, till the glafs began to foften, he drew it out till it was as fine as a hair, and broke; then putting each of the ends into the pureft part of the flame, he had two globules prefently, which he could make larger or lefs at pleafure. If they were held a long time in the flame, they would have fpots in them, fo that he drew them out prefently after they became round. The ftem he broke off as near to the globule as he could, and lodging the remainder between the plates, in which holes were drilled exactly round, the microfcope, he fays, performed to admiration. Through thefe magnifiers, he fays, that the fame thread of very fine muflin appeared three or four times bigger than it did in the largeft of Mr Wilfon's magnifiers.

102 Temporary microfcopes by Mr Grey. The ingenious Mr Grey hit upon a very eafy expedient to make very good temporary microfcopes, at a very little expence. They confift of nothing but very fmall drops of water, taken up with a point of a pin, and put into a fmall hole made in a piece of metal. Thefe globules of water do not, indeed, magnify fo much as thofe which are made of glafs of the fame fize, becaufe the refractive power of water is not fo great; but the fame purpofe will be anfwered nearly as well by making them fomewhat fmaller.

The fame ingenious perfon, obferving that fmall heterogeneous particles inclofed in the glafs of which microfcopes are made, were much magnified when thofe glaffes were looked through, thought of making his microfcopes of water that contained living animalcula, to fee how they would look in this new fituation; and he found his fcheme to anfwer even beyond his utmoft expectation, fo that he could not even account for their being magnified fo much as they were: for it was much more than they would have been magnified if they had been placed beyond the globule, in the proper place for viewing objects. But Montucla obferves, that, when any object is inclofed within this fmall tranfparent globule, the hinder-part of it acts like a concave mirror, provided they be fituated between that furface and the focus; and that, by this means, they are magnified above $3\frac{1}{2}$ times more than they would have been in the ufual way.

After the happy execution of the reflecting telefcope, it was natural to expect that attempts would alfo be made to render a fimilar fervice to microfcopes. Accordingly we find two plans of this kind. The firft was that of Dr Robert Barker. His inftrument differs in nothing from the reflecting telefcope, excepting the diftance of the two fpeculums, in order to adapt it to thofe pencils of rays which enter the telefcope diverging; whereas they come from very diftant objects nearly parallel to each other. 103 Dr Barker's reflecting microfcope.

This microfcope is not fo eafy to manage as the common fort. For vifion by reflection, as it is much more perfect, fo it is far more difficult than that by refraction. Nor is this microfcope fo ufeful for any but very fmall or tranfparent objects. For the object, being between the fpeculum and image, would, if it were large and opaque, prevent a due reflection.

In Dr Smith's reflecting microfcope there are two reflecting mirrors, one concave and the other convex, and the image is viewed by a lens. 104 Dr Smith's reflecting microfcope.

This microfcope, though far from being executed in the beft manner, performed, Dr Smith fays, nearly as well as the very beft refracting microfcopes; fo that he did not doubt but that it would have excelled them, if it had been executed properly. Dr Smith's own account of this inftrument may be feen in his Optics, Remarks, p. 94.

In 1738 or 1739, M. Lieberkuhn made two capital improvements in microfcopes, by the invention of the *folar microfcope*, and the *microfcope for opaque objects*. When he was in England in the winter of 1739, he fhewed an apparatus of his own making, for each of thefe purpofes, to feveral gentlemen of the Royal Society, as well as to fome opticians, particularly Mr Cuff in Fleet-ftreet, who took great pains to improve them. 105 Solar microfcope, and that for opaque objects.

The folar microfcope, as made by Mr Cuff, was compofed of a tube, a looking-glafs, a convex lens, and a Wilfon's microfcope. Of this, and of another conftructed by Mr Martin, a particular defcription will be afterwards given.

The microfcope for opaque objects remedies the inconvenience of having the dark fide of an object next the eye. For by means of a concave fpeculum of filver, highly polifhed, in the centre of which a magnifying lens is placed, the object is fo ftrongly illuminated that it may be examined with all imaginable eafe and pleafure. A convenient apparatus of this kind, with four different fpeculums and magnifiers of different powers, was brought to perfection by Mr Cuff.

M. Lieberkuhn made confiderable improvements in his folar microfcope, particularly in adapting it to the view of opaque objects; but in what manner this end was effected, M. Æpinus, who was highly entertained with the performance, and who mentions the fact, was not able to recollect; and the death of the ingenious inventor prevented his publifhing any account of it himfelf. M. Æpinus invites thofe perfons who came into the poffeffion of M. Lieberkuhn's apparatus to publifh an account of this inftrument; but it doth not appear that his method was ever publifhed.

This improvement of M. Lieberkuhn's induced M. Æpinus himfelf to attend to the fubject; and by this means produced a very valuable improvement in this inftrument. For by throwing the light upon the forefide of any object by means of a mirror, before it is tranfmitted through the object-lens, all kinds of objects are equally well reprefented by it.

M.

106 Reflected light introduced into the microscope and magic lantern.

M. Euler proposed a scheme to introduce vision by reflected light into the magic lantern and solar microscope, by which many inconveniences to which those instruments are subject, might be avoided. For this purpose, he says, that nothing is necessary but a large concave mirror, perforated as for a telescope; and that the light be so situated, that none of it may pass directly through the perforation, so as to fall on the images of the objects upon the screen. He proposes to have four different machines, for objects of different sizes; the first for those of six feet long, the second for those of one foot, the third for those of two inches, and the fourth for those of two lines. An idea of this contrivance is given in Plate CCVIII. fig. 3. in which OD represents the concave mirror, E the object, *l*, *l* the lights, and A the lens, through which the rays are transmitted to the screen.

Several improvements were made in the apparatus to the solar microscope, as adapted to view opaque objects, by M. Zeiher, who made one construction for the larger kind of objects, and another for the small ones.

107 Mr Martin's improvement in the solar microscope.

Mr Martin having constructed a solar microscope of a larger size than common, for his own use, the illuminating lens being $4\frac{1}{2}$ inches in diameter, and all the other parts of the instrument in proportion, found, that by the help of an additional part, which he does not describe, he could see even opaque objects very well. If he had made the lens any larger, he was aware that the heat produced at the focus would be too great for the generality of objects to bear. The expence of this instrument, he says, does not much exceed the price of the common solar microscope.

108 Di Torre's extraordinary magnifying microscope.

The smallest globules, and consequently the greatest magnifiers, for microscopes, that have yet been executed, were made by T. Di Torre of Naples, who, in 1765, sent four of them to the Royal Society. The largest of them was only two Paris points in diameter, and it was said to magnify the diameter of an object 640 times. The second was the size of one Paris point, and the third was no more than half of a Paris point, or the 144th part of an inch in diameter, and was said to magnify the diameter of an object 2560 times. One of these globules was wanting when they came into the hands of Mr Baker, to whose examination they were referred by the Royal Society. This gentleman, so famous for his skill in microscopes, and his extraordinary expertness in managing them, was not able to make any use of these. With that which magnifies the least, he was not able to see any object with satisfaction; and he concludes his account with expressing his hopes only, that, as his eyes had been much used to microscopes, they were not injured by the attention he had given to them, though he believed there were few persons who would not have been blinded by it.

109 Could not be used by Mr Baker.

The construction of a telescope with six eye-glasses led M. Euler to a similar construction of microscopes, by introducing into them six lenses, one of which admits of so small an aperture, as to serve, instead of a diaphragm, to exclude all foreign light, though, as he says, it neither lessens the field of view, nor the brightness of objects.

110 Difficulties attending the construction of dioptric instruments.

The improvement of all dioptric instruments is greatly impeded by inequalities in the substance of the glass of which they are made; but though many attempts have been made to make glass without that imperfection, none of them have been hitherto quite effectual. M. A. D. Merklein, having found some glass which had been melted when a building was on fire, and which proved to make excellent object-glasses for telescopes, concluded that its peculiar goodness arose from its not having been disturbed when it was in a fluid state; and therefore he proposed to take the metal out of the furnace in iron vessels, of the same form that was wanted for the glass; and after it had been perfectly fluid in those vessels, to let it stand to cool, without any disturbance. But this is not always found to answer.

PART II. THEORY OF OPTICS.

THIS part of the science contains all that hath been discovered concerning the various motions of the rays of light either through different mediums, or when reflected from different substances in the same medium. It contains also the rationale of every thing which hath been discovered with regard to vision; the optical deceptions to which we are liable; and, in short, ought to give the reason of all the known optical phenomena.—The science is commonly divided into three parts, viz. dioptrics, which contains the laws of refraction, and the phenomena depending upon them; catoptrics, which contains the laws of reflection, and the phenomena which depend on them; and lastly chromatics, which treats of the phenomena of colour. But this definition is of no use in a treatise of Optics, as most of the phenomena depend both on refraction and reflection; colour itself not excepted. For this reason we have not followed that method of dividing our subject; but have explained the particular laws of refraction and reflection, afterwards showing how, by these, the most remarkable optical phenomena may be accounted for.

SECT. I. *Of the properties of Light in general.*

WITHOUT entering into any repetition of the controversies concerning the nature of LIGHT, which are fully set forth under that article, we shall here give a brief description of its properties considered as the subject of the optical science, and which hold good in all cases without regard to other theories.

Every visible body emits or reflects inconceivably small particles of matter from each point of its surface, which issue from it continually (not unlike sparks from a coal) in straight lines and in all directions. These particles entering the eye, and striking upon the retina, (a nerve expanded on the back part of the eye to receive their impulses), excite in our minds the idea of light. And as they differ in substance, density, velocity, or magnitude, they produce in us the ideas of different colours; as will be explained in its proper place.

That the particles which constitute light are exceedingly small, appears from hence, *viz.* that if a hole be made through a piece of paper with a needle, rays of

Of Light.

of light from every object on the farther fide of it are capable of paffing through it at once without the leaft confufion; for any one of thofe objects may as clearly be feen through it, as if no rays paffed through it from any of the reft. Further, if a candle is lighted, and there be no obftacle in the way to obftruct the progrefs of its rays, it will fill all the fpace within two miles of it every way with luminous particles, before it has loft the leaft fenfible part of its fubftance thereby.

That thefe particles proceed from every point of the furface of a vifible body, and in all directions, is clear from hence, *viz.* becaufe wherever a fpectator is placed with regard to the body, every point of that part of the furface which is turned towards him is vifible to him. That they proceed from the body in right lines, we are affured, becaufe juft fo many and no more will be intercepted in their paffage to any place by an interpofed object, as that object ought to intercept, fuppofing them to come in fuch lines.

The velocity with which they proceed from the furface of the vifible body is no lefs furprifing than their minutenefs: the method whereby philofophers eftimate their fwiftnefs, is by obfervations made on the eclipfes of Jupiter's fatellites; which eclipfes to us appear about feven minutes fooner than they ought to do by calculation, when the earth is placed between the fun and him, that is, when we are neareft to him; and as much later, when the fun is between him and us, at which time we are fartheft from him; from whence it is concluded, that they require about feven minutes to pafs over a fpace equal to the diftance between the fun and us, which is about 95,000,000 of miles.

A ftream of thefe particles iffuing from the furface of a vifible body in one and the fame direction, is called a *ray of light.*

As rays proceed from a vifible body in all directions, they neceffarily become thinner and thinner, continually fpreading themfelves as they pafs along into a larger fpace, and that in proportion to the fquares of their diftances from the body; that is, at the diftance of two fpaces, they are four times thinner than they are at one; at the diftance of three fpaces, nine times thinner, and fo on: the reafon of which is, becaufe they fpread themfelves in a twofold manner, *viz.* upwards and downwards, as well as fidewife.

The particles of light are fubject to the laws of attraction of cohefion, like other fmall bodies; for if a ray of light be made to pafs by the edge of a knife, it will be diverted from its natural courfe, and be inflected towards the edge of the knife. The like inflection happens to a ray when it enters obliquely into a denfer or rarer fubftance than that in which it was before, in which cafe it is faid to be refracted; the laws of which refraction are the fubject of the following fection.

Sect. II. *Of Refraction.*

111 Refraction defined.

Light, when proceeding from a luminous body, without being reflected from any opaque fubftance, or inflected by paffing very near one, is invariably found to proceed in ftraight lines, without the leaft deviation. But if it happens to pafs from one medium to another, it always leaves the direction it had before, and affumes a new one; and this change of courfe is called its *refraction.* After having taken this new direction, it then proceeds invariably in a ftraight line till it meets with a different medium, when it is again turned out of its courfe. It muft be obferved, however, that tho' by this means we may caufe the rays of light make any number of angles in their courfe, it is impoffible for us to make them defcribe a curve, except in one fingle cafe, namely, where they pafs through a medium, the denfity of which uniformly either increafes or decreafes. This is the cafe with the light of the celeftial bodies, which paffes downwards thro' our atmofphere, and likewife with that which is reflected upwards through it by terreftrial objects. In both thefe cafes, it defcribes a curve of the hyperbolic kind; but at all other times it proceeds in ftraight lines, or in what may be taken for ftraight lines without any fenfible error.

Of Refraction.

112 In what cafe the rays of light defcribe a curve.

§ 1. *The caufe of Refraction, and the law by which it is performed.*

113 Phenomena of refraction folved by an attractive power in the medium.

The phenomena of refraction are explained by an attractive power in the medium through which light paffes, in the following manner. All bodies being endowed with an attractive force, which is extended to fome diftance beyond their furfaces; when a ray of light paffes out of a rarer into a denfer medium (if this latter has a greater attractive force than the former, as is commonly the cafe) the ray, juft before its entrance, will begin to be attracted towards the denfer medium; and this attraction will continue to act upon it, till fome time after it has entered the medium; and therefore, if a ray approaches a denfer medium in a direction perpendicular to its furface, its velocity will be continually accelerated during its paffage through the fpace in which that attraction exerts itfelf; and therefore, after it has paffed that fpace, it will move on, till it arrives at the oppofite fide of the medium, with a greater degree of velocity than it had before it entered. So that in this cafe its velocity only will be altered. Whereas, if a ray enters a denfer medium obliquely, it will not only have its velocity augmented thereby, but its direction will become lefs oblique to the furface. Juft as when a ftone is thrown downwards obliquely from a precipice, it falls to the furface of the ground in a direction nearer to a perpendicular one, than that with which it was thrown from the hand. From hence we fee a ray of light, in paffing out of a rarer into a denfer medium, is refracted towards the perpendicular; that is, fuppofing a line drawn perpendicularly to the furface of the medium, through the point where the ray enters, and extended both ways, the ray in paffing through the furface is refracted or bent towards the perpendicular line; or, which is the fame thing, the line which it defcribes by its motion after it has paffed through the furface, makes a lefs angle with the perpendicular, than the line it defcribed before. All which may be illuftrated in the following manner.

Plate CCVIII.

Let us fuppofe firft, that the ray paffes out of a vacuum into the denfer medium ABCD, (fig. 4.) and that the attractive force of each particle in the medium is extended from its refpective centre to a diftance equal to that which is between the lines AB and EF, or AB and GH; and let KL be the path defcribed by a ray of light in its progrefs towards the denfer me-

Of Refraction.

medium. This ray, when it arrives at L, will enter the attractive forces of those particles which lie in AB the surface of the denser medium, and will therefore cease to proceed any longer in the right line KLM, but will be diverted from its course by being attracted towards the line AB, and will begin to describe the curve LN, passing thro' the surface AB in some new direction, as OQ; thereby making a less angle with a line, as PR, drawn perpendicularly through the point N, than it would have done had it proceeded in its first direction KLM.

Farther, whereas we have supposed the attractive force of each particle to be extended through a space equal to the distance between AB and EF, it is evident, that the ray, after it has entered the surface, will still be attracted downwards, till it has arrived at the line EF; for, till that time, there will not be so many particles above it which will attract it upwards, as below, that will attract it downwards. So that after it has entered the surface at N, in the direction OQ, it will not proceed in that direction, but will continue to describe a curve, as NS; after which it will proceed straight on towards the opposite side of the medium, being attracted equally every way; and therefore will at last proceed in the direction XST, still nearer the perpendicular PR than before.

Now if we suppose ABYZ not to be a vacuum, but a rarer medium than the other, the case will still be the same; but the ray will not be so much refracted from its rectilineal course, because the attraction of the particles of the upper medium being in a contrary direction to that of the attraction of those in the lower one, the attraction of the denser medium will in some measure be destroyed by that of the rarer.

On the contrary, when a ray passes out of a denser into a rarer medium, if its direction be perpendicular to the surface of the medium, it will only lose somewhat of its velocity, in passing through the spaces of attraction of that medium (that is, the space wherein it is attracted more one way than it is another.) If its direction be oblique, it will continually recede from the perpendicular during its passage, and by that means have its obliquity increased, just as a stone thrown up obliquely from the surface of the earth increases its obliquity all the time it rises. Thus, supposing the ray TS passing out of the denser medium ABCD into the rarer ABYZ, when it arrives at S it will begin to be attracted downwards, and so will describe the curve SNL, and then proceed in the right line LK; making a larger angle with the perpendicular PR, than the line TSX in which it proceeded during its passage through the other medium.

The space through which the attraction of cohesion of the particles of matter is extended is so very small, that in considering the progress of a ray of light out of one medium into another, the curvature it describes in passing through the space of attraction is generally neglected; and its path is supposed to be bent, or, in the usual terms, the ray is supposed to be refracted only in the point where it enters the denser medium.

Now the line which a ray describes before it enters a denser or a rarer medium, is called the *incident ray*; that which it describes after it has entered, is the *refracted ray*.

The angle comprehended between the incident ray and the perpendicular, is the *angle of incidence*; and that between the refracted ray and the perpendicular, is the *angle of refraction*.

There is a certain and immutable law or rule, by which refraction is always performed; and that is this: Whatever inclination a ray of light has to the surface of any medium before it enters it, the degree of refraction will always be such, that the proportion between the sine of the angle of its incidence, and that of the angle of its refraction, will always be the same in that medium.

Plate CCVIII.

To illustrate this: Let us suppose ABCD (fig. 5.) to represent a rarer, and ABEF a denser medium: let GH be a ray of light passing through the first and entering the second at H, and let HI be the refracted ray: then supposing the perpendicular PR drawn thro' the point H, on the centre H, and with any radius, describe the circle APBR; and from G and I, where the incident and refracted rays cut the circle, let fall the lines GK and IL perpendicularly upon the line PR; the former of these will be the sine of the angle of incidence, the latter of refraction. Now if in this case the ray GH is so refracted at H, that GK is double or triple, &c. of IL, then, whatever other inclination the ray GH might have had, the sine of its angle of incidence would have been double or triple, &c. to that of its angle of refraction. For instance, had the ray passed in the line MH before refraction, it would have passed in some line as HN afterwards, so situated that MO should have been double or triple &c. of NQ.

When a ray passes out of a vacuum into air, the sine of the angle of incidence is found to be to that of refraction, as 100036 to 100000.

When it passes out of air into water, as about 4 to 3.

When out of air into glass, as about 17 to 11.

When out of air into a diamond, as about 5 to 2.

This relation of the sine of the angle of incidence to that of refraction may be demonstrated mathematically in the following manner.

Lemma. If from a point at M (fig. 6.) taken any where without the circle PNQ, a line as MP be drawn passing through L the centre of the circle, and terminated in the circumference at P, the product of MQ multiplied by MP is equal to the difference between the squares of ML and PL.

Demonstration of the Lemma. Call MQ, a; and the radius of the circle LQ or LP, b; then will the diameter QP be expressible by $2b$, and the whole line MP, by $a+2b$; then multiplying MQ by MP, that is, a by $a+2b$, we have for the product of this, $aa+2ab$. Now the square of the line ML, which is expressible by $a+b$, is $aa+2ab+bb$; and the square of PL is bb; but the difference between these squares, *viz.* $aa+2ab+bb$ and bb, is evidently $aa+2ab$; and therefore the product of MQ multiplied by MP is equal to the difference between the squares of ML and PL. *Q. E. D.*

Demonstration of the Proposition. When a ray of light passes through the space of attraction of any medium, it is evident that its motion will be subject to the like laws with that of projectiles, provided we suppose it to be acted upon with an equal degree of force during its whole passage through that space, as is commonly supposed to be the case in projectiles to whatever

ever height they are thrown from the earth. We will therefore ſuppoſe firſt, that the force of attraction of the denſer medium is at all diſtances the ſame as far as it reaches, and that the ray proceeds out of a denſer into a rarer medium; in which caſe it will be attracted back towards the denſer medium, during its paſſage thro' the ſpace of attraction, in like manner as a projectile thrown upwards is while it riſes from the earth. Let then ABCD (fig. 6.) repreſent the denſer medium, and ABEF the ſpace of attraction; and let GH be a ray about to enter the force of attraction at H, and let GH be produced to M. Now it is evident, that, in this ſuppoſition, the ray, when at H, is in the ſame circumſtances with a projectile about to be thrown upwards from H towards M: it will therefore deſcribe a portion of a parabola as HI; to which the line HM will be a tangent at H; and the line IK, in which it would proceed after it had paſſed the ſpace of attraction, a tangent to it at I; for after having left the attractive force at I, it goes ſtraight on in its laſt direction. Let the perpendicular IR be drawn meeting GH produced in M, and let KI be produced to L. On the centre L, with the radius LI, deſcribe the circle PNQ, let fall the perpendicular LO upon MR, and join the points L and N. Now it is demonſtrated in the caſe of projectiles†, that the parameter of the point H is equal to $\frac{HMq}{MI}$, and therefore the parameter multiplied by MI is equal to HM*q*. And it is there farther demonſtrated, that the ſaid parameter is equal to four times the height which a body muſt fall from, to acquire the velocity the projectile has at H. This parameter therefore is a quantity not at all depending on the direction of the projectile, but on its velocity only; and conſequently, in the preſent ſuppoſition, it is a given quantity, the ray GH being ſudpoſed to have the ſame velocity, whatever is its inclination to the ſurface HB. Now the tangent KI being produced to L, will, by the property of the parabola, biſect the other tangent HM: wherefore the line LO being parallel to HR, MR will alſo be biſected in O; and adding the equal lines OI and ON to each part, MN will be equal to IR; but the line IR is alſo a line independent of the inclination of the ray GH, its length being determined by the breadth of the ſpace of attraction ABEF only, and therefore MN is a given quantity. Now, whereas MI, when multiplied by the parameter of the point H, which before was ſhewn to be a given line, is equal to the ſquare of HM, therefore the ſame line MI, when multiplied by any other given line (*viz.* MN) if it is not equal to, will nevertheleſs bear a given proportion to, the ſquare of HM: but ſince MI multiplied by MN bears a given proportion (*viz.* a proportion that does not depend on the inclination of the ray GH) to the ſquare of MH, its equal, *viz.* the product of MQ multiplied by MP, or what is equal to this, the difference between the ſquares of ML and PL (by the foregoing *lemma*), or, which is the ſame thing, of ML and LI, (becauſe PL and LI are radii of the ſame circle), does ſo too. Now the ſquare of ML bears alſo a given proportion to the ſquare of MH (ML being equal to half MH); conſequently there is a given proportion between the ſquare of ML and the difference of the ſquares of ML and LI; and therefore there is a certain proportion between the lines themſelves, *viz.* between ML and LI. But in every triangle the ſides are proportionable to the ſines of their oppoſite angles; therefore in the triangle MLI, the ſine of the angle LMI has a given proportion to the ſine of the angle LIM, or of its complement to two right ones MIK (for they have the ſame ſine): But LMI, being an angle made by the incident ray GH produced, with the perpendicular RM, is the angle of incidence; and MIK, being made by the refracted ray IK, and the ſame perpendicular, is the angle of refraction; therefore in this caſe there is a conſtant ratio between the ſine of the angle of incidence, and that of the angle of refraction.

Plate CCVIII.

† See the article *Projectiles*.

We have here ſuppoſed that the force of attraction is every where uniform; but if it be otherwiſe, provided it be the ſame every where at the ſame diſtances from the ſurface AB, the proportion between the forementioned ſines will ſtill be a given one. For, let us imagine the ſpace of attraction divided into parallel planes, and the attraction to be the ſame through the whole breadth of each plane though different in different planes, the ſine of the angle of incidence out of each will, by what has been demonſtrated above, be to the ſine of the angle of refraction into the next in a given ratio; and therefore, ſince the ſine of the angle of refraction out of one will be the ſine of the angle of incidence into the next, it is evident that the ſine of the angle of incidence into the firſt will be in a given ratio to the ſine of the angle of refraction out of the laſt. Now let us ſuppoſe the thickneſs of theſe planes diminiſhed *in infinitum*, and their number proportionably increaſed, the law of refraction will ſtill continue the ſame; and therefore, whether the attraction be uniform or not, there will be a conſtant ratio between the ſine of the angle of incidence and of refraction. *Q. E. D.*

For the ſame reaſon that a ray is bent towards the perpendicular when paſſing from a rare medium into one that is denſer, it is refracted from the perpendicular when it paſſes from a denſe medium into one that is rarer—From this and the foregoing propoſition may be deduced the following corollaries.

I. When parallel rays fall obliquely on a plane ſurface of a medium of different denſity, they are parallel alſo after refraction; for, having all the ſame inclination to the ſurface, they ſuffer an equal degree of refraction.

II. When diverging rays paſs out of a rarer into a denſer medium through a plain ſurface, they are made thereby to diverge leſs.

III. When they proceed out of a denſer into a rarer medium, the contrary happens, and they diverge more.

IV. When converging rays paſs out of a rarer into a denſer medium through a plain ſurface, they are made thereby to converge leſs.

V. When converging rays proceed out of a denſer into a rarer medium, they are refracted the contrary way, and ſo made to converge more.

All theſe may be illuſtrated in the following manner. 1. Let AB, CD (fig. 7.) be two parallel rays falling on the plain ſurface EF of a medium of different denſity: now becauſe they both make equal angles of incidence with their reſpective perpendicular GH, IK, before refraction, they will make equal angles of refrac-

Of Refraction.

refraction with them afterwards, and fo proceed on in the parallel lines BL, DM. 2. Let the diverging rays AB, AE, AF, (fig. 8.) pafs out of a rarer into a denfer medium through the plain furface GH, and let the ray AB be perpendicular to that furface; the reft being refracted towards their refpective perpendiculars EK, FM, and thofe the moft that fall the fartheft from B, they will proceed in the directions EN and FO, diverging in a lefs degree from the ray AP than they did before refraction. 3. Had they proceeded out of a denfer into a rarer medium, they would have been refracted from their perpendicular EK, FM; and thofe the moft which were the moft oblique, and therefore would have diverged more than before. 4. Let the converging rays AB, CD, EF (fig. 9.) pafs out of a rarer into a denfer medium through the plain furface GH, and let the ray AB be perpendicular to that furface; then the other rays being refracted towards their refpective perpendiculars DK, FM; and EF, for inftance, more than CD; they will proceed in the directions DN, FN, converging in a lefs degree towards the ray AN, than they did before. 5. Laftly, had the firft medium been the denfer, they would have refracted the other way, and therefore converged more.

VI. When rays proceed out of a rarer into a denfer medium through a convex furface of the denfer, if they are parallel before refraction, they become converging afterwards.—For in this cafe the perpendiculars at the points where the rays enter the furface are all drawn from the centre of the convexity on the other fide; and therefore, as the rays are refracted towards thefe perpendiculars, they are neceffarily refracted towards each other, and thereby made to converge.

VII. If they enter diverging, then for the fame reafon they are made to diverge lefs, to be parallel, or to converge, according to the degree of divergency they have before they enter.

For, if they diverge very much, their being bent towards their refpective perpendiculars in paffing thro' the furface, may only diminifh the divergency; whereas, if they diverge in a fmall degree, it may make them parallel, or even to converge.

VIII. If they converge in fuch a manner as to tend directly towards the centre of convexity before they enter the furface, they fall in with their refpective perpendiculars, and fo pafs on to the centre without fuffering any refraction.

IX. If they converge lefs than their perpendiculars, that is, if they tend to a point beyond the centre of convexity, they are made by refraction to converge more; and if they converge more than their perpendiculars, that is, if they tend towards a point between the centre and the furface, then, by being refracted towards them, they are made to converge lefs.

This and the three foregoing corollaries may be illuftrated in the following manner. 1. Let AB, CD (fig. 10.) be two parallel rays entering a denfer medium through the convex furface DB, whofe centre of convexity is E; and let one of thefe, viz. AB, be perpendicular to the furface. This will pafs on through the centre, without fuffering any refraction; but the other being oblique to the furface, will be refracted towards the perpendicular ED, and will therefore be made to proceed in fome line, as DG, converging towards the other ray, and meeting it in G, which point for that reafon is called the *focus*. 2. Had the ray CD diverged from the other, fuppofe in the line AD, it would, by being refracted towards its perpendicular ED, have been made either to diverge lefs, be parallel, or made to converge. 3. Let the line ED be produced to F, and if the ray had converged, fo as to have defcribed the line FD, it would have been coincident with its perpendicular, and have fuffered no refraction at all. 4. If it had proceeded from any point between C and F, as from H, or, which is the fame thing, towards any point beyond E in the line BE produced, it would have been made to converge more by being refracted towards the perpendicular DE, which converges more than it; and, had it proceeded from the fame point, as I, on the other fide of F, that is towards any point between B and E, it would then have converged more than its perpendicular, and fo, being refracted towards it, would have been made to have converged lefs.

X. When rays proceed out of a denfer into a rarer medium through a concave furface of the denfer, the contrary happens in each cafe.

For, being now refracted from their refpective perpendiculars, as they were before towards them, if they are parallel before refraction, they diverge afterwards; if they diverge, their divergency is increafed; if they converge in the direction of their perpendiculars, they fuffer no refraction; if they converge lefs than their refpective perpendiculars, they are made to converge ftill lefs, to be parallel, or to diverge; if they converge more, their convergency is increafed. All which may be clearly feen by the figure, without any further illuftration; imagining the rays AD, CD, &c. bent the contrary way in their refractions to what they were in the former cafes.

XI. When rays proceed out of a rarer into a denfer medium through a concave furface of the denfer, if they are parallel before refraction, they are made to diverge.—For in this cafe the perpendiculars at the points where the rays enter the furface, being drawn from a point on that fide of the furface from which the rays tend; if we conceive them to pafs through the furface, they will be fo many diverging lines on the other fide; and therefore the rays, after they have paffed through the fame points, muft neceffarily be rendered diverging in being refracted towards them.

XII. If they diverge before refraction, then, for the fame reafon, they are made to diverge more.

XIII. Unlefs they proceed directly from the centre; in which cafe they fall in with their perpendiculars, and fuffer no refraction: Or from fome point between the centre of convexity and the furface; for then they diverge more than their refpective perpendiculars, and therefore being by refraction brought towards them they become lefs diverging.

XIV. If they converge, then, being refracted towards their perpendiculars, they are either made lefs converging, parallel, or diverging, according to the degree they converged in before refraction.

To illuftrate this, and the three foregoing cafes, 1. Let AB, CD (fig. 11.), be two parallel rays entering the concave and denfer medium X, the centre of whofe convexity is E, and the perpendicular to the refracting

Of Refraction.

refracting surface at the point D is EF: the ray AB, if we suppose it perpendicular to the surface at B, will proceed on directly to G; but the oblique one CD being refracted towards the perpendicular DF, will recede from the other ray AG in some line as DH. 2. If the ray CD had proceeded from A, diverging in the direction AD, it would have been bent nearer the perpendicular, and therefore have diverged more. 3. But if it had diverged from the centre E, it would have fallen in with the perpendicular EF, and not have been refracted at all: and had it proceeded from S, a point on the other side of the centre E, it would, by being refracted towards the perpendicular DF, have proceeded in some line nearer it than it would otherwise have done, and so would diverge less than before refraction. 4. If it had converged in the line LD, it would have been rendered less converging, parallel, or diverging, according to the degree of convergency which it had before it entered into the refracting surface.

XV. If the same rays proceed out of a denser into a rarer medium, through a convex surface of the denser, the contrary happens in each supposition. The parallels are made to converge; those which diverge less than their respective perpendiculars, that is, those which proceed from a point beyond the centre, are made less diverging, parallel, or converging, according to the degree in which they diverge before refraction; those which diverge more than their respective perpendiculars, that is, those which proceed from a point between the centre and the refracting surface, are made to diverge still more; and those which converge are made to converge more. All which may easily be seen by considering the situation of the rays AB, CD, &c. with respect to the perpendicular EF; and therefore requires no further illustration.

XVI. When diverging rays are by refraction made to converge, the nearer the radiant point (or point whence the rays proceed) is to the refracting surface, the farther is their focus from it on the other side, and *vice versa*. For the nearer the radiant point is to the refracting surface, the more the rays which fall upon the same points of it diverge before refraction, upon which account they converge the less afterwards.

XVII. When the radiant point is at that distance from the surface at which parallel rays coming through it from the other side would be collected by refraction, then rays flowing from that point become parallel on the other side, and are said to have their focus at an infinite distance. For the power of refraction in the medium is the same, whether the ray passes one way or other. For instance, if the parallel rays AB, CD, (fig. 10.) in passing through the refracting surface BD, are brought to a focus in G, then rays flowing from G as a radiant point, will afterwards proceed in the parallel lines BA and DC. And the point G, where the parallel rays AB and CD meet after refraction, is called the *focus of parallel rays*.

XVIII. When rays proceed from a point nearer the refracting surface than the focus of parallel rays, they continue to diverge after refraction, and their focus is then an imaginary one, and situated on the same side of the surface with the radiant. For, in this case, the divergency being greater than that which they would have if they had proceeded from the focus of parallel rays, they cannot be brought to a parallelism with one another, much less to converge; and therefore they continue to diverge, though in a less degree than before they passed through the refracting surface: upon which account they proceed after refraction as if they came from some point farther distant from the refracting surface than their radiant.

All these corollaries may be expressed more determinately, and demonstrated, in the following manner:

I. When rays pass out of one medium into another of different density through a plain surface; if they diverge, the focal distance will be to that of the radiant point; if they converge, it will be to that of the imaginary focus of the incident rays, as the sine of the angle of incidence is to that of the angle of refraction.

This proposition admits of four cases.

Case 1. Of diverging rays passing out of a rarer into a denser medium.

Dem. Let X (fig. 12.) represent a rarer, and Z a denser medium, separated from each other by the plane surface AB; suppose CE and CD to be two diverging rays proceeding from the point C, the one perpendicular to the surface, the other oblique; through E draw the perpendicular PK. The ray CD being perpendicular to the surface, will proceed on in the right line CQ; but the other falling on it obliquely at E, and there entering a denser medium, will suffer a refraction towards the perpendicular EK. Let then EG be the refracted ray, and produce it back till it intersects DC produced also in F; this will be the focal point. On the centre E, and with the radius EF, describe the circle AFBQ, and produce EC to H; draw HI the sine of the angle of incidence, and GK that of refraction; equal to this is FP or CM, which let be drawn. Now if we suppose the points D and E contiguous, or nearly so, then will the line HE be almost coincident with FD, and therefore FD will be to CD as HE to CE; but HE is to CE as HI to CM, because the triangles HIE and CME are similar; that is, the focal distance of the ray CE is to the distance of the radiant point, as the sine of the angle of incidence is to that of the angle of refraction. *Q. E. D.*

Obs. 1. Whereas the ratio of FE to ME, or, which is the same thing, that of nD to CD, bears the exact proportion of HI to CM, and because this (being the ratio of the sine of the angle of incidence to that of the angle of refraction) is always the same, the line In is in all inclinations of the ray CE, at the same distance from CM; consequently, had CE been coincident with CD, the point H had fallen upon n; and because the circle passes through both H and F, F would also have fallen upon n; upon which account the focus of the ray CE would have been there. But the ray CE being oblique to the surface DB, the point H is at some distance from n; and therefore the point F is necessarily so too, and the more so by how much the greater that distance is: from whence it is clear, that no two rays flowing from the radiant point C, and falling with different obliquities on the surface BD, will, after refraction there, proceed as from the same point; therefore, strictly speaking, there is no one

Of Refraction.

one point in the line D produced, that can more properly be called the *focus of rays flowing from* C, than another: for thofe which enter the refracting furface near D, will after refraction proceed, as has been obferved, from the parts about *n;* thofe which enter near E, will flow as from the parts about F; thofe which enter about T, as from fome points in the line DF produced, &c. And it is farther to be obferved, that, when the angle DCE becomes large, the line *n*F increafes apace; wherefore thofe rays which fall near T, proceed, after refraction, as from a more diffufed fpace than thofe which fall at the fame diftance from each other near the point D. Upon which account it is ufual with optical writers to fuppofe the diftance between the points where the rays enter the plain furface of a refracting medium, to be inconfiderable with regard to the diftance of the radiant point, if they diverge; or to that of their imaginary focus, if they converge: and unlefs there be fome particular reafon to the contrary, they confider them as entering the refracting medium in a direction as nearly perpendicular to its furfaces as may be.

Case 2. Of diverging rays proceeding out of a denfer into a rarer medium.

Dem. Let X be the denfer, Z the rarer medium, FD and FE two diverging rays proceeding from the point F; and fuppofing the perpendicular PK drawn as before, FP will be the fine of the angle of incidence of the oblique ray FE; which in this cafe being refracted from the perpendicular, will pafs on in fome line as ER, which being produced back to the circumference of the circle, will cut the ray FD fomewhere, fuppofe in C; this therefore will be the imaginary focus of the refracted ray ER: draw RS the fine of the angle of refraction, to which HI will be equal: but here alfo FP, or its equal CM, is to HI as EC to EH, or (if the point D and E be confidered as contiguous) as DC to DF; that is, the fine of the angle of incidence is to the fine of the angle of refraction, as the focal diftance to that of the radiant point. *Q. E. D.*

Case 3. Of converging rays paffing out of a denfer medium into a rarer.

Dem. Let Z be the denfer, X the rarer medium, and GE the incident ray; this will be refracted from the perpendicular into a line, as EH; then all things remaining as before, GK, or its equal FP, or CM, will be the fine of the angle of incidence, and HI that of refraction: but thefe lines, as before, are to each other as DC to DF; that is, the focal diftance is to the diftance of the imaginary focus, as the fine of the angle of incidence to that of the angle of refraction. *Q. E. D.*

Case 4. Of converging rays paffing out of a rarer into a denfer medium.

Dem. Let Z be the rarer, X the denfer medium, and RE the incident ray; this will be refracted towards the perpendicular into a line, as EF; C will be the imaginary focus, and F the real one; HI, which is equal to RS, the fine of the angle of incidence, and FP that of the angle of refraction: but thefe are to each other, as DF to DC; and therefore the focal diftance is to that of the imaginary focus, as the fine of the angle of incidence is to that of the angle of refraction. *Q. E. D.*

II. When parallel rays fall upon a fpherical furface of different denfity, the focal diftance will be to the diftance of the centre of convexity, as the fine of the angle of incidence is to the difference between that fine and the fine of the angle of refraction.

This propofition admits of four cafes.

Case 1. Of parallel rays paffing out of a rarer into a denfer medium, through a convex furface of the denfer.

Plate CCVIII.

Dem. Let AB (fig. 13.) reprefent a convex furface; C its centre of convexity; HA and DB two parallel rays, paffing out of the rarer medium X into the denfer Z, the one perpendicular to the refracting furface, the other oblique: draw CB; this being a radius, will be perpendicular to the furface at the point B; and the oblique ray DB, being in this cafe refracted towards the perpendicular, will proceed in fome line, as BF, meeting the other ray in F, which will therefore be the focal point: produce CB to N; then will DBN, or its equal BCA, be the angle of incidence, and FBC that of refraction. Now, whereas any angle has the fame fine with its complement to two right ones, the angle FCB being the complement of ACB, which is equal to the angle of incidence, may here be taken for that angle; and therefore, as the fides of a triangle have the fame relation to each other that the fines of their oppofite angles have, FB being oppofite to this angle, and FC being oppofite to the angle of refraction, they may here be confidered as the fines of the angles of incidence and of refraction. And for the fame reafon CB may be confidered as the fine of the angle CFB; which angle being, together with the angle FBC, equal to the external one ACB, (32. El. 1.) is itfelf equal to the difference between thofe two laft angles; and therefore the line FB is to CB as the fine of the angle of incidence is to the fine of an angle which is equal to the difference between the angle of incidence and of refraction. Now, becaufe in very fmall angles as thefe are, (for we fuppofe in this cafe alfo the diftance AB to vanifh, the reafon of which will be fhewn by-and-by,) their fines bear nearly the fame proportion to each other that they themfelves do, the diftance FB will be to CB as the fine of the angle of incidence is to the difference between that fine and the fine of the angle of refraction; but becaufe BA vanifhes, FB and FA are equal, and therefore FA is to CA in that proportion. *Q. E. D.*

Obs. 2. It appears from the foregoing demonftration, that the focal diftance of the oblique ray DB is fuch, that the line BF fhall be to the line CB or CA as the fine of the angle of incidence to the fine of an angle, which angle is equal to the difference between the angle of incidence and refraction; therefore, fo long as the angles BCA, &c. are fmall, fo long the line BF is pretty much of the fame length, becaufe fmall angles have nearly the fame relation to each other that their fines have. But when the point B is removed far from A, fo that the ray DB enters the furface, fuppofe about O, the angles BCA, &c. becoming large, the fine of the angle of incidence begins to bear a confiderably lefs proportion to the fine of an angle which is equal to the difference between the angle of incidence and refraction than before, and therefore the line BF begins to bear a much lefs proportion to BC; wherefore its length decreafes apace: upon which account thofe rays which enter the furface about

about O, not only meet nearer the centre of convexity than thofe which enter at A, but are collected into a more diffufed fpace. From hence it is, that the point where thofe only which enter near A are collected, is reckoned the true focus; and the diftance AB in all demonftrations relating to the foci of parallel rays entering a fpherical furface whether convex or concave, is fuppofed to vanifh.

CASE 2. Of parallel rays paffing out of a denfer into a rarer medium through a concave furface of the denfer.

DEM. Let X be the denfer, Z the rarer medium. AB the furface by which they are feparated, C the centre of convexity, and HA and DB two parallel rays, as before. Through B, the point where the oblique ray DB enters the rarer medium, draw the perpendicular CN; and let the ray DB, being in this cafe refracted from the perpendicular, proceed in the direction BM; produce BM back to H; this will be the imaginary focus; and DBN, or its equal ACB, will be the angle of incidence, and CBM, or its equal HBN (for they are vertical) that of refraction: produce DB to L, and draw BF fuch, that the angle LBF may be equal to DBH: then becaufe NBD and DBH together are equal to NBH the angle of refraction, therefore BCA which is equal to the firft, and LBF which is equal to the fecond, are together equal to the angle of refraction; but LBF is equal to BFA (as being alternate to it); confequently BFA and BCA together are equal to the angle of refraction; and therefore fince one of them, *viz.* BCA, is equal to the angle of incidence, the other is the difference between that angle and the angle of refraction. Now FB, the fine of the angle FCB, or, which is the fame thing, of its complement to two right ones, BCA, the angle of incidence, is to CB the fine of the angle BFC, as FB to CB, that is, as HB to CB; for the angles DBH and LBF being equal, the lines BF and BH are fo too; but the diftance BA vanifhing, HB is to CB, as HA to CA: that is, the fine of the angle of incidence is to the fine of an angle which is the difference between the angle of incidence and refraction, or, becaufe the angles are fmall, to the difference between the fine of the angle of incidence and that of refraction, as the diftance of the focus from the furface is to that of the centre from the fame. *Q. E. D.*

CASE 3. Of parallel rays paffing out of a rarer into a denfer medium through a concave furface.

DEM. Let X be the denfer medium having the concave furface AB, and let LB and FA be the incident rays. Now, whereas, when DB was the incident ray, and paffed out of a rarer into a denfer medium, as in Cafe 1. it was refracted into the line BF, this ray LB, having the fame inclination to the perpendicular, will alfo fuffer the fame degree of refraction, and will therefore pafs on afterwards in the line FB produced, *v. g.* towards P. So that, whereas in that cafe the point F was the real focus of the incident ray DB, the fame point will in this be the imaginary focus of the incident ray LB: but it was there demonftrated, that the diftance FA is to CA, as the fine of the angle of incidence is to the difference between that and the fine of the angle of refraction; therefore the focal diftance of the refracted ray BP is to the diftance of the centre of convexity in that pro portion. *Q. E. D.*

CASE 4. Of parallel rays paffing out of a denfer into a rarer medium through a convex furface of the denfer.

DEM. Let Z be the denfer medium, having the convex furface AB, and let LB and FA be the incident rays, as before. Now, whereas, when DB was the incident ray paffing out of a denfer into a rarer medium, it was refracted into BM, as in Cafe 2. having a point as H in the line MB produced for its imaginary focus; therefore LB, for the like reafon as was given in the laft cafe, will in this be refracted into BH, having the fame point H for its real focus. So that here alfo the focal diftance will be to that of the centre of convexity, as the fine of the angle of incidence is to the difference between that and the fine of the angle of refraction. *Q. E. D.*

III. When diverging or converging rays enter into a medium of different denfity through a fpherical furface, the ratio compounded of that which the focal diftance bears to the diftance of the radiant point (or of the imaginary focus of the incident rays, if they converge), and of that which the diftance between the fame radiant point (or imaginary focus) and the centre bears to the diftance between the centre and focus, is equal to the ratio which the fine of the angle of incidence bears to the fine of the angle of refraction.

This propofition admits of 16 cafes.

CASE 1. Of diverging rays paffing out of a rarer into a denfer medium, thro' a convex furface of the denfer, with fuch a degree of divergency, that they fhall converge after refraction.

Plate CCVIII.

DEM. Let BD (fig. 14.) reprefent a fpherical furface, C its centre of convexity; and let there be two diverging rays AB and AD proceeding from the radiant point A, the one perpendicular to the furface, the other oblique. Thro' the centre C produce the perpendicular one to F; and draw the radius CB, and produce it to K, and let BF be the refracted ray; then will F be the focal point; produce AB to H, and through the point F draw the line FG parallel to CB. AB being the incident ray, and CK perpendicular to the furface at the point B, the angle ABK, or, which is equal to it, becaufe of the parallel lines CB and FG, FGH, is the angle of incidence. Now, whereas, the complement of any angle to two right ones has the fame fine with the angle itfelf, the fine of the angle FGB, that being the complement of FGH to two right ones, may be confidered as the fine of the angle of incidence; which fine the line FB, as the fides of a triangle have the fame relation to each each other that the fines of their oppofite angles have, may be taken for. Again, the angle FBC is the angle of refraction, or its equal, becaufe alternate to it, BFG; to which BG, being an oppofite fide, may be looked upon as the fine. But FB is to BG in a ratio compounded of FB to BA, and of BA to BG; for the ratio that any two quantities bear to each other, is compounded of the ratio which the firft bears to any other, and of the ratio which that other bears to the fecond. Now FB is to BA, fuppofing BD to vanifh, as FD to DA; and BA is to BG, becaufe of the parallel lines CB and FG, as AC to CF. That is, the ratio

Of Refraction.

ratio compounded of FD the focal diftance, to DA the diftance of the radiant point, and of AC, the diftance between the radiant point and the centre, to CF, the diftance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Plate CCVIII. fig. 14.

Obs. Whereas the focal diftance of the oblique ray AB is fuch, that the compound ratio of FB to BA and of AC to CF, fhall be the fame, whatever be the diftance between B and D; it is evident, that fince AC is always of the fame length, the more the line AB lengthens, the more FB muft lengthen too, or elfe FC muft fhorten: but it appears by infpection of the figure, that if BF lengthens, CF will do fo too, and in a greater proportion with refpect to its own length than BF will; therefore the lengthening of BF will conduce nothing towards preferving the equality of the proportion; but as AB lengthens, BF and CF muft both fhorten, which is the only poffible way wherein the proportion may be continued the fame. And it is alfo apparent, that the farther B moves from D towards O, the fafter AB lengthens; and therefore the farther the rays enter from D, the nearer to the refracting furface is the place where they meet, but the fpace they are collected in is the more diffufed: and therefore, in this cafe, as well as thofe taken notice of in the two foregoing obfervatfons, different rays, tho' flowing from the fame point, fhall conftitute different focufes; and none are fo effectual as thofe which enter at, or very near, the point D. And fince the fame is obfervable of converging as well as of diverging rays, none except thofe which enter very near that point are ufually taken into confideration; upon which account it is, that the diftance DB, in determining the focal diftances of diverging or converging rays entering a convex or concave furface, is fuppofed to vanifh.

Thofe who would fee a method of determining the precife point, which the ray AB, whether it be parallel, converging, or diverging to the ray AF, converges to or diverges from after refraction at B or any other given point in the furface DO, may find it in the Appendix to Molineux's Optics; which, for the fake of thofe who have not the book, we fhall fubjoin at the end of this fection.

Case 2. Of converging rays paffing out of a rarer into a denfer medium through a concave furface of the denfer with fuch a degree of convergency, that they fhall diverge after refraction.

Dem. Let the incident rays be HB and FD paffing out of a rarer into a denfer medium thro' the concave furface BD, and tending towards the point A, from whence the diverging rays flowed in the other cafe; then the oblique ray HB, having its angle of incidence HBC equal to ABK the angle of incidence in the former cafe, will be refracted into the line BL, fuch, that its refracted angle KBL will be equal to FBC the angle of refraction in the former cafe; that is, it will proceed after refraction in the line FB produced, having the fame focal diftance FD with the diverging rays AB, AD, in the other cafe. But, by what has been already demonftrated, the ratio compounded of FD, the focal diftance, to DA, in this cafe, the diftance of the imaginary focus of the incident rays, and of AC, the diftance between the fame imaginary focus and the centre, to CF, the diftance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Case 3. Of diverging rays paffing out of a rarer into a denfer medium through a convex furface of the denfer with fuch a degree of divergency as to continue diverging.

Plate CCVIII.

Dem. Let AB, AD (fig. 15.) be the diverging rays, and let their divergency be fo great, that the refracted ray BL fhall alfo diverge from the other; produce LB back to F, which will be the focal point; draw the radius CB, and produce it to K; produce BA likewife towards G, and draw FG parallel to BC. Then will ABK be the angle of incidence, whofe fine BF may be taken for, as being oppofite to the angle BGF, which is the complement of the other to two right ones. And LBC is the angle of refraction, or its equal KBF, or, which is equal to this, BFG, as being alternate; therefore BG, the oppofite fide to this, may be taken for the fine of the angle of refraction. But BF is to BG, for the like reafon as was given in cafe the firft, in a ratio compounded of BF to BA, and of BA to BG. Now BF is to BA, (DB vanifhing) as DF to DA; and becaufe of the parallel lines FG and BC, the triangles CBA and AGF are fimilar; therefore BA is to AG as CA to AF; confequently BA is to BA together with AG, that is, to BG, as CA is to CA together with AF, that is, CF. Therefore the ratio compounded of DF the focal diftance to DA the diftance of the radiant point, and of CA the diftance between the radiant point and the centre, to CF the diftance between the centre and the focus, is equal to that which the fine of the angle of incidence bears to the fine of the angle of refraction. *Q. E. D.*

Case 4. Of converging rays paffing out of a rarer into a denfer medium thro' a concave furface of the denfer in fuch manner that they fhall continue converging.

Dem. Let HB and CD be the incident rays paffing out of the rarer into the denfer medium thro' the concave furface BD, and tending towards A the fame point from whence the diverging rays flowed in the laft Cafe. Then becaufe the ray HB has the fame inclination to the perpendicular CK that AB had before, it will fuffer the fame degree of refraction, and pafs on in the line LB produced, having its focus F at the fame diftance from the refracting furface as that of the diverging ray AB in the other cafe. Therefore, &c. *Q. E. D.*

Case 5. Of diverging rays paffing out of a denfer into a rarer medium through a convex furface of the denfer.

Dem. Let AB, AD (fig. 16.) be the incident rays paffing out of a denfer into a rarer medium through the concave furface BD whofe centre is C; and let BL be the refracted ray, which produce back to F, and draw FG parallel to CB. Here ABK is the angle of incidence, to which its alternate one FGB being equal, FB the oppofite fide may be confidered as the fine of it. The angle of refraction is LBC or FBK; of which BFG being the complement to two right ones, BG the oppofite fide may be looked upon as its fine. But BF is to BG, in the

Of Refraction. compound ratio of BF to BA, and of BA to BG, for the reason given above. Now (BD vanishing) BF is to BA as DF to DA, and BA is to BG as CA to CF; that is, the ratio compounded of the focal distance to the distance of the radiant point, &c. *Q. E. D.*

Case 6. Of converging rays passing out of a denser into a rarer medium through a concave surface of the denser.

Dem. Let HB, CD, be the incident rays tending towards the point A which was the radiant in the last Case. Then, for the reason already given, the oblique ray will suffer such a degree of refraction, as to have its focus F at the same distance from the surface, as the diverging rays AB, AD, had in that case. Therefore, &c. *Q. E. D.*

When the mediums through which rays pass, and the refracting surfaces are such, that rays flowing from A (fig. 14.) are collected in F, then rays flowing from F through the same mediums the contrary way, will be collected in A. For when rays pass out of one medium into another, the sine of the angle of incidence bears the same proportion to the sine of the angle of refraction, as the sine of the angle of refraction does to the sine of the angle of incidence, when they pass the contrary way. This is applicable to each of the six following Cases compared respectively with the six foregoing: therefore they may be considered as the converse of them; or they may be demonstrated independently of them, as follows.

Plate CCVIII.

Case 7. Of diverging rays passing out of a denser into a rarer medium through a concave surface of the denser, so as to converge afterwards.

Plate CCIX.

Dem. Let AB, AD (fig. 1.) be two diverging rays passing thro' the concave surface BD into a rarer medium. Let C be the centre of concavity, and BF the refracted ray. Draw CB, and produce it to K; and draw FG parallel to it, meeting AB produced in G. Then will ABC be the angle of incidence; of which FB being opposite to its alternate and equal angle FGB, may be considered as the sine. The angle of refraction is FBK; of which GB, being opposite to its complement to two right ones GFB, may be taken for the sine. Now FB is to BG in a ratio compounded of FB to BA, and of BA to BG. But (BD vanishing) FB is to BA as FD to DA; and because of the parallel lines CB and FG, BA is to BG as CA to CF. Therefore the focal distance, &c. *Q. E. D.*

Case 8. Of converging rays passing out of a denser into a rarer medium thro' a convex surface of the denser, so as to diverge afterwards.

Dem. Let GB and FD be the incident rays tending towards A, and produce FB to L. Then as AB in the last Case was refracted into BF, GB will in this be refracted into BL, for the reasons already given, having F for its focal point. Therefore, &c. *Q. E. D.*

Case. 9. Of diverging rays passing out of a denser into a rarer medium thro' a concave surface of the denser, in such a manner as to continue diverging.

Dem. Let AB, AD (fig. 2.) be two rays passing out of a denser into a rarer medium, through the concave surface DB, whose centre of concavity is C. Draw CB, produce it to K, and let BL be the refracted ray; produce BL back to F, and draw FG parallel to CB meeting BC produced in G. Then will ABC be the angle of incidence, of which FB being opposite to its alternative and equal angle FGB, may be considered as the sine. The refracted angle is LBK, or its equal CBF; of which BG, being opposite to its complement to two right ones BFG, is the sine. Now BF is to BG in the compound ratio of BF to BA and of BA to BG: but BF is to BA as DF to DA; and because of the parallel lines CB and FG, the triangles BCA, AGF, are similar: therefore BA is to AG as CA to AF, and consequently BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

Case 10. Of converging rays passing out of a denser into a rarer medium through a convex surface of the denser, in such manner as to continue converging.

Dem. Let HB, MD, be the incident rays tending towards the point A. Then will the oblique ray HB, for the reasons already given, be refracted in BF. Therefore, &c. *Q. E. D.*

Case 11. Of diverging rays passing out of a rarer into a denser medium through a concave surface of the denser.

Dem. Let AB, AD (fig. 3.) be the incident rays passing out of a rarer into a denser medium, through the concave surface BD, whose centre of convexity is C, and supposing the line CB drawn and produced to K, the refracted ray BL drawn and produced back to F, and also FG drawn parallel to CB, ABC will be the angle of incidence; of which FB, being opposite to its complement to two right ones BGF, is the sine. The angle of refraction will be LBK, or its equal FBC; of which BG, being opposite to its equal and alternate one BFG, is the sine. Now FB is to BG in the compound ratio of FB to BA and of BA to BG. But (BD vanishing) FB is to BA as FD to DA, and because of the parallel line FG and CB, BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

Case 12. Of converging rays passing out of a rarer into a denser medium through a convex surface of the denser.

Dem. Let HB, MD, be the incident rays tending towards A the radiant point in the last case; then, as was explained above, BF will be the refracted ray. Therefore, &c. *Q. E. D.*

Case 13. Of rays passing out of a rarer into a denser medium from a point between the centre of convexity and the surface.

Dem. Let AB, AD (fig. 4.) be two rays passing out of a rarer into a denser medium from the point A, which let be posited between C the centre of convexity and the refracting surface BD; through B draw CK, and let BL be the refracted ray; produce BL back to F, and draw FG parallel to BC. Then will ABC be the angle of incidence; of which BF, being opposite to its complement to two right ones BGF, is the sine. LBK will be the angle of refraction, or its equal FBC; of which BG, being opposite to its alternate and equal one BFG, is the sine. But, as before, BF is to BG in a compound ratio of BF to BA and of BA to BG; and (BD vanishing) BF is to BA as DF to DA, and because the lines CB and FG are pa-

Of Refraction.

parallel, BA is to BG as CA to CF. Therefore, &c. *Q. E. D.*

CASE 14. Of rays paſſing out of a denſer into a rarer medium towards a point between the centre of convexity and the ſurface.

DEM. Let the incident rays be MD, HB, tending towards A, from whence the other proceeded in the laſt caſe. Then, as in that caſe the refracted ray BL being produced back paſſed through F, in this the refracted ray itſelf, for the like reaſons as were given in the foregoing caſes, will paſs through that point. Therefore, &c. *Q. E. D.*

CASE 15. Of rays paſſing out of a rarer into a denſer medium from a point between the centre of convexity and the ſurface.

Plate CCIX.

DEM. Let AB, AD (fig. 5.) be two diverging rays paſſing out of a denſer into a rarer medium thro' the refracting ſurface BD, whoſe centre of convexity is C, a point beyond that from whence the rays flow. Through B draw CK, and let BL be the refracted ray; produce it back to F, and draw FG parallel to BC, meeting BA produced in G. ABC will be the angle of incidence; of which BF, being oppoſite to its alternate and equal angle BGF, is the ſine. The angle of refraction is LBK, or its equal FBC; of which BG, being oppoſite to its complement to two right ones BFG, is the ſine. But BF is to BG in the compound ratio of BF to BA and of BA to BG; and (BD vaniſhing) BF is to BA as DF to DA; and becauſe of the parallel lines CB and GF, the triangles AFG and ABC are ſimilar. BA therefore is to AG, as CA to AF; conſequently BA is to BA and AG together, that is, to BG, as CA is to CA and AF together, that is, to CF; and therefore the focal diſtance, &c. *Q. E. D.*

CASE 16. Of rays paſſing out of a denſer into a rarer medium towards a point between the centre of convexity and the ſurface.

DEM. Let HB, MD, be the incident rays having for their imaginary focus the point A, which was the radiant in the laſt caſe; and let C the centre of convexity of the refracting ſurface be poſited beyond this point. Then will HB, for the reaſons already given, be refracted into BF, having the point F for its real focus, which was the imaginary one of the diverging rays AB, AD, in the former caſe. Therefore, as before, the ratio compounded of that which the focal diſtance bears to the diſtance of the imaginary focus of the incident rays, and of that which the diſtance between the ſame imaginary focus and the centre bears to the diſtance between the centre and the focus, is equal to the ratio which the ſine of the angle of incidence bears to the ſine of the angle of refraction. *Q. E. D.*

The firſt term in the foregoing proportion (viz. that in propoſition 3d) being always an unknown quantity, thoſe who are not well verſed in the uſe of ſuch propoſitions, may think it impoſſible to inveſtigate the focal diſtance of any refracting ſurface by it, we ſhall therefore exemplify in the following inſtance, by which the manner of doing it in all others will clearly be underſtood. *V. g.* Let it be required to determine the focal diſtance of diverging rays paſſing out of air into glaſs through a convex ſurface; and let the diſtance of the radiant point be 20, and the radius of convexity be 5: now, becauſe we muſt make uſe of the focal diſtance before we know it, let that be expreſſed by ſome ſymbol or character as x: Then, becauſe by the aforeſaid propoſition the ratio compounded of that which the focal diſtance bears to the diſtance of the radiant point (that is, in this ſuppoſition, of x to 20), and of the ratio which the diſtance of the ſame radiant point from the centre bears to the diſtance between the centre and the focus (in this caſe, of 25 to $x-5$), is equal to the ratio which the ſine of the angle of incidence bears to the ſine of the angle of refraction (that is, of 17 to 11), we ſhall have, in the inſtance before us, the following proportion, viz.

$$\left.\begin{matrix} x : 20 \\ 25 : x-5 \end{matrix}\right\} :: 17 : 11;$$ and compounding them into one, which is done by multiplying the two firſt parts together, we have $25x : 20x-100 :: 17 : 11$, and multiplying the extreme terms and middle terms together $340x-1700=275x$, which equation after due reduction gives $x=\frac{1700}{65}$.

In ſome caſes which might have been put, the quantity 65 would have been negative; and then the quotient ariſing from 1700, divided by that, would have been ſo too: that is, x the focal diſtance would have been negative; in which caſe, the focus muſt have been taken on the contrary ſide of the ſurface to that on which it was ſuppoſed to fall in ſtating the problem; that is, it muſt have been taken on the ſame ſide with the radiant point; for in calling the diſtance between the centre and the focus $x-5$, it was ſuppoſed the focus would fall on the ſame ſide with the centre, or on that which is oppoſite to the radiant point; becauſe otherwiſe that diſtance muſt have been expreſſed by $x+5$; as any one may ſee by inſpection of the 13th or 14th figure, in which the focus of diverging rays entering a convex ſurface, is ſuppoſed to fall on the ſame ſide with the radiant point.

In like manner as this problem was performed, a general theorem may be raiſed to ſolve it in all caſes whatſoever, by uſing characters inſtead of figures; as every one who is not unacquainted with algebraic operations very well knows.

See this done, and applied to the paſſage of rays through the ſurface of lenſes, in the following ſection.

A method of determining the point which a ray, entering a ſpherical ſurface at any given diſtance from the vortex of it, converges to, or diverges from, after refraction at the ſame. *From the Appendix to Molineux's Dioptrics.*

"PROP. To find the focus of any parcel of rays diverging from, or converging to, a given point in the axis of a ſpherical lens [ſurface], and inclined thereto under the ſame angle; the ratio of the ſines in refraction being known.

"Let GL (fig. 6.) be the lens, P any point in its ſurface, V the pole [vertex] thereof, C the centre of the ſphere whereof it is a ſegment, O the object or point in the axis to or from which the rays do proceed, OP a given ray; and let the ratio of refraction be as r to s; make CR to CO as s to r for the immerſion of a ray, or as r to s for the emerſion, (that is, as the ſines of the angles in the medium which the ray

Of Refraction.

ray enters, to their correſponding ſines in the medium out of which it comes); and laying CR from C towards O, the point R ſhall be the ſame for all the rays of the point O. Then draw the radius PC (if need be) continued, and with the centre R and diſtance OP ſweep a touch of an arch, interſecting PC in Q; the line QR being drawn ſhall be parallel to the refracted ray, and PF being made parallel thereto ſhall interſect the axis in the point F; which is the focus ſought. Or make it as CQ : CP : : CR : CF, and CF ſhall be the diſtance of the focus from the centre of the ſphere.

"DEM. Let fall the perpendiculars PX on the axis, CY on the given ray, and CZ on the refracted ray. By the conſtruction QF and PR are parallel, whence the triangles QRC and PFC are ſimilar, and CR to QR, as CF to PF; that is, CR to OP, as CF to PF. Now CF : PF : : CZ : PX *ob ſimilia triang.*; whence CR : OP : : CZ : PX, and CR : CZ : : OP : PX. Again, CR is to CO as the ſines of refraction by conſtruction; that is, as s to r, or r to s; and as CR to CZ, ſo (CO=) $\frac{r}{s}$ or $\frac{s}{r}$CR to $\frac{r}{s}$ or $\frac{s}{r}$CZ; and ſo is PO to PX: But as PO to PX, ſo CO to CY. *Ergo*, CY= $\frac{r}{s}$ or $\frac{s}{r}$CZ; that is, CY to CZ is as the ſines of refraction; but CY is the ſine of the angle of incidence, and CZ of the refracted angle. *Ergo conſtat propoſitio.*——

"Hitherto we have conſidered only oblique rays; it now remains to add ſomething concerning rays parallel to the axis: in this caſe the point O muſt be conſidered as infinitely diſtant, and conſequently OP, OC, and CR are all infinite: and OP and OC are in this caſe to be accounted as always equal, (ſince they differ but by a part of the radius of the ſphere GPVL, which is no part of either of them): wherefore the ratio of CR to OP will be always the ſame, *viz.* as s to r for immerging rays, and as r to s for thoſe that emerge. And by this propoſition CF is to PF in the ſame ratio. It remains therefore to ſhew on the baſe CP how to find all the triangles CPF, wherein CF is to PF in the ratio given by the degree of refraction. This problem has been very fully conſidered by the celebrated Dr Wallis in his late treatiſe of Algebra, p. 258, to which we refer; but we ſhall here repeat the conſtruction thereof. (See fig. 7. 8.)

Plate CCIX.

"Let GPVL be a lens, VC or PC the radius of its ſphere, and let it be required to find all the points f, f, ſuch as Cf may be to Pf in the given ratio of s to r for immerging rays, or as r to s for the emerging. Divide CV in K, and continue CV to F, that CK may be to VK, and CF to VF, in the propoſed ratio. Then divide KF equally in the point a, and with that centre ſweep the circle FKF; this circle being drawn, gives readily all the foci of the parallel rays OP, OP. For having continued CP till it interſect the circle in F, PF ſhall be always equal to Vf, the diſtance of the focus of each reſpective parcel of rays OP from the vertex or pole of the lens.

"To demonſtrate this, draw the pricked line VF, and by what is delivered by Dr Wallis in the above-cited place, VF and CF will be always in the ſame propoſed ratio. Again, Vf being made equal to PF, CF and Cf will be likewiſe equal, as are CP, VC; and the angles PCf, VCF, being *ad verticem*, are alſo equal: Wherefore Pf will be equal to VF, and conſequently Cf to Pf in the ſame ratio as CF to VF; whence, and by what foregoes, the points f, f, are the ſeveral reſpective foci of the ſeveral parcels of rays OP, OP. *Q. E. D.*

Of Refraction.

§ 2. *Of Glaſſes.*

GLASS may be ground into eight different ſhapes at leaſt, for optical purpoſes, *viz.*

1. A *plane-glaſs*, which is flat on both ſides, and of equal thickneſs in all its parts, as A. Fig. 9.

2. A *plano-convex*, which is flat on one ſide, and convex on the other, as B.

3. A *double-convex*, which is convex on both ſides, as C.

4. A *plano-concave*, which is flat on one ſide, and concave on the other, as D.

5. A *double concave*, which is concave on both ſides, as E.

6. A *meniſcus*, which is concave on one ſide, and convex on the other, as F.

7. A *flat plano-convex*, whoſe convex ſide is ground into ſeveral little flat ſurfaces, as G.

8. A *priſm*, which has three flat ſides, and when viewed endwiſe appears like an equilateral triangle, as H.

Glaſſes ground into any of the ſhapes B, C, D, E, F, are generally called *lenſes*.

A right line LIK, (fig. 9.) going perpendicularly through the middle of a lens, is called the *axis of the lens*.

A ray of light Gh, (fig. 10.) falling perpendicularly on a plane glaſs EF, will paſs thro' the glaſs in the ſame direction $h\,i$, and go out of it into the air in the ſame right courſe iH.

A ray of light AB, falling obliquely on a plane glaſs, will go out of the glaſs in the ſame direction, but not in the ſame right line: for in touching the glaſs, it will be refracted in the line BC; and in leaving the glaſs, it will be refracted in the line CD.

A ray of light CD, (fig. 11.) falling obliquely on the middle of a convex glaſs, it will go forward in the ſame direction DE, as if it had fallen with the ſame degree of obliquity on a plane glaſs; and will go out of the glaſs in the ſame direction with which it entered: for it will be equally refracted at the points D and E, as if it had paſſed through a plane ſurface. But the rays CG and CI will be ſo refracted, as to meet again at the point F. Therefore, all the rays which flow from the point C, ſo as to go through the glaſs, will meet again at F; and if they go farther onward, as to L, they croſs at F, and go forward on the oppoſite ſides of the middle ray CDEF, to what they were in approaching it in the directions HF and KF.

When parallel rays, as ABC, (fig. 12.) fall directly upon a plano-convex glaſs DE, and paſs through it, they will be ſo refracted, as to unite in a point f behind it: and this point is called the *principal focus*; the diſtance of which, from the middle of the glaſs, is called the *focal diſtance*, which is equal to twice the radius of the ſphere of the glaſs's convexity. And,

When parallel rays, as ABC, (fig. 13.) fall directly upon

Plate CCIX.

upon a glafs DE, which is equally convex on both fides, and pafs through it; they will be fo refracted, as to meet in a point or principal focus *f*, whofe diftance is equal to the radius or femidiameter of the fphere of the glafs's convexity. But if a glafs be more convex on one fide than one the other, the rule for finding the focal diftance is this: As the fum of the femidiameters of both convexities is to the femidiameter of either, fo is double the femidiameter of the other to the diftance of the focus. Or divide the double product of the radii by their fum, and the quotient will be the diftance fought.

Since all thofe rays of the fun which pafs through a convex glafs are collected together in its focus, the force of all their heat is collected into that part; and is in proportion to the common heat of the fun, as the area of the glafs is to the area of the focus. Hence we fee the reafon why a convex glafs caufes the fun's rays to burn after paffing through it.

All thefe rays crofs the middle ray in the focus *f*, and then diverge from it, to the contrary fides, in the fame manner F*f*G, as they converged in the fpace D*f*E in coming to it.

If another glafs FG, of the fame convexity as DE, be placed in the rays at the fame diftance from the focus, it will refract them fo, as that, after going out of it, they will be all parallel, as *a b c*; and go on in the fame manner as they came to the firft glas DE, thro' the fpace ABC; but on the contrary fides of the middle ray B*fb*: for the ray AD*f* will go on from *f* in the direction *fGa*, and the ray CE*f* in the direction *f*F*c*; and fo of the reft.

The rays diverge from any radiant point, as from a principal focus: Therefore if a candle be placed at *f*, in the focus of the convex glafs FG, the diverging rays in the fpace F*f*G will be fo refracted by the glafs, as that, after going out of it, they will become parallel, as fhewn in the fpace *c b a*.

If the candle be placed nearer the glafs than its focal diftance, the rays will diverge after paffing thro' the glafs more or lefs as the candle is more or lefs diftant from the focus.

If the candle be placed farther from the glafs than its focal diftance, the rays will converge after paffing thro' the glafs, and meet in a point, which will be more or lefs diftant from the glafs as the candle is nearer to or farther from its focus: and where the rays meet, they will form an inverted image of the flame of the candle; which may be feen on a paper placed in the meeting of the rays.

Hence, if any object ABC (fig. 15.) be placed beyond the focus F of the convex glafs *def*, fome of the rays which flow from every point of the object, on the fide next the glafs, will fall upon it; and after paffing through it, they will be converged into as many points on the oppofite fide of the glafs, where the image of every point will be formed, and confequently the image of the whole object, which will be inverted. Thus, the rays A*d*, A*e*, A*f*, flowing from the point A, will converge in the fpace *daf*, and by meeting at *a*, will there form the image of the point A. The rays B*b*, B*e*, B*f*, flowing from the point B, will be united at *b* by the refraction of the glafs, and will there form the image of the point B. And the rays C*d*, C*e*, C*f*, flowing from the point C, will be united at *c*, where they will form the image of the point C. And fo of all the other intermediate points between A and C. The rays which flow from every particular point of the object, and are united again by the glafs, are called *pencils of rays*.

If the object ABC be brought nearer to the glafs, the picture *a b c* will be removed to a greater diftance. For then more rays flowing from every fingle point, will fall more diverging upon the glafs; and therefore cannot be fo foon collected into the correfponding points behind it. Confequently, if the diftance of the object ABC (fig. 16.) be equal to the diftance *e*B of the focus of the glafs, the rays of each pencil will be fo refracted by paffing through the glafs, that they will go out of it parallel to each other; as *d*I, *e*H, *fh*, from the point C; *d*G, *e*K, *f*D, from the point B; and *d*K, *e*E, *f*L, from the point A: and therefore, there will be no picture formed behind the glafs.

If the focal diftance of the glafs, and the diftance of the object from the glafs, be known, the diftance of the picture from the glafs may be found by this rule, viz. Multiply the diftance of the focus by the diftance of the object, and divide the product by their difference; the quotient will be the diftance of the picture.

The picture will be as much bigger or lefs than the object, as its diftance from the glafs is greater or lefs than the diftance of the object. For, as B*e* (fig. 15.) is to *e*B, fo is AC to *ca*. So that if ABC be the object, *c b a* will be the picture; or if *c b a* be the object, ABC will be the picture.

114 How to find the focus of any lens.

For determining the progrefs of the rays after refraction by any lens, whatever be its form or matter, Mr Rowning gives the following method. "Suppofe GH (fig. 14.) to be a given lens, and E a point in its axis from whence the diverging rays EL, &c. fall upon the lens, AL, the radius of the firft convexity, and CK that of the fecond; let LK*f* be the direction of the diverging ray EL after its refraction at the firft furface, and KF its direction after refraction at both. Then will *f* be the focus of the rays after their firft refraction, and F the point they will meet in after both. Let BD be the thicknefs of the lens, and let the proportion which the fine of the angle of incidence bears to the fine of the angle of refraction be expreffed by the ratio of I to R. Call EB, *d*; BD, *t*; AB, *r*; CD, *s*; B*f*, *x*; DF, *y*: Now, to find *f* their focus after refraction at L where they enter the firft furface of the lens, comes under the third propofition abovementioned: according to which the ratio compounded of *x*, the focal diftance fought, to *d*, the diftance of the radiant point; and of $d+r$, the diftance between the fame point and the centre, to $x-r$, the diftance between the centre and the focus, is as I to R; compounding thefe two ratios therefore (that is, multiplying them together) we have $dx+rx : dx-dr :: \mathrm{I} : \mathrm{R}$; which proportion being converted into an equation, and duly reduced, gives $x=\frac{\mathrm{I}dr}{\mathrm{I}d-\mathrm{R}d-\mathrm{R}r}$.

Thus having found the diftance B*f*, and confequently the point *f*, to which the rays converge from L, we muft proceed to find F, that to which they will converge after having paffed through K, where they fuffer as a fecond refraction: this comes under the fame propofition. But, if we would ufe the fame letters as before, to exprefs the proportion which the fine of the angle of incidence bears to that of the angle of refraction, they muft be put one for the other; becaufe, when rays pafs out of a denfer into a rarer medium, the fine of the angle of incidence bears the fame proportion to the fine of the angle of refraction, that the fine of the angle of refraction does to the fine of the angle of incidence, when they pafs out of a rarer into a denfer. This being obferved, by the aforefaid propofition, we fhall have the ratio compounded of y, the focal diftance, to $\frac{Idr}{Id-Rd-Rr}-t$, the imaginary focus in the incident rays, and of $\frac{Idr}{Id-Rd-Rr}t-+s$, the diftance between the imaginary focus and the centre, to $y+s$, the diftance between the centre and the focus, as R to I. Which equation, if we reduce the mixed quantities $\frac{Idr}{Id-Rd-Rr}-t$, and $\frac{Idr}{Id-Rd-Rr}-t+s$, into improper fractions, will ftand thus:

$$\left.\begin{array}{c} y : \frac{Idr-Idt+Rdt+Rrt}{Id-Rd-Rr} \\ \text{and} \\ \frac{Idr-Idt+Rdt+Rrt+Ids-Rds-Rrs}{Id-Rd-Rr} : y+s \end{array}\right\} :: R : I.$$

And, compounding thefe ratios, we have

$$\frac{Idry-Idty+Rdty+Rrty+Idsy+Rdsy-Rrsy}{Id-Rd-Rr} : \frac{Idry-Idty+Rdty+Rrty+Idrs-Idts-Rdts+Rrts}{Rr} :: R : I.$$

And throwing out the two equal denominartors $Id-Rd-Rr$, and $Id-Rd-Rr$, and multiplying extremes together and means together, we have $IIdry-IIdty+IRdty+IRrty+IIdsy-IRdsy-IRrsy=IRdry-IRdty+RRdty+RRrty+IRdrs-IRdts+RRdts+RRrts$; which equation being reduced, gives $y=\frac{IRdrs-IRdts+RRdts+RRrts}{IIdr-IIdt+I2Rdt+IRrt+IIds-IRds-IRrs-IRdr-RRdt-RRrt}$.

This theorem may be applied to all cafes whatever; even to plane furfaces *mutatis mutandis*, *v. g.* the radius of a concave furface being negative (as lying the contrary way) with refpect to that of a convex, and the radius of a plain furface being an infinite line. If we would apply this theorem to a concave furface, we muft change all the figns of thofe members wherein the fymbol expreffing the radius of that furface occurs; and if to a plane furface, all the members which involve the radius muft be confidered as infinite quantities: that is, all, except them, muft be ftruck out of the equation as nothing. So, likewife, if we would have it extend to other rays befides diverging ones, the point where converging rays would meet, lying on the contrary fide to that from whence the diverging ones were fuppofed to flow, its diftance muft be made negative; and the diftance where parallel rays meet being infinite, it is only changing the figns of all thofe members in which d is found, if the rays are fuppofed converging; or making thofe members infinite, in cafe the rays are fuppofed parallel; which is done by ftriking out all the reft, as bearing no proportion to them.

§ 3. *Of Vifion.*

HAVING defcribed how the rays of light, flowing from objects, and paffing through convex glaffes, are collected into points, and form the images of the objects; it will be eafy to underftand how the rays are affected by paffing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For, the different humours of the eye, and particularly the cryftalline humour, are to be confidered as a convex glafs; and the rays in paffing through them to be affected in the fame manner as in paffing through a convex glafs. A defcription of the coats and humours, &c. has been given at large in anatomy: but for the reader's convenience in this place, we fhall repeat in a few words as much of the defcription as will be fufficient for our prefent purpofe.

The eye is nearly globular. It confifts of three coats and three humours. The part DHHG of the outer coat, is called the *fclerotica;* the reft, DEFG, the *cornea*. Next within this coat is that called the *choroides*, which ferves as it were for a lining to the other, and joins with the iris, *mn*, *mn*. The iris is compofed of two fets of mufcular fibres; the one of a circular form, which contracts the hole in the middle called the *pupil*, when the light would otherwife be too ftrong for the eye; and the other of radial fibres, tending every where from the circumference of the iris towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in the more of its rays. The third coat is only a fine expanfion of the optic nerve L, which fpreads like net-work all over the infide of the choroides, and is therefore called the *retina;* upon which are painted (as it were) the images of all vifible objects, by the rays of light which either flow or are reflected from them.

Plate CCX. fig. 1.

115 Defcription of the eye.

Under the cornea is a fine tranfparent fluid like water, which is therefore called the *aqueous humour*. It gives a protuberant figure to the cornea, fills the two cavities *mm* and *nn*, which communicate by the pupil P; and has the fame limpidity, fpecific gravity, and refractive power, as water. At the back of this lies the cryftalline humour II, which is fhaped like a double convex glafs; and is a little more convex on the back than the fore part. It converges the rays, which pafs through it from every vifible object to its focus at the bottom of the eye. This humour is tranfparent like cryftal, is much of the confiftence of hard jelly, and exceeds the fpecific gravity of water in the proportion of 11 to 10. It is inclofed in a fine tranfparent membrane, from which proceed radial fibres *oo*, called the *ligamentum ciliare*, all around its edge; and join to the circumference of the iris.

At the back of the cryftalline, lies the vitreous humour KK, which is tranfparent like glafs, and is largeft of all in quantity, filling the whole orb of the eye, and giving it a globular fhape. It is much of a confiftence with the white of an egg, and very little exceeds the fpecific gravity and refractive power of water.

As every point of an object ABC, (*ibid.*) fends out

Of Refraction.

out rays in all directions, ſome rays, from every point on the ſide next the eye, will fall upon the cornea between E and F; and by paſſing on thro' the humours and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a diſtinct inverted picture *c b a* of the object. Thus, the pencil of rays *q r s* that flows from the point A of the object, will be converged to the point *a* on the retina; thoſe from the point B will be converged to the point *b*; thoſe from the point C will be converged to the point *c*; and ſo of all the intermediate points; by which means the whole image *a b c* is formed, and the object made viſible: altho' it muſt be owned, that the method by which this ſenſation is carried from the eye by the optic nerve to the common ſenſory in the brain, and there diſcerned, is above the reach of our comprehenſion.

But that viſion is effected in this manner, may be demonſtrated experimentally. Take a bullock's eye whilſt it is freſh; and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will ſee an inverted picture of the object upon the paper.

116 Why we ſee objects upright.

Since the image is inverted, many have wondered why the object appears upright. But we are to conſider, 1. That inverted is only a relative term: and, 2. That there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a diſtant proſpect are painted upon the retina, they are all right with reſpect to one another, as well as the parts of the proſpect itſelf; and we can only judge of an object's being inverted, when it is turned reverſe to its natural poſition with reſpect to other objects which we ſee and compare it with.—If we lay hold of an upright ſtick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Juſt ſo we find by experience, that upon directing our eyes towards a tall object, we cannot ſee its top by turning our eyes downward, nor its foot by turning our eyes upward; but muſt trace the object the ſame way by the eye to ſee it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one caſe, ſo it is alſo by the motion of the eye in the other.

Plate CCX.

In fig. 2. is exhibited the manner of ſeeing the ſame object ABC, by both the eyes D and E at once.

117 Optic nerve inſenſible of light.

When any part of the image *cba* falls upon the optic nerve L, the correſponding part of the object becomes inviſible. On which account, nature has wiſely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the ſide next the noſe; ſo that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point *a* of the image *c b a* falls upon the optic nerve of the eye D, but not of the eye E; and the point *c* falls upon the optic nerve of the eye E, but not of the eye D: and therefore, to both eyes taken together, the whole object ABC is viſible.

The nearer that any object is to the eye, the larger is the angle under which it is ſeen, and the magnitude under which it appears. Thus to the eye D, (fig. 3.) the object ABC is ſeen under the angle APC; and its image *c b a* is very large upon the retina: but to the eye E, at a double diſtance, the ſame object is ſeen under the angle A*p*C, which is equal only to half the angle APC, as is evident by the figure. The image *c b a* is likewiſe twice as large in the eye D, as the other image *c b a* is in the eye E. In both theſe repreſentations, a part of the image falls on the optic nerve, and the object in the correſponding part is inviſible.

As the ſenſe of ſeeing is allowed to be occaſioned by the impulſe of the rays from the viſible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the expanſion of the optic nerve all over the choroides; it ſhould ſeem ſurpriſing, that the part of the image which falls on the optic nerve ſhould render the like part of the object inviſible; eſpecially as that nerve is allowed to be the inſtrument by which the impulſe and image are conveyed to the common-ſenſory in the brain.

118 Proved by experiment.

That the part of the image which falls upon the middle of the optic nerve is loſt, and conſequently the correſponding part of the object is rendered inviſible, is plain by experiment. For if a perſon fixes three patches, A, B, C, (fig. 4.) upon a white wall, at the height of the eye, and the diſtance of about a foot from each other, and places himſelf before them, ſhutting the right eye, and directing the left towards the patch C, he will ſee the patches A and C, but the middle patch B will diſappear. Or, if he ſhuts his left eye, and directs the right towards A, he will ſee both A and C, but B will diſappear; and if he directs his eye towards B, he will ſee both B and A, but not C. For whatever patch is directly oppoſite to the optic nerve N, vaniſhes. This requires a little practice, after which he will find it eaſy to direct his eye ſo as to loſe the ſight of whichever patch he pleaſes.

119 Diſpute concerning the ſeat of viſion.

This experiment, firſt tried by M. Mariotte, occaſioned a new hypotheſis concerning the ſeat of viſion, which he ſuppoſed not to be in the retina, but in the choroides. An improvement was afterwards made upon it by M. Picard, who contrived that an object ſhould diſappear when both the eyes were kept open. He faſtened upon a wall a round white paper, an inch or two in diameter; and by the ſide of it he fixed two marks, one on the right hand, and the other on the left, each at about 2 feet diſtance from the paper, and ſomewhat higher. He then placed himſelf directly before the paper, at the diſtance of 9 or 10 feet, and putting the end of his finger over againſt both his eyes, ſo that the left-hand mark might be hid from the right eye, and the right-hand mark from the left eye. Remaining firm in this poſture, and looking ſteadily, with both eyes, on the end of his finger, the paper which was not at all covered by it would totally diſappear. This, he ſays, is the more ſurpriſing, becauſe, without this particular encounter of the optic nerves, where no viſion is made, the paper will appear double, as is the caſe when the finger is not rightly placed.

M. Marriotte obſerves, that this improvement on his

Of Refraction.

his experiment, by M. Picard, is ingenious, but difficult to execute, fince the eyes muft be confiderably ftrained in looking at any object fo near to them as four inches; and propofes another not lefs furprifing, and more eafy. Place, fays he, on a dark ground, two round pieces of white paper, at the fame height, and three feet from one another; then place yourfelf oppofite to them, at the diftance of 12 or 13 feet, and hold your thumb before your eyes, at the diftance of about eight inches, fo that it may conceal from the right eye the paper that is to the left hand, and from the left eye the paper to the right hand. Then, if you look at your thumb fteadily with both eyes, you will lofe fight of both the papers; the eyes being fo difpofed, that each of them receives the image of one of the papers upon the bafe of the optic nerve, while the other is intercepted by the thumb.

M. Le Cat purfued this curious experiment a little farther than M. Marriotte had done. In the place of the fecond paper, he fixed a large white board, and obferved, that at a proper diftance he loft fight of a circular fpace in the centre of it. He alfo obferved the fize of the paper which is thus concealed from the fight, correfponding to feveral diftances, which enabled him to afcertain feveral circumftances relating to this part of the ftructure of the eye more exactly than had been done before.

The manner in which this curious experiment is now generally made, and which is both the eafieft with refpect to the eye, and the moft indifputable with refpect to the fact, is the following. Let three pieces of paper be faftened upon the fide of a room, about two feet afunder; and let a perfon place himfelf oppofite to the middle paper, and, beginning near to it, retire gradually backwards, all the while keeping one of his eyes fhut, and the other turned obliquely towards that outfide paper which is towards the covered eye, and he will find a fituation (which is generally at about five times the diftance at which the papers are placed from one another), where the middle paper will entirely difappear, while the two outermoft continue plainly vifible; becaufe the rays which come from the middle paper will fall upon the retina where the optic nerve is inferted.

It will not furprife any perfon, even thofe who are the ftrongeft advocates for the retina being the place at which the pencils of rays are terminated, and confequently the proper feat of vifion, that M. Mariotte was led by this remarkable obfervation to fufpect the contrary. He not only did fo; but, in confequence of attentively confidering the fubject, a variety of other arguments in favour of the choroides occurred to him, particularly his obfervation, that the retina is tranfparent, as well as the cryftalline, and other humours of the eye, which he thought could only enable it to tranfmit the rays farther; and he could not perfuade himfelf that any fubftance could be confidered as being the termination of the pencils, and the proper feat of vifion, at which the rays are not ftopped in their progrefs.

He was farther confirmed in his opinion of the fmall degree of fenfibility in the retina, and of the greater fenfibility of the choroides, by obferving that the pupil dilates itfelf in the fhade, and contracts itfelf in a great light; which involuntary motion, he thought, was a clear proof that the fibres of the iris are extremely fenfible to the action of light; and this part of the eye is only a continuation of the choroides (A). He alfo thought that the dark colour of the choroides was intended to make it more fufceptible of the impreffion of light.

M. Pecquet, in anfwer to M. Mariotte's obfervation concerning the tranfparency of the retina, fays, that it is very imperfectly fo, refembling only oiled paper, or the horn that is ufed for lanterns; and befides, that its whitenefs demonftrates it to be fufficiently opaque for ftopping the rays of light, as much as is neceffary for the purpofe of vifion; whereas, if vifion be performed by means of thofe rays which are tranfmitted through fuch a fubftance as the retina, it muft be very indiftinct.

As to the blacknefs of the choroides, which M. Marriotte thought to be neceffary for the purpofe of vifion, M. Pecquet obferves, that it is not the fame in all eyes, and that there are very different fhades of it among the individuals of mankind, as alfo among birds, and fome other animals, whofe choroides is generally black; and that in the eyes of lions, camels, bears oxen, ftags, fheep, dogs, cats, and many other animals, that part of the choroides which is the moft expofed to light, very often exhibits colours as vivid as thofe of mother of pearl, or of the iris. He admits that there is a defect of vifion at the infertion of the optic nerve; but he thought that it was owing to the blood-veffels of the retina, the trunks of which are fo large in that place as to obftruct all vifion.

To M. Pecquet's objection, founded on the opacity of the retina, M. Marriotte obferves, that there muft be a great difference betwixt the ftate of that fubftance in living and dead fubjects; and as a farther proof of the tranfparency of the retina, and the power of the choroides beyond it to reflect light, he fays, that if a lighted candle be held near to a perfon's eyes, and a dog, at the diftance of eight or ten fteps, be made to look at him, he would fee a bright light in the dog's eyes, which he thought to proceed from the reflection of the light of the candle from the choroides of the dog, fince the fame appearance cannot be produced in the eyes of men, or other animals, whofe choroides is black.

To M. Pecquet's remark concerning the blood veffels of the retina, M. Marriotte obferves, that they are not large enough to prevent vifion in every part of the bafe of the nerve, fince the diameter of each of the two veffels occupy no more than $\frac{1}{8}$ part of it. Befides, if this were the caufe of this want of vifion, it would vanifh gradually, and the fpace to which it is confined would not be fo exactly terminated as it appears to be.

We muft add, that M. Pecquet alfo obferved, that notwithftanding the infenfibility of the retina at the infertion of the optic nerve when the light is only moderate; yet that luminous objects, fuch as a bright candle placed at the diftance of four or five paces, do not

(A) M. Muffchenbroeck fays, that in many animals, as the lion, camel, bear, ox, ftag, fheep, dog, cat, and many birds, the choroides is not black, but blue, green, yellow, or fome other colour. *Introductio*, Vol. II. p. 748.

not abfolutely difappear, in the fame circumftances in which a white paper would; for that this ftrong light may be perceived though the picture fall on the bafe of the nerve. "I cannot help fufpecting, however, (fays Dr Prieftley), that M. Pecquet did not make this obfervation with fufficient care. A large candle makes no impreffion on that part of my eye, though it is by no means able to bear a ftrong light."

The common opinion was alfo favoured by the anatomical defcription of feveral animals by the members of the French academy, and particularly their account of the fea-calf and porcupine; in both of which the optic nerve is inferted in the very axis of the eye, exactly oppofite to the pupil, which was thought to leave no room to doubt, but that in thefe animals the retina is perfectly fenfible to the impreffion of light at the infertion of the nerve. But this obfervation may deferve to be reconfidered.

M. De la Hire took part with M. Pecquet, arguing in favour of the retina from the analogy of the fenfes, in all of which the nerves are the proper feat of fenfation. This philofopher, however, fuppofed that the choroides receives the impreffions of images, in order to tranfmit them to the retina.

M. Perrault alfo took the part of M. Pecquet againft M. Marriotte, and in M. Perrault's works we have feveral letters that paffed between thefe two gentlemen upon this fubject.

This difpute about the immediate inftrument of vifion was revived upon the occafion of an odd experiment of M. Mery, recorded in the memoirs of the French academy for 1704. He plunged a cat in water, and expofing her eye to the ftrong light of the fun, obferved that the pupil was not at all contracted by it; from which he concluded, that the contraction of the iris is not produced by the action of the light, but by fome other circumftance. For he contended that the eye receives more light in this fituation than in the open air. At the fame time he thought he obferved that the retina of the cat's eye was tranfparent, and that he could fee the opaque choroides beyond it; from which he concludes, that the choroides is the fubftance intended to receive the rays of light, and to be the chief inftrument of vifion. But M. De la Hire replies to this argument of M. Mery, in a memoir for the year 1709, p. 119; in which he endeavours to fhew that fewer rays enter the eye under water, and that in thofe circumftances it is not fo liable to be affected by them. Befides, it is obvious to be remarked, that the cat muft be in great terror in this fituation; and being an animal that has a very great voluntary power over the mufcles of the iris, and being now extremely attentive to every thing about her, fhe might keep her eye open notwithftanding the action of the light upon it, and though it might be very painful to her. We are informed, that when a cat is placed in a window through which the fun is fhining, and confequently her iris nearly clofed, if fhe hear a ruftling, like that which is made by a moufe, on the outfide of the window, fhe will immediately open her eyes to their greateft extent, without in the leaft turning her face from the light.

M. Le Cat took part with M. Marriotte in this controverfy, it being peculiarly agreeable to this general hypothefis, *viz.* that the pia mater, of which the choroides is a production, and not the nerves themfelves, is the proper inftrument of fenfation. He thought that the change which takes place in the eyes of old people (the choroides growing lefs black with age) favoured his hypothefis, as they do not fee with that diftinctnefs with which young perfons do. M. Le Cat fuppofed that the retina anfwers a purpofe fimilar to that of the fcarf-fkin, covering the papillæ pyramidales, which are the immediate organ of feeling, or that of the porous membrane which covers the glandulous papillæ of the tongue. The retina, he fays, receives the impreffion of light, moderates it, and prepares it for its proper organ, but is not itfelf fenfible of it.

It muft be obferved, that M. Le Cat had difcovered that the pia mater, after clofely embracing and conftringing the optic nerve at its entrance into the eye, divides into two branches, one of which clofely lines the cornea, and at length is loft in it, while the fecond branch makes what is called the *choroides*, or *uvea*. He alfo fhewed that the fclerotica is an expanfion of the dura mater; and he fent diffections of the eye to the royal academy of fciences in 1739, to prove thefe affertions, and feveral others which he had advanced in his *Traité des Sens*, that were contrary to the opinions of the celebrated Winflow.

To thefe arguments in favour of the choroides, alleged by thofe gentlemen among whom the fubject was firft difcuffed, Dr Prieftley in his hiftory adds the following that had efcaped their notice, but which were fuggefted to him by his friend Mr Michell.

In order that vifion be diftinct, the pencils of rays which iffue from the feveral points of any object, muft be collected either accurately, or at leaft very nearly, to correfponding points in the eye, which can only be done upon fome uniform furface. But the retina being of a confiderable thicknefs, and the whole of it being uniformly nervous, and at leaft nearly, if not perfectly, tranfparent, prefents no particular furface; fo that, in whatever part of it the pencils be fuppofed to have their foci, the rays belonging to them will be feparated from one another, either before or after they arrive there, and confequently vifion would be confufed.

If we fuppofe the feat of vifion to be at the nearer furface of the retina, and the images of objects be formed by direct rays, a confiderable degree of confufion could not but arife from the light reflected by the choroides, in thofe animals in which it is white, or coloured. On the other hand, it would be impoffible that vifion fhould be performed at this place by light reflected from the choroides, becaufe in many animals it is perfectly black, and reflects no light at all; and yet fuch animals fee even more diftinctly than others. And we cannot but fuppofe that, in whatever manner vifion is effected, it is the fame in the eyes of all animals.

If the feat of vifion be at the farther furface of the retina, and it be performed by direct rays, a white choroides could be of no ufe; and if it were by reflected rays, a black one could not anfwer the purpofe.

It is likewife an argument in favour of the choroides being the organ of vifion, that it is a fubftance which receives a more diftinct impreffion from the rays of light than any other membrane in any part of the animal fyftem, excepting (and perhaps not excepting) that white cuticle which lies under the fcales of fifhes; whereas

Of Refraction.

whereas the retina is a ſubſtance on which the light makes an exceedingly faint impreſſion, and perhaps no impreſſion at all; ſince light, in paſſing out of one tranſparent medium into another immediately contiguous to it, ſuffers no refraction or reflection, nor are any of the rays abſorbed, unleſs there is ſome difference in the refracting power of the two media, which probably is not the caſe between the retina and the vitreous humour, which is in contact with it. And wherever the light is not affected by the medium it falls upon, we can hardly ſuppoſe the medium to receive any impreſſion from the light, the action being probably always mutual and reciprocal.

Beſides, the retina is ſo ſituated, as to be expoſed to many rays beſides thoſe which terminate in it, and which, therefore, cannot be ſubſervient to viſion, if it be performed there. Now this is not the caſe with the choroides, which is in no ſhape tranſparent, and has no reflecting ſubſtance beyond it.

It is, moreover, peculiarly favourable to the hypotheſis of the ſeat of viſion being in the choroides, that we can then ſee a ſufficient reaſon for the diverſity of its colour in different animals, according as they are circumſtanced with reſpect to viſion. In all terreſtrial animals, which have occaſion to make uſe of their eyes by night, the choroides is either of a bright white, or of ſome very vivid colour, which reflects the light very ſtrongly. On this account viſion may be performed with leſs light, but it cannot be with great diſtinctneſs, the reflection of the rays doubling their effect; ſince it muſt extend over ſome ſpace, all reflection being made at a diſtance from the reflecting body. Beſides, the choroides in brutes is not in general perfectly white, but a little inclined to blue; and is therefore, probably, better adapted to ſee by the fainter coloured light, which chiefly prevails in the night; and, we would add, is on the ſame account more liable to be ſtrongly impreſſed by the colours to which they are chiefly expoſed.

On the other hand, the choroides of birds in general, eſpecially eagles, hawks, and other birds of prey, is black; by which means they are able to ſee with the greateſt diſtinctneſs, but only in bright day-light. The owl, however, ſeeking her food by night, has the choroides white, like that of a cat. Laſtly, in the eyes of man, which are adapted to various uſes, the choroides is neither ſo black as that of birds, nor ſo white as that of thoſe animals who make the greateſt uſe of their eyes in the night.

As to a third hypotheſis, which is in effect that of M. De la Hire, which makes both the retina and the choroides equally neceſſary to viſion, and ſuppoſe it be performed by the impreſſion of light on the choroides communicated to the retina; Mr Michell obſerves, that the perceptions can hardly be ſuppoſed to be ſo acute, when the nerves, which are the chief inſtruments of ſenſation, do not receive the impreſſions immediately, but only after they have been communicated to another ſubſtance. Beſides, it muſt be more natural to ſuppoſe, that, when the principal impreſſion is made upon the choroides, it is communicated to the brain by its own proper nerves, which are abundantly ſufficient for the purpoſe.

120 Dimenſions of the ſpot in the eye where there is no viſion.

The dimenſions and preciſe form of the ſpot in the eye in which there is no viſion, were more accurately calculated by Daniel Bernoulli, in the following manner. He placed a piece of money O, fig. 1, upon the floor; and then ſhutting one of his eyes, and making a pendulum to ſwing, ſo that the extremity of it might be nearly in the line AO, he obſerved at what place C it began to be inviſible, and where it again emerged into view at A. Raiſing the pendulum higher and lower, he found other points, as H, N, P, G, B, at which it began to be inviſible; and others, as M, L, E, A, at which it began to be viſible again; and drawing a curve through them, he found that it was elliptical; and, with reſpect to his own eye, the dimenſions of it were as follows, OC was 23, AC 10, BD 3, DH 13, and EG 14; ſo that the centre being at F, the greater axis was to the leſs as 8 to 7.

Plate CCXI.

From theſe *data*, the plane on which the figure was drawn being obliquely ſituated with reſpect to the eye, he found, that the place in the eye that correſponded to it was a circle, the diameter of which was a ſeventh part of the diameter of the eye, the centre of it being 27 parts of the diameter from the point oppoſite to the pupil, a little above the middle. He concludes with obſerving, that, in order that this ſpace in which there is no viſion, may be as ſmall as poſſible, it was neceſſary that the nerve ſhould enter the eye perpendicularly, and that both this end, and alſo its entering the eye at a diſtance from its axis, are gained by the particular manner in which the two optic nerves unite and become ſeparate again, by croſſing one another.

In favour of one of the obſervations of Mr Michell, concerning the uſe of the choroides in viſion, Dr Prieſtley obſerves, that Aquapendente mentions the caſe of a perſon at Piſa, who could ſee very well in the night, but very little or none at all in the daytime. This is alſo ſaid to be the caſe with thoſe white people among the blacks of Africa, and the inhabitants of the iſthums of America, who, from this circumſtance, are called *moon eyed*. Our author thinks it probable that their choroides is not of a dark colour, as it is in others of the human ſpecies; but white, or light coloured, as in thoſe animals which have moſt occaſion for their eyes in the night.

The following conſiderations in favour of the retina being the proper ſeat of viſion are worthy of remark.

Dr Porterfield obſerves, that the reaſon why there is no viſion at the enterance of the optic nerve into the eye, may be, that it wants that ſoftneſs and delicacy, which it has when it is expanded upon the choroides; and that, in thoſe animals in which that nerve is inſerted in the axis of the eye, it is obſerved to be equally delicate, and therefore probably equally ſenſible, in that place as in any other part of the retina. In general, the nerves, when conſtringed by their coats, have but little ſenſibility, in compariſon of what they are endued with when they are diveſted of them, and unfolded in a ſoft and pulpy ſubſtance.

Haller obſerves, that the choroides cannot be the univerſal inſtrument of viſion, becauſe that ſometimes in men and birds, but eſpecially in fiſhes, it is covered internally with a black mucus, through which the rays cannot penetrate. This writer ſpeaks of a fibrous membrane in the retina diſtinct from its pulpy ſubſtance. On theſe fibres, he conjectures, that the images of objects are painted.

M. De la Hire's argument in favour of the retina, from

Of Refraction.

from the analogy of the ſenſes, is much ſtrengthened by conſidering that the retina is a large nervous apparatus, immediately expoſed to the impreſſion of light; whereas the choroides receives but a ſlender ſupply of nerves, in common with the ſclerotica, the conjunctiva, and the eyelids, and that its nerves are much leſs expoſed to the light than the naked fibres of the optic nerve. Indeed, from anatomical conſiderations, one might imagine that any other part of the body was as ſenſible of the impreſſion of light, as the choroides.

That the optic nerve is of principal uſe in viſion is farther probable from ſeveral phenomena attending ſome of the diſeaſes in which the ſight is affected. When an amauroſis has affected one eye only, the optic nerve of that eye has been found manifeſtly altered from its ſound ſtate. Dr Prieſtley was preſent when Mr Hey examined the brain of a young girl, who had been blind of one eye, and ſaw that the optic nerve belonging to it was conſiderably ſmaller than the other; and he informed him, that, upon cutting into it, he found it to be much harder, and cineritious. Morgagni, indeed, mentions two caſes, in one of which he found the optic nerves ſmaller than uſual, and of a cineritious colour, when, upon inquiry, he was informed that the perſon had not been blind, though there might have been ſome defect in the ſight of one of the eyes. In the other caſe, only one of the optic nerves was affected in that manner, and the eye itſelf was in other reſpects very perfect. Here, alſo, he was expreſly told that the perſon was not blind of that eye: but it appears that he himſelf had not been acquainted with the perſons whom he diſſected; and there have been many caſes of perſons being blind of one eye, without knowing it themſelves, for a conſiderable time.

Moreover, as the optic nerve is ſolely ſpent in forming the retina, ſo no function of the eye, not immediately ſubſervient to viſion, is affected by an amauroſis. On the contrary, thoſe nerves which go to the choroides are found to retain, in this diſeaſe, their natural influence. The iris will contract in a recent gutta ſerena of one eye, if the other remains ſound, and is ſuddenly expoſed to a ſtrong light. The ſclerotis, conjunctiva, and eyelids, which receive their nerves from the ſame branches as the choroides retain their ſenſibility in this diſorder.

The manner in which perſons recover from an amauroſis, favours the ſuppoſition of the ſeat of viſion being in the retina; ſince thoſe parts which are the moſt diſtant from the inſertion of the nerve recover their ſenſibility the ſooneſt, being, in thoſe places, the moſt pulpy and ſofteſt; whereas there is no reaſon to think that there is any difference in this reſpect in the different parts of the choroides. Mr Hey has been repeatedly informed, by perſons labouring under an imperfect amauroſis, or gutta ſerena, that they could not, when looking at any object with one eye, ſee it ſo diſtinctly when it was placed directly oppoſite to the pupil, as when it was ſituated ſomewhat obliquely. And thoſe perſons whom he had known to recover from a perfect amauroſis, firſt diſcovered the objects whoſe images fell upon that part of the retina which is at the greateſt diſtance from the optic nerve.

We ſhall conclude theſe remarks with obſerving, that, if the retina be as tranſparent as it is generally repreſented to be, ſo that the termination of the pencils muſt neceſſarily be either upon the choroides, or ſome other opaque ſubſtance interpoſed between it and the retina, the action and reaction occaſioned by the rays of light being at the common ſurface of this body and the retina, both theſe mediums (ſuppoſing them to be equally ſenſible to the impreſſion of light) may be equally affected; but the retina, being naturally much more ſenſible to this kind of impreſſion, may be the only inſtrument by which the ſenſation is conveyed to the brain, though the choroides, or the black ſubſtance with which it is ſometimes lined, may alſo be abſolutely neceſſary for the purpoſe of viſion. Indeed, when the reflection of the light is made at the common boundary of any two mediums, it is with no propriety that this effect is aſcribed to one of them rather than the other; and the ſtrongeſt reflections are often made back into the denſeſt mediums, when they have been contiguous to the rareſt, or even to a vacuum. This is not far from the hypotheſis of M. De la Hire, and will completely account for the entire defect of viſion at the inſertion of the optic narve.

121 Of bright and obſcure viſion.

Viſion is diſtinguiſhed into *bright* and *obſcure*, *diſtinct* and *confuſed*.—It is ſaid to be bright, when a ſufficient number of rays enter the pupil at the ſame time; obſcure, when too few. It is diſtinct when each pencil of rays is collected into a focus exactly upon the retina; *confuſed*, when they meet before they come at it, or when they would paſs it before they meet; for, in either of theſe laſt caſes, the rays flowing from different parts of the object, will fall upon the ſame part of the retina, which muſt neceſſarily render the image confuſed and indiſtinct.—Now, that objects may appear with a due brightneſs, whether more or fewer rays proceed from them, we have a power of contracting or dilating the pupil by means of the muſcular fibres of the iris, in order to take in more or fewer rays as occaſion requires. But this power has its limits. In ſome animals it is much greater than in others; particularly in ſuch as are obliged to ſeek their food by night, as well as by day, as in cats, &c.

122 Of diſtinct viſion at different diſtances.

That the rays may be collected into points exactly upon the retina, that is, that objects may appear diſtinct, whether they be nearer or farther off, *i. e.* whether the rays proceeding from them diverge more or leſs, we have a power of contracting or relaxing the ligamenta ciliaria, and thereby altering the form of the cryſtalline humour, and with it the focal diſtance of the rays. Thus, when the object we view is far off, and the rays fall upon the pupil with a very ſmall degree of divergency, we contract the *ligamenta ciliaria*, which, being concave towards the vitreous humour, do thereby compreſs it more than otherwiſe they would do: by this means it is made to preſs harder upon the backſide of the cryſtalline humour, which is thereby rendered flatter; and thus the rays proceed farther before they meet in a focus, than otherwiſe they would have done. Add to this, that we dilate the pupils of our eyes (unleſs in caſes where the light is ſo ſtrong that it offends the eye), and thereby admit rays into them that are more diverging than thoſe which would otherwiſe enter. And, when the rays come from an object that is very near, and there-

Of Refraction.

fore diverge too much to be collected into their respective foci upon the retina; by relaxing the *ligamenta ciliaria*, we give the cryſtalline a more convex form, by which means the rays are made to ſuffer a proportionably greater degree of refraction in paſſing through it. Some philoſophers are of opinion that we do this by a power of altering the form of the eye; and others, by removing the cryſtalline forwards or backwards as occaſion requires: but neither of theſe opinions is probable; for the coats of the eye are too hard, in ſome animals, for the firſt; and, as to moving the cryſtalline out of its place, the cavities of the eye ſeem to be too well filled with the other humours to admit of ſuch removal.

Beſides this, in the caſe above-mentioned, by contracting the pupils of our eyes, we exclude the more diverging rays, and admit only ſuch as are more eaſily refracted into their reſpective foci (A). But viſion is not diſtinct at all diſtances, for our power of contracting and relaxing the ligamenta ciliaria is alſo circumſcribed within certain limits.

123 Of ſhort-ſighted and long-ſighted people.

In thoſe eyes where the tunica cornea is very protuberant and convex, the rays of light ſuffer a very conſiderable refraction at their entrance into the aqueous humour, and are therefore collected into a focus before they fall upon the retina, unleſs the object be placed very near, ſo that the rays which enter the eye may have a conſiderable degree of divergency. People that have ſuch eyes are ſaid to be *purblind*. Now, the nearer an object is to the eye, the greater is the image of it therein, as explained above: theſe people therefore can ſee much ſmaller objects than others, as ſeeing much nearer ones with the ſame diſtinctneſs; and their ſight continues good longer than that of other people, becauſe the tunica cornea of their eyes, as they grow old, becomes plainer, for want of that redundancy of humours with which they were filled before. On the contrary, old men, having the cornea of their eyes too flat for want of a ſufficient quantity of the aqueous humour to fill them out, if the rays diverge too much before they enter the eye, they cannot be brought to a focus before they reach the retina; on which account thoſe people cannot ſee diſtinctly, unleſs the object be ſituated at a greater diſtance from the eye, than is required for thoſe whoſe eyes are of a due form. The latter require the aſſiſtance of convex glaſſes, to make them ſee objects diſtinctly; the former of concave ones. For if either the cornea *abc* (fig. 5.), or cryſtalline humour *e*, or both of them, be too flat, as in the eye A, their focus will not be on the retina as at A, where it ought to be, in order to render viſion diſtinct; but beyond the eye, as at *f*. This is remedied by placing a convex glaſs *gh* before the eye, which makes the rays converge ſooner, and imprints the image duely on the retina at *d*. Again, if either the cornea, or cryſtalline humour, or both of them, be too convex, as in the eye B, the rays that enter it from the object C will be converged to a focus in the vitreous humour, as at *f*; and by diverging from thence to the retina, will form a very confuſed image thereon; and ſo, of courſe, the obſerver will have as confuſed a view of the object as if his eye had been too flat. This inconvenience is remedied by placing a concave glaſs *gh* before the eye; which glaſs, by cauſing the rays to diverge between it and the eye, lengthens the focal diſtance ſo, that if the glaſs be properly choſen, the rays will unite at the retina, and form a diſtinct image of the object upon it.

Plate CCX.

124 Of the leaſt angle of viſion.

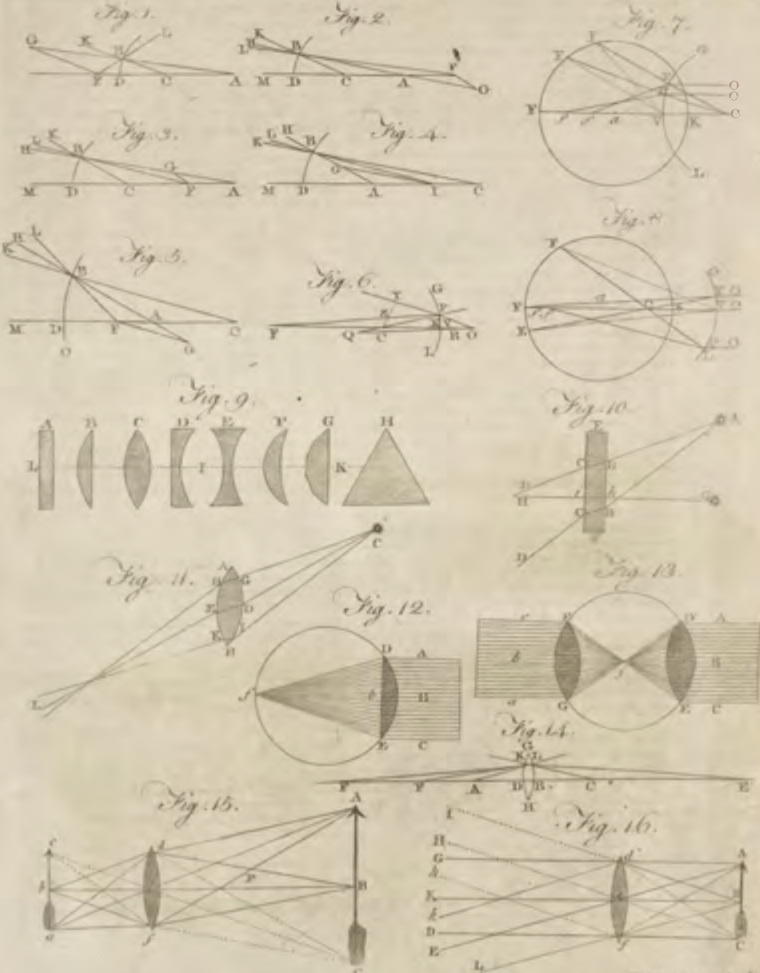
Such eyes as are of a due convexity, cannot ſee any object diſtinctly at leſs diſtance than ſix inches; and there are numberleſs objects too ſmall to be ſeen at that diſtance, becauſe they cannot appear under any ſenſible angle.—Concerning the leaſt angle under which any object is viſible, there was a debate between Dr Hooke and Hevelius. The former aſſerted, that no object could well be ſeen if it ſubtended an angle leſs than one minute; and, if the object be round, as a black circular ſpot upon a white ground, or a white circle upon a black ground, it follows, from an experiment made by Dr Smith, that this is near the truth; and from thence he calculates, that the diameter of the picture of ſuch leaſt viſible point upon the retina is the 8000th part of an inch; which he therefore calls a *ſenſible point of the retina*. On the other hand, Mr Courtivron concluded from his experiments, that the ſmalleſt angle of viſion was 40 ſeconds. According to Dr Jurin, there are caſes in which a much ſmaller angle than one minute can be diſcerned by the eye; and in order to throw light upon the ſubject, he obſerves, that, in order to our perceiving the impreſſion made by any object upon our ſenſes, it muſt either be of a certain degree of force, or of a certain degree of magnitude. For this reaſon a ſtar, which appears only as a lucid point through a teleſcope, ſubtending not ſo much as an angle of one ſecond, is viſible to the eye; though a white or black ſpot, of 25 or 30 ſeconds, is not to be perceived. Alſo a line of the ſame breadth with the circular ſpot will be viſible, at ſuch a diſtance as the ſpot is not to be perceived at; becauſe the quantity of impreſſion from the line is much greater than from the ſpot; and a longer line is viſible at a greater diſtance than a ſhorter one of the ſame breadth. He found by experience, that a ſilver wire could be ſeen when it ſubtended an angle of three ſeconds and an half; and that a ſilk thread could be ſeen when it ſubtended an angle of two ſeconds and a half.

125 Lines can be ſeen under ſmaller angles than ſpots, and why.

This greater viſibility of a line than of a ſpot, ſeems to ariſe only from the greater quantity of the impreſſion; but without the limits of perfect viſion, our author obſerves, that another cauſe concurs, whereby the difference of viſibility between the ſpot and the line is rendered much more conſiderable. For the impreſſion upon the retina made by the line is then not only much greater, but alſo much ſtronger than that of the ſpot; becauſe the faint image, or penumbra, of any one point of the line, when the whole is placed beyond the limits of diſtinct viſion, will fall within the faint image of the next point, and thereby much increaſe the light that comes from it.

In ſome caſes our author found the cauſe of indiſtinct viſion to be the unſteadineſs of the eye; as our being able to ſee a ſingle black line upon a white ground, or a ſingle white line upon a black ground, and

(A) Accordingly it is obſerved, that if we make a ſmall hole with the point of a needle through a piece of paper, and apply that hole cloſe to the eye, making uſe of it, as it were, inſtead of a pupil, we ſhall be able to ſee an object diſtinctly through it, though the object be placed within half an inch of the eye.



J. Bell sculpt.

Of Refraction.

and not a white line between two black ones on a white ground. In viewing either of the former objects, if the eye be imperceptibly moved, all the effect will be, that the object will be painted upon a different part of the retina; but, wherever it is painted, there will be but one picture, single and uncompounded with any other. But in viewing the other, if the eye fluctuate ever so little, the image of one or other of the black lines will be shifted to that part of the retina which was before possessed by the white line; and this must occasion such a dazzle in the eye, that the white line cannot be distinctly perceived, and distinguished from the black lines; which, by a continual fluctuation, will alternately occupy the space of the white line, whence must arise an appearance of one broad dark line, without any manifest separation.

By trying this experiment with two pins of known diameters, set in a window against the sky light, with a space between them equal in breadth to one of the pins, he found that the distance between the pins could hardly be distinguished when it subtended an angle of less than 40 seconds, though one of the pins alone could be distinguished when it subtended a much less angle. But though a space between two pins cannot be distinguished by the eye when it subtends an angle less than 40 seconds, it would be a mistake to think that the eye must necessarily commit an error of 40 seconds in estimating the distance between two pins when they are much farther from one another. For if the space between them subtend an angle of one minute, and each of the pins subtend an angle of four seconds, which is greater than the least angle the eye can distinguish, it is manifest that the eye may judge of the place of each pin within two seconds at the most; and consequently the error committed in taking the angle between them cannot at the most exceed four seconds, provided the instrument be sufficiently exact. And yet, says he, upon the like mistake was founded the principal objection of Dr Hooke against the accuracy of the celestial observations of Hevelius.

A black spot upon a white ground, or a white spot upon a black ground, he says, can hardly be perceived by the generality of eyes when it subtends a less angle than one minute. And if two black spots be made upon white paper, with a space between them equal in breadth to one of their diameters, that space is not to be distinguished, even within the limits of perfect vision, under so small an angle as a single spot of the same size can be distinguished. To see the two spots distinctly, therefore, the breadth of the space between them must subtend an angle of more than a minute. It would be very difficult, he says, to make this experiment accurately, within the limits of perfect vision; because the objects must be extremely small: but by a rude trial, made with square bits of white paper, placed upon a black ground, he judged, that the least angle under which the interval of two objects could be perceived, was at least a fourth part greater than the least angle under which a single object can be perceived. So that an eye which cannot perceive a single object under a smaller angle than one minute, will not perceive the interval between two such objects under a less angle than 75 seconds.

Without the limits of perfect vision, the distance at which a single object ceases to be perceivable will be much greater in proportion than the distance at which a space of equal breadth between two such objects ceases to be perceivable. For, without these limits, the image of each of the objects will be attended with a penumbra, and the penumbra of the two near objects will take up part of the space between them, and thereby render it less perceivable; but the penumbra will add to the breadth of the single object, and will thereby make it more perceivable, unless its image be very faint. Upon the same principles he likewise accounts for the radiation of the stars, whereby the light seems to project from them different ways at the same time.

Mr Mayer made many experiments in order to ascertain the smallest angle of vision in a variety of respects. He began with observing at what distance a black spot was visible on white paper; and found, that when it could barely be distinguished, it subtended an angle of about 34 seconds. When black lines were disposed with intervals broader than themselves, they were distinguished at a greater distance than they could be when the objects and the intervals were of an equal breadth. In all these cases it made no difference whether the objects were placed in the shade, or in the strong light of the sun; but when the degrees of light were small, their differences had a considerable effect, though by no means in proportion to the differences of the light. For if an object was illuminated to such a degree as to be just visible at the distance of nine feet, it would be visible at the distance of four feet, tho' the light was diminished above 160 times. It appeared in the course of these experiments, that common day-light is, at a medium, equal to that of 25 candles placed at the distance of one foot from the object.

126 Of single vision with two eyes.

As an image of every visible object is painted on the retina of each of our eyes, it thence becomes a natural question, Why we do not see every thing double? It was the opinion of Sir Isaac Newton and others, that objects appear single because the two optic nerves unite before they reach the brain. But Dr Porterfield shews, from the observation of several anatomists, that the optic nerves do not mix, or confound their substance, being only united by a close cohesion; and objects have appeared single where the optic nerves were found to be disjoined.

Dr Briggs supposed that single vision was owing to the equal tension of the corresponding parts of the optic nerves, whereby they vibrated, in a synchronous manner. But, besides several improbable circumstances in this account, Dr Porterfield shews that facts do by no means favour it.

To account for this phenomenon, this ingenious writer supposes, that by an original law in our natures, we imagine objects to be situated somewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil. Consequently, the same object appearing to both eyes to be in the same place, the mind cannot distinguish it into two. In answer to an objection to this hypothesis, from objects appearing double when one eye is distorted, he says the mind mistakes the position of the eye, imagining that it had moved in a manner corresponding to the other, in which case the conclusion would have

have been juſt. In this he ſeems to have recourſe to the power of habit, tho' in words he diſclaims that hypotheſis.

This principle, however, has generally been thought to be ſufficient to account for this appearance. Originally, every object making two pictures, one in each eye, is imagined to be double; but, by degrees, we find, that when two correſponding parts of the retina are impreſſed, the object is but one; but if thoſe correſponding parts be changed, by the diſtortion of one of the eyes, the object muſt again appear double as at the firſt. This ſeems to be verified by Mr Cheſelden; who informs us, that a gentleman, who from a blow on his head had one eye diſtorted, found every object to appear double; but by degrees the moſt familiar ones came to appear ſingle again, and in time all objects did ſo, without any amendment of the diſtortion. A caſe ſimilar to this is mentioned by Dr Smith.

On the other hand, Dr Reid is of opinion, that the correſpondence of the centres of the two eyes, on which ſingle viſion depends, does not ariſe from cuſtom, but from ſome natural conſtitution of the eye and of the mind. He makes ſeveral juſt objections to the caſe of Mr Foſter, recited by Dr Smith and others; and thinks that the caſe of the young man couched by Cheſelden, who ſaw ſingly with both eyes immediately upon receiving his ſight, is nearly deciſive in proof of his ſuppoſition. He alſo found that three young gentlemen, whom he endeavoured to cure of ſquinting, ſaw objects ſingly, as ſoon as ever they were brought to direct the centres of both their eyes to the ſame object, though they had never been uſed to do ſo from their infancy; and he obſerves, that there are caſes, in which, notwithſtanding the fulleſt conviction of an object being ſingle, no practice of looking at it will ever make it appear ſo, as when it is ſeen thro' a multiplying glaſs.

We are indebted to Dr Jurin for the following curious experiments to determine whether an object ſeen by both eyes appears brighter than when ſeen with one only.

He laid a ſlip of clean white paper directly before him on a table, and applying the ſide of a book cloſe to his right temple, ſo as that the book was advanced conſiderably more forward than his face, he held it in ſuch a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was ſeen by both eyes, without any impediment.

Then looking at the paper with both eyes, he obſerved it to be divided, from the top to the bottom, by a dark line, and the part which was ſeen with one eye only was manifeſtly darker than that which was ſeen with both eyes; and, applying the book to his left temple, he found, by the reſult of the experiment, that both his eyes were of equal goodneſs.

He then endeavoured to find to what degree this exceſs of brightneſs amounted; and comparing it with the appearance of an object illuminated partly by one candle and parly by two, he was ſurpriſed to find that an object ſeen with two eyes is by no means twice as luminous as when it is ſeen with one only; and after a number of trials, by which he made the proportion leſs and leſs continually, he found, that when one paper was illuminated by a candle placed at the diſtance of three feet, and another paper by the ſame candle at the ſame diſtance, and by another candle at the diſtance of 11 feet, the former ſeen by both eyes, and the latter with one eye only, appeared to be of equal whiteneſs; ſo that an object ſeen with both eyes appears brighter than when it is ſeen with one only by about a 13th part. But he acknowledges, that is difficult to make this experiment exactly.

He then proceeded to inquire, whether an object ſeen with both eyes appears any thing larger than when ſeen with one only; but he concluded that it did not, except on account of ſome particular circumſtances, as in the caſe of the binocular teleſcope, and the concave ſpeculum.

M. Du Tour maintains, that the mind attends to no more than the image made in one eye at a time; and produces ſeveral curious experiments in favour of this hypotheſis, which had alſo been maintained by Kepler and almoſt all the firſt opticians. But, as M. Buffon obſerves, it is a ſufficient anſwer to this hypotheſis, how ingeniouſly ſoever it may be ſupported, that we ſee more diſtinctly with two eyes than one; and that when a round object is near us we plainly ſee more of the ſurface in one caſe than in the other. There are, alſo, other facts, which clearly prove the contrary of what is maintained by M. Du Tour.

With reſpect to ſingle viſion with two eyes, Dr Hartley obſerves, that it deſerves particular attention, that the optic nerves of men, and ſuch other animals as look the ſame way with both eyes, unite in the *ſella turcica* in a ganglion, or little brain, as one may call it, peculiar to themſelves; and that the aſſociations between ſynchronous impreſſions on the two retinas muſt be made ſooner and cemented ſtronger on this account; alſo that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impreſſion made on the right eye alone, by a ſingle object, may propagate itſelf into the left, and there raiſe up an image almoſt equal in vividneſs to itſelf; and conſequently when we ſee with one eye only, we may, however, have pictures in both eyes.

A curious deception in viſion, ariſing from the uſe of both eyes, was obſerved and accounted for by Dr Smith. It is a common obſervation, he ſays, that objects ſeen with both eyes appear more vivid and ſtronger than they do to a ſingle eye; eſpecially when both of them are equally good. A perſon not ſhort-ſighted may ſoon be convinced of this fact, by looking attentively at objects that are pretty remote, firſt with one eye, and then with both. This obſervation gave occaſion to the conſtruction of the binocular teleſcope, in the uſe of which the phenomenon is ſtill more ſtriking.

Beſides this, our author obſerves, that there is another phenomenon obſervable with this inſtrument, which is very remarkable. In the foci of the two teleſcopes there are two equal rings, as uſual, which terminate the pictures of the objects there formed, and conſequently the viſible area of the objects themſelves. Theſe equal rings, by reaſon of the equal eye-glaſſes, appear equal, and equally diſtant when ſeen ſeparately by each eye; but when they are ſeen with both eyes, they appear much larger, and more diſtant alſo; and the

Of Refraction.

the objects seen through them do also appear much larger, though circumscribed by their united rings, in the same places as when they were seen separately.

He observes, that the phenomenon of the enlarged circle of the visible area in the binocular telescope, may be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about four or five inches, and held steady at that distance. The two innermost of the four apparent rings, which hold the glasses, will then appear united in one larger and more distant ring than the two outermost, which will hardly be visible unless the spectacles be farther removed.

A curious circumstance relating to the effect of one eye upon the other, was noticed by M. Æpinus, who observed, that, when he was looking through a hole made in a plate of metal, about the 10th part of a line in diameter, with his left eye, both the hole itself appeared larger, and also the field of view seen thro' it was more extended, whenever he shut his right eye; and both these effects were more remarkable when that eye was covered with his hand. He found considerable difficulty in measuring this augmentation of the apparent diameter of the hole, and of the field of view; but at length he found, that, when the hole was half an inch, and the tablet which he viewed through it was three feet from his eye, if the diameter of the field when both his eyes were open was 1, it became $1\frac{1}{2}$ when the other eye was shut, and nearly 2 when his hand was laid upon it.

Upon examining this phenomenon, it presently appeared to depend upon the enlargement of the pupil of one eye when the other is closed, the physical or anatomical cause of which he did not pretend to assign; but he observes, that it is wisely appointed by divine Providence, in order that when one eye fails, the field of view in the other may be extended. That this effect should be more sensible when the eye is covered with the hand, is owing, he observes, to the eye-lids not being impervious to the light. But the enlargement of the pupil does not enlarge the field of view, except in looking through a hole, as in this particular case; and therefore persons who are blind of one eye can derive no advantage from this circumstance. Before we applaud the wisdom of Providence in any part of the constitution of nature, we should be very sure that we do not mistake concerning the effects of that constitution.

A great deal has been written by Gassendi, Le Clerc, Muschenbroek, and Du Tour, concerning the place to which we refer an object viewed by one or both eyes. But the subject is not of much consequence. Any person may presently satisfy himself with respect to every thing belonging to this circumstance, either by experiment, holding his finger before his eyes, and looking at it and an object beyond it; or by figures, in which lines representing the optic axes may be made to cross one another at different distances from the eye.

§ 4. *Of the Appearance of Objects seen through Media of different Forms.*

For the more easy apprehension of what relates to this subject, we shall premise the five following particulars, which either have been already mentioned, or follow from what has been before laid down.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place; and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye; we from hence acquire an habit of judging the point to be situated in that line: and, because the mind is unacquainted with what refractions the rays suffer before they enter the eye, therefore, in cases where they are diverted from their natural course, by passing through any medium, it judges the point to be in that line produced back in which the axis of a pencil of rays flowing from it is situated the instant they enter the eye, and not in that it was in before refraction. We shall therefore, in what follows, suppose the apparent place of an object, when seen thro' a refracting medium, to be somewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have passed through the medium.

2. That we are able to judge, though imperfectly, of the distance of an object by the degree of divergency, wherein the rays flowing from the same point of the object enter the pupil of the eye, in cases where that divergency is considerable; but because in what follows it will be necessary to suppose an object, when seen through a medium whereby its apparent distance is altered, to appear in some determinate situation, in those cases where the divergency of the rays at their entrance into the eye is considerable, we will suppose the object to appear where those lines which they describe in entering, if produced back, would cross each other: though it must not be asserted, that this is the precise distance; because the brightness, distinctness, and apparent magnitude of the object, on which its apparent distance in some measure depends, will also suffer an alteration by the refraction of the rays in passing through that medium.

3. That we estimate the magnitude of an object by that of the optic angle.

4. That vision is the brighter, the greater the number of rays is which enter the pupil. And,

5. That, in some cases, the apparent brightness, distinctness, and magnitude of an object, are the only means whereby our judgment is determined in estimating the distance of it.

Prop. I. An object placed within a medium terminated by a plane surface on that side which is next the eye, if the medium be denser than that in which the eye is (as we shall always suppose it to be, unless where the contrary is expressed), appears nearer to the surface of the medium than it is.

Thus, if A be a point of an object placed within the medium BDCE (fig. 2.), and A *b* A *c* be two rays proceeding from thence, these rays passing out of a denser into a rarer medium, will be refracted from their respective perpendiculars *b d*; *c e*, and will enter the eye at H, suppose in the directions *b f*, *c g*, let then these lines be produced back till they meet in F; this will be the apparent place of the point A: and because the refracted rays *b f*, *c g* will diverge more than the incident ones A *b*, A *c*, it will be nearer to the points *b* and *c*, than the point A; and as the same is true of each point in the object, the Plate CCXI. whole

whole will appear to an eye at H, nearer to the surface BC than it is.

From hence it is, that when one end of a straight stick is put under water, and the stick is held in an oblique position, it appears bent at the surface of the water; viz. because each point that is under water appears nearer the surface, and consequently higher than it is.

From hence likewise it is, that an object at the bottom of a vessel may be seen when the vessel is filled with water, though it be so placed with respect to the eye, that it cannot be seen when the vessel is empty. To explain this, let ABCD (fig. 3.) represent a vessel, and let E be an object lying at the bottom of it. This object, when the vessel is empty, will not be seen by an eye at F, because HB, the upper part of the vessel, will obstruct the ray EH; but when it is filled with water to the height GH, the ray EK being refracted at the surface of the water into the line KF, the eye at F shall see the object by means of that.

Plate CCXI.

In like manner, an object situated in the horizon appears above its true place, upon account of the refraction of the rays which proceed from it in their passage through the atmosphere of the earth. For, first, if the object be situated beyond the limits of the atmosphere, its rays in entering it will be refracted towards the perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmosphere: and as they pass on, they will be continually refracted the same way, because they are all along entering a denser part, the centre of whose convexity is still the same point; upon which account the line they describe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the surface of the earth, except what enter the atmosphere higher than they need to do if they could come in a right line from the object: consequently the object must appear above its proper place. Secondly, if the object be placed within the atmosphere, the case is still the same; for the rays which flow from it must continually enter a denser medium whose centre is below the eye; and therefore being refracted towards the centre, that is, downwards as before, those which enter the eye must necessarily proceed as from some point above the object; wherefore the object will appear above its proper place.

From hence it is, that the sun, moon, and stars, appear above the horizon, when they are just below it; and higher than they ought to do, when they are above it: Likewise distant hills, trees, &c. seem to be higher than they are.

Further, the lower these objects are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmosphere, or pass from the rarer into the denser parts of it; and therefore they appear to be the more elevated by refraction: upon which account the lower parts of them are apparently more elevated than the other. This makes their upper and under parts seem nearer than they are; as is evident from the sun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the same length they would do if the rays suffered no refraction, while their vertical ones are shortened thereby.

Prop. II. An object seen through a medium terminated by plane and parallel surfaces, appears nearer, brighter, and larger, than with the naked eye.

For instance, let A B (fig. 4.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confusion in the figure. And, 1st, let RK, RL, be two rays proceeding from the point R, and entering the denser medium at K and L; these rays will here by refraction be made to diverge less, and to proceed afterwards, suppose in the lines K*a*, L*b*; at *a* and *b*, where they pass out of the denser medium, they will be as much refracted the contrary way, proceeding in the lines *ac*, *bd*, parallel to their first directions. Produce these lines back till they meet in *e*: this will be the apparent place of the point R; and it is evident from the figure, that it must be nearer the eye than that point; and because the same is true of all other pencils flowing from the object AB, the whole will be seen in the situation *fg*, nearer to the eye than the line AB. 2d, As the rays RK, RL, would not have entered the eye, but have passed by it in the directions K*r*, L*t*, had they not been refracted in passing through the medium, the object appears brighter. 3d, The rays A*h*, B*i*, will be refracted at *h* and *i* into the less converging lines *hk*, *il*, and at the other surface into *k*M, *l*M, parallel to A*h* and B*i* produced; so that the extremities of the object will appear in the lines M*k*, M*l* produced, viz. in *f* and *g*, and under as large an angle *f*M*g*, as the angle A*q*B under which an eye at *q* would have seen it had there been no medium interposed to refract the rays; and therefore it appears larger to the eye at GH, being seen through the interposed medium, than otherwise it would have done. But it is here to be observed, that the nearer the point *e* appears to the eye on account of the refraction of the rays RK, RL, the shorter is the image *fg*, because it is terminated by the lines M*f* and M*g*, upon which account the object is made to appear less; and therefore the apparent magnitude of an object is not much augmented by being seen through a medium of this form.

Farther, it is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickness; for the distance between the lines R*r* and *ec*, and consequently the distance between the points *e* and R, depends upon the length of the line K*a*: Again, the distance between the lines AM and *f*M, depends on the length of the line *hk*; but both K*u* and *kh* depend on the distance between the surfaces CE and DF, and therefore the effect of this medium depends upon its thickness.

Prop. III. An object seen through a convex lens, appears larger, brighter, and more distant, than with the naked eye.

To illustrate this, let AB (fig. 5.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AY*r*, BX*r*, crossing each other in the pupil of the eye; the angle A*r*B comprehended between these lines, is the angle under which the object would be seen with the naked eye. But by the interposition of a lens of this form, whose property it is to render converging rays more so, the

Of Refraction.

Plate CCXI. fig. 5.

the rays AY and BX will be made to crofs each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of thefe rays (for they will pafs it without entering), but by fome others which muft fall without the points Y and X, or between them; but if they fall between them, they will be made to concur fooner than they themfelves would have done; and therefore, if the extremities of the object could not be feen by them, it will much lefs be feen by thefe. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, muft fall upon the lens without the points Y and X; let then the rays AO and BP be fuch. Thefe after refraction entering the eye at *r*, the extremities of the object will be feen in the lines *r* Q, *r* T, produced, and under the optic angle Q *r* T, which is larger than A *r* B, and therefore the apparent magnitude of the object will be increafed. 3. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays lefs diverging, parallel, or converging, it is evident, that fome of thofe rays, which would proceed on to M and N, and mifs the eye, were they to fuffer no refraction in paffing through the lens, will now enter it; by which means the object will appear brighter. 3. As to the apparent diftance of the object, that will vary according to the fituation of it with refpect to the focus of parallel rays of the lens. 1. Then, let us fuppofe the object placed fo much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered lefs diverging by paffing through it, may yet have a confiderable degree of divergency, fo that we may be able to form a judgment of the diftance of the object thereby. In this cafe, the object ought to appear where EK, FL, produced back concur; which, becaufe they diverge lefs than the rays GH, GI, will be beyond G, that is, at a greater diftance from the lens than the object is. But becaufe both the brightnefs and magnitude of the object will at the fame time be augmented, prejudice will not permit us to judge it quite fo far off as the point where thofe lines meet, but fomewhere between that point and its proper place. 2. Let the object be placed in the focus of parallel rays, then will the rays KE and LF become parallel; and though in this cafe the object would appear at an immenfe diftance, if that diftance were to be judged of by the direction of the rays KE and LF, yet upon account of the brightnefs and magnitude of it, we fhall not think it much farther from us than if it were feen by the naked eye. 3. If the object be fituated beyond the focus of parallel rays, as in BA (fig. 6.) the rays flowing from thence and falling upon the lens CD, will be collected into their refpective foci at *a* and *b*, and the intermediate points *m*, *n*, &c. and will there form an image of the object AB; and after croffing each other in the feveral points of it, as expreffed in the figure, will pafs on diverging as from a real object. Now if an eye be fituated at *c*, where A*c*, B*c*, rays proceeding from the extreme points of the object, make not a much larger angle A *c* B, than they would do if there were no lens interpofed, and the rays belonging to the fame pencil do not converge fo much as thofe the eye would receive if it were placed nearer to *a* or *b*, the object upon thefe accounts appearing very little larger or brighter than with the naked eye, is feen nearly in its proper place; but if the eye recedes a little way towards *a b*, the object then appearing both brighter and larger, feems to approach the lens: which is an evident proof of what has been fo often afferted, viz. that we judge of the diftance of an object in fome meafure by its brightnefs and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the diftance of the object by the direction of the rays which flow from it, we ought in this cafe to conceive it at a greater diftance, than when the rays were parallel, or diverged at their entrance into the eye.

That the object fhould feem to approach the lens in this cafe, was a difficulty that exceedingly puzzled the learned Barrow, and which he pronounces infuperable, and not to be accounted for by any theory we have of vifion. Molineux alfo leaves it to the folution of others, as that which will be inexplicable, till a more intimate knowledge of the vifive faculty, as he expreffes it, be obtained by mortals.

They imagined, that feeing an object appears farther off, the lefs the rays diverge which fall upon the eye: if they fhould proceed parallel to each other, it ought to appear exceeding remote; and if they fhould converge, it fhould then appear more diftant ftill: the reafon of this was, becaufe they looked upon the apparent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or fplendor.

Perhaps it may proceed from our judging of the diftance of an object in fome meafure by its magnitude, that that deception of fight commonly obferved by travellers may arife; viz. that upon the firft appearing of a building larger than ufual, as a cathedral church, or the like, it generally feems nearer to them, than they afterwards find it to be.

Prop. IV. If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be fituated farther from it on the other fide than the place where the rays of the feveral pencils are collected into their refpective foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

To explain this, let AB (fig. 6.) reprefent the object, CD the lens; and let the rays of the pencil ACD be collected in *a*, and thofe of BCD in *b*, forming there an inverted image of the object AB, and let the eye be placed in F: it is apparent from the figure, that fome of the refracted rays which pafs thro' each point of the image, will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the propofition afferts. But we are fo little accuftomed to fee objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are fituated in fuch a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, it is eafy to be perceived.

If the eye be fituated in *a* or *b*, or very near them on either fide, the object appears exceedingly confufed, viz. if at *d*, the rays which proceed from the fame point of the object converge fo very much, and if at *e*, they diverge fo much, that they can-

Of Reflection.

not be collected together upon the retina, but fall upon it as if they were the axes of so many distinct pencils coming through every point of the lens; wherefore little more than one single point of the object is seen at a time, and that appears all over the lens; from whence nothing but confusion arises.

If the lens be so large that both eyes may be applied to it, as in *h* and *k*, the object will appear double; for it is evident from the figure, that the rays which enter the eye at *h* from either extremity of the object A or B, do not proceed as from the same point with that from whence those which enter the other at *k* seem to flow; the mind therefore is here deceived, and looks upon the object as situated in two different places, and therefore judges it to be double.

Prop. V. An object seen through a concave lens appears nearer, smaller, and less bright, than with the naked eye.

Plate CCXI.

Thus, let AB (fig. 7.) be the object, CD the pupil of an eye, and EF the lens. Now, as it is the property of a lens of this form, to render diverging rays more so, and converging ones less so, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and so to enter the eye as from some nearer point *g*; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye as from the points *a* and *b*; wherefore the object will appear in the situation *agb*, less and nearer than without the lens. Farther, as the rays which proceed from G are rendered more diverging, some of them will be made to pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright.

Prop. VI. An object seen thro' a polygonous glass, that is, such as is terminated by several plain surfaces, is multiplied thereby.

For instance, let A (fig. 8.) be an object, and BC a polygonous glass terminated by the plain surfaces BD, DE, &c. and let the situation of the eye F be such, that the rays AB being refracted in passing thro' the glass, may enter it in the direction BF, and the rays AC in the direction CF. Then will the eye, by means of the former, see the object in G, and by the latter in H; and by means of the rays AI, the object will appear also in its proper situation A.

Sect. II. *Of the Reflection of Light.*

When a ray of light falls upon any body, however transparent, the whole of it never passes through the body, but some part is always driven back or reflected from it; and it is by this reflected light that all bodies which have no light of their own become visible to us. Of that part of the ray which enters, another part is also reflected from the second surface, or that which is farthest from the luminous body. When this part arrives again at the first surface, part of it is reflected back from that surface; and thus it continues to be reflected between the two surfaces, and to pass backwards and forwards within the substance of the medium, till some part is totally extinguished and lost. Besides this inconsiderable quantity, however, which is lost in this manner, the second surface often reflects much more than the first; insomuch that, in certain positions, scarce any rays will pass through both sides of the medium. A very considerable quantity is also unaccountably lost or extinguished at each reflecting surface; insomuch that no body, however transparent, can transmit all the rays which fall upon it; neither, tho' it be ever so well fitted for reflection, will it reflect them all.

§ 1. *Of the Cause of Reflection.*

The reflection of light is by no means so easily accounted for as the refraction of the same fluid. This property, as we have seen in the last section, may be accounted for in a satisfactory manner by the supposition of an attractive power diffused throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there seems to be no satisfactory hypothesis hitherto invented. Of the principal opinions on this subject Mr Rowning hath given us the following account.

I. It was the opinion of philosophers before Sir Isaac Newton discovered the contrary, that light is reflected by impinging upon the solid parts of bodies. But that it is not so, is clear for the following reasons.

127 Light is not reflected by impinging on the solid parts of bodies at the first surface.

And first, it is not reflected at the first surface of a body by impinging against it.

For it is evident, that in order to the due and regular reflection of light, that is, that the reflected rays should not be dispersed and scattered one from another, there ought to be no rasures or unevenness in the reflecting surface large enough to bear a sensible proportion to the magnitude of a ray of light; because if the surface abounds with such, the reflected rays will rather be scattered like a parcel of pebbles thrown upon a rough pavement, than reflected with that regularity with which light is observed to be from a well-polished surface. Now those surfaces, which to our senses appear perfectly smooth and well polished, are far from being so; for to polish, is no other than to grind off the larger eminences and protuberances of the metal with the rough and sharp particles of sand, emery, or putty, which must of necessity leave behind them an infinity of rasures and scratches, which, tho' inconsiderable with regard to the former roughnesses, and too minute to be discerned by us, must nevertheless bear a large proportion to, if not vastly exceed, the magnitude of the particles of light.

128 Nor at the second.

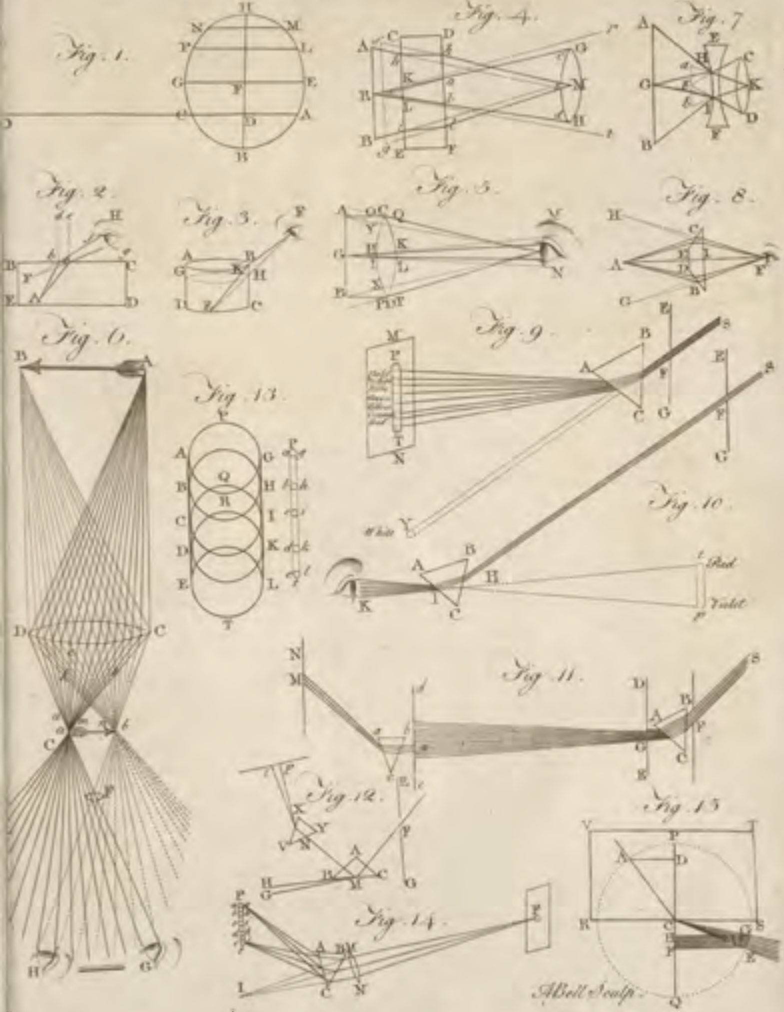
Secondly, it is not reflected at the second surface, by impinging against any solid particles.

That it is not reflected by impinging upon the solid particles which constitute this second surface, is sufficiently clear from the foregoing argument; the second surfaces of bodies being as uncapable of a perfect polish as the first; and it is farther confirmed from hence, *viz.* that the quantity of light reflected differs according to the different density of the medium behind the body: And that it is not reflected by impinging upon the particles which constitute the surface of the medium behind it, is evident, because the strongest reflection of all at the second surface of a body, is when there is a vacuum behind it. This therefore wants no farther proof.

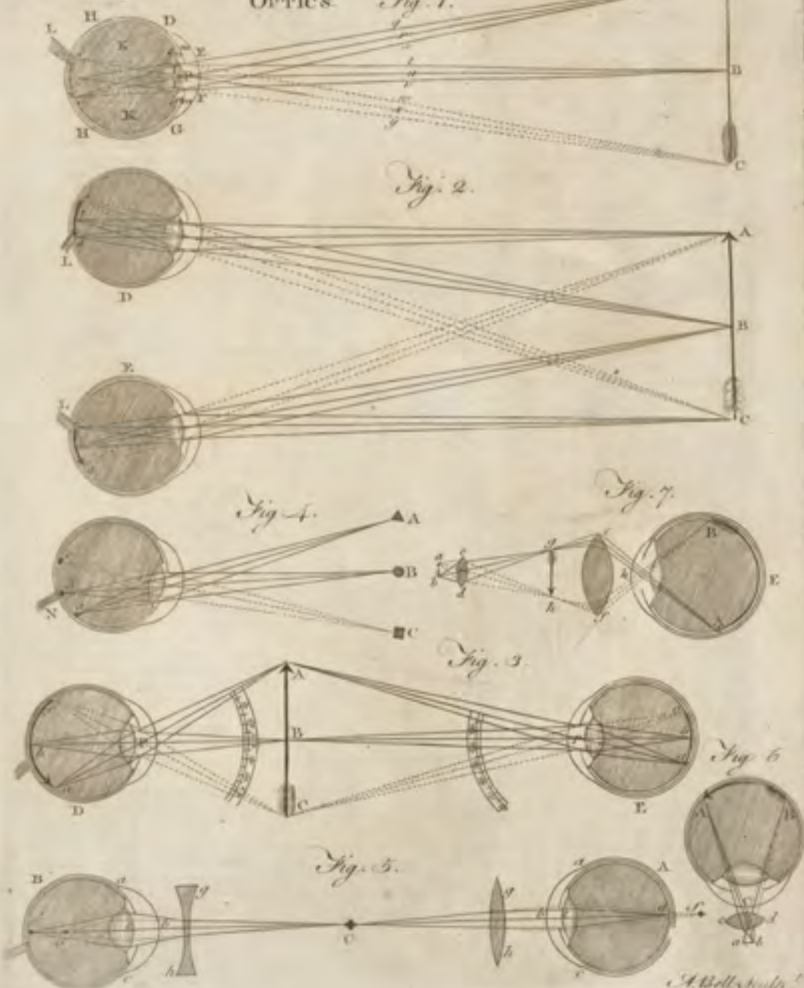
129 Supposition of a repulsive force.

II. It has been thought by some, that it is reflected at the first surface of a body, by a repulsive force equally diffused over it; and at the second, by an attractive force.

1. If



A. Bell Sculpt.



A. Bell Sculp.

Of Reflection.

130 Objected to.

1. If there be a repulsive force diffused over the surface of bodies that repels rays of light at all times, then, since by increasing the obliquity of a ray we diminish its perpendicular force (which is that only, whereby it must make its way through this repulsive force), however weakly that force may be supposed to act, rays of light may be made to fall with so great a degree of obliquity on the reflecting surface, that there shall be a total reflection of them there, and not one particle of light be able to make its way through: which is contrary to observation; the reflection of light at the first surface of a transparent body being never total in any obliquity whatever. The hypothesis therefore in this particular must be false.

131 Attractive force supposed.

2. As to the reflection at the second surface by the attractive force of the body; this may be considered in two respects: first, when the reflection is total; secondly, when it is partial.

And first, in cases where the reflection is total, the cause of it is undoubtedly that same attractive force by which light would be refracted in passing out of the same body. This is manifest from that analogy which is observable between the reflection of light at this second surface, and its refraction there. For otherwise, what can be the reason that the total reflection should begin just when the obliquity of the incident ray, at its arrival at the second surface, is such, that the refracted angle ought to be a right one; or when the ray, were it not to return in reflection, ought to pass on parallel to the surface, without going from it? For in this case it is evident, that it ought to be returned by this very power, and in such manner that the angle of reflection shall be equal to the angle of incidence: just as a stone thrown obliquely from the earth, after it is so far turned out of its course by the attraction of the earth, as to begin to move horizontally, or parallel to the surface of the earth, is then by the same power made to return in a curve similar to that which is described in its departure from the earth, and so falls with the same degree of obliquity that it was thrown with.

But secondly, as to the reflection at the second surface, when it is partial; an attractive force uniformly spread over it, as the maintainers of this hypothesis conceive it to be, can never be the cause thereof. Because it is inconceivable, that the same force, acting in the same circumstances in every respect, can sometimes reflect the violet coloured rays and transmit the red, and at other times reflect the red and transmit the violet.

This argument concludes equally against a repulsive force uniformly diffused over the first surface of a body, and reflecting light there; because some bodies reflect the violet and transmit the red, others reflect the red and transmit the violet, at their first surface; which cannot possibly be upon this supposition, the rays of whichever of these colours we suppose to be the strongest.

132 Another hypothesis.

III. Some, being apprehensive of the insufficiency of a repulsive and attractive force diffused over the surfaces of bodies and acting uniformly, have supposed, that, by the action of light upon the surface of bodies, the matter of these forces is put into an undulatory motion; and that where the surface of it is subsiding light is transmitted, and in those places where it is rising light is reflected. But this seems not to advance us one jot farther; for in those cases, suppose where red is reflected and violet transmitted, how comes it to pass that the red impinges only on those parts when the waves are rising, and the violet when they are subsiding?

133 Sir Isaac Newton's hypothesis.

IV. The next hypothesis that we shall take notice of, is that remarkable one of Sir Isaac Newton's fits of easy reflection and transmission, which we shall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light, in its passage from the luminous body, is disposed to be alternately reflected by and transmitted through any refracting surface it may meet with; that these dispositions (which he calls *fits of easy reflection and easy transmission*) return successively at equal intervals: and that they are communicated to it at its first emission out of the luminous body it proceeds from, probably by some very subtle and elastic substance diffused through the universe, and that in the following manner. As bodies falling into water, or passing through the air, cause undulations in each, so the rays of light may excite vibrations in this elastic substance. The quickness of which vibrations depending on the elasticity of the medium (as the quickness of the vibrations in the air, which propagate sound, depend solely on the elasticity of the air, and not upon the quickness of those in the sounding body) the motion of the particles of it may be quicker than that of the rays: and therefore, when a ray at the instant it impinges upon any surface, is in that part of a vibration of this elastic substance which conspires with its motion, it it may be easily transmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He farther supposes, that when light falls upon the first surface of a body, none is reflected there; but all that happens to it there is, that every ray that is not in a fit of easy transmission is there put into one, so that when they come at the other side (for this elastic substance, easily pervading the pores of bodies, is capable of the same vibrations within the body as without it) the rays of one colour shall be in a fit of easy transmission, and those of another in a fit of easy reflection, according to the thickness of the body, the intervals of the fits being different in rays of a different kind. This very well accounts for the different colours of the bubble and thin plate of air and water, as is obvious enough; and likewise for the reflection of light at the second surface of a thicker body; for the light reflected from thence is also observed to be coloured, and to form rings according to the different thickness of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glass be ground concave on one side and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to pass through a small hole in a piece of paper held in that common centre, and be permitted to fall on the glass; besides those rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings surrounding the hole, not unlike those occasioned by the reflection of light from thin plates.

Of Reflection. The fame will happen if the rays be reflected from a metalline fpeculum, but the light will not be coloured; which fhews, that the colours arife from that light which is reflected from the back-fide, and that in the following manner: Befides that light which is regularly reflected from the farther furface of the glafs, there is fome reflected irregularly, which, paffing from the back furface under the different obliquities, does as it were pafs through glaffes of different thickneffes, and therefore is in part reflected back again when it comes to the firft furface, and is in part tranfmitted through it, the tranfmited light, when received upon the white paper, exhibiting the rings of colours abovementioned.

As to the light which is fuppofed to be reflected at the firft furface, his opinion feems to be, That it is not there reflected, but that it really enters the furface, and is reflected from the back-fide of the firft feries of particles that lie therein: fo that, according as thefe particles are larger or fmaller, the rays of light which at their entrance into them (for they are tranfparent, whether the body they compofe be fo or not) are thereby put into fits of eafy tranfmiffion, at their emerfion at the other fide are fome in a fit of eafy tranfmiffion, others in a fit of eafy reflection, according as the interval of their fits are large or fmall. So that the particles of a body may be of fuch a fize that they fhall reflect the red and tranfmit the violet, or that they may reflect the violet and tranfmit the red; or, in general, that the ftrongeft and moft forcible rays may be tranfmitted while the weaker are reflected; or the weaker may be tranfmitted while the ftronger are reflected.

§. 2. *Of the Laws of Reflection.*

The fundamental law of the reflection of light is, that in all cafes the angle of reflection is equal to the angle of incidence. This is found by experiment to be the cafe, and befides may be demonftrated mathematically from the laws of percuffion in bodies perfectly elaftic. The axiom therefore holds good in every cafe of reflection, whether it be from plain furfaces or fpherical ones, and that whether they are convex or concave; and hence the feven following propofitions relating to the reflection of light from plain and fpherical furfaces may be deduced.

I. Rays of light reflected from a plain furface have the fame degree of inclination to one another that their refpective incident ones have.—For the angle of reflection of each ray being equal to that of its refpective incident one, it is evident, that each reflected ray will have the fame degree of inclination to that portion of the furface from whence it is reflected that its incident one has: but it is here fuppofed, that all thofe portions of furface from whence the rays are reflected, are fituated in the fame plain; confequently the reflected rays will have the fame degree of inclination to each other that their incident ones have, from whatever part of the furface they are reflected.

II. Parallel rays reflected from a concave furface are rendered converging.—To illuftrate this, let AF, CD, EB, (fig. 1.) reprefent three parallel rays falling upon the concave furface FB, whofe centre is C. To the points F and B draw the lines CF, CB; thefe being drawn from the centre, will be perpendicular to the furface at thofe points. The incident ray CD alfo paffing through the centre, will be perpendicular to the furface, and therefore will return after reflection in the fame line; but the oblique rays AF and EB will be reflected into the lines FM and BM, fituated on the contrary fide of their refpective perpendiculars CF and CB. They will therefore proceed converging after reflection towards fome point, as M, in the line CD.

Plate CCXII.

III. Converging rays falling on the like furface, are made to converge more.—For, every thing remaining as above, let GF, HB, be the incident rays. Now, becaufe thefe rays have larger angles of incidence than the parallel ones AF and EB in the foregoing cafe, their angles of reflection will alfo be larger than thofe of the others; they will therefore converge after reflection, fuppofe in the lines FN and BN, having their point of concourfe N farther from the point C than M, that to which the parallel rays AF and EB converged to in the foregoing cafe; and their precife degree of convergency will be greater than that wherein they converged before reflection.

IV. Diverging rays falling upon the like furface, are, after reflection, parallel, diverging, or converging. If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the furface than that, they will diverge, but in a lefs degree than before reflection; if from a point between that and the centre, they will converge after reflection, and that to fome point on the contrary fide of the centre, but fituated farther from it than the point from which they diverged. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other fide of it, but nearer to it than the point they diverged from; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from M, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM, (by Prop. II.) thefe rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the furface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BH, which the incident rays GF and HB defcribed that were fhewn to be reflected into them in the foregoing propofition; but the degree wherein they diverge will be lefs than that wherein they diverged before reflection.

3. Let them proceed diverging from X, a point between the focus of parallel rays and the centre; they then make lefs angles of incidence than the rays MF and MB, which became parallel by reflection: they will confequently have lefs angles of reflection, and proceed therefore converging towards fome point, as Y; which point will always fall on the contrary fide of the centre, becaufe a reflected ray always falls on the contrary fide of the perpendicular with refpect to that on which its incident one falls; and of confequence it will be farther diftant from the centre than X.

4. If the incident ones diverge from Y, they will, after reflection, converge to X; thofe which were the incident rays in the former cafe being the reflected ones

ones in this. And, laftly,

5. If the incident rays proceed from the centre, they fall in with their refpective perpendiculars; and for that reafon are reflected thither again.

V. Parallel rays reflected from a convex furface, are rendered diverging.—For, let AB, GD, EF, (fig. 2.) be three parallel rays falling upon the convex furface BF, whofe centre of convexity is C, and let one of them, viz. GD, be perpendicular to the furface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, becaufe they pafs through the centre, will be perpendicular to the furface at thefe points. The incident ray GD being perpendicular to the furface, will return after reflection in the fame line, but the oblique ones AB and EF in the lines BK and FL fituated on the contrary fide of their refpective perpendiculars BV and FT. They will therefore diverge, after reflection, as from fome point M in the line GD produced; and this point will be in the middle between D and C.

VI. Diverging rays reflected from the like furface, are rendered more diverging.—For, every thing remaining as above, let GB, GF, be the incident rays. Thefe having larger angles of incidence than the parallel ones AB and EF in the preceding cafe, their angles of reflection will alfo be larger than theirs: they will therefore diverge after reflection, fuppofe in the lines BP and FQ, as from fome point N, farther from C than the point M; and the degree wherein they will diverge will be greater than that wherein they diverged before reflection.

VII. Converging rays reflected from the like furface, are parallel, converging, or diverging. If they tend towards the focus of parallel rays, they then become parallel; if to a point nearer the furface than that, they converge, but in a lefs degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from fome point on the contrary fide of the centre, but fituated farther from it than the point they converged to: if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary fide of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will proceed as from thence.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB EF were reflected into the lines BK and FL (by Prop. V.), thofe rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the furface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB GF proceeded that were fhewn to be reflected into them by the laft propofition: but the degree wherein they will converge will be lefs than that wherein they converged before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre; their angles of incidence will then be lefs than thofe of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be lefs; on which account they muft neceffarily diverge, fuppofe in the lines BH and FI, from fome point, as Y; which point, (by Prop. IV.) will fall on the contrary fide of the centre with refpect to X, and will be farther from it than that.

4. If the incident rays tend towards Y, the reflected ones will diverge as from X; thofe which were the incident ones in one cafe, being the reflected ones in the other.

5. Laftly, if the incident rays converge towards the centre, they fall in with their refpective perpendiculars; on which account they proceed after reflection as from the centre.

We have already obferved, that in fome cafes there is a very great reflection from the fecond furface of a tranfparent body. The degree of inclination neceffary to caufe a total reflection of a ray at the fecond furface of a medium, is that which requires that the refracted angle (fuppofing the ray to pafs out there) fhould be equal to or greater than a right one; and confequently it depends on the refractive power of the medium through which the ray paffes, and is therefore different in different media. When a ray paffes through glafs furrounded with air, and is inclined to its fecond furface under an angle of 42 degrees or more, it will be wholly reflected there. For, as 11 is to 17, (the ratio of refraction out of glafs into air), fo is the fine of an angle of 42 degrees to a fourth number, that will exceed the fine of a right angle. From hence it follows, that when a ray of light arrives at the fecond furface of a tranfparent fubftance with as great, or a greater degree of obliquity, than that which is neceffary to make a total reflection, it will there be all returned back to the firft; and if it proceeds towards that with as great an obliquity as it did towards the other, (which it will do if the furfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but pafs from fide to fide, till it be wholly fuffocated and loft within the body.—From hence may arife an obvious inquiry, how it comes to pafs, that light falling very obliquely upon a glafs widow from without, fhould be tranfmitted into the room? In anfwer to this it muft be confidered, that however obliquely a ray falls upon the furface of any medium whofe fides are parallel, (as thofe of the glafs in a window are), it will fuffer fuch a degree of refraction in entering there, that it fhall fall upon the fecond with a lefs obliquity than that which is neceffary to caufe a total reflection. For inftance, let the medium be glafs, as fuppofed in the prefent cafe; then, as 17 is to 11, (the ratio of refraction out of air into glafs), fo is the fine of the largeft angle of incidence with which a ray can fall upon any furface to the fine of a lefs angle than that of total reflection. And therefore, if the fides of the glafs be parallel, the obliquity with which a ray falls upon the firft furface, cannot be fo great, but that it fhall pafs the fecond without fuffering a total reflecton there.

When light paffes out of a denfer into a rarer medium, the nearer the fecond medium approaches the firft in denfity (or more properly in its refractive power), the lefs of it will be refracted in paffing from one to the other; and when their refracting powers are equal,

Of Reflection.

equal, all of it will paſs into the ſecond medium.

The above propoſitions may be all mathematically demonſtrated in the following manner.

Prop. I. Of the reflection of rays from a plain ſurface.

" When rays fall upon a plain ſurface, if they diverge, the focus of the reflected rays will be at the ſame diſtance behind the ſurface, that the radiant point is before it: if they converge, it will be at the ſame diſtance before the ſurface, that the imaginary focus of the incident rays is behind it."

This propoſition admits of two caſes.

Case 1. Of diverging rays.

Plate CCXII.

Dem. Let AB, AC, (fig. 3.) be two diverging rays incident on the plain ſurface DE, the one perpendicularly, the other obliquely: the perpendicular one AB will be reflected to A, proceeding as from ſome point in the line AB produced; the oblique one AC will be reflected into ſome line as CF, ſuch that the point G, where the line FG produced interſects the line AB produced alſo, ſhall be at an equal diſtance from the ſurface DE with the radiant A. For the perpendicular CH being drawn, ACH and HCF will be the angles of incidence and reflection; which being equal, their complements ACB and FCE are ſo too: but the angle BCG is equal to FCE, as being vertical to it: therefore in the triangles ABC and GBC the angles at C are equal, the ſide BC is common, and the angles at B are alſo equal to each other, as being right ones; therefore the lines AB and BG, which reſpect the equal angles at C, are alſo equal; and conſequently the point G, the focus of the incidents rays AB, AC, is at the ſame diſtance behind the ſurface, that the point A is before it. *Q. E. D.*

Case 2. Of converging rays.

This is the converſe of the former caſe. For ſuppoſing FC and AB to be two converging incident rays, CA and BA will be the reflected ones (the angles of incidence in the former caſe being now the angles of reflection, and *vice verſa*), having the point A from their focus; but this, from what was demonſtrated above, is at an equal diſtance from the reflecting ſurface with the point G, which in this caſe is the imaginary focus of the incident rays, FC, and AB.

Obs. It is not here, as in the refraction of rays in paſſing through a plain ſurface, where ſome of the refracted rays proceed as from one point, and ſome as from another: but they all proceed after reflection as from one and the ſame point, however obliquely they may fall upon the ſurface; for what is here demonſtrated of the ray AC holds equally of any other, as AI, AK, &c.

The caſe of parallel rays incident on a plain ſurface, is included in this propoſition: for in that caſe we are to ſuppoſe the radiant to be at an infinite diſtance from the ſurface, and then by the propoſition the focus of the reflected rays will be ſo too; that is, the rays will be parallel after reflection, as they were before.

Prop. II. Of the reflection of parallel rays from a ſpherical ſurface.

" When parallel rays are incident upon a ſpherical ſurface, the focus of the reflected rays will be the middle point between the centre of convexity and the ſurface."

This propoſition admits of two caſes.

Case 1. Of parallel rays falling upon a convex ſurface.

Dem. Let AB, DH, (fig. 4.) repreſent two parallel rays incident on the convex ſurface BH, the one perpendicularly, the other obliquely; and let C be the centre of convexity; ſuppoſe HE to be the reflected ray of the oblique incident one DH proceeding as from F, a point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the ſurface at that point; and the angles DHI and IHF, being the angles of incidence and reflection, will be equal. To the former of theſe, the angle HCF is equal, the lines AC and DH being parallel, and to the latter the angle CAF as being vertical; wherefore the triangle CFH is iſoſceles, and conſequently the ſides CF and FH are equal: but ſuppoſing BH to vaniſh, FH is equal to FB; and therefore upon this ſuppoſition FC and FB are equal, that is, the focus of the reflected rays is the middle point between the centre of convexity and the ſurface. *Q. E. D.*

Case 2. Of parallel rays falling upon a concave ſurface.

Dem. Let AB, DH (fig. 5.) be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave ſurface BH, whoſe centre of concavity is C. Let BF and HF be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CH, the angles DHC and FHC, being the angles of incidence and reflection, will be equal, to the former of which the angle HCF is equal, as alternate; and therefore the triangle CFH is iſoſceles. Wherefore CF and FH are equal: but if we ſuppoſe BH to vaniſh, FB and FH are alſo equal, and therefore CF is equal to FB; that is, the focal diſtance of the reflected rays is the middle point between the centre and the ſurface. *Q. E. D.*

Obs. It is here obſervable, that the farther the line DH, either in fig. 4. or 5. is taken from AB, the nearer the point F falls to the ſurface. For the farther the point H recedes from B, the larger the triangle CFH will become; and conſequently, ſince it is always an iſoſceles one, and the baſe CH, being the radius, is every where of the ſame length, the equal legs CF and FH will lengthen; but CF cannot grow longer unleſs the point F approach towards the ſurface. And the farther H is removed from B, the faſter F approaches to it.

This is the reaſon, that whenever parallel rays are conſidered as reflected from a ſpherical ſurface, the diſtance of the oblique one from the perpendicular one is taken ſo ſmall with reſpect to the focal diſtance of that ſurface, that without any phyſical error it may be ſuppoſed to vaniſh.

From hence it follows, that if a number of parallel rays, as AB, CD, EG, &c. fall upon a convex ſurface, (as fig. 6.) and if BA, DK, the reflected rays of the incident ones AB, CD, proceed as from the point F, thoſe of the incident ones CD, EG, viz. DK, GL, will proceed as from N, thoſe of the incident ones EG, HI, as from O, &c. becauſe the farther the incident ones CD, EG, &c. are from AB, the nearer to the ſurface are the points F, *f*, *f*, in the line BF, from which they proceed after reflection; ſo that properly the foci of the reflected rays BA, DK, GL, &c. are not

not in the line AB produced, but in a curve line passing thro' the points F, N, O, &c.

The same is applicable to the case of parallel rays reflected from a concave surface, as expressed by the pricked lines on the other half of the figure, where PQ, RS, TV, are the incident rays; QF, S*f*, V*f*, the reflected ones, intersecting each other in the points X, Y, and F; so that the foci of those rays are not in the line FB, but in a curve passing through those points.

Plate CCXII.

Had the surface BH in fig. 4. or 5. been formed by the revolution of a parabola about its axis having its focus in the point F, all the rays reflected from the convex surface would have proceeded as from the point F, and those reflected from the concave would have fallen upon it, however distant their incident ones AB, DH, might have been from each other. For in the parabola, all lines drawn parallel to the axis make angles with the tangents to the points where they cut the parabola (that is, with the surface of the parabola) equal to those which are made with the same tangents by lines drawn from thence to the focus; therefore, if the incident rays describe those parallel lines, the reflected ones will necessarily describe these other, and so will all proceed as from, or meet in, the same point.

Prop. III. Of the reflection of diverging and converging rays from a spherical surface.

" When rays fall upon any spherical surface, if they diverge, the distance of the focus of the reflected rays from the surface is to the distance of the radiant point from the same (or, if they converge, to that of the imaginary focus of the incident rays), as the distance of the focus of the reflected rays from the centre is to the distance of the radiant point (or imaginary focus of the incident rays) from the same."

This proposition admits of ten cases.

Case 1. Of diverging rays falling upon a convex surface.

Dem. Let RB, RD (fig. 7.) represent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex surface BD, whose centre is C. Let DE be the reflected ray of the incident one RD, produce ED to F, and through R draw the line RH parallel to FE till it meets CD produced in H. Then will the angle RHD be equal to EDH the angle of reflection, as being alternate to it, and therefore equal also to RDH which is the angle of incidence; wherefore the triangle DRH is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar, (or to express it in Euclid's way, the sides of the triangle RHC are cut proportionably, 2 Elem. 6.): and therefore FD is to RH, or its equal RD, as CF to CR; but BD vanishing, FD and RD differ not from FB and RB: wherefore FB is to RB also, as CF to CR; that is, the distance of the focus from the surface is to the distance of the radiant point from the same, as the distance of the focus from the centre is to the distance of the radiant from thence. *Q. E. D.*

Case 2. Of converging rays falling upon a concave surface.

Dem. Let KD and CB be the converging incident rays having their imaginary focus in the point R, which was the radiant in the foregoing case. Then as RD was in that case reflected into DE, KD will in this be reflected into DF; for, since the angles of incidence in both cases are equal, as they are by being vertical, the angles of reflection will be so too; so that F will be the focus of the reflected rays: but it was there demonstrated, that FB is to RB as CF to CR; that is, the distance of the focus from the surface is to the distance (in this Case) of the imaginary focus of the incident rays, as the distance of the focus from the centre is the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

Case 3. Of converging rays falling upon a convex surface, and tending to a point between the focus of parallel rays and the centre.

Dem. Let BD (fig. 8.) represent a convex surface whose centre is C, and whose focus of parallel rays is P; and let AB, KD, be two converging rays incident upon it, and having their imaginary focus at R, a point between P and C. Now because KD tends to a point between the focus of parallel rays and the centre, the reflected ray DE will diverge from some point on the other side the centre, suppose F; as explained above (p. 5547.) under prop. 7. Through D draw the perpendicular CD, and produce it to H; then will KDH and HDE be the angles of incidence and reflection, which being equal, their vertical ones RDC and CDF will be so too, and therefore the vertex of the triangle RDF is bisected by the line DC: wherefore (3 El. 6.) FD and DR or BD vanishing, FB and BR are to each other as FC to CR; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

Case 4. Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the centre.

Dem. Let RB, RD, be the diverging rays incident upon the concave surface BD, having their radiant point in the point R, the imaginary focus of the incident rays in the foregoing case. Then as KD was in that case reflected into DE, RD will now be reflected into DF. But it was there demonstrated, that FB and RB are to each other, as CF to CR; that is, the distance of the focus is to that of the radiant, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

The angles of incidence and reflection being equal, it is evident, that if, in any case, the reflected ray be made the incident one, the incident will become the reflected one: and therefore the four following cases may be considered respectively as the converse of the four foregoing; for in each of them the incident rays are supposed to coincide with the reflected ones in the other. Or they may be demonstrated independently of them as follows.

Case 5. Of converging rays falling upon a convex surface, and tending to a point nearer the surface than the focus of parallel rays.

Dem. Let ED, RB (fig. 7.) be the converging rays incident upon the convex surface BD whose centre

tre is C, and focus of parallel rays is at P; and let the imaginary focus of the incident rays be at F, a point between P and B; and let DR be the reflected ray. From C and R draw the lines CH, RH, the one passing through D, the other parallel to FE. Then will the angle RHD be equal to HDE the angle of incidence, as alternate to it; and therefore equal to HDR, the angle of reflection: wherefore the triangle HDR is isosceles, and consequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are similar; and therefore RH, or RD, is to FD as CR to CF: but BD vanishing, RD and FD coincide with RB and FB, wherefore RB is to FB as CR to CF; that is, the distance of the focus from the surface is to the distance of the imaginary focus of the incident rays, as the distance of the focus from the centre is to the distance of the imaginary focus of the incident rays from the same. *Q. E. D.*

Case 6. Of diverging rays falling upon a concave surface, and proceeding from a point between the focus of parallel rays and the surface.

Dem. Let FD and FB represent two diverging rays flowing from the point F as a radiant, which was the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DR, FD will be reflected into DK, (for the reason mentioned in Case the second), so that the reflected ray will proceed as from the point R: but it was demonstrated in the case immediately foregoing, that RB is to FB as CR to CF; that is, the distance of the focus from the surface is to that of the radiant from the same, as the distance of the former from the centre is to that of the latter from the same. *Q. E. D.*

Case 7. Of converging rays falling upon a convex surface, and tending towards a point beyond the centre.

Plate CCXII.

Dem. Let AB, ED, (fig. 8.) be the incident rays tending to F, a point beyond the centre C, and let DK be the reflected ray of the incident one ED. Then because the incident ray ED tends to a point beyond the centre, the reflected ray DK will proceed as from one on the contrary side, suppose R; as explained above under Prop. VII. Through D draw the perpendicular CD, and produce it to H. Then will EDH and HDK be the angles of incidence and reflection; which being equal, their vertical ones CDF and CDR will be so too: consequently the vertex of the triangle FDR is bisected by the line CD: wherefore, RD is to DF, or (3 Elem. 6.) BD vanishing, RB is to BF as RC to CF; that is, the distance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the distance of the former from the centre is to the distance of the latter from the same. *Q. E. D.*

Case 8. Of diverging rays falling upon a concave surface, and proceeding from a point beyond the centre.

Dem. Let FB, FD, be the incident rays having their radiant in F, the imaginary focus of the incident rays in the foregoing case. Then as ED was in that case reflected into DK, FD will now be reflected into DR; so that R will be the focus of the reflected rays. But it was demonstrated in the foregoing case, that RB is to FB as RC to CF; that is, the distance of the focus of the reflected rays from the surface is to the distance of the radiant from the same, as the distance of the focus of the reflected rays from the centre is to the distance of the radiant from thence. *Q. E. D.*

The two remaining cases may be considered as the converse of those under Prop. II. (p. 5548.), because the incident rays in these are the reflected ones in them; or they may be demonstrated in the same manner with the foregoing, as follows.

Case 9. Converging rays falling upon a convex surface, and tending to the surface of parallel rays, become parallel after reflection.

Dem. Let ED, RB, (fig. 7.) represent two converging rays incident on the convex surface BD, and tending towards F, which we will now suppose to be the focus of parallel rays; and let DR be the reflected ray, and C the centre of convexity of the reflecting surface. Through C draw the line CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonstrated (Case 5.) where the incident rays are supposed to tend to the point F, that RB is to FB as RC to CF; but F in this Case being supposed to be the focus of parallel rays, it is the middle point between C and B (by proposition 2d), and therefore FB and FC are equal; and consequently the two other terms in the proportion, viz. RB and RC, must be so too; which can only be upon a supposition that R is at an infinite distance from B; that is, that the reflected rays BR and DR be parallel. *Q. E. D.*

Case 10. Diverging rays falling upon a concave surface, and proceeding from the focus of parallel rays, become parallel after reflection.

Dem. Let RD, RB (fig. 8.) be two diverging rays incident upon the concave surface BD, as supposed in Case 4.; where it was demonstrated that FB is to RB as CF to CR. But in the present case RB and CR are equal, because R is supposed to be the focus of parallel rays; therefore FB and FC are so too. Which cannot be unless F be taken at an infinite distance from B; that is, unless the reflected rays BF and DF be parallel. *Q. E. D.*

Obs. It is here observable, that in the case of diverging rays falling upon a convex surface, (see fig. 7.) the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant R remains the same. For it is evident from the curvature of a circle, that the point D (fig. 9.) may be taken so far from B, that the reflected ray DE shall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the faster the point from which it proceeds, approaches towards R: as will easily appear if we draw several incident rays with their respective reflected ones, in such manner that the angles of reflection may be all equal to their respective angles of incidence, as is done in the figure. The like is applicable to any of the other cases of diverging or converging rays incident upon a spherical surface. This is the reason, that when rays are considered as reflected from a spherical surface, the distance of the oblique rays from the perpendicular one is taken so small, that it may be supposed to vanish.

From

Of Reflection. From hence it follows, that if a number of diverging rays are incident upon the convex ſurface BD at the ſeveral points B, D, D, &c. they ſhall not proceed after reflection as from any point in the line RB produced, but as from a curve line paſſing thro' the ſeveral points F, *f*, *f*, &c. The ſame is applicable in all the other caſes.

Plate CCXII. Had the curvature BD (fig. 7.) been hyperbolical, having its foci in R and F; then R being the radiant, (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and *vice verſa*, however diſtant the points B and D might be taken from each other. In like manner, had the curve BD (fig. 8.) been elliptical, having its foci in F and R, the one of theſe being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and *vice verſa*. For both in the hyperbola and ellipſis, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other. So that, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting ſurface muſt be formed by the revolution of an hyperbola about its longer axis, when the incident rays are ſuch, that their radiant, or imaginary focus of incident rays, ſhall fall on one ſide the ſurface, and the focus of the reflected ones on the other: when they are both to fall on the ſame ſide, it muſt be formed by the revolution of an ellipſis about its longer axis. However, upon account of the great facility with which ſpherical ſurfaces are formed in compariſon of that with which ſurfaces formed by the revolution of any of the conic ſections about their axes are made, the latter are very rarely uſed. Add to this another inconvenience, *viz.* that the foci of theſe curves being mathematical points, it is but one point of the ſurface of an object that can be placed in any of them at a time, ſo that it is only in theory that ſurfaces formed by the revolution of theſe curves about their axes render reflection perfect.

Now, becauſe the focal diſtance of rays reflected from a ſpherical ſurface cannot be found by the analogy laid down in the third propoſition, without making uſe of the quantity ſought; we ſhall here give an inſtance whereby the method of doing it in all others will readily appear.

Prob. Let it be required to find the focal diſtance of diverging rays incident upon a convex ſurface, whoſe radius of convexity is 5 parts, and the diſtance of the radiant from the ſurface is 20.

Sol. Call the focal diſtance ſought x; then will the diſtance of the focus from the centre be $5-x$, and that of the radiant from the ſame 25: therefore by prop. 3. we have the following proportion, *viz.* $x : 20 :: 5-x : 25$; and multiplying extremes together and means together, we have $25x = 100-20x$, which, after due reduction, gives $x=\frac{100}{45}$.

If in any caſe it ſhould happen that the value of x ſhould be a negative quantity, the focal point muſt then be taken on the contrary ſide the ſurface to that on which it was ſuppoſed that it would fall in ſtating the problem.

If letters inſtead of figures had been made uſe of in the foregoing ſolution, a general theorem might have been raiſed, to have determined the focal diſtance of reflected rays in all caſes whatever. See this done in Suppl. to *Gregory's Optics*, 2d edit. p. 112. Of Reflection.

Becauſe it was, in the preceding ſection, obſerved, that different incident rays, though tending to or from one point, would after refraction proceed to or from different points, a method was there inſerted of determining the diſtinct point, which each ſeparate ray entering a ſpherical ſurface converges to, or diverges from, after refraction: the ſame has been obſerved here with regard to rays reflected from a ſpherical ſurface, (ſee obſ. in caſe 2. and caſe 10.) But the method of determining the diſtinct point to or from which any given incident ray proceeds after reflection, is much more ſimple. It is only neceſſary to draw the reflected ray ſuch, that the angle of reflection may be equal to the angle of incidence, which will determine the point it proceeds to or from in any caſe whatever.

§ 3. *Of the Appearance of Bodies ſeen by Light reflected from plane and ſpherical Surfaces.*

Whatever hath been ſaid concerning the appearance of bodies ſeen by refracted light through lenſes, reſpects alſo the appearance of bodies ſeen by reflection. But beſides theſe, there is one thing peculiar to images by reflection, *viz.* that each point in the repreſentation of an object made by reflection appears ſituated ſomewhere in an infinite right line that paſſes through its correſpondent point in the object, and is perpendicular to the reflecting ſurface.

The truth of this appears ſufficiently from the propoſitions formerly laid down; in each of which, rays flowing from any radiant point, are ſhewn to proceed, after reflection, to or from ſome point in a line that paſſes through the ſaid radiant, and is perpendicular to the reflecting ſurface. For inſtance, (fig. 1.) rays Plate CCXII.
flowing from Y are collected in X, a point in the perpendicular CD, which, being produced, paſſes through Y; again, (fig. 2.) rays flowing from from G, proceed, after reflection, as from N, a point in the perpendicular CD, which, being produced, paſſes thro' G; and ſo of the reſt.

This obſervation, however, except where an object is ſeen by reflection from a plain ſurface, relates only to thoſe caſes where the repreſentation is made by means of ſuch rays as fall upon the reflecting ſurface with a very ſmall degree of obliquity; becauſe ſuch as fall at a conſiderable diſtance from the perpendicular, proceed not after reflection as from any point in that perpendicular, but as from other points ſituated in a certain curve, as hath already been explained; upon which account theſe rays are neglected, as making a confuſed and deformed repreſentation. And therefore it is to be remembered, that however the ſituation of the eye with reſpect to the object and reflecting ſurface may be repreſented in the following figures, it is to be ſuppoſed as ſituated in ſuch a manner with reſpect to the object, that rays flowing from thence and entering it after reflection, may be ſuch only as fall with a very ſmall degree of obliquity upon the ſurface; that is, the eye muſt be ſuppoſed to be placed almoſt directly behind the object, or between it and the reflecting ſurface. The reaſon why it is not always ſo placed, is only to avoid confuſion in the figures.

I. When an object is seen by reflection from a plane surface, the image of it appears at the same distance behind the surface that the object is placed before it, of the same magnitude therewith, and directly opposite to it.

Plate CCXII.

To explain this, let AB (fig. 10.) represent an object seen by reflection from the plain surface SV; and let the rays AF, AG, be so inclined to the surface, that they shall enter an eye at H after reflection; and let AE be perpendicular to the surface: then, by the observation just mentioned, the point A will appear in some part of the line AE produced; suppose I, that is, the oblique rays AF and AG will proceed after reflection as from that point; and further, because the reflected rays FH, GK, will have the same degree of inclination to one another that their incident ones have, that point must necessarily be at the same distance from the surface that the point A is; the representation therefore of the point A, will be at the same distance behind the surface that the point itself is before it, and directly opposite to it: consequently, since the like may be shewn of the point B, or of any other, the whole image IM will appear at the same distance behind the surface that the object is before it, and directly opposite to it; and because the lines AI, BM, which are perpendicular to the plain surface, are for that reason parallel to each other, it will also be of the same magnitude therewith.

II. When an object is seen by reflection from a convex surface, its image appears nearer to the surface, and less than the object.

Let AB (fig. 12.) represent the object, SV a reflecting surface whose centre of convexity is C: and let the rays AF, AG, be so inclined to the surface, that after reflection thereat they shall enter the eye at H: and let AE be perpendicular to the surface: then will the oblique rays AF, AG, proceed after reflection as from some point in the line AE produced, suppose from I; which point, because the reflected rays will diverge more than the incident ones, must be nearer to the surface than the point A. And since the same is also true of the rays which flow from B, or any other point, the representation IM will be nearer to the surface than the object; and because it is terminated by the perpendiculars AE and BF which incline to each other, as concuring at the centre, it will also appear less.

III. When an object is seen by reflection from a concave surface, the representation of it is various, both with regard to its magnitude and situation, according as the distance of the object from the reflecting surface is greater or less.

1. When the object is nearer to the surface than its focus of parallel rays, the image falls on the opposite side of the surface, is more distant from it, and larger than the object.

Thus, let AB (fig. 13.) be the object, SV the reflecting surface, F the focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the line CE, CR, which will be perpendicular to the surface; and let the rays AR, AG, be incident upon such points of it that they shall be reflected into an eye at H. Now, because the radiant points A and B are nearer the surface than F the focus of parallel rays, the reflected rays will diverge, and will therefore proceed as from some points on the opposite side the surface; which points, by the observation laid down at the beginning of this section, will be in the perpendiculars AE, BR, produced, suppose in I and M: but they will diverge in a less degree than their incident ones (see the proposition just referred to), and therefore the said points will be farther from the surface than the points A and B. The image therefore will be on the opposite side of the surface with respect to the object; it will be more distant than it; and consequently, being terminated by the perpendiculars CI and CM, it will also be larger.

2. When the object is placed in the focus of parallel rays, the reflected rays enter the eye parallel, in which case the image ought to appear at an infinite distance behind the reflecting surface; but the representation of it, for the like reasons that were given in the foregoing case, being large and distinct, we judge it not much farther from the surface than the image.

3. When the object is placed between the focus of parallel rays and the centre, the image falls on the opposite side the centre, is larger than the object, and in an inverted position.

Thus let AB (fig. 14.) represent the object, SV the reflecting surface, F its focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE and CN, which will be perpendicular to the surface; and let AR, AG, be a pencil of rays flowing from A. These rays proceeding from a point beyond the focus of parallel rays will after reflection converge towards some point on the opposite side the centre, which will fall upon the perpendicular EC produced, but at a greater distance from C than the radiant A from which they diverged. For the same reason, rays flowing from B will converge to a point in the perpendicular NC produced, which shall be farther from C than the point B; from whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary side the centre, and that their positions are inverted with respect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre, and the focus of parallel rays is less than the object, and its position is inverted.

The proposition is the converse of the foregoing: for as in that case rays proceeding from A were reflected to I, and from B to M; so rays flowing from I and M will be reflected to A and B; if therefore an object be supposed to be situated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be less than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting surface, the object and its image will be coincident; but the image will be inverted with respect to the object.

That the place of the image and the object should be the same in this case needs little explication; for the middle of the object being in the centre, rays flowing from thence will fall perpendicularly upon the surface, and therefore necessarily return thither again; so that the middle of the image will be coincident with the

Of Reflection.

the middle of the object. But that the image should be inverted is perhaps not so clear. To explain this, let AB (fig. 15.) be the object, having its middle point C in the centre of the reflecting surface SV; through the centre and the point R draw the line CR, which will be perpendicular to the reflecting surface; join the points AR and BR, and let AR represent a ray flowing from A; this will be reflected into RB: for C being the middle point between A and B, the angles ARC and CRB are equal; and a ray from B will likewise be reflected to A; and therefore the position of the image will be inverted with respect to that of the object.

In this proposition it is to be supposed that the object AB is so situated with respect to the reflecting surface, that the angle ACR may be right; for otherwise the angles ARC and BRC will not be equal, and part of the image will therefore fall upon the object and part off.

6. If in any of the three last cases, in each of which the image is formed on the same side the reflecting surface with the object, the eye be situated farther from the surface than the place where the image falls, the rays of each pencil, crossing each other in the several points of the image, will enter the eye as from a real object situated there; so that the image will appear pendulous in the air between the eye and the reflecting surface, and in the position wherein it is formed, viz. inverted with respect to the object in the same manner that an image formed by refracted light appears to an eye placed beyond it; which was fully explained under Prop. IV. (p. 5543.) and therefore needs not be repeated here.

But as to what relates to the appearance of the object when the eye is placed nearer to the surface than the image, that was not there fully inquired into. That point shall therefore now be more strictly examined under the following case, which equally relates to refracted and reflected light.

7. If the eye be situated between the reflecting surface and the place of the image, the object is then seen beyond the surface; and the farther the eye recedes from the surface towards the place of the image, the more confused, larger, and nearer the object appears.

Plate CCXII.

To explain this, let AB (fig. 16.) represent the object; IM its image, one of whose points M is formed by the concurrence of the reflected rays DM, EM, &c. which before reflection came from B; the other, I, by the concurrence of DI, EI, &c. which came from A: and let ab be the pupil of an eye, situated between the surface DP and the image. This pupil will admit the rays Ha, Kb; which, because they are tending towards I, are such as came from A, and therefore the point A will appear diffused over the space RS. In like manner the pupil will also receive into it the reflected rays Ka and Lb, which, because they are tending towards M, by supposition came from B; and therefore the point B will be seen spread as it were over the space TV, and the object will seem to fill the space RV; but the representation of it will be confused, because the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for instance, the appearance of that point in the object, whose representation falls upon c in the image, will fill the space mn; and so of the rest. Now if the same pupil be removed into the situation ef, the reflected rays Ee and Gf will then enter the eye, and therefore one extremity of the object will appear to cover the space XY; and because the rays Of and Le will also enter it in their progress towards M, the point B, from whence they came, will appear to cover ZV; the object therefore will appear larger and more confused than before. And when the eye recedes quite to the image, it sees but one single point of the object, and that appears diffused all over the reflecting surface: for instance, if the eye recedes to the point M, then rays flowing from the point B enter it upon whatever part of the surface they fall; and so for the rest. The object also appears nearer to the surface, the farther the eye recedes from it towards the place of the image; probably because, as the appearance of the object becomes more and more confused, its place is not so easily distinguished from that of the reflecting surface itself, till at last when it is quite confused (as it is when the eye is arrived at M) they both appear as one, the surface assuming the colour of the object.

As to the precise apparent magnitude of an object seen after this manner, it is such that the angle it appears under shall be equal to that which the image of the same object would appear under were we to suppose it seen from the same place: that is, the apparent object (for such we must call it to distinguish it from the image of the same object) and the image subtend equal angles at the eye.

Dem. Here we must suppose the pupil of the eye to be a point only, because the magnitude of that causes small alteration in the apparent magnitude of the object; as we shall see by and by. Let then the point a represent the pupil, then will the extreme rays that can enter it be Ha and Ka; the object therefore will appear under the angle HaK, which is equal to its vertical one MaI, under which the image IM would appear were it to be seen from a. Again, if the eye be placed in f, the object appears under the angle GfO equal to IfM, which the image subtends at the same place, and therefore the apparent object and image of it subtend equal angles at the eye. *Q. E. D.*

Now if we suppose the pupil to have any sensible magnitude, such, suppose, that its diameter may be ab; then the object seen by the eye in that situation will appear under the angle HxL, which is larger than the angle HaK, under which it appeared before; because the angle at x is nearer than the angle at a, to the line IM, which is a subtense common to them both.

From this proposition it follows, that, were the eye close to the surface at K, the real and apparent object would be seen under equal angles (for the real object appears from that place under the same angle that the image does, as will be shewn at the end of this section): therefore, when the eye is nearer to the image than that point, the image will subtend a larger angle at it than the object does; and consequently, since the image and apparent object subtend equal angles at the eye, the apparent object must necessarily be seen under a larger angle than the object itself, where-

Of Reflection.

wherever the eye be placed, between the furface and the image.

As each point in the reprefentation of an object made by reflection is fituated fomewhere in a right line that paffes through its correfpondent point in the object, and is perpendicular to the reflecting furface, as was fhewn in the beginning of this fection; we may from hence deduce a moft eafy and expeditious method of determining both the magnitude and fituation of the image in all cafes whatever. Thus,

Plate CCXII.

Through the extremities of the object AB and the centre C, (fig. 17, 18, or 19.) draw the lines AC BC, and produce them as the cafe requires; thefe lines will be perpendicular to the reflecting furface, and therefore the extremities of the image will fall upon them. Through F the middle point of the object and the centre, draw the line FC, and produce it till it paffes through the reflecting furface; this will alfo be perpendicular to the furface. Through G, the point where this line cuts the furface, draw the lines AG and BG, and produce them this way or that, till they crofs the former perpendiculars; and where they crofs, there I and M the extremities of the image will fall. For fuppofing AG to be a ray proceeding from the point A and falling upon G, it will be reflected to B; becaufe FA is equal to FB, and FG is perpendicular to the reflecting furface; and therefore the reprefention of the point A will be in BG produced as well as in AC; confequently it will fall on the point I, where they crofs each other. Likewife the ray BG will for the fame reafon be reflected to A; and therefore the reprefentation of the point B will be in AG produced as well as in fome part of BC, that is, in M where they crofs. From whence the propofition is clear.

If it happens that the lines will not crofs which way foever they are produced, as in fig. 20. then is the object in the focus of parallel rays of that furface, and has no image formed in any place whatever. For in this cafe the rays AH, AG, flowing from the point A, become parallel after reflection in the lines HC, GB, and therefore do not flow as to or from any point: in like manner, rays flowing from B are reflected into the parallel lines KB and GA; fo that no reprefentation can be formed by fuch reflection.

From hence we learn another circumftance relating to the magnitude of the image made by reflection; viz. that it fubtends the fame angle at the vertex of the reflecting furface that the object does. This appears by infpection of the 17th, 18th, or 19th figure, in each of which the angle IGM, which the image fubtends at G the vertex of the reflecting furface, is equal to the angle AGB, which the object fubtends at the fame place; for in the two firft of thofe figures they are vertical, in the third they are the fame. And,

Farther, the angle ICM, which the image fubtends at the centre, is alfo equal to the angle ACB which the object fubtends at the fame place; for in the two firft figures they are the fame, in the laft they are vertical to each other.

From whence it is evident, that the object and its image are to each other in diameter, either as their refpective diftances from the vertex of the reflecting furface, or as their diftances from the centre of the fame.

Different Refrangibility of Light.

IV. As objects are multiplied by being feen thro' tranfparent media, whofe furfaces are properly difpofed, fo they may alfo by reflecting furfaces. Thus,

1. If two reflecting furfaces be difpofed at right angles, as the furfaces AB, BC, (fig. 21.), an object at D may be feen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the firft at G, the fecond at H, in the line EH produced; and alfo, after one reflection made at A, in the line EA produced.

2. If the furfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus, it may be feen in the line FG produced, after one reflection at G; in the line FH produced, after two reflections, the firft at I, the fecond at H; and alfo in FP produced, after feveral fucceffive reflections of the ray EL, at the points L, M, N, O, and P: and fo on *in infinitum*. But the greater the number of reflections are, the weaker the reprefentation will be.

Sect. IV. *Of the different Refrangibility of Light.*

As this property of light folves a great number of the phenomena which could not be underftood by former opticians, we fhall give an account of it in the words of Sir Ifaac Newton, who firft difcovered it; efpecially as his account is much more full, clear, and perfpicuous, than thofe of fucceeding writers.

Plate CCXI. fig. 9.

"In a very dark chamber, at a round hole F, about one third of an inch broad, made in the fhut of a window, I placed a glafs prifm ABC, whereby the beam of the fun's light, SF, which came in at that hole, might be refracted upwards, toward the oppofite wall of the chamber, and there form a coloured image of the fun, reprefented at PT. The axis of the prifm, (that is, the line paffing thro' the middle of the prifm, from one end of it to the other end, parallel to the edge of the refracting angle) was in this and the following experiments perpendicular to the incident rays. About this axis I turned the prifm flowly, and faw the refracted light on the wall, or coloured image of the fun, firft to defcend, and then to afcend. Between the defcent and afcent when the image feemed ftationary, I ftopped the prifm and fixed it in that pofture.

"Then I let the refracted light fall perpedicularly upon a fheet of white paper, MN, placed at the oppofite wall of the chamber, and obferved the figure and dimenfions of the folar image, PT, formed on the paper by that light. This image was oblong and not oval, but terminated by two rectilinear and parallel fides and two femicircular ends. On its fides it was bounded pretty diftinctly; but on its ends very confufedly and indiftinctly, the light there decaying and vanifhing by degrees. At the diftance of 18½ feet from the prifm the breadth of the image was about 2⅛ inches, but its length was about 10¼ inches, and the length of its rectilinear fides about eight inches; and ACB, the refracting angle of the prifm, whereby fo great a length was made, was 64 degrees. With a lefs angle the length of the image was lefs, the breadth remaining the fame. It is farther to be obferved, that the rays went on in ftraight lines from the prifm to the image, and

Different Refrangibility of Light.

and therefore at their going out of the prism had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual succession perpetually varying."

Our author concludes from this experiment, and many more to be mentioned hereafter, "that the light of the sun consists of a mixture of several sorts of coloured rays, some of which at equal incidences are more refracted than others, and therefore are called *more refrangible*. The red at T, being nearest to the place Y, where the rays of the sun would go directly if the prism was taken away, is the least refracted of all the rays; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the course of the direct light. For by mathematical reasoning he has proved, that when the prism is fixed in the posture above-mentioned, so that the place of the image shall be the lowest possible, or at the limit between its descent and ascent, the figure of the image ought then to be round like the spot at Y, if all the rays that tended to it were equally refracted. Therefore, seeing by experience it is found that this image is not round, but about five times longer than broad, it follows that all the rays are not equally refracted. And this conclusion is farther confirmed by the following experiments.

Plate CCXI. fig. 10.

"In the sun-beam SF, which was propagated into the room thro' the hole in the window-shut EG, at the distance of some feet from the hole, I held the prism ABC in such a posture, that its axis might be perpendicular to that beam: then I looked thro' the prism upon the hole F, and turning the prism to and fro about its axis to make the image pt of the hole ascend and descend, when between its two contrary motions it seemed stationary, I stopped the prism; in this situation of the prism, viewing through it the said hole F, I observed the length of its refracted image pt to be many times greater than its breadth; and that the most refracted part thereof appeared violet at p; the least refracted red, at t; and the middle parts indigo, blue, green, yellow, and orange, in order. The same thing happened when I removed the prism out of the sun's light, and looked through it upon the hole shining by the light of the clouds beyond it. And yet if the refractions of all the rays were equal according to one certain proportion of the sines of incidence and refraction, as is vulgarly supposed, the refracted image ought to have appeared round, by the mathematical demonstration above-mentioned. So then by these two experiments it appears, that in equal incidences there is a considerable inequality of refractions."

For the discovery of this fundamental property of light, which has opened the whole mystery of colours, we see our author was not only beholden to the experiments themselves, which many others had made before him, but also to his skill in geometry; which was absolutely necessary to determine what the figure of the refracted image ought to be upon the old principle of an equal refraction of all the rays: but having thus made the discovery, he contrived the following experiment to prove it at sight.

Plate CCXI. fig. 11.

"In the middle of two thin boards, DE, de, I made a round hole in each, at G and g, a third part of an inch in diameter; and in the window-shut a much larger hole being made, at F, to let into my darkened chamber a large beam of the sun's light, I placed a prism, ABC, behind the shut in that beam, to refract it towards the opposite wall; and close behind this prism I fixed one of the boards DE, in such a manner that the middle of the refracted light might pass through the hole made in it at G, and the rest be intercepted by the board. Then at the distance of about 12 feet from the first board, I fixed the other board, de, in such manner that the middle of the refracted light, which came through the hole in the first board, and fell upon the opposite wall, might pass through the hole g in this other board de, and the rest being intercepted by the board, might paint upon it the coloured spectrum of the sun. And close behind this board I fixed another prism abc, to refract the light which came through the hole g. Then I returned speedily to the first prism ABC, and by turning it slowly to and fro about its axis, I caused the image which fell upon the second board de, to move up and down upon that board, that all its parts might pass successively through the hole in that board, and fall upon the prism behind it. And in the mean time I noted the places, *M*, *N*, on the opposite wall, to which that light after its refraction in the second prism did pass; and by the difference of the places at *M* and *N*, I found that the light, which being most refracted in the first prism ABC, did go to the blue end of the image, was again more refracted by the second prism abc, than the light which went to the red end of that image. For when the lower part of the light which fell upon the second board de, was cast through the hole g, it went to a lower place M on the wall; and when the higher part of that light was cast through the same hole g, it went to a higher place, N, on the wall; and when any intermediate part of the light was cast through that hole, it went to some place in the wall between M and N. The unchanged position of the holes in the boards made the incidence of the rays upon the second prism to be the same in all cases. And yet in that common incidence some of the rays were more refracted and others less: and those were more refracted in this prism, which by a greater refraction in the first prism were more turned out of their way; and therefore, for their constancy of being more refracted, are deservedly called *more refrangible*."

Our author shews also, by experiments made with a convex glass, that lights (reflected from natural bodies) which differ in colour, differ also in degrees of refrangibility: and that they differ in the same manner as the rays of the sun do.

Fig. 12.

"The sun's light consists of rays differing in reflexibility, and those rays are more reflexible than others which are more refrangible. A prism, ABC, whose two angles, at its base BC, were equal to one another and half right ones, and the third at A a right one, I placed in a beam FM of the sun's light, let into a dark chamber through a hole F one third part of an inch broad. And turning the prism slowly about its axis until the light which went through one of its angles

Different Refrangibility of Light.

angles ACB, and was refracted by it to G and H, began to be reflected into the line MN by its base BC, at which till then it went out of the glass; I observed that those rays, as MH, which had suffered the greatest refraction, were sooner reflected than the rest. To make it evident that the rays which vanished at H were reflected into the beam MN, I made this beam pass thro' another prism VXY, and being refracted by it to fall afterwards upon a sheet of white paper *pt* placed at some distance behind it, and there by that refraction to paint the usual colours at *pt*. Then causing the first prism to be turned about its axis according to the order of the letters ABC, I observed, that when those rays MH, which in this prism had suffered the greatest refraction, and appeared blue and violet, began to be totally reflected, the blue and violet light on the paper which was most refracted in the second prism received a sensible increase at *p*, above that of the red and yellow at *t*: and afterwards, when the rest of the light, which was green, yellow, and red, began to be totally reflected and vanished at G, the light of those colours at *t*, on the paper *pt*, received as great an increase as the violet and blue had received before. Which puts it past dispute, that those rays became first of all totally reflected at the base BC, which before at equal incidences with the rest upon the base BC had suffered the greatest refraction. I do not here take notice of any refractions made in the sides AC, AB, of the first prism, because the light enters almost perpendicularly at the first side, and goes out almost perpendicularly at the second; and therefore suffers none, or so little, that the angles of incidence at the base BC are not sensibly altered by it; especially if the angles of the prism at the base BC be each about 40 degrees. For the rays FM begin to be totally reflected when the angle CMF is about 50 degrees, and therefore they will then make a right angle of 90 degrees with AC.

" It appears also from experiments, that the beam of light MN, reflected by the base of the prism, being augmented first by the more refrangible rays and afterwards by the less refrangible, is composed of rays differently refrangible.

" The light whose rays are all alike refrangible, I call *simple homogeneal* and *similar;* and that whose rays are some more refrangible than others, I call *compound heterogeneal* and *dissimilar*. The former light I call *homogeneal*, not because I would affirm it so in all respects; but because the rays which agree in refrangibility agree at least in all their other properties which I consider in the following discourse.

" The colours of homogeneal lights I call *primary*, *homogeneal* and *simple;* and those of heterogeneal lights, *heterogeneal* and *compound*. For these are always compounded of homogeneal lights, as will appear in the following discourse.

" The homogeneal light and rays which appear red, or rather make objects appear so, I call *rubrific* or *red making;* those which make objects appear yellow, green, blue, and violet, I call *yellow-making*, *green-making*, *blue-making*, *violet-making;* and so the rest. And if at any time I speak of light and rays as coloured or endowed with colours, I would be understood to speak not philosophically and properly, but grossly, and according to such conceptions as vulgar people in seeing all these experiments would be apt to frame. For the rays, to speak properly, are not coloured. In them there is nothing else than a certain power and disposition to stir up a sensation of this or that colour. For as sound in a bell or musical string or other sounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the sensorium it is a sense of that motion under the form of sound; so colours in the object are nothing but a disposition to reflect this or that sort of rays more copiously than the rest: in rays they are nothing but their dispositions to propagate this or that motion into the sensorium; and in the sensorium they are sensations of those motions under the forms of colours.

" By the mathematical proposition above-mentioned, it is certain that the rays which are equally refrangible do fall upon a circle answering to the sun's apparent disk, which will also be proved by experiment by and by. Now let AG represent the circle which all the most refrangible rays, propagated from the whole disk of the sun, would illuminate and paint upon the opposite wall if they were alone; EL the circle, which all the least refrangible rays would in like manner illuminate if they were alone; BH, CI, DK, the circles which so many intermediate sorts would paint upon the wall, if they were singly propagated from the sun in successive order, the rest being intercepted; and conceive that there are other circles without number, which innumerable other intermediate sorts of rays would successively paint upon the wall, if the sun should successively emit every sort apart. And seeing the sun emits all these sorts at once, they must all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual series, that oblong spectrum PT is composed, which was described in the first experiment.

Plate CCXI. fig. 13.

" Now if these circles, whilst their centres keep their distances and positions, could be made less in diameter, their interfering one with another, and consequently the mixture of the heterogeneous rays, would be proportionably diminished. Let the circles AG, BH, CI, &c. remain as before; and let *ag*, *bh*, *ci*, &c. be so many less circles lying in a like continual series, between two parallel right lines *ae* and *gl*, with the same distances between their centres, and illuminated with the same sorts of rays: that is, the circle *ag* with the same sort by which the corresponding circle AG was illuminated; and the rest of the circles *bh*, *ci*, *dk*, *el* respectively with the same sorts of rays by which the corresponding circles BH, CI, DK, EL, were illuminated. In the figure PT composed of the great circles, three of those, AG, BH, CI, are so expanded into each other, that three sorts of rays, by which those circles are illuminated, together with innumerable other sorts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almost the whole length of the figure PT. But in the figure *pt*, composed of the less circles, the three less circles *ag*, *bh*, *ci*, which answer to those three greater, do not extend into one another; nor are there any where mingled so much as any two of the three sorts of rays by which those circles are illuminated, and which in the figure PT are all of them intermingled at QR. So then, if we would diminish the mixture

Different Refrangibility of Light.

mixture of the rays, we are to diminiſh the diameters of the circles. Now theſe would be diminiſhed if the ſun's diameter, to which they anſwer, could be made leſs than it is, or (which comes to the ſame purpoſe) if without doors, at a great diſtance from the priſm towards the ſun, ſome opaque body were placed with a round hole in the middle of it to intercept all the ſun's light, except ſo much as coming from the middle of his body could paſs through that hole to the priſm. For ſo the circles AG, BH, and the reſt, would not any longer anſwer to the whole diſk of the ſun, but only to that part of it which could be ſeen from the priſm through that hole; that is, to the apparent magnitude of that hole viewed from the priſm. But that theſe circles may anſwer more diſtinctly to that hole, a lens is to be placed by the priſm to caſt the image of the hole (that is, every one of the circles AG, BH, &c.) diſtinctly upon the paper at PT; after ſuch a manner, as by a lens placed at a window the pictures of objects abroad are caſt diſtinctly upon a paper within the room. If this be done, it will not be neceſſary to place that hole very far off, no not beyond the window. And therefore, inſtead of that hole, I uſed the hole in the window-ſhut as follows.

Plate CCXI. fig. 14.

"In the ſun's light let into my darkened chamber through a ſmall round hole in my window-ſhut, at about 10 or 12 feet from the window, I placed a lens MN, by which the image of the hole F might be diſtinctly caſt upon a ſheet of white paper placed at I. Then immediately after the lens I placed a priſm ABC, by which the trajected light might be refracted either upwards or ſideways, and thereby the round image which the lens alone did caſt upon the paper at I, might be drawn out into a long one with parallel ſides, as repreſented at *p t*. This oblong image I let fall upon another paper at about the ſame diſtance from the priſm as the image at I, moving the paper either towards the priſm or from it, until I found the juſt diſtance where the rectilinear ſides of the image *p t* become moſt diſtinct. For in this caſe the circular images of the hole, which compoſe that image, after the manner that the circles *a g*, *b h*, *c i*, &c. do the figure *p t*, were terminated moſt diſtinctly, and therefore extended into one another the leaſt that they could, and by conſequence the mixture of the heterogeneous rays was now the leaſt of all. The cirlces *a g*, *b h*, *c i*, &c. which compoſe the image *p t*, are each equal to the circle at I; and therefore, by diminiſhing the hole F, or by removing the lens farther from it, may be diminiſhed at pleaſure, whilſt their centres keep the ſame diſtances from each other. Thus, by diminiſhing the breadth of the image *p t*, the circles of heterogeneal rays that compoſe it may be ſeparated from each other as much as you pleaſe. Yet inſtead of the circular hole F, it is better to ſubſtitute an oblong hole ſhaped like a parallellogram with its length parallel to the length of the priſm. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image *p t* will be as ſimple as before, or ſimpler; and the image being much broader, is therefore fitter to have experiments tried in its light than before.

"Homogeneal light is refracted regularly without any dilatation, ſplitting, or ſhattering of the rays; and the confuſed viſion of objects ſeen through refracting bodies by heterogeneal light, ariſes from the different refrangibility of ſeveral ſorts of rays. This will appear by the experiments which will follow. In the middle of a black paper I made a round hole about a fifth or a ſixth part of an inch in diameter. Upon this paper I cauſed the ſpectrum of homogeneal light, deſcribed in the former article, ſo to fall that ſome part of the light might paſs through the hole in the paper. This tranſmitted part of the light I refracted with a priſm placed behind the paper; and, letting this refracted light fall perpendicularly upon a white paper, two or three feet diſtant from the priſm, I found that the ſpectrum formed on the paper by this light was not oblong, as when it is made in the firſt experiment, by refracting the ſun's compound light, but was, ſo far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which ſhews that this light is refracted regularly without any dilatation of the rays, and is an ocular demonſtration of the mathematical propoſition mentioned above.

"In the homogeneal light I placed a paper circle of a quarter of an inch in diameter; and in the ſun's unrefracted, heterogeneal, white light, I placed another paper circle of the ſame bigneſs; and going from theſe papers to the diſtance of ſome feet, I viewed both circles through a priſm. The circle illuminated by the ſun's heterogeneal light appeared very oblong, as in the ſecond experiment, the length being many times greater than the breadth. But the other circle illuminated with homogeneal light appeared circular, and diſtinctly defined, as when it is viewed by the naked eye; which proves the whole propoſition mentioned in the beginning of this article.

"In the homogeneal light I placed flies and ſuch like minute objects, and viewing them through a priſm I ſaw their parts as diſtinctly defined as if I had viewed them with the naked eye. The ſame objects placed in the ſun's unrefracted heterogeneal light, which was white, I viewed alſo through a priſm, and ſaw them moſt confuſedly defined, ſo that I could not diſtinguiſh their ſmaller parts from one another. I placed alſo the letters of a ſmall print one while in the homogeneal light, and then in the heterogeneal; and viewing them through a priſm, they appeared in the latter caſe ſo confuſed and indiſtinct that I could not read them; but in the former, they appeared ſo diſtinct that I could read readily, and thought I ſaw them as diſtinct as when I viewed them with my naked eye; in both caſes, I viewed the ſame objects through the ſame priſm, at the ſame diſtance from me, and in the ſame ſituation. There was no difference but in the lights by which the objects were illuminated, and which in one caſe was ſimple, in the other compound; and therefore the diſtinct viſion in the former caſe, and confuſed in the latter, could ariſe from nothing elſe than from that difference in the lights. Which proves the whole propoſition.

"In theſe three experiments, it is farther very remarkable, that the colour of homogeneal light was never changed by the refraction. And as theſe colours were not changed by refractions, ſo neither were they by reflections. For all white, grey, red, yellow, green, blue, violet bodies, as paper, aſhes, red lead, orpiment, indigo, bice, gold, ſilver, copper, graſs, blue flowers, violets, bubbles of water tinged with various colours,

Different Refrangibility of Light.

colours, peacocks feathers, the tincture of lignum nephriticum, and such like, in red homogeneal light appeared totally red, in blue light totally blue, in green light totally green, and so of other colours. In the homogeneal light of any colour they all appeared totally of that same colour; with this only difference, that some of them reflected that light more strongly, others more faintly. I never yet found any body which by reflecting homogeneal light could sensibly change its colour.

" From all which it is manifest, that if the sun's light consisted of but one sort of rays, there would be but one colour in the world, nor would it be possible to produce any new colour by reflections and refractions, and by consequence, that the variety of colours depends upon the composition of light.

" The solar image *pt*, formed by the separated rays in the 5th experiment, did in the progress from its end *p*, on which the most refrangible rays fell, unto its end *t*, on which the least refrangible rays fell, appear tinged with this series of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continual succession perpetually varying; so that there appeared as many degrees of colours as there were sorts of rays differing in refrangibility. And since these colours could not be changed by refractions nor by reflections, it follows, that all homogeneal light has its proper colour answering to its degree of refrangibility.

" Every homogeneal ray considered apart is refracted, according to one and the same rule; so that its sine of incidence is to its sine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has proved by experiment, and by other experiments has determined by what numbers those given ratios are expressed. For instance, if an heterogeneal white ray of the sun emerges out of glass into air; or, which is the same thing, if rays of all colours be supposed to succeed one another in the same line AC, and AD their common sine of incidence in glass be divided into 50 equal parts, then EF and GH, the sines of refraction into air, of the least and most refrangible rays, will be 77 and 78 such parts respectively. And since every colour has several degrees, the sines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to $77\frac{1}{8}$, of all the degrees of orange from $77\frac{1}{8}$ to $77\frac{1}{5}$, of yellow from $77\frac{1}{5}$ to $77\frac{1}{3}$, of green from $77\frac{1}{3}$ to $77\frac{1}{2}$, of blue from $77\frac{1}{2}$ to $77\frac{2}{3}$, of indigo from $77\frac{2}{3}$ to $77\frac{7}{9}$, and of violet from $77\frac{7}{9}$ to 78.
