"That the greater part of the gold and silver which, being forced abroad by those operations of banking, is employed in purchasing foreign goods for home-consumption, is and must be employed for purchasing those of this second kind, seems not only probable, but almost unavoidable. Though some particular men may sometimes increase their expence very considerably, though their revenue does not increase at all, we may be assured that no class or order of men ever does so; because, though the principles of common prudence do not always govern the conduct of every individual, they always influence that of the majority of every class or order. But the revenue of idle people, considered as a class or order, cannot in the smallest degree be increased by those operations of banking. Their expence in general, therefore, cannot be much increased by them, tho' that of a few individuals among them may, and in reality sometimes is. The demand of idle people, therefore, for foreign goods, being the same, or very nearly the same, as before, a very small part of the money, which being forced abroad by those operations of banking, is employed in purchasing foreign goods for home-consumption, is likely to be employed in purchasing those for their use. The greater part of it will naturally be destined for the employment of industry, and not for the maintenance of idleness.

"When we compute the quantity of industry which the circulating capital of any society can employ, we must always have regard to those parts of it only which consist in provisions, materials, and finished work: the other, which consists in money, and which serves only

Paper.

Paper.

to circulate those three, must always be deducted. In order to put industry into motion, three things are requisite; materials to work upon, tools to work with, and the wages or recompence for the sake of which the work is done. Money is neither a material to work upon, nor a tool to work with; and though the wages of the workman are commonly paid to him in money, his real revenue, like that of all other men, consists, not in the money, but in the money's worth; not in the metal pieces, but in what can be got for them.

"The quantity of industry which any capital can employ, must evidently be equal to the number of workmen whom it can supply with materials, tools, and a maintenance suitable to the nature of the work. Money may be requisite for purchasing the materials and tools of the work, as well as the maintenance of the workmen. But the quantity of industry which the whole capital can employ, is certainly not equal both to the money which purchases, and to the materials, tools, and maintenance, which are purchased with it; but only to one or other of those two values, and to the latter more properly than to the former.

"When paper is substituted in the room of gold and silver money, the quantity of the materials, tools, and maintenance, which the whole circulating capital can supply, may be increased by the whole value of gold and silver which used to be employed in purchasing them. The whole value of the great wheel of circulation and distribution is added to the goods which are circulated and distributed by means of it. The operation, in some measure, resembles that of the undertaker of some great work, who, in consequence of some improvement in mechanics, takes down his old machinery, and adds the difference between its price and that of the new to his circulating capital, to the fund from which he furnishes materials and wages to his workmen.

"What the proportion is which the circulating money of any country bears to the whole value of the annual produce circulated by means of it, it is perhaps impossible to determine. It has been computed by different authors at a fifth, at a tenth, at a twentieth, and at a thirtieth part of that value. But how small soever the proportion which the circulating money may bear to the whole value of the annual produce, as but a part, and frequently but a small part, of that produce, is ever destined for the maintenance of industry, it must always bear a very considerable proportion to that part. When, therefore, by the substitution of paper, the gold and silver necessary for circulation is reduced to perhaps a fifth part of the former quantity, if the value of only the greater part of the other four-fifths be added to the funds which are destined for the maintenance of industry, it must make a very considerable addition to the quantity of that industry, and consequently to the value of the annual produce of land and labour.

"An operation of this kind has, within these 25 or 30 years, been performed in Scotland, by the erection of new banking companies in almost every considerable town, and even in some country villages. The effects of it have been precisely those above described. The business of the country is almost entirely carried on by means of the paper of those different banking compa-

nies, with which purchases and payments of all kinds are commonly made. Silver very seldom appears, except in the change of a twenty shillings bank-note, and gold still feldomer. But though the conduct of all those different companies has not been unexceptionable, and has accordingly required an act of parliament to regulate it; the country, notwithstanding, has evidently derived great benefit from their trade. I have heard it asserted, that the trade of the city of Glasgow doubled in about 15 years after the first erection of the banks there; and that the trade of Scotland has more than quadrupled since the first erection of the two public banks at Edinburgh; of which the one, called *The Bank of Scotland*, was established by act of parliament in 1695, the other, called *The Royal Bank*, by royal charter in 1727. Whether the trade, either of Scotland in general, or of the city of Glasgow in particular, has really increased in so great a proportion during so short a period, I do not pretend to know. If either of them has increased in this proportion, it seems to be an effect too great to be accounted for by the sole operation of this cause. That the trade and industry of Scotland, however, have increased very considerably during this period, and that the banks have contributed a good deal to this increase, cannot be doubted.

"The value of the silver money which circulated in Scotland before the Union, in 1707, and which immediately after it was brought into the bank of Scotland in order to be re-coined, amounted to 411,117l. 10s. 9d. sterling. No account has been got of the gold coin; but it appears from the ancient accounts of the mint of Scotland, that the value of the gold annually coined somewhat exceeded that of the silver. There were a good many people too upon this occasion, who, from a diffidence of repayment, did not bring their silver in to the bank of Scotland; and there was, besides, some English coin which was not called in. The whole value of the gold and silver, therefore, which circulated in Scotland before the Union, cannot be estimated at less than 1,000,000 sterling. It seems to have constituted almost the whole circulation of that country; for though the circulation of the bank of Scotland, which had then no rival, was considerable, it seems to have made but a very small part of the whole. In the present times, the whole circulation of Scotland cannot be estimated at less than 2,000,000, of which that part which consists in gold and silver must probably does not amount to 500,000. But though the circulating gold and silver of Scotland have suffered so great a diminution during this period, its real riches and prosperity do not appear to have suffered any. Its agriculture, manufactures, and trade, on the contrary, the annual produce of its land and labour, have evidently been augmented."

**PAPER-Office**, an office in the palace of Whitehall, in which all the public writings, matters of state and council, proclamations, letters, intelligences, negotiations abroad, and generally all dispatches that pass through the offices of the secretaries of state, are lodged, by way of library.

**PAPIER-MACHE**. This is a substance made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced into a kind of paste, and then boiled with a solution of gum Arabic

Paper,  
Papier.

Paphla-  
gonia  
Papiilo.

arabic or of fize, to give tenacity to the paffe, which is afterwards formed into different toys, &c. by preffing it into oiled moulds. When dry, it is done over with a mixture of fize and lamp-black, and afterwards varnished. The black varnish for thefe toys, according to Dr Lewis, is prepared as follows: Some colophony, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vefel, and thrice as much amber in fine powder fprinkled in by degrees, with the addition of a little fpirit or oil of turpentine now and then: when the amber is melted, fprinkle in the fame quantity of farcocolla, continuing to ftir them, and to add more fpirit of turpentine, till the whole becomes fluid; then ftain out the clear through a coarfe hair-bag, preffing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper-paffe; which is then fet in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let ftand each time till the oven grows cold. The paffe thus varnished is hard, durable, glossy, and bears liquors hot or cold.

PAPHLAGONIA (anc. geog.) a country of the Hither Asia, beginning at Parthenius, a river of Bethlynia, on the weft, and extending in length to the Halys eafterward, with the Euxine to the north, and Galatia to the fouth. Pliny enlarges the limits on the weft fide to the river Billis, on this fide the Parthenius. It is called *Pylemenia* by fome, (Pliny). *Paphlagoner*, the people, mentioned by Homer, and therefore of no small antiquity. A fuperftitious and filly people, (Lucian); a brave people, (Homer); taking their name from Phaleg, (Bochart).

PAPHOS (anc. geog.) two adjoining iflands on the weft fide of the ifland of Cyprus; the one called *Pale Paphos*, (Strabo, Ptolemy, Pliny); the other *Nea Paphos*; and when mentioned without an adjunct, this latter is always underftood. Both dedicated to Venus, and left undiftinguished by the poets, (Virgil, Horace). Hence Venus is furnamed *Paphia*; *Paphii* the people, (Coins, Stephanus). It was reftored by Auguftus, after a fhock of an earthquake, and called *Augufta*, (Dio).

PAPIAS, bifhop of Hieropolis, a city of Phrygia, was the difciple of St John the Evangelift, and the companion of Polycarp, as St Jerome obferves, and not of John the Ancient, as fome other authors have maintained. He compofed a work in five books, intitled *Expositions of the Difcourfes of our Lord*, of which there are only fome fragments now remaining. He it was who introduced the opinion of the Millennium.

PAPILIO, the BUTTERFLY; in zoology, a genus of infects belonging to the order of lepidoptera. It has four wings, imbricated with a kind of downy fcales; and the tongue is convoluted in a fpiral form; and the body is hairy. There are 273 fpecies, principally diftinguished by the colour of their wings.

The world is well acquainted with the beauties of this part of the animal-creation; but Mr Reaumur has given accounts of fome very fingular fpecies, which deserve a peculiar regard.

One fpecies of thefe he has called the *bundle of dry leaves*. This, when it is in a ftate of reft, has wholly the appearance of a little clufter of the decayed leaves of

some herb. The pofition and colour of its wings greatly favour this refemblance, and they have very large ribs; wholly like thofe of the leaves of plants, and are indented in the fame manner at their edges as the leaves of many plants are. This feems to point out the care of nature for the animal, and frequently may preferve it from birds, &c.

The skull butterfly is another fingular fpecies, fo called from its head refembling, in fome degree, a death's head, or human skull. This very remarkable appearance is terrible to many people; but it has another yet greater fingularity attending it, which is, that, when frighted, it has a mournful and harfh voice. This appeared the more furprizing to Mr Reaumur, as no other known butterfly had any the leaft voice at all; and he was not ready of belief that it was a real voice, but fufpected the noife, like that of the cicadæ, to be owing to the attrition of fome part of the body; and, in fine, he, by great pains, difcovered that this noife was not truly vocal, but was made by a hard and brisk rubbing of the trunk againft two other hard bodies between which it is placed.

Another butterfly there is, fo small that it might be miftaken for a small fly. This is certainly the extreme in degree of fize of all the known butterflies, and cannot but have been proportionally small in the ftate of a caterpillar and chryfalis: this creature fpend its whole life in all the three ftages of caterpillar, chryfalis, and butterfly, on the leaf of the celandine. It lives on the under fide of the leaf; and though in the caterpillar ftate it feeds on it, yet it does no damage. It does not eat the fubftance of the leaf, but draws from it only a fine juice, which is foon repaired again, without occafioning any change in the appearance of the leaf. This fpecies is very fhort-lived; and paffes through its three ftates in fo fhort a time, that there are frequently ten generations of it in one year; whereas, in all the other butterflies, two generations in the year are all that are to be had. Thefe two generations are fufficient to make a prodigious increafe: in a large garden, if there are twenty caterpillars in fpring, thefe may be overlooked, and there may be eafily concluded to be none there, even on a narrow fearch; but if thefe twenty caterpillars afterwards become twenty butterflies, ten of which are male and ten female, and each female lay the fame number of eggs that the common filk-worm does, that is, four hundred; if all the caterpillars hatched of thefe become butterflies, and thefe lay eggs in the fame proportion, which remain the winter, and come to be hatched in the fucceeding fpring; then from thefe twenty, in only one year, you will have eight hundred thoufand; and if we add to this the increafe of thefe in a fucceeding year, the account muft appear terrible, and fuch as no art could guard againft. The great ruler of the world has put fo many hindrances in the way of this over-abundant production, that it is very rare fuch years of deftruction happen. Some fuch have happened, however; and much mifchief has been dreaded from them, not only from their eating all the herbage, but from themfelves being eaten with herbs in fallads and otherwife: but experiments have proven this an erroneous opinion, and they are found to be innocent, and eatable as fnails or oysters.

PAPILIONACEOUS, among botanifts, an appellation

Papilio,  
Papilionaceous.

pellation given to the flowers of plants belonging principally to the diabelhia class, from their resembling the wings of a butterfly.

**PAPINIAN**, a celebrated Roman lawyer of the third century, under the emperor Severus; who had so high an opinion of his worth, that he recommended his sons Caracalla and Geta to his care. Caracalla having first murdered his brother, ordered Papinian to compose a discourse to excuse this murder to the senate and people; which when he refused to undertake, the brutal emperor ordered him to be beheaded; and his body was dragged through the streets of Rome. Papinian wrote several treatises in the line of his profession.

**PAPISTS**, are those who profess the Popish religion in this kingdom; concerning whom there have been many statutes since the Reformation. See NON-CONFORMISTS.

**PAPPUS**, in botany, a soft downy substance that grows on the seeds of certain plants, as thistles, hawkweed, &c. serving to scatter and buoy them up in the air.

**PAPPUS**, an eminent philosopher of Alexandria, said by Suidas to have flourished under the emperor Theodosius the Great, who reigned from A. D. 379 to 395. His writings shew him to have been a consummate mathematician: Many of them are lost; the rest continued long in manuscript, detached parts having only been occasionally published in the last century, until Carolus Manoleffius published his remains entire at Bologna in 1660, in folio.

**PAPYRUS**, called also *Cyperus Niliacus*, the plant from which the Egyptians were in use to make their paper. It is a large plant that grows wild in the midst of the stagnating water left in hollow places after the inundation of the Nile. We are told by Theophrastus and Pliny, that the natives used the root of it for firing, as well as for other purposes of wood: that they built little boats of the plant itself; and formed the inner bark into sails, garments, coverlids, and cordage; that they chewed it both raw and sodden, and swallowed the juice as a dainty; but, of all its uses, the most celebrated was that of its serving to write upon, like the paper of these days, which derives its name from this plant of Egypt. The intermediate part of the stalk was cut and separated into different laminæ, which were set apart, and dried in the sun for the manufacture. These laminæ were joined together horizontally and transversely, in sheets or leaves, upon a smooth board; then moistened with water, which dissolved a kind of viscous glue in the pores of the plant, serving to cement and render the whole uniform. The sheet being thus formed, was put into a press, and afterwards dried for use. Such was the process of making paper in Egypt: but as the sheets were coarse, brown, unequal, and imperfect, the Romans invented methods to bring the fabric to perfection. They contrived a glue or gum, by means of which they could occasionally enlarge the size and volume. They bleached it to a surprising degree of whiteness: they beat it with hammers, so as to render it more thin and less porous: they smoothed and polished it with ivory; and by a sort of calendar gave it a shining gloss like that of the Chinese paper. According to the different degrees of delicacy, whiteness, and size, it acquired different ap-

Par  
||  
Paradise.

pellations, either from the names of particular manufactures, from the great personages who used it, or from the particular uses to which it was put; such as the *Famian*, the *Leviathan*, the *Claudian*, the *Imperial*, the *Hieratic*, and the *Amphitheatric*.

**PAR**, in commerce, signifies any two things equal in value. See EXCHANGE.

**PARABLE**, a fable or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn by comparing it with something in which the people are more immediately concerned; such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, &c.

**PARABOLA**. See CONIC SECTIONS.

**PARABOLE**. See ORATORY, n° 84.

**PARACELSUS**, (Aurelius Philipp Theophrastus Bombastus de Hohenheim), a famous physician, born at Einsfelden, a town in the canton of Schweiz in Switzerland. He was educated with great care by his father, who was the natural son of a prince, and in a little time made a great progress in the study of physic. He afterwards travelled into France, Spain, Italy, and Germany, in order to become acquainted with the most celebrated physicians. At his return to Switzerland, he stopped at Basil, where he read lectures on physic in the German tongue. He was one of the first who made use of chemical remedies with success, by which he acquired a very great reputation. Paracelsus gloried in destroying the method established by Galen, which he believed to be very uncertain; and by this means drew upon himself the hatred of the other physicians. It is said, that he boasted of being able by his remedies to preserve the life of man for several ages: but he himself experienced the vanity of his promises, by his dying at Saltzburg, in 1504, at 37 years of age, according to some, and at 48, according to others. The best edition of his works is that of Geneva in 1658, in 3 vols folio.

**PARACENTESIS**, an operation in surgery, commonly called *Tapping*. See SURGERY.

**PARACLET**, the COMFORTER, a name given to the Holy Ghost.

**PARADE**, in a military sense, the place where troops assemble or draw together to mount guard, or for any other purpose.

**PARADE**, in fencing, implies the action of parrying or turning off any thrust.

**PARADISE**, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

As to this terrestrial paradise, there have been many inquiries about its situation. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the place possessed by the Caspian sea, and under the arctic pole. The learned Huetius places it upon the river that is produced by the conjunction of the Tigris and Euphrates, now called the *river of the Arabs*, between this conjunction and the division made by the same river before it falls into the Persian sea. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxis, and the Phasis, which they suppose to be the four rivers described by Moses. But

Paradise. concerning the exact place we must necessarily be very uncertain, if indeed it can be thought at all to exist at present, considering the many changes which have taken place on the surface of the earth since the creation.

The celestial paradise is that place of pure and refined delight in which the souls of the blessed enjoy everlasting happiness.

*Bird of PARADISE.* See the following article.

See Plate  
CCXXXIII

PARADISEA, in ornithology, a genus of birds belonging to the order of picæ. The beak is covered with a belt or collar of downy feathers at the base; and the feathers on the sides are very long. The Portuguese first found these birds on the island of Gilolo, the Papua islands, and New Guinea; and they were known by the name of *birds of the sun*. The inhabitants of Ternate call them *manuco dewata*, the "bird of God;" whence the name *manuco diata*, used by some naturalists, is derived. According to some fabulous accounts, this bird has no legs, lives constantly on wing, and in the air; and, in confirmation of these accounts, the legs of all the dead birds offered to sale were cut off. But the inhabitants of Aroo, who resort yearly to Banda, undeceived the Dutch, and freed them from those prejudices. Another reason for cutting off the legs is, that the birds are more easily preserved without them; besides that the Moors wanted the birds without legs, in order to put them on in their mock fights as ornaments to their helmets. The inhabitants of Aroo, however, have brought the birds with legs for 70 or 80 years; and Pijafetta, shipmate of Ferdinand Magellan, proved, about the year 1525, an eye-witness that these creatures were not without legs. However, the peculiar length and structure of their scapular feathers hinders them from settling, in high winds, on trees; and when they are thrown on the ground by these winds, they cannot rise again. If taken by the natives, they are immediately killed, as their food is not known; and they defend themselves with great courage with their formidable bills. There are reckoned six species of these birds.

1. The largest bird of Paradise is commonly two foot four inches in length; the head is small; the bill hard and long, of a pale colour. The head and back-part of the neck is lemon-coloured, a little black about the eyes; about the neck, the bird is of the brightest glossy emerald green, soft like velvet; as is also the breast, which is black: the wings are large, and chestnut-coloured; the back-part of the body is covered with long, straight, narrow feathers, of a pale brown colour, similar to the plumes of the ostrich. These feathers are spread when the bird is on the wing; for which reason he can keep very long in the air. On both sides of the belly are two tufts of stiff and shorter feathers, of a golden yellow, and shining. From the rump proceed two long stiff shafts, which are feathered on their extremities.

These birds are not found in Key, an island fifty Dutch miles east of Banda; but they are found at the Aroo islands, lying 15 Dutch miles farther east than Key, during the westerly or dry monsoon; and they return to New Guinea as soon as the easterly or wet monsoon sets in. They come always in a flock of 30 or 40, and are led by a bird which the inhabitants of Aroo call the *king*. This leader is black, with red spots; and constantly flies higher than

the rest of the flock, which never forsake him, but settle as soon as he settles: a circumstance that frequently proves their ruin when the king lights on the ground, whence they are not able to rise on account of the singular structure and disposition of their plumage. They are likewise unable to fly with the wind, which would ruin their loose plumage; but take their flight constantly against it, cautious not to venture out in hard blowing weather, as a strong wind frequently obliges them to come to the ground. During their flight they cry like starlings. Their note, however, approaches more to the croaking of ravens; which is heard very plainly, when they are in distress from a fresh gale blowing on the back of their plumage. In Aroo, these birds settle on the highest trees, especially on the ficus benjamina of the hortus malabaricus, commonly called the *swinging tree*. The natives catch them with bird-lime or in nooses, or shoot them with blunt arrows; but though some are killed alive when they fall into their hands, the catchers kill them immediately, and sometimes cut the legs off; then they draw out the entrails, dry and fumatize the bodies with sulphur or smoke only, and sell them at Banda for half a rixdollar each; but at Aroo they may be bought for a spike-nail or a piece of old iron. Flocks of these birds are often seen flying from one island to the other against the wind. In case they find the wind become too powerful, they fly straight up into the air, till they come to a place where it is less agitated, and then continue their flight. During the eastern monsoon their tails are moulted, so that they have them only during four months of the western monsoon.

2. The smaller bird of Paradise is about 20 inches long. His beak is lead-coloured, and paler at the point. The eyes are small, and inclosed in black about the neck. The head and back of the neck are of a dirty yellow; the back of a greyish yellow; the breast and belly of a dusky colour; the wings small, and chestnut coloured. The long plumage is about a foot in length, and paler than in the large species; as in general the colours of this bird are less bright than the former. The two long feathers of the tail are constantly thrown away by the natives.—This is in all respects like the greater sort; and they likewise follow a king or leader, who is, however, blacker, with a purplish cast, and finer in colour than the rest. The neck and bill are larger in the male than in the female. They roost on the tops of the highest trees, and do not migrate like the other kind. Some say, that the birds of this species, finding themselves weak through age, fear straight towards the sun till they are tired, and fall dead to the ground. The natives draw the entrails, scar the birds with a hot iron, and put them in a tube of bamboo for preservation.

3. and 4. The large black bird of Paradise is brought without wings or legs for sale; so that no accurate description of it hath yet been given. Its figure, when stuffed, is narrow and round, but stretched in length to the extent of four spans. The plumage on the neck, head, and belly, is black and velvet-like, with a hue of purple and gold, which appears very strong. The bill is blackish, and one inch in length. On both sides are two bunches of feathers, which have the appearance of wings, although they

Forrest's  
Voyage to  
New Guinea.

Paradise. they be very different; the wings being cut off by the natives. This plumage is soft, broad, similar to peacocks feathers, with a glorious gloss and greenish blue, and all bent upwards; which Valentine thinks is occasioned by the birds being kept in hollow bamboo reeds. The feathers of the tail are of unequal length; those next to the belly are narrow, like hair; the two uppermost are much longer, and pointed; those immediately under them are a span and a half longer than the upper ones; they are stiff, on both sides fringed with a plumage like hair, black above, but glossy below. Birds of this kind are brought only from one particular place of New Guinea. Besides the large black bird of Paradise, there is still another sort, whose plumage is equal in length, but thinner in body, black above, and without any remarkable gloss, not having those shining peacock-feathers which are found on the greater species. This wants likewise the three long-pointed feathers of the tail belonging to the larger black species.

5. The white bird of Paradise is the most rare, and has two varieties; one quite white, and the other black and white. The former is very rare. The second has the fore-part black, and the back-part white; with 12 crooked wiry shafts, which are almost naked, tho', in some places, covered with hairs.

6. In the year 1689, a new species of the black bird of Paradise was seen in Amboyna. This was only one foot in length, with a fine purple hue, a small head, and a straight bill. On its back, near the wings, are feathers of a blue and purple colour, as on the other birds of paradise; but under the wings, and over all the belly, they are yellow-coloured, as in the common sort: on the back of the neck they are mouse-coloured mixed with green. It is remarkable in this species, that there are before the wings two roundish tufts of feathers, which are green-edged, and may be moved at pleasure by the bird, like wings. Instead of a tail, he has 12 or 13 black, naked, wire-like shafts, hanging promiscuously like feathers. His legs are strong, and have sharp claws. The head is remarkably small; and the eyes are also small, and surrounded with black.

7. The last species is the king's bird. This creature is about seven inches long, and somewhat larger than a titmouse. Its head and eyes are small; the bill straight; the eyes included in circles of black plumage; the crown of the head is flame-coloured; the back of the neck blood-coloured; the neck and breast of a chestnut colour, with a ring of the brightest emerald-green. Its wings are in proportion strong; and the quill-feathers dark, with red shining plumes, spots, and stripes. The tail is straight, short, and brown. Two long naked black shafts project from the rump, at least a hand-breadth beyond the tail; having at their extremities semilinear twisted plumage, of the most glaring green colour above, and dusky below. The belly is white and green sprinkled; and on each side is a tuft of long plumage, feathered with a broad margin, being on one side green, and on the other dusky. The back is blood-red and brown, shining like silk. The legs are in size like those of a lark, three fore-toes, and one back-toe. This bird associates not with any of the other birds of paradise; but sits solitary from bush to bush, wherever he sees

red berries, without ever getting on tall trees.

PARADOX, in philosophy, a proposition seemingly absurd, as being contrary to some received opinions, but yet true in fact.

No science abounds more with paradoxes than geometry: thus, that a right line should continually approach to the hyperbola, and yet never reach it, is a true paradox; and in the same manner a spiral may continually approach to a point, and yet not reach it in any number of revolutions, however great.

PARAGOGE, in grammar, a figure whereby a letter or syllable is added to the end of a word; as *med, for me; dicier, for dici, &c.*

PARAGRAPH, in general, denotes a section or division of a chapter; and in references is marked thus, ¶.

PARAGUAY, or LA PLATA, a province of Spanish America, bounded on the north by the river of the Amazons; on the east, by Brazil; on the south, by Patagonia; and on the west, by Chili. This country was first discovered by Sebastian Cabot, who, in 1526, passed from Rio de la Plata to the river Parana in small barks, and thence entered the river called *Paraguay*. It was not, however, thoroughly reduced till the Jesuits obtained possession of it. A few of these went to Paraguay, soon after the city of Assumption was founded, and converted about 50 Indian families, who soon induced many others to follow their example, on account of the peace and tranquillity they enjoyed under the fathers. They had long resisted the Spaniards and Portuguese; but the Jesuits, by learning their language, conforming to their manners, &c. soon acquired great authority among them; till at last, by steadily pursuing the same artful measures, they arrived at the highest degree of power and influence, being in a manner the absolute sovereigns of a great part of this extensive country; for above 350,000 families are said to have been subject to them, living in obedience and awe bordering on adoration, yet procured without the least violence or constraint. There were above 60,000 parishes on the banks of the rivers Paraguay and Parana, not exceeding the distance of 30 miles from each other: in each of these there was a Jesuit, supreme in all causes, civil, military, and ecclesiastical, who might be regarded as a petty prince, governing not only with the sway of a sovereign, but with the influence and reputation of an oracle. He nominated the chiefs in all the different departments: the cacique held of him; the general received his commission and instructions from him; and all his decisions were without appeal. The same reverend father who presided over the civil economy, assisted by two others, performed also the duties of a parish-priest; catechizing the Indians, saying mass, exhorting, marrying, imposing penance, visiting the sick, &c.

The above was the account given of the behaviour of the Jesuits by their own writers. Others, however, treated their characters with more severity; accusing them of pride, haughtiness, and abusing their authority to the greatest degree; inasmuch that they would have caused the magistrates to be whipped in their presence, and obliged persons of the highest distinction within their jurisdiction to kiss the hem of their garment, as the greatest honour at which they could possibly arrive. To this might be added, the utter abolition

Parallactic.

lition of all ideas of property; which indeed was rendered useless by the general magazines and store-houses which they established, and from which, together with the herds of cattle kept for the public use, they supplied the want of individuals as occasion required; yet still it was objected to the character of the fraternity, that they possessed large property themselves, and claimed the absolute disposal of the meanest effects in Paraguay. All manufactures belonged to them; every natural commodity was brought to them; and the treasures annually remitted to the superior of the order were thought to be a proof that zeal for religion was not the only motive by which they were influenced.

Besides the parochial or provincial governments, there was a kind of supreme council, composed of an annual meeting of all the fathers, who concerted the measures necessary for promoting the common concerns of the mission, framed new laws, corrected or abolished old ones, and, in a word, adapted every thing to circumstances. It is said to have been one of the great objects of the annual councils to take such measures as should effectually deprive strangers of all intelligence concerning the state of the mission. Hence the natives were restrained from learning the Spanish tongue, and were taught, that it was dangerous for their salvation to hold any conversation with a subject of Spain or Portugal. But the circumstance that rendered their designs most suspicious, was the establishment of a military force. Every parish had its corps of horse and foot, who were duly exercised every Sunday; and it was said, that the whole amounted to a body of 70,000 or 80,000 troops, well disciplined.—Such was the state of this country some time ago; but as to its situation since the abolition of the sect of Jesuits, we can say nothing, as very little authentic intelligence is permitted to pass from that country to this.

The climate of Paraguay is very little different from that of Spain; and the distinctions between the seasons are much the same. In winter indeed, violent tempests of wind and rain are very frequent, accompanied with such dreadful claps of thunder and lightning as fill the inhabitants, though used to them, with terror and consternation. In summer, the excessive heats are mitigated by gentle breezes, which constantly begin at eight or nine in the morning.

The soil is very fertile, producing maize, manioc, and potatoes, besides many fruits and simples unknown in Europe. Vines, however, do not thrive, except in some particular places. Wheat has also been tried; but it is only used for cakes, and other things of that kind. There are great numbers of poisonous serpents, and others of an enormous size, many of which live on fish. Almost every forest of the country abounds with bees, which make their hives in hollow trees. The country produces also cotton, hemp, and flax; and there are such numbers of wild cattle, that they are killed only for their hides. The natives differ not much from those described under the article AMERICA.

PARALIPOMENA, in matters of literature, denotes a supplement of things omitted in a preceding work.

PARALEPSIS. See ORATORY, n° 87.

PARALLACTIC, in general, something relating to the parallax of heavenly bodies. See PARALLAX.

PARALLAX, in astronomy. See there, n° 182, &c.

PARALLEL, in geometry, an appellation given to lines, surfaces, and bodies every where equidistant from each other. See GEOMETRY.

PARALLEL Sphere, that situation of the sphere wherein the equator coincides with the horizon, and the poles with the zenith and nadir.

PARALLEL Sailing. See NAVIGATION, sect. iii.

PARALLELS of Latitude, in astronomy, are lesser circles of the sphere parallel to the ecliptic, imagined to pass through every degree and minute of the colures.

PARALLELS of Altitude, or Almucantars, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, having their poles in the zenith.

PARALLELS of Declination, in astronomy, are the same with parallels of latitude in geography.

PARALLELOPIPED, in geometry, a regular solid comprehended under six parallelograms, the opposite ones whereof are similar, parallel, and equal to each other.

PARALLELOPIPEDIA, in natural history, a genus of spars, externally of a determinate and regular figure, always found loose, detached, and separate from all other bodies, and in form of an oblique parallelopipe, with six parallelogram sides and eight solid angles; easily fissile either in an horizontal or perpendicular direction; being composed of numbers of thin plates, and those very elegantly and regularly arranged bodies, each of the same form with the whole mass, except that they are thinner in proportion to their horizontal planes, and naturally fall into these and no other figures, on being broken with a slight blow.

PARALOGISM, in logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false; or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

PARALYSIS, the Palsy. See MEDICINE, n° 376.

PARAMECIA, in natural history, a name given to such animalcules as have no visible limbs or tails, and are of an irregularly oblong figure.

PARAMOUNT, (compounded of two French words, *par*, i. e. *per*, and *monter* *ascendere*), signifies in our law the “highest lord of the fee, of lands, tenements, and hereditaments.” As there may be a lord meane where lands are held of an inferior lord, who holds them of a superior under certain services; so this superior lord is lord *paramount*. Also the king is the chief lord, or lord *paramount* of all the lands in the kingdom. *Co. Lit. 1.*

PARANYMPH, among the ancients, the person who waited on the bridegroom, and directed the nuptial solemnities; called also *pronubus* and *auspex*, because the ceremonies began by taking auspices. As the paranymphe officiated only on the part of the bridegroom, a woman called *pronuba* officiated on the part of the bride.

PARAPET, in fortification, an elevation of earth designed for covering the soldiers from the enemy's cannon or small shot. See FORTIFICATION.

PARAPHERNALIA, or PARAPHERNA, in the civil law, those goods which a wife brings her husband besides

Parallax  
||  
Paraphernalia.

besides her dower, and which are still to remain at her disposal exclusive of her husband, unless there are some provision made to the contrary in the marriage-contract. Some of our English civilians define the paraphernalia to be such goods as a wife challengeth over and above her dower or jointure, after her husband's death; as furniture for her chamber, wearing apparel, and jewels, which are not to be put into the inventory of her husband's goods; and a French civilian calls paraphernalia the moveables, linen, and other female necessaries, which are adjudged to a wife in prejudice of the creditors, when she renounces the succession of her husband.

**PARAPHIMOSIS**, a disorder of the penis, where-in the prepuce is shrunk, and withdrawn behind the glans, so as not to be capable of being brought to cover the same; which generally happens in venereal disorders. See **SURGERY**.

**PARAPHRASE**, an explanation of some text in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject. Such are esteemed Erasmus's paraphrase on the New Testament, the Chaldee Paraphrase on the Pentateuch, &c.

**PARAPHRENITIS**, an inflammation of the diaphragm. See **MEDICINE**, n° 290.

**PARAPHROSIS**, a word used by medical writers to denote a delirium, or an alienation of mind in fevers, or from whatever other cause.

**PARAPLEGIA**, a species of palsy. See **MEDICINE**, n° 379.

**PARASANG**, an ancient Persian measure, different at different times, and in different places; being usually 30, sometimes 40, and sometimes 50 stadia, or furlongs.—The word, according to Littleton, has its rise from *parasab angarius, q. d.* the space a post-man rides from one station, *angaria*, to another.

**PARASELENE**, in natural philosophy, a mock moon; a meteor or phenomenon encompassing or adjacent to the moon, in form of a luminous ring; where-in are observed sometimes one, and sometimes two or more images of the moon.

**PARASITE**, among the Greeks, was originally a very reputable title; the parasites being a kind of priests, at least ministers, of the gods, in the same manner as the epulones were at Rome. They took care of the sacred corn, or the corn destined for the service of the temples and the gods, *viz.* sacrifices, feasts, &c. They had even the intendance over sacrifices; and took care that they were duly performed. At Athens there was a kind of college of 12 parasites; each people of Attica furnishing one, who was always chosen out of the best families. Polybius adds, that a parasite was also an honourable title among the ancient Gauls, and was given to their poets. But of late it has been made a term of reproach, and used for a flatterer or mean dependent.

**PARASITES**, or **PARASITICAL Plants**, in botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow on the ground. Such are the mistletoe, &c.

**PARASTATE**, in anatomy. See **PROSTATE**.

**PARABUNCLE**, in a ship, the name of a rope al-

most like a pair of slings: it is seized both ends together, and then put almost double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner latched into it, to hoist it up by.

**PARCÆ**, in heathen mythology, goddesses who were supposed to preside over the accidents and events, and to determine the date or period of human life.

The **Parcæ** were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us, the **Parcæ** spun the thread of men's lives; that Clotho held the distaff, and drew the thread; Lachesis twirled the spindle, and spun it; and Atropos cut it. *Clotho colun retinet, Lachesis net, Atropos occat.*

The ancients represent the **Parcæ** divers ways: Luvian, in the shape of three poor old women, having large locks of wool, mixed with distaffs on their heads; one of which holds a distaff, the other a wheel, and the third a pair of scissars, wherewith to cut the thread of life.—Others represent them otherwise: Clotho appearing in a long robe of divers colours, wearing a crown upon her head adorned with seven stars, and holding a distaff in her hand; Lachesis in a robe beset with stars, with several spindles in her hand; and Atropos, clad in black, cutting the thread with a pair of large scissars.

The ancients imagined that the **Parcæ** used white wool for a long and happy life, and black for a short and unfortunate one.

**PARCHMENT**, the skins of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

The word comes from the Latin *pergamena*, the ancient name of this manufacture; which is said to have been taken from the city Pergamos, to Eumenes, king whereof, its invention is usually ascribed; tho', in reality, that prince appears rather to have been the improver, than the inventor of parchment. For the Persians of old, according to Diodorus, wrote all their records on skins; and the ancient Ionians, as we are told by Herodotus, made use of sheep-skins and goat-skins in writing, many ages before Eumenes's time. Nor need we doubt that such skins were prepared and dressed for that purpose, after a manner not unlike that of our parchment; tho' probably not so artificially.—The manufacture of parchment is begun by the skinner, and finished by the parchment-maker.

The skin having been stripped of its wool, and placed in the lime-pit, in the manner described under the article **SHAMMY**, the skinner stretches it on a kind of frame, and pares off the flesh with an iron instrument; this done, it is moistened with a rrg; and powdered chalk being spread over it, the skinner takes a large pumice-stone, flat at bottom, and rubs over the skin, and thus scowers off the flesh; he then goes over it again with the iron instrument, moistens it as before, and rubs it again with the pumice-stone without any chalk underneath: this smooths and softens the flesh-side very considerably. He then drains it again, by passing over it the iron instrument as before. The flesh-side being thus drained, by scraping off the moisture, he in the same manner passes the iron over the wool or hair-side: then stretches it tight on a frame, and scrapes the flesh-side again: this finishes its draining; and the

more

Pardies

Pardon.

Pardon.

more it is drained, the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb-skin that has the wool on; and this smooths it still farther. It is now left to dry, and when dried, taken off the frame by cutting it all round. The skin thus far prepared by the skinner, is taken out of his hands by the parchment-maker, who first, while it is dry, pares it on a summer, (which is a calf skin stretched in a frame), with a sharper instrument than that used by the skinner; and working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin thus equally pared on the flesh-side, is again rendered smooth, by being rubbed with the pumice-stone, on a bench covered with a sack stuffed with flacks; which leaves the parchment in a condition fit for writing upon. The parings thus taken off the leather, are used in making glue, size, &c. See the article *GLUE*, &c.

What is called *vellum*, is only parchment made of the skins of aboves, or at least sucking calves. This has a much finer grain, and is whiter and smoother than parchment; but is prepared in the same manner, except its not being passed through the lime-pit.

**PARDIES** (Ignatius Gaston), an ingenious and learned French Jesuit, born at Paris in 1636. He taught polite literature for several years; during which time he composed several small pieces, both in prose and verse, with peculiar delicacy of thought and style. At length he devoted himself entirely to mathematics and natural philosophy, and read all authors, ancient as well as modern, in those branches of knowledge. He died in 1673, of an infectious disorder contracted by confessing and preaching to the prisoners in the Bicetre during the Easter holidays. Father Pardies published several works; of which his *Elements of Geometry* are well known in this country, where a translation of them has gone thro' several editions. In 1672 he had a dispute with Sir Isaac Newton respecting his *Theory of Light and Colours*; which may be seen in the *Philosophical Transactions* for that year.

**PARDALIS**, in natural history. See *LEO*.

**PARDON**, in criminal law, is the remitting or forgiving an offence committed against the king.

*Beccaria on Crimes and Punishments*

Laws (says an able writer), cannot be framed on principles of compassion to guilt; yet justice, by the constitution of England, is bound to be administered in mercy: this is promised by the king in his coronation oath; and it is that act of his government which is the most personal and most entirely his own. The king condemns no man; that rugged task he leaves to his courts of justice: the great operation of his sceptre is mercy. His power of pardoning was said by our Saxon ancestors to be derived *à lege sue dignitatis*; and it is declared in parliament, by stat. 27 Hen. VIII. c. 24. that no other person hath power to pardon or remit any treason or felonies whatsoever; but that the king hath the whole and sole power thereof, united and knit to the imperial crown of this realm.

This is indeed one of the great advantages of monarchy in general above any other form of government, that there is a magistrate who has it in his power to extend mercy wherever he thinks it is deserved; holding a court of equity in his own breast, to soften the rigour of the general law, in such criminal cases as merit an exemption from punishment. Pardons

(according to some theorists) should be excluded in a perfect legislation, where punishments are mild, but certain; for that the clemency of the prince seems a tacit disapprobation of the laws. But the exclusion of pardons must necessarily introduce a very dangerous power in the judge or jury; that of confuting the criminal law by the spirit instead of the letter: or else it must be holden, what no man will seriously avow, that the situation and circumstances of the offender (though they alter not the essence of the crime) ought to make no distinction in the punishment. In democracies, however, this power of pardon can never subside; for there nothing higher is acknowledged than the magistrate who administers the laws: and it would be impolitic for the power of judging and of pardoning to centre in one and the same person. This (as the president Montequien observes) would oblige him very often to contradict himself, to make and to unmake his decisions: it would tend to confound all ideas of right among the mass of people; as they would find it difficult to tell, whether a prisoner were discharged by his innocence, or obtained a pardon through favour. In Holland therefore, if there be no stadholder, there is no power of pardoning lodged in any other member of the state. But in monarchies the king acts in a superior sphere; and though he regulates the whole government as the first mover, yet he does not appear in any of the disagreeable or invidious parts of it. Whenever the nation see him personally engaged, it is only in works of legislature, magnificence, or compassion. To him therefore the people look up as the fountain of nothing but bounty and grace; and these repeated acts of goodness, coming immediately from his own hand, endear the sovereign to his subjects, and contribute more than any thing to root in their hearts that filial affection and personal loyalty which are the sure establishment of a prince.

The king may pardon all offences merely against the crown or the public; excepting, 1. That, to preserve the liberty of the subject, the committing any man to prison out of the realm, is by the *habeas corpus* act, 31 Car. II. c. 2. made a *premunire*, unpardonable even by the king. Nor, 2. can the king pardon, where private justice is principally concerned in the prosecution of offenders: *Non potest rex gratiam facere cum injuria et damno aliorum*. Therefore, in appeals of all kinds, (which are the suit, not of the king, but of the party injured), the prosecutor may release; but the king cannot pardon. Neither can he pardon a common nuisance, while it remains undressed, or so as to prevent an abatement of it; though afterwards he may remit the fine: because though the prosecution is vested in the king to avoid the multiplicity of suits, yet (during its continuance) this offence favours more of the nature of a *private* injury to each individual in the neighbourhood, than of a *public* wrong. Neither, lastly, can the king pardon an offence against a popular or penal statute, after information brought; for thereby the informer hath acquired a private property in his part of the penalty.

There is also a restriction of a peculiar nature, that affects the prerogative of pardoning, in case of parliamentary impeachments, viz. that the king's pardon cannot be pleaded to any such impeachment, so as to impede the inquiry, and stop the prosecution of great and

Paragories  
||  
Paren-  
chyma.

Paren-  
chyma,  
Parent.

and notorious offenders. Therefore when, in the reign of Charles the second, the earl of Danby was impeached by the house of commons of high treason and other misdemeanors, and pleaded the king's pardon in bar of the same, the commons alleged, "That there was no precedent that ever any pardon was granted to any person impeached by the commons of high treason, or other high crimes, depending the impeachment;" and thereupon resolved, "That the pardon so pleaded was illegal and void, and ought not to be allowed in bar of the impeachment of the commons of England;" for which resolution they assigned this reason to the house of lords, "That the setting up a pardon to be a bar of an impeachment defeats the whole use and effect of impeachments: for should this point be admitted, or stand doubted, it would totally discourage the exhibiting any for the future; whereby the chief institution for the preservation of the government would be destroyed." Soon after the Revolution, the commons renewed the same claim, and voted, "That a pardon is not pleadable in bar of an impeachment." And at length, it was enacted by the act of settlement, 12 & 13 W. III. c. 2. "That no pardon under the great seal of England shall be pleadable to an impeachment by the commons in parliament." But, after the impeachment has been solemnly heard and determined, it is not understood that the king's royal grace is farther restrained or abridged: for, after the impeachment and attainder of the six rebel lords in 1715, three of them were from time to time reprieved by the crown; and at length received the benefit of the king's most gracious pardon.

The effect of such pardon by the king, is to make the offender a new man; to acquit him of all corporal penalties and forfeitures annexed to that offence for which he obtains his pardon; and not so much to restore his former, as to give him a new credit and capacity. But nothing can restore or purify the blood when once corrupted, if the pardon be not allowed till after attainder, but the high and transcendent power of parliament. Yet if a person attainted receives the king's pardon, and afterwards hath a son, that son may be heir to his father; because the father being made a new man, might transmit new inheritable blood; though, had he been born before the pardon, he could never have inherited at all.

PAREGORIES, in pharmacy, medicines that assuage pain, otherwise called ANODYNES.

PAREIRA FRAYA, in the materia medica, a kind of oblong and large root brought from the Brasils.—It is certainly a diuretic of no mean character, and has done great service in nephritic cases. In pleuritis and quinries, it has been attended with more success than almost any medicine we know of singly.

PARELCON, in grammar, a figure by which a word or syllable is added to the end of another.

PAREMBOLE, in rhetoric, a figure wherein something relating to the subject is inserted in the middle of a period. All the differences between the parembolè and parenthesis, according to Vossius, is, that the former relates to the subject in hand, whereas the latter is foreign to it.

PARENCHYMA, in anatomy, a term introduced by Erasistratus, signifying all that substance which is

contained in the interstices betwixt the blood-vessels of the viscera, which he imagined to be extravasated and concentered blood.

PARENCHYMA of Plants. Grew applies the term *parenchyma* to the pith or pulp, or that inner part of a fruit or plant through which the juice is supposed to be distributed. See PLANTS.

PARENT, a term of relation applicable to those from whom we immediately derive our being. See MORAL PHILOSOPHY, n<sup>o</sup>. 122, 132.—135.

To this article belongs an inquiry into, 1. The legal duties of parents to their legitimate children. 2. Their power over them.

1. The duties of parents to legitimate children consist in three particulars; their *maintenance*, their *protection*, and their *education*.

1. The duty of parents to provide for the maintenance of their children, is a principle of natural law; an obligation, says Puffendorff, laid on them not only by nature herself, but by their own proper act, in bringing them into the world; for they would be in the highest manner injurious to their issue, if they only gave their children life, that they might afterwards see them perish. By begetting them, therefore, they have entered into a voluntary obligation, to endeavour, as far as in them lies, that the life which they have bestowed shall be supported and preserved. And thus the children will have a perfect right of receiving maintenance from their parents. And the president Montesquieu has a very just observation upon this head, that the establishment of marriage, in all civilized states, is built on this natural obligation of the father to provide for his children; for that ascertains and makes known the person who is bound to fulfil this obligation; whereas, in promiscuous and illicit conjunctions, the father is unknown; and the mother finds a thousand obstacles in her way; shame, remorse, the constraint of her sex, and the rigour of laws, that stifle her inclinations to perform this duty; and besides, she generally wants ability.

The municipal laws of all well-regulated states have taken care to enforce this duty: though providence has done it more effectually than any laws, by implanting in the breast of every parent that natural *regret*, or insuperable degree of affection, which not even the deformity of person or mind, not even the wickedness, ingratitude, and rebellion of children, can totally suppress or extinguish.

The civil law obliges the parent to provide maintenance for his child; and if he refuses, *judeex de ea re cognoscet*. Nay, it carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing; and there are 14 such reasons reckoned up, which may justify such disinherison. If the parent alleged no reason, or a bad, or a false one, the child might set the will aside, *tanquam testamentum inefficacium*, a testament contrary to the natural duty of the parent. And it is remarkable under what colour the children were to move for relief in such a case; by suggesting, that the parent had lost the use of his reason when he made the *inefficacious* testament. And this, as Puffendorff observes, was not to bring into dispute the testator's power of disinheriting his own offspring; but to examine the motives upon which he did it; and if they

Black's  
Comment.

they were found defective in reason, then to set them aside. But perhaps this is going rather too far: every man has, or ought to have, by the laws of society, a power over his own property: and, as Grotius very well distinguishes, natural right obliges to give a *necessary* maintenance to children; but what is more than that they have no right to, than as it is given by the favour of their parents, or the positive constitutions of the municipal law.

Let us next see what provision our own laws have made for this natural duty. It is a principle of law, that there is an obligation on every man to provide for those descended from his loins; and the manner in which this obligation shall be performed, is thus pointed out. The father and mother, grandfather and grandmother of poor impotent persons shall maintain them at their own charges, if of sufficient ability, according as the quarter-sessions shall direct; and, if a parent runs away, and leaves his children, the churchwardens and overseers of the parish shall seize his rents, goods, and chattels, and dispose of them toward their relief. By the interpretations which the courts of law have made upon these statutes, if a mother or grandmother marries again, and was before full second marriage of sufficient ability to keep the child, the husband shall be charged to maintain it; for this being a debt of her's, when single, shall, like others, extend to charge the husband. But, at her death, the relation being dissolved, the husband is under no farther obligation.

No person is bound to provide a maintenance for his issue, unless where the children are impotent and unable to work, either through infancy, disease, or accident; and then is only obliged to find them with necessaries, the penalty on refusal being no more than 20 s. a-month. For the policy of our laws, which are ever watchful to promote industry, did not mean to compel a father to maintain his idle and lazy children in ease and indolence; but thought it unjust to oblige the parent, against his will, to provide them with superfluities, and other indulgences of fortune; imagining they might trust to the impulse of nature, if the children were deserving of such favours. Yet, as nothing is so apt to stifle the calls of nature as religious bigotry, it is enacted, that if any Popish parent shall refuse to allow his Protestant child a fitting maintenance, with a view to compel him to change his religion, the lord chancellor shall by order of court constrain him to do what is just and reasonable. But this did not extend to persons of another religion, of no less bitterness and bigotry than the Popish; and therefore, in the very next year, we find an instance of a Jew of immense riches, whose only daughter having embraced Christianity, he turned her out of doors; and on her application for relief, it was held she was entitled to none. But this gave occasion to another statute, which ordains, that if Jewish parents refuse to allow their Protestant children a fitting maintenance, suitable to the fortune of the parent, the lord chancellor, on complaint, may make such order therein as he shall see proper.

Our law has made no provision to prevent the disinheriting of children by will; leaving every man's property in his own disposal, upon a principle of liberty in this as well as every other action; though perhaps it had not been amiss if the parent had been bound

to leave them at the least a necessary subsistence. Indeed, among persons of any rank or fortune, a competence is generally provided for younger children, and the bulk of the estate settled upon the eldest by the marriage-articles. Heirs also, and children, are favourites of our courts of justice, and cannot be disinherited by any dubious or ambiguous words; there being required the utmost certainty of the testator's intentions to take away the right of an heir.

2. From the duty of maintenance we may easily pass to that of *protection*; which is also a natural duty, but rather permitted than enjoined by any municipal laws; nature, in this respect, working so strongly as to need rather a check than a spur. A parent may, by our laws, maintain and uphold his children in their law-suits, without being guilty of the legal crime of maintaining quarrels. A parent may also justify an assault and battery in defence of the persons of his children; nay, where a man's son was beaten by another boy, and the father went near a mile to find him, and there revenged his son's quarrel by beating the other boy, of which beating he afterwards unfortunately died; it was not held to be murder, but manslaughter merely. Such indulgence does the law shew to the frailty of human nature, and the workings of parental affection.

3. The last duty of parents to their children is that of giving them an *education* suitable to their station in life: a duty pointed out by reason, and of far the greatest importance of any. For, as Puffendorff very well observes, it is not easy to imagine or allow, that a parent has conferred any considerable benefit upon his child by bringing him into the world, if he afterwards entirely neglects his culture and education, and suffers him to grow up like a mere beast, to lead a life useless to others, and shameful to himself. Yet the municipal laws of most countries seem to be defective in this point, by not confining the parent to bestow a proper education upon his children. Perhaps they thought it punishment enough to leave the parent, who neglects the instruction of his family, to labour under those griefs and inconveniences which his family, so uninstructed, will be sure to bring upon him. Our laws, though their defects in this particular cannot be denied, have in one instance made a wise provision for breeding up the rising generation; since the poor and laborious part of the community, when past the age of nurture, are taken out of the hands of their parents, by the statutes for apprenticing poor children; and are placed out by the public in such a manner as may render their abilities, in their several stations, of the greatest advantage to the commonwealth. The rich indeed are left at their own option, whether they will breed up their children to be ornaments or disgraces to their family. Yet in one case, that of religion, they are under peculiar restrictions: for it is provided, that if any person sends any child under his government beyond the seas, either to prevent its good education in England, or in order to enter into, or reside in, any Popish college, or to be instructed, persuaded, or strengthened in the Popish religion; in such case, besides the disabilities incurred by the child so sent, the parent or person sending shall forfeit 100 l. which shall go to the sole use and benefit of him that shall discover the offence. And if any parent, or other, shall send

Parent.

or convey any person beyond sea, to enter into, or be resident in, or trained up in, any priory, abbey, nunnery, Popish university, college, or school, or house of Jesuits or priests, or in any private Popish family, in order to be instructed, persuaded, or confirmed, in the Popish religion; or shall contribute any thing towards their maintenance when abroad by any pretext whatever, the person both sending and sent shall be disabled to sue in law or equity, or to be executor or administrator to any person, or to enjoy any legacy or deed of gift, or to bear any office in the realm, and shall forfeit all his goods and chattels, and likewise all his real estate for life.

II. The power of parents over their children is derived from the former consideration, their duty: this authority being given them, partly to enable the parent more effectually to perform his duty, and partly as a recompence for his care and trouble in the faithful discharge of it. And upon this score the municipal laws of some nations have given a much larger authority to the parents than others. The ancient Roman laws gave the father a power of life and death over his children; upon this principle, that he who gave had also the power of taking away. But the rigour of these laws was softened by subsequent constitutions; so that we find a father banished by the emperor Hadrian for killing his son, though he had committed a very heinous crime, upon this maxim, that *patria potestas in pietate debet, non in atrocitate, consistere*. But still they maintained to the last a very large and absolute authority: for a son could not acquire any property of his own during the life of his father; but all his acquisitions belonged to the father, or at least the profits of them, for his life.

The power of a parent by our English law is much more moderate; but still sufficient to keep the child in order and obedience. He may lawfully correct his child, being under age, in a reasonable manner; for this is for the benefit of his education. The consent or concurrence of the parent to the marriage of his child under age, was also directed by our ancient law to be obtained: but now it is absolutely necessary; for without it the contract is void. And this also is another means which the law has put into the parent's hands, in order the better to discharge his duty; first, of protecting his children from the snares of artful and designing persons; and next, of settling them properly in life, by preventing the ill consequences of too early and precipitate marriages. A father has no other power over his son's estate, than as his trustee or guardian; for though he may receive the profits during the child's minority, yet he must account for them when he comes of age. He may indeed have the benefit of his children's labour while they live with him, and are maintained by him; but this is no more than he is entitled to from his apprentices or servants. The legal power of a father, (for a mother, as such, is entitled to no power, but only to reverence and respect), the power of a father, we say, over the persons of his children ceases at the age of 21; for they are then enfranchised by arriving at years of discretion, or that point which the law has established (as some must necessarily be established) when the empire of the father, or other guardian, gives place to the empire of reason. Yet, till that age arrives, this empire of the father

Vol. VIII.

I

continues even after his death; for he may by his will appoint a guardian to his children. He may also delegate part of his parental authority, during his life, to the tutor or schoolmaster of his child; who is then *in loco parentis*, and has such a portion of the power of the parent committed to his charge, viz. that of restraint and correction, as may be necessary to answer the purposes for which he is employed. See CHILDREN.

PARENTALIA, in antiquity, funeral obsequies, or the last duties paid by children to their deceased parents.

PARENTHESIS, in grammar, certain intercalary words inserted in a discourse, which interrupt the sense or thread, but seem necessary for the better understanding of the subject.

PARENZO, a small but strong town of Italy, and in Istria, with a bishop's see and a good harbour; situated on the gulph of Venice, in E. Long. 13. 46. N. Lat. 39. 28. It submitted to the Venetians in 1267.

PARESIS, in medicine, a palsy of the bladder, wherein the urine is either suppressed or discharged involuntarily.

PARETONIUM, in natural history, the name of an earth found on the shores of Egypt, Cyrene, and the island of Crete, used by the ancients in painting.

PARGET, in natural history, a name given to several kinds of gypsum, or plaster-stone.

PARGETING, in building, is used for the plastering of walls, and sometimes for plaster itself.

PARHELION, or PARHELIUM, in natural philosophy, a mock-sun or meteor, in form of a very bright light, appearing on one side of the sun.

Appearances of this kind have been made mention of both by the ancients and moderns. Aristotle observes, that in general they are seen only when the sun is near the horizon, though he takes notice of two that were seen in Bosphorus from morning to evening; and Pliny has related the times when such phenomena were observed at Rome. Gassendi says, that, in 1635 and 1636, he often saw one mock-sun. Two were observed by M. de la Hire in 1689; and the same number by Cassini in 1693, Mr Grey in 1700, and Dr Halley in 1702: but the most celebrated appearances of this kind were seen at Rome by Scheiner, by Muschenbroeck at Utrecht, and by Hevelius at Sedan. By the two former, four mock-suns were observed, and by the latter seven.

Parhelia are apparently of the same size with the sun, though not always of the same brightness, nor even of the same shape; and when a number appear at once, there is some difference in both these respects among them. Externally, they are tinged with colours like the rainbow; and many have a long fiery tail opposite to the sun, but paler towards the extremity. Parhelia are generally accompanied with coronas, some of which are tinged with rainbow-colours, but others are white. They differ in number and size; but all agree in breadth, which is that of the apparent diameter of the sun.

A very large white circle, parallel to the horizon, generally passes through all the parhelia; and, if it were entire, it would go through the centre of the sun. Sometimes there are arcs of lesser circles concentric to this, touching those coloured circles which

33 C

surround

**Parhelion.** furround the sun. They are also tinged with colours, and contain other parhelia. There are also said to have been other circles obliquely situated with respect to all those we have mentioned; but of this we have met with no authentic account. The order of the colours in these circles is the same as in the rainbow; but on the inside, with respect to the sun, they are red, as is also observed in many other corona's.

Parhelia have been visible for 1, 2, 3, and 4 hours together; and in North America they are said to continue some days, and to be visible from sun-rise to sun-set.

When the parhelia disappear, it sometimes rains, or there falls snow in the form of oblong spiculae, as Maraldi, Weidler, Kraft, and others, have observed; and because the air in North America abounds with such frozen spiculae, which are even visible to the eye, according to Ellis and Middleton, such particles have been thought to be the cause of all corona's and parhelia.

Mr Wales says, that, at Churchill in Hudson's Bay, the rising of the sun is always preceded by two long streams of red light, one on each side of him, and about 20° distant from him. These rise as the sun rises; and as they grow longer begin to bend towards each other, till they meet directly over the sun, just as he rises, forming there a kind of parhelion or mock-sun. These two streams of light, he says, seem to have their source in two other parhelia, which rise with the true sun; and in the winter-season, when the sun never rises above the haze or fog, which he says is constantly found near the horizon, all these accompany him the whole day, and set with him in the same manner as they rise. Once or twice he saw a fourth parhelion directly under the true sun; but this, he says, is not common. These facts being constant, are very valuable, and may throw great light on the theory of these remarkable phenomena.

Sometimes parhelia appear in a different manner; as when three suns have been seen in the same vertical circle, well defined, and touching one another. The true sun was in the middle, and the lowest touched the horizon; and they set one after the other. This appearance was seen by M. Malezew in 1722. Other appearances similar to this are recited by M. Mufchenbroeck.

Sometimes the sun has risen or set with a luminous tail projecting from him, of the same breadth with his diameter, and perpendicular to the horizon. Such an appearance was seen by Cassini in 1672 and 1692, by de la Hire in 1702, and by Mr Ellis in Hudson's Bay.

As M. Feuillée was walking on the banks of the river La Plata, he saw the sun rising over the river with a luminous tail projecting downwards, which continued till he was six degrees high.

Paraselenae, or mock-moons, have also been seen, accompanied with tails and coloured circles, like those which accompany the parhelia. An account of several, and a particular description of a fine appearance of this kind, may be seen in Mufchenbroeck.

The Roman phenomenon, observed by Scheiner, is famous on account of its having been the first appearance of the kind that engaged the attention of philosophers. It is represented in fig. 4.; in which A is the place of the observer, B his zenith, C the true

sun, AB a plane passing through the observer's eye, the true sun, and the zenith. About the sun C, there appeared two concentric rings, not complete, but diversified with colours. The lesser of them, DEF, was fuller, and more perfect; and though it was open from D to F, yet those ends were perpetually endeavouring to unite; and sometimes they did so. The outer of these rings was much fainter, so as scarcely to be discernible. It had, however, a variety of colours; but was very inconstant. The third circle, KLMN, was very large, and all over white, passing through the middle of the sun, and every where parallel to the horizon. At first this circle was entire; but towards the end of the appearance it was weak and ragged, so as hardly to be perceived from M towards N.

In the intersection of this circle, and the outward iris GKI, there broke out two parhelia or mock-suns, N and K, not quite perfect; K being rather weak, but N shone brighter and stronger. The brightness of the middle of them was something like that of the sun; but towards the edges they were tinged with colours like those of the rainbow; and they were uneven and ragged. The parhelion N was a little wavering, and sent out a spiked tail, NP, of a colour somewhat fiery, the length of which was continually changing.

The parhelia at L and M in the horizontal ring were not so bright as the former; but were rounder, and white, like the circle in which they were placed. The parhelion N disappeared before K; and while M grew fainter, K grew brighter, and vanished the last of all.

It is to be observed farther, that the order of the colours in the circles DEF, GKN, was the same as in the common halos, namely, red next the sun; and the diameter of the inner circle was also about 45 degrees; which is the usual size of a halo.

Various hypotheses have been framed by philosophers to account for this phenomenon. None of them are satisfactory; but the reader who chooses to know them may consult Dr Priestley's *History of Vision, Light, and Colours*, vol. ii. p. 619.

**PARIA, or NEW ANDALUSIA**, a country of Terra Firma in South America; bounded on the north by the north sea; on the east, by Surinam; on the west, by New Granada and the Caraccas; and on the south, by Guiana. It produces colouring drugs, gums, medicinal roots, Brazil-wood, sugar, tobacco, and some valuable timber; the inland parts being woody and mountainous, but interspersed with fine valleys that yield corn and pasturage. Comana is the capital town.

**PARIAN MARBLE**, in the natural history of the ancients, the white marble used then, and to this day, for carving statues, &c. and called by us at this time *statuary marble*.

Too many of the later writers have confounded all the white marbles under the name of the *Parian*; and among the workmen, this and all the other white marbles have the common name of *alabasters*; so that it is in general forgotten among them, that there is such a thing as alabaster different from marble; which, however, is truly the case. Almost all the world also have confounded the Carrara marble with this, though they are really very different; the Carrara kind being of a finer structure and clearer white than the Parian; but

See Plate  
CXXXII  
sophers. It is represented in fig. 4.; in which A is

but less bright and splendid, harder to cut, and not capable of so glittering a polish.

The true Parian marble has usually somewhat of a faint bluish tinge among the white, and often has blue veins in different parts of it. It is supposed by some to have had its name from the island Paros, one of the Cyclades in the *Ægean* Sea, where it was first found; but others will have it to have been so called from Agoracritus Parius, a famous statuary, who ennobled it by cutting a statue of a Venus in it.

PARIETALIA ossa, in anatomy. See there n° 12.

PARIETARIA, PELLITORY of the wall; a genus of the order of monœcia belonging to the polygamia class of plants. There are six species, of which one named the *officinalis*, is used in medicine. This has a creeping root. The stalk grows erect, is rough to the touch, and adhesive. The leaves are alternate, elliptical, lanceolate, veined, and a little rough. The flowers grow out of the axils of the leaves, in sessile, branched, verticillate clusters, of a greenish colour tinged with red. The anthers have a great degree of sensibility; for, if irritated with the point of a pin, they fly from the calix with elastic force, and throw out their powder.—The plant has a cooling and diuretic quality. Three ounces of the juice taken internally, or a fomentation externally applied, have been found serviceable in the strangury.—The plant laid upon heaps of corn infested with weevils, is said to drive away those destructive insects.

PARIS (Matthew), one of our best historians from William the Conqueror, to the latter end of the reign of Henry III. But of his life few particulars have been transmitted to us. Leland, his original biographer, without determining whether he was born in France or England, informs us, that he was a monk of St Alban's, and that he was sent by pope Innocent to reform the monks of the convent at Holm in Norway. Bishop Bale, the next in point of time, adds to the above relation, that, on account of his extraordinary gifts of body and mind, he was much esteemed, particularly by king Henry III. who commanded him to write the history of his reign. Fuller makes him a native of Cambridgeshire, because there was an ancient family of his name in that county. He also mentions his being sent by the pope to visit the monks in the diocese of Norwich. Bishop Tanner, bishop Nicolson, Monsieur du Pin, and the *Nouveau Dictionnaire Historique*, add not a single fact to those above related. Matthew Paris died in the monastery of St Alban's in the year 1259. He was doubtless a man of extraordinary knowledge for the 13th century; of an excellent moral character, and, as an historian, of strict integrity. His style is unpolished; but that defect is sufficiently atoned for by the honest freedom with which he relates the truth, regardless of the dignity or sanctity of the persons concerned. His works are, 1. *Historia ab Adamo ad Conquestum Angliæ*, lib. i. manuscript. col. C. C. Cantab. c. ix. Most of this book is transcribed, by Matthew of Westminster, into the first part of his *Florilegium*. 2. *Historia major, seu rerum Anglicanarum historia à Gul. Conquestoris adventu ad annum 43 Henrici III. &c.* several times printed. The first

part of this history, viz. to the year 1235, is transcribed almost verbatim from the Chronicle of Roger Wendover; and the Appendix, from the year 1260, is the work of William Rishanger, who was also a monk of St Alban's. 3. *Vite duorum Offarum, Mercurii regum, S. Albani fundatorum*. 4. *Gesta 22 abbatum S. Albani*. 5. *Additamenta chroniconum ad hist. majorem*; printed. 6. *Historia minor, sive epitome majoris historie*; manuscript. Besides many other things in manuscript.

PARIS, the son of Priam king of Troy, memorable in history for carrying off Helena the wife of Menelaus king of Sparta in his absence, which occasioned the famous siege of Troy. Slain there about 1188 B.C.

PARIS, the capital of the kingdom of France; is situate on the river Seine, in the isle of France, being one of the largest and finest cities in Europe. It derived its modern name from the ancient Parisii; and is supposed by some to have had the Latin name of *Lutetia*, from *Lutum*, "mud," the place where it now stands having been anciently very marshy and muddy. Ever since the reign of Hugh Capet, that is, for near 800 years, this city hath been the usual residence of the kings of France: it is of a circular form, and, including the suburbs, about five French leagues, or 15 English miles, in circumference. The number of its inhabitants is computed at about 500,000; that of its streets 912; and that of its houses upwards of 20,000, exclusive of the public structures of all sorts. Its greatest defect, according to some, is the want of good drinking-water; but others tell us, that very fine water is brought by an aqueduct from the village of Arcueil, not far from Paris, but own the water of the Seine, and the city, is not good. The streets are of a proper breadth, well built, paved, and lighted. There is a great number of tribunals and offices here; most of which are kept in the Palais, situated on an island, to which it gives name. The number of churches, convents, hospitals, market-places, fountains, gates, and bridges, in this city is very great; besides the university, several academies, public libraries, royal palaces and castles, and above 100 hotels, some of them very stately. But to be more particular, that part called *la Cité*, lies in the centre, and consists of three islands formed by the Seine, viz. L'Isle de Palais, L'Isle de Notre Dame, and L'Isle Louviers. It is the principal of the three parts into which the city is divided, and contains the following remarkable structures: 1. Several bridges; of which some are of wood and others of stone, and have most of them a row of houses on each side. The chief of these are the Pont-neuf and Pont-royal: the first consists of 12 arches, which, properly speaking, make two bridges, the one leading from the suburbs of St Germain to the city, and the other from thence to that part called *la Ville*: there is a carriage-way in the middle, 30 feet broad, and foot-walks on each side, raised two feet high; and in the centre stands a brass statue of king Henry IV. on horseback. On this bridge is also the building called *La Samaritaine*, from a group of figures upon it representing our Saviour and the Samaritan woman, standing near Jacob's well. Here is a pump to raise the water, which through several pipes supplies the quarter of the Louvre, and some other parts of the town.

The Pont-royal, which leads to the Thuilleries, was built by order of Lewis XIV. in the room of a wooden bridge that was carried away by the current in 1684. 2. The cathedral of Notre Dame, or our Lady, being dedicated to the Holy Virgin, which is a large stately Gothic structure, said to have been founded by king Chillicric, and built in the form of a cross. Here, besides other great personages, are interred the cardinals de Retz and Noailles. From the two square towers belonging to it, is a noble prospect of the city and neighbouring country. Here is a vast quantity of gold and silver plate, rich tapestry, and fine paintings; and the number of the canons is no less than 50. Near it stands the palace of the archbishop, in which is the advocates library: the revenue of the archbishop amounts to about 180,000 livres; and his taxation to the court of Rome is 4283 guilders. 3. The priory and parish-church of St Bartholomew; the last of which is the most beautiful in all this part of the city, and stands near the Palais. 4. The Palais, which gives name to an island, and in which the parliament, with a great many other courts, are held. It was anciently the residence of the kings; but was given to the officers of justice by Philip the Fair, who also settled the parliament here in 1302. The parliament, consisting of several chambers, each of which has its department, is opened the day after Martinmas with a solemn mass, celebrated by a bishop, and continues sitting till the 8th of September, when a vacation-chamber is appointed during the interval, for criminal causes, and others which require dispatch. The jurisdiction of this court is of great extent. There is a beautiful chapel belonging to the Palais; in which is also the prison, or jail, for the jurisdiction of the parliament, called in French *La Conciergerie*. 5. The Hotel Dieu, the most ancient and largest hospital in Paris, in which 8000 sick and infirm poor are taken care of, and attended by the nuns of the order of St Augustine. 6. The hospital of St Catharine, where poor women and maidens are entertained three days, and attended by the abovementioned nuns. 7. The Grande Chatelet, where some of the inferior courts of justice hold their sessions. 8. Fort l'Eveque, in which is the mint and a prison. It stands in or near the street La Ferroniere, in which Henry IV. was stabbed by Ravilliac. 9. St Germain l'Auxerrois, which is called the *royal palace church*; because the palaces of the Louvre and Thuilleries stand in its parish. 10. The Louvre, an ancient royal palace, of which a part was rebuilt by Lewis XIV. Had it been completed on the same plan, it would have been a most magnificent structure. On one of its gates is the following inscription, *Dum totum impleret orbem*: the meaning of which is, "May it last till the owner of it hath extended his sway over the whole world;" which implies what the French kings have constantly aimed at. Another inscription shews, at the same time, the vanity of the nation, and their abject flattery of their grande monarque. It may be rendered in English thus:

Louvre is a palace for great Lewis fit:  
God him alone exceeds, as heaven does it.

This palace is joined to the Thuilleries by a gallery, in which are 180 models of fortresses, some situated in France, and some in other countries, executed with the utmost accuracy. Here is a valuable collection

of paintings, the king's printing-house, the mint where the king's medals are struck, together with a prodigious quantity of rich tapestry hangings, and a collection of ancient arms, among which are those worn by Francis I. at the famous battle of Pavia. Here also the French academy, the academy of inscriptions and belles letters, the royal academy of sciences, the academy of painting and sculpture, and the royal academy of architecture, have their meetings. The first of these was founded for the improvement of the French language; and as for the others, their names explain the design of their institution. 11. Le Palais Royal, which was built by cardinal Richlieu, in the year 1636, and belongs to the duke of Orleans. It is said to contain pictures to the value of four millions of livres, which were purchased by the regent of that title, and of which a part belonged to Christina queen of Sweden. 12. The palace des Tuilleries, so called from a tile or brick-kiln which stood there formerly. This palace, as we observed above, communicates with the Louvre by a gallery. Behind it are exceeding pleasant gardens, adorned with fine walks, planted with ever-greens, and other trees, and with beautiful parterres, where are to be seen, all the year round, every flower according to its season. There are also three fine fountains, the garden, and a canal. Behind the Tuilleries, on the bank of the river, are pleasant walks, composed of four rows of lofty elms, to which vast crowds of people resort in the fine weather, as well as to the gardens. In the palace is a spacious and magnificent theatre, and hard by it are the Elysian fields, where a surprising number of coaches are to be seen in fair weather: not far off is the church of St Roche, where the celebrated poet Corneille is interred. 13. La place de Louis le Grand, a very beautiful square, in the centre of which is an equestrian statue of that king, which is justly accounted a master-piece. 14. The Place, or Square des Victoires, which is round, and contains a statue of Lewis XIV. of gilt brass, erected to him by the duke de la Fuillade, with this inscription, *Viro immortalis*. 15. The Royal Library in the Rue Vivien, which contains 94,000 printed books, 30,000 manuscripts, and a prodigious collection of copperplates and medals. Near by, in the church-yard of St Josph, lies the famous comic poet Moliere. 16. The parish-church of St Eustace, which stands in the quarter of the same name, and contains the tomb of the great minister Colbert. 17. The gate of St Dennis, which was erected as a triumphal arch in honour of Lewis XIV. 18. The gate of St Martin, erected also in form of a triumphal arch, in honour of the same king. Not far from hence, in the church-yard of St Nicholas des Champs, Peter Gassendi, and other learned men, are buried. 19. La Greve, an open place, where all public rejoicings are celebrated, and malefactors executed. 20. The Hotel de Ville, which is a large building of Gothic architecture, tho' adorned with columns of the Corinthian order. 21. The arsenal in the quarter of St Paul, consisting of many spacious buildings, among which are a foundry, and a house for making saltpetre. Here is a musketoon of two barrels, which it is said will pierce a thick board at the distance of six miles; and, for discerning an object at that distance, has a telescope fixed to the barrel. 22. The Bastile, a kind of fortress like the

Paris.

the Tower of London, which is used as a prison for state-criminals, and for such as are taken up by letters de cachet, i. e. by warrants signed by the king, and sealed. 23. Le Temple, a commandery of the knights of Malta, which gives name to a quarter, wherein, being a privileged place, artificers, that are not freemen, may carry on their business without molestation. The temple is the residence of the grand prior of the French nation. 24. That formerly called *La Maison professes des Jesuites*, in the quarter of St Anthony, in the church of which the hearts of Lewis XIII. and XIV. are preserved, each in a casket of gold, supported by two angels of massy silver, and as big as the life, hovering with expanded wings. In the same quarter is a fine looking-glass manufacture, where above 500 persons are employed in polishing plates cast at St Gobin; with a convent of Franciscans, the monks of which are called *Pique-puces*, or *Prick fleas*.

In that part of the city called the *University*, the principal places are,

1. The university which gives name to it, and which was first founded, as it is said, by Charles the Great: all the arts and sciences are taught here, particularly law, physic, and divinity. There are above forty colleges; of which the chief are those of Sorbonne, of Navarre, of the faculty of physic, and of the four nations; but lectures are read only in eleven of them. The head of the university is the rector, who is chosen every three months, but sometimes is continued several years. All the professors have settled salaries; the whole annual income of the university amounting, it is said, to about 50,000 livres. 2. The Gobelins, a house or palace, where a great number of ingenious artists, in various manufactures and handicrafts, are employed by the government. The most curious tapestry of all sorts is made here. 3. The General Hospital, a most noble foundation for the poor of the female sex, near 7000 objects being taken care of and provided for. The sick are carefully tended; and those that are in health are obliged to work; different wards being allotted for foundlings, for girls who sew or knit, prostitutes, idiots, and poor women; of the last, some are kept gratis, and others pay a small matter. In the castle of Bicetre, belonging to this hospital, and consisting of many large buildings, are near 4000 persons of the other sex, among which are persons disordered in their senses, and such as are afflicted with the venereal disease. To this hospital are also sent children who abuse their parents, and lead dissolute lives. The fund for the maintenance of it, and the hospital de la Pitié, where poor children are brought up, together with the Hotel Dieu, amounts to above two millions of livres *per annum*. 4. The King's Physic Garden, in which are an infinite variety of plants and trees, a certain sum being allotted by the king for keeping the garden in order, and improving it, and for lectures on botany, anatomy, chemistry, and the materia medica. A curious collection of natural curiosities is kept here. 5. The abbey of St Victor, in which is a public library, containing some very ancient and scarce books, several curious manuscripts, and a prodigious collection of maps and copperplates. 6. The College of Physicians, to which belong five professors. 7. The Little Chatelet, an old fortress, now used for a prison. 8. The Rue St Jacques, chief-

ly inhabited by bookellers. 9. The Royal College, and that of Lewis the Great: to the former belong twelve professors. 10. The Abbey of St Genevieve, in which is the marble monument of king Clovis, the shrine of St Genevieve, a large library, with a cabinet of antiquities and natural curiosities. 11. The Royal Observatory, a most stately edifice, built on the highest part of the city. Several astronomers are maintained here by the king. 12. The Royal Academy of surgery, instituted in 1731. 13. The Convent of Franciscans, in the quarter of St Andrew, the richest in France. In the same quarter are some remains of the palace of Julian the Apostate, in which Chilbert, and some other kings of the Franks, afterwards resided. 14. The Play-house. 15. The Convent of Carthusians, in the quarter of Luxemburg, containing fine paintings. 16. The Palace of Luxemburg, or Orleans, a magnificent structure, containing also some fine paintings by Rubens, and embellished with a noble garden. In the Hotel des Ambassadeurs, ambassadors extraordinary are entertained for three days, and those of remote countries all the time they stay at Paris. 17. The Abbey of St Germain des Prez, which contains a very valuable library, the manuscripts alone making 8,000 volumes: here also is a cabinet of antiquities. 18. The Hotel royal des Invalides, erected by Lewis XIV. in which lame and superannuated officers and soldiers are maintained. The buildings take up no less than 17 acres. The number of common soldiers here amount to about 3000, and of officers to about 500. The chapel is very magnificent. Hard by is a military academy, in which 500 young gentlemen are instructed in the art of war.

PARIS, *herb Paris*, or *truelove*; a genus of the trigynia order, belonging to the octandria class of plants. There are but one species, growing naturally in woods and shady places both in Scotland and England. It hath a single naked stem, greenish blossoms, and bluish black berries.—The leaves and berries are said to partake of the properties of opium; and the juice of the berries is useful in inflammations of the eyes. Linnaeus says, that the root will vomit as well as ipecacuanha, but must be taken in double the quantity. Goats and sheep eat the plant; cows, horses, and swine, refuse it.

PARISH, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church, and are under the particular charge of its minister.

The word comes from the Latin *parochia*, the Greek *παροικια*, "habitation;" compounded of *παρ*, "near," and *οικος*, "house."—Accordingly Du Cange observes, that the name *παροικια* was anciently given to the whole territory of a bishop, and derives it from neighbourhood; because the primitive Christians, not daring to assemble openly in cities, were forced to meet secretly in neighbour-houses.

In the ancient church there was one large edifice in each city for the people to meet in; and this they called *parochia*, *parish*. But the signification of the word was afterwards enlarged, and by a parish was meant a diocese, or the extent of the jurisdiction of a bishop, consisting of several churches; unless we will suppose, as some do, that those bishops were only

Paris,  
Parish.

only pastors of single churches. See *DIOCESE* and *BISHOP*.

Du PIN observes, that country parishes had not their origin before the 4th century; but those of cities are more ancient. The city of Alexandria is said to have been the first that was divided into parishes.

PARISII, (anc. geog.), a people of Gallia Celtica, inhabiting the country about the Sequana and Matrona. Now a great part of the Isle of France.—*Parisi*, (Ptolemy), a people of Britain, having the Brigantes to the north and west, the German sea to the east, and the Coritani to the south, from whom they were separated by the Humber. Now *Holderness*, a peninsula of the East Riding of Yorkshire.

PARISIORUM CIVITAS. See LUTETIA.

PARIUM, (anc. geog.), a noble city of Mysia Minor, with a port on the Propontis; called *Adrasia* by Homer, according to Pliny; but Strabo distinguishes them: according to others, the *Paestoi* of Homer. *Pariani*, the people, (Strabo). The birthplace of Neoptolemus surnamed *Glossographus*, (Strabo). Here stood a Cupid equal, in exquisite workmanship, to the Cnidian Venus.

PARK, (French *parque*, i. e. *locus inclusus*), is a large quantity of ground inclosed and privileged for wild beasts of chase, by the king's grant or prescription. See *CHASE* and *FOREST*.

Manwood defines a chase to be “a privileged place for beasts of venary, and other wild beasts of the forest and chase, *tam Sylvestres, quam Campestres*,” and differs from a chase or warren, in that it must be inclosed: for if it lies open, it is good cause of seizure into the king's hands, as a thing forfeited: as a free chase is, if it be inclosed: besides, the owner cannot have an action against such as hunt in his park, if it lies open. No man can erect a park without licence under the broad seal; for the common law does not encourage matter of pleasure, which brings no profit to the commonwealth. But there may be a park in reputation, erected without any lawful warrant; and the owner may bring his action against persons killing his deer.

To a park three things are required. 1. A grant thereof. 2. Inclosures by pale, wall, or hedge. 3. Beasts of a park; such as the buck, doe, &c. And where all the deer are destroyed, it shall no more be accounted a park; for a park consists of vert, venison, and inclosure; and if it is determined in any of them, it is a total disparking.

Parks as well as chases are subject to the common law, and are not to be governed by the forest laws.

PARK, as connected with gardening. See *GARDENING*.

A park and a garden are more nearly allied than a farm and a garden\*, and can therefore be accommodated to each other without any disparagement to either. A farm loses some of its characteristic properties by the connection, and the advantage is on the part of the garden; but a park thus bordered retains all its own excellencies; they are only enriched, not counteracted, by the intermixture. The most perfect composition of a place that can be imagined, consists of a garden opening into a park, with a short walk through the latter to a farm, and ways along its glades to ridings in the country; but to the farm and the ri-

dings the park is no more than a passage; and its woods and its buildings are but circumstances in their views;—its scenes can be communicated only to the garden.

The affinity of the two subjects is so close, that it would be difficult to draw the exact line of separation between them. Gardens have lately encroached very much both in extent and in style on the character of a park; but still there are scenes in the one which are out of the reach of the other. The small sequestered spots which are agreeable in a garden would be trivial in a park; and the spacious lawns which are among the noblest features of the latter, would in the former fatigue by their want of variety; even such as, being of a moderate extent, may be admitted into either, will seem bare and naked, if not broken in the one; and lose much of their greatness, if broken, in the other. The proportion of a part to the whole is a measure of its dimensions: it often determines the proper size for an object, as well as the space fit to be allotted to a scene; and regulates the style which ought to be assigned to either.

But whatever distinctions the extent may occasion between a park and a garden, a state of highly cultivated nature is consistent with each of their characters; and may in both be of the same kind, though in different degrees.

The excellencies both of a park and of a garden are happily blended at Hagley (A), where the scenes are equally elegant and noble. It is situated in the midst of a fertile and lovely country, between the Clent and the Witchberry hills; neither of which are within the pale, but both belong to the place. The latter rise in three beautiful swells. One of them is covered with wood; another is an open sheep-walk, with an obelisk on the summit; on the third, the portico of the temple of Theseus, exactly on the model of that at Athens, and little less in the dimensions, stands boldly out upon the brow, backed by the dark ground of a plantation, and has a most majestic appearance above the trees which fall before and beside it. The house is seen to the greatest advantage from these eminences, and every point of them commands some beautiful prospect. The busy town of Stourbridge is just below them; the ruins of Dudley castle rise in the offskip; the country is full of industry and inhabitants; and a small portion of the moor, where the minerals, manufactured in the neighbourhood, are dug, breaking in upon the horizon, accounts for the richness, without derogating from the beauty, of the landscape. From the Clent hills the views are still greater; they extend on one side to the black mountains in Wales, a long ridge which appears, at 60 miles distance, in the interval between the unweildy heap of the Malvern hills, and the solitary peak of the Wrekin, each 30 miles off, and as many asunder. The smoke of Worcester, the churches in Birmingham, and the houses in Stourbridge, are distinctly visible. The country is a mixture of hill and dale, and strongly inclosed; except in one part, where a heath, varied by rising grounds, pieces of water, and several objects, forms an agreeable contrast to the cultivation which surrounds it. From the other extremity of the Clent hills, the prospect is less extensive; but the ground is more rude and broken: it is often overpread with large and beautiful woods; and the view is dignified with numerous seats. The hills also  
being

\* See *Farm and Gardening*.

being very irregular, large advanced promontories frequently interrupt the sight, and vary the scene: in other parts, deep valleys shelving down towards the country below, exhibit the objects there in different lights. In one of these hollows is built a neat cottage, under a deep descent, sheltered besides by plantations, and presenting ideas of retirement in the midst of so much open exposure; from the heights above it, is seen all that view which before was commanded from the Witchberry hills, but which is seen here over Hagley park; a noble fore-ground, beautiful in itself, and completing the landscape.

The house, though low in the park, is yet above the adjacent country, which it overlooks to a very distant horizon. It is surrounded by a lawn of fine uneven ground, and diversified with large clumps, little groupings, and single trees. It is open in front, but covered on one side by the Witchberry hills; on the other side, and behind, by the eminences in the park, which are high and steep, and all overpread with a lofty hanging wood. The lawn pressing to the foot, or creeping up the slopes of these hills, and sometimes winding along glades into the depth of the wood, traces a beautiful outline to a sylvan scene, already rich to luxuriance in masses of foliage and stateliness of growth.

But though the wood appears to be entire, it in reality opens frequently into lawns, which occupy much of the space within it. In the number, the variety, and the beauty of these lawns, in the shades of the separations between them, in their beauties also, and their varieties, the glory of Hagley consists. No two of the openings are alike in dimensions, in shape, or in character. One is of no more than five or six acres; another of not less than fifty; and others are of all the intermediate sizes. Some stretch out into lengthened glades; some widen every way: they are again distinguished by buildings, by prospects, and often by the style only of the plantations around them. The boundary of one is described by a few careless lines; that of another is composed of many parts, very different and very irregular; and the ground is never flat; but falls sometimes in steep descents, sometimes in gentle declivities waves along easy swells, or is thrown into broken inequalities, with endless variety.

An octagon seat, sacred to the memory of Thomson, and erected on his favourite spot, stands on the brow of a steep; a mead winds along the valley beneath, till it is lost on either hand behind some trees. Opposite to the seat, a noble wood crowns the top, and feathers down to the bottom of a large, oval, swelling hill. As it defends on one side, the distant country becomes the offskip. Over the fall, on the other side, the Clent hills appear. A dusky antique tower stands just below them, at the extremity of the wood; and in the midst of it is seen a Doric portico, called *Pope's Building*, with part of the lawn before it. The scene is very simple: the principal features are great; they prevail over all the rest, and are intimately connected with each other.

The next opening is small, circling about a rotunda on a knole, to the foot of which the ground rises every way. The trees which surround it are large; but their foliage is not very thick; and their stems appearing beneath, their ramifications between the boughs are, in so confined a spot, very distinguished and agreeable

circumstances. It is retired; has no prospect; no visible outlet but one, and that is short and narrow, to a bridge with a portico upon it, which terminates a piece of water.

The grove behind the rotunda separates this from a large, airy, forest glade, thinly skirted with wood, careles of dress, and much overgrown with fern. The wildness is an acceptable relief in the midst of so much elegance and improvement as reign in the neighbouring lawns; and the place is in itself pleasant; in no part confined; and from a Gothic seat at the end is a perspective view of that wood and tower which were seen before in front, together with the Witchberry hills, and a wide range of country.

The tower, which in prospect is always connected with wood, stands however on a piece of down, which stretches along the broad ridge of a hill, and spreads on each hand for some way down the sides. Thick groves catch the falls. The descent on the right is soon lost under the trees; but that on the left being steeper and shorter, it may be followed to the bottom. A wood hangs on the declivity, which is continued in the valley beneath. The tower overlooks the whole: it seems the remains of a castle, partly entire, partly in ruins, and partly overgrown with bushes. A finer situation cannot be imagined: It is placed in an exposed unfrequented spot; commands an extensive prospect; and is every where an interesting object.

At the end of the valley below it, in an obscure corner, and shut out from all view, is a hermitage, composed of roots and of moss: high banks, and a thick covert darkened with horse-chestnuts, confine the sequestered spot: a little rill trickles through it, and two small pieces of water occupy the bottom. They are seen on one side through groups of trees; the other is open, but covered with fern. This valley is the extremity of the park; and the Clent hills rise in all their irregularity immediately above it.

The other descent from the castle is a long declivity, covered like the rest with noble woods, in which fine lawns are again embosomed, differing still from the former, and from each other. In one, the ground is very rough, the boundary is much broken, and marked only by the trunks of the trees which shoot up high before the branches begin. The next is more simple; and the ground falls from an even brow into one large hollow, which slopes towards the glen, where it sinks into the covert. This has a communication thro' a short glade, and between two groves, with another called the *Tinian lawn*, from the resemblance which it is said to bear to those of that celebrated island: it is encompassed with the stateliest trees, all fresh and vigorous, and so full of leaf, that not a stem, not a branch, appears, but large masses of foliage only describe an undulating outline: the effect, however, is not produced by the boughs feathering down to the bottom; they in appearance shoot out horizontally, a few feet above the ground, to a surprising distance, and form underneath an edging of shade, into which the retreat is immediate at every hour of the day. The verdure of the turf is as luxuriant there as in the open space: the ground gently waves in both over easy swells and little dips, just varying, not breaking, the surface. No strong lines are drawn; no striking objects are admitted; but all is of an even temper, all mild,

Park.

mild, placid, and serene; in the gayest season of the day not more than cheerful, in the stillest watch of night not gloomy. The scene is indeed peculiarly adapted to the tranquillity of the latter, when the moon seems to repose her light on the thick foliage of the grove, and steadily marks the shade of every bough. It is delightful then to saunter here, and see the grails, and the gossamer which entwines it, glistening with dew; to listen and hear nothing stir, except perhaps a withered leaf dropping gently through a tree; and, sheltered from the chill, to catch the freshness of the evening air: a solitary urn, chosen by Mr Pope for the spot, and now inscribed to his memory, when shewn by a gleam of moon-light through the trees, fixes that thoughtfulness and composure to which the mind is infensibly led by the rest of this elegant scene.

The Doric Portico, which also bears his name, tho' not within sight, is near: it is placed on the declivity of a hill; and Thomson's seat, with its groves and appendages, are agreeable circumstances in the prospect before it. In the valley beneath is fixed a bench, which commands a variety of short views; one is up the ascent to the portico, and others thro' openings in the wood to the bridge and the rotunda.

The next lawn is large: the ground is steep and irregular, but inclines to one direction, and falls from every side into the general declivity: the outline is diversified by many groupes of trees on the slopes; and frequent glimpses of the country are seen in perspective through openings between them. In the brow is a seat, in the proudest situation of all Hagley; it commands a view down the bold sweep of the lawn, and over a valley filled with the noblest trees, up to the heights beyond. One of those heights is covered with a hanging wood; which opens only to shew Thomson's seat, and the groves and the steep about it: the others are the Witchberry hills, which seem to press forward into the landscape; and the massy heads of the trees in the vale, uniting into a continued surface, form a broad base to the temple of Theseus, hide the swell on which it is built, and crowd up to the very foundation. Farther back stands the obelisk; before it is the sheep-walk; behind it the Witchberry wood. The temple is backed by the firs; and both these plantations are connected with that vast sylvan scene, which overpreads the other hill, and all the intermediate valley. Such extent of wood; such variety in the disposition of it; objects so illustrious in themselves, and ennobled by their situations, each contrasted to each, every one distinct, and all happily united: the parts so beautiful of a whole so great, seen from a charming lawn, and surrounded by a delightful country, compose all together a scene of real magnificence and grandeur.

The several lawns are separated by the finest trees; which sometimes grow in airy groves, chequered with gleams of light, and open to every breeze; but more frequently, whose great branches meeting or crossing each other, cast a deep impenetrable shade. Large boughs feathering down often intercept the sight; or a vacant space is filled with coppice-wood, nut, hawthorn, and hornbeam, whose tufted heads mixing with the foliage, and whose little stems clustering about the trunks of the trees, thicken and darken the planta-

Park.

tion. Here and there the division is of such coppice-wood only, which then being less constrained and oppressed, springs up stronger, spreads further, and joins in a low vaulted covering: in other places the shade is high, over-arched by the tallest ash, or spreads under the branches of the most venerable oaks. They rise in every shape, they are disposed in every form in which trees can grow. The ground beneath them is sometimes almost level; sometimes a gentle swell; but generally very irregular and broken. In several places, large hollows wind down the sides of the hills, worn in the stormy months by water-courses, but worn many ages ago. Very old oaks in the midst of the channels prove their antiquity: some of them are perfectly dry most part of the year; and some are watered by little rills all the summer: they are deep and broad; the sides are commonly steep; often abrupt and hollow; and the trees on the bank sometimes extend their roots, all covered with moss, over the channels of the water. Low down in one of these glens, under a thick shade of horse-chestnuts, is a plain bench, in the midst of several little currents and water-falls, running among large loose stones, and the stumps of dead trees, with which the ground is broken. On the brink of another glen, which is distinguished by a numerous rookery, is a seat in a still wilder situation, near a deeper hollow, and in a darker gloom: the falls are nearly perpendicular; the roots of some of the trees are almost bare, from the earth having crumbled away; large boughs of others, sinking with their own weight, seem ready to break from the trunks they belong to; and the finest ash, still growing, lie all afloat the water-course below, which, tho' the stream runs in winter only, yet constantly retains the black tinge of damp, and casts a chill all around.

Gravel-walks are conducted across the glens, thro' the woods, the groves, for the thickets, and along the sides of the lawns, concealed generally from the sight, but always ready for the communication, and leading to the principal scenes. The frequency of these walks, the number and the style of the buildings, and the high preservation in which all the place is kept, give to the whole park the air of a garden. There is, however, one spot more peculiarly adapted to that purpose, and more artificially disposed than the rest; it is a narrow vale, divided into three parts: one of them is quite filled with water, which leaves no room for a path, but thick trees on either side come down quite to the brink; and between them the sight is conducted to the bridge with a portico upon it, which closes the view: another part of this vale is a deep gloom, overhung with large ash and oaks, and darkened below by a number of yews: these are scattered over very uneven ground, and open underneath; but they are encompassed by a thick covert, under which a stream falls, from a stony channel, down a rock; other rills drop into the current, which afterwards pours over a second cascade into the third division of the vale, where it forms a piece of water, and is lost under the bridge. The view from this bridge is a perfect opera scene, through all the divisions of the vale, up to the rotunda. Both these buildings, and the other decorations of the spot, are of the species generally confined to a garden. The hermitage also, which has been described, and its appendages, are in a style which does

not

Park,  
Parker.

not belong to a park; but through all the rest of the place, the two characters are intimately blended. The whole is one subject; and it was a bold idea to conceive that one to be capable of so much variety; it required the most vigorous efforts of a fertile fancy to carry that idea into execution. See GARDENING.

*Park of Artillery.* See ARTILLERY.

*PARK of Provisions*, in military affairs, the place where the sutlers pitch their tents in the rear, and sell their provisions to the soldiers. Likewise that place where the bread-waggons are drawn up, and where the troops receive their ammunition-bread, being the store of the army.

*PARKER* (Matthew), the second Protestant archbishop of Canterbury, was born at Norwich in the year 1504, the 19th of Henry VII. His father, who was a man in trade, died when our author was about 12 years old; but his mother took special care of his education, and at the age of 17 sent him to Corpus-Christi college in Cambridge, where, in 1523, he took his bachelor's degree. In 1527 he was ordained, created master of arts, and chosen fellow of the college. Having obtained a licence to preach, he frequently held forth at St Paul's cross in London, and in other parts of the kingdom. [In 1533 or 1534, he was made chaplain to queen Anne Boleyn, who obtained for him the deanery of Stoke-Clare in Suffolk, where he founded a grammar-school. After the death of the queen, king Henry made him his own chaplain, and in 1541, prebendary of Ely. In 1544, he was, by the king's command, elected master of Corpus-Christi college, and the following year, vice-chancellor of the university. In 1547, he lost the deanery of Stoke, by the dissolution of that college. In the same year he married the daughter of Robert Harlestone, a Norfolk gentleman.

In the year 1552, he was nominated, by Edward VI. to the deanery of Lincoln, which, with his other preferments, enabled him to live in great affluence: but the Papist Mary was hardly seated on the throne, before he was deprived of every thing he held in the church, and obliged to live in obscurity, frequently changing his place of abode to avoid the fate of the other reformers.

Queen Elizabeth ascended the throne in 1558; and in the following year Dr Parker, from indigence and obscurity, was at once raised to the see of Canterbury, an honour which he neither solicited nor desired. In this high station he acted with spirit and propriety. He repaired and beautified his palace at Lambeth at a vast expence; founded several scholarships in Bennet or Corpus-Christi college in Cambridge, and gave large presents of plate to that and to other colleges in this university. He gave 100 volumes to the public library. He likewise founded a free-school at Rochdale in Lancashire. He took care to have the fees filled with pious and learned men; and, considering the great want of libels in many places, he, with the assistance of other learned men, improved the English translation, had it printed on a large paper, and dispersed through the kingdom.

This worthy prelate died in the year 1575, aged 72, and was buried in his own chapel at Lambeth. He was pious without affectation or austerity, cheerful and contented in the midst of adversity, moderate

in the height of power, and beneficent beyond example. He wrote several books; and also published four of our best historians, *Matthew of Westminster*; *Matthew Paris*; *Asser's Life of king Alfred*; and *Tho. Walsingham*.

*PARLEY*, a conference with an enemy. Hence, to beat or sound a parley, is to give a signal for holding such a conference by beat of drum, or sound of trumpet.

*PARLIAMENT*, the grand assembly of the three states of this kingdom, summoned together by the king's authority, to consider of matters relating to the public welfare, and particularly to enact and repeal laws.

The original or first institution of parliaments is one of those matters which lie so far hidden in the dark ages of antiquity, that the tracing of it out is a thing equally difficult and uncertain. The word *parliament* itself (or *colloquium*, as some of our historians translate it) is, comparatively, of modern date; derived from the French, and signifying the place where they met and conferred together. It was first applied to general assemblies of the states under Louis VII. in France, about the middle of the 12th century. But it is certain, that, long before the introduction of the Norman language into England, all matters of importance were debated and settled in the great councils of the realm. A practice which seems to have been universal among the northern nations, particularly the Germans; and carried by them into all the countries of Europe, which they over-ran at the dissolution of the Roman empire. Relics of which constitution, under various modifications and changes, are still to be met with in the diets of Poland, Germany, and Sweden, and the assembly of the estates in France; for what is there now called the *parliament* is only the supreme court of justice, consisting of the peers, certain dignified ecclesiastics, and judges; which neither is in practice, nor is supposed to be in theory, a general council of the realm.

With us in England, this general council hath been held immemorably, under the several names of *michelsynoth*, or "great council," *michel-gemote*, or "great meeting," and more frequently *wittena-gemote*, or "the meeting of wise men." It was also styled in Latin, *commune concilium regni*, *magnum concilium regis*, *curia magna*, *conventus magnatum* vel *procerum*, *assisa generalis*, and sometimes *communitas regni Anglie*. We have instances of its meeting to order the affairs of the kingdom, to make new laws, and to amend the old, or, as Fleta expresses it, *novis injuriis emerfis nova constituere remedia*, so early as the reign of Ina king of the west Saxons. Offa king of the Mercians, and Ethelbert king of Kent, in the several realms of the heptarchy. And, after their union, the Mirrour informs us, that king Alfred ordained for a perpetual usage, that these councils should meet twice in the year, or oftener, if need be, to treat of the government of God's people; how they should keep themselves from sin, should live in quiet, and should receive right. Our succeeding Saxon and Danish monarchs held frequent councils of this sort, as appears from their respective codes of laws; the titles whereof usually speak them to be enacted, either by the king with the advice of his wittena-gemote, or wise men, as,

Parley,  
Parliament.

*Parliament. Hæc sunt instituta, quæ Edgarus rex consilio sapientum suorum instituit; or to be enacted by those sages with the advice of the king, as, Hæc sunt judicia, quæ sapientes consilio regis Ethelstani instituerunt; or lastly, to be enacted by them both together, as, Hæc sunt institutiones, quas rex Edmundus et episcopi sui cum sapientibus suis instituerunt.*

There is also no doubt but these great councils were occasionally held under the first princes of the Norman line. Glanvil, who wrote in the reign of Henry II. speaking of the particular amount of an amerement in the sheriff's court, says, it had never yet been ascertained by the general assize, or assembly, but was left to the custom of particular counties. Here the general assize is spoken of as a meeting well known, and its statutes or decisions are put in a manifest contradiction to custom, or the common law. And in Edward III's time an act of parliament, made in the reign of William the Conqueror, was pleaded in the case of the abbey of St Edmund's-bury, and judicially allowed by the court.

Hence it indisputably appears, that parliaments, or general councils, are coeval with the kingdom itself. How those parliaments were constituted and composed, is another question, which has been matter of great dispute among our learned antiquarians; and particularly, whether the commons were summoned at all; or, if summoned, at what period they began to form a distinct assembly. But without entering into controversies of this sort, it may be sufficient to observe, that it is generally agreed, that in the main the constitution of parliament, as it now stands, was marked out so long ago as the 17th year of king John, A. D. 1215, in the great charter granted by that prince; wherein he promises to summon all archbishops, bishops, abbots, earls, and greater barons, personally; and all other tenants in chief under the crown, by the sheriff and bailiffs; to meet at a certain place, with 40 days notice, to assent aids and scutages when necessary. And this constitution has subsisted in fact at least from the year 1266, 49 Hen. III. there being still extant writs of that date, to summon knights, citizens, and burgesses, to parliament. We proceed therefore to inquire wherein consists this constitution of parliament, as it now stands, and has stood for the space of at least 500 years. And in the prosecution of this inquiry, we shall consider, first, The manner and time of its assembling; Secondly, Its constituent parts: Thirdly, The laws and customs relating to parliament: Fourthly, The methods of proceeding, and of making statutes, in both houses: And, lastly, The manner of the parliament's adjournment, prorogation, and dissolution.

I. *As to the manner and time of assembling.* The parliament is regularly to be summoned by the king's writ or letter, issued out of chancery by advice of the privy-council, at least 40 days before it begins to sit. It is a branch of the royal prerogative, that no parliament can be convened by its own authority, or by the authority of any, except the king alone. And this prerogative is founded upon very good reason. For, supposing it had a right to meet spontaneously, without being called together, it is impossible to conceive that all the members, and each of the houses, would agree unanimously upon the proper time and place of

meeting: and if half of the members met, and half Parliament absented themselves, who shall determine which is really the legislative body, the part assembled, or that which stays away? It is therefore necessary, that the parliament should be called together at a determinate time and place; and, highly becoming its dignity and independence, that it should be called together by none but one of its own constituent parts: and, of the three constituent parts, this office can only appertain to the king; as he is a single person, whose will may be uniform and steady; the first person in the nation, being superior to both houses in dignity; and the only branch of the legislature that has a separate existence, and is capable of performing any act at a time when no parliament is in being. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor: for this revived parliament must have been originally summoned by the crown.

It is true, that the convention-parliament which restored king Charles II. met above a month before his return; the lords by their own authority, and the commons in pursuance of writs issued in the name of the keepers of the liberty of England by authority of parliament; and that the said parliament sat till the 29th of December, full seven months after the Restoration; and enacted many laws, several of which are still in force. But this was for the necessity of the thing, which supercedes all law; for if they had not so met, it was morally impossible that the kingdom should have been settled in peace. And the first thing done after the king's return was, to pass an act declaring this to be a good parliament, notwithstanding the defect of the king's writs. So that as the royal prerogative was chiefly wounded by their so meeting, and as the king himself, who alone had a right to object, consented to waive the objection, this cannot be drawn into an example in prejudice of the rights of the crown. Besides, we should also remember, that it was at that time a great doubt among the lawyers, whether even this healing act made it a good parliament, and held by very many in the negative; though it seems to have been too nice a scruple. And yet, out of abundant caution, it was thought necessary to confirm its acts in the next parliament, by statute 13 Car. II. c. 7. & c. 14.

It is likewise true, at the time of the Revolution, A. D. 1688, the lords and commons by their own authority, and upon the summons of the prince of Orange, (afterwards king William), met in a convention, and therein disposed of the crown and kingdom. But it must be remembered, that this assembling was upon a like principle of necessity as at the Restoration; that is, upon a full conviction that king James the second had abdicated the government, and that the throne was thereby vacant: which supposition of the individual members was confirmed by their concurrent resolution, when they actually came together. And, in such a case as the palpable vacancy of a throne, it follows *ex necessitate rei*, that the form of the royal writs must be laid aside, otherwise no parliament can ever meet again. For let us put another possible case, and suppose, for the sake of argument, that the whole

Parliament. whole royal line should at any time fail, and become extinct, which would indubitably vacate the throne: in this situation it seems reasonable to presume, that the body of the nation, consisting of lords and commons, would have a right to meet and settle the government; otherwise there must be no government at all. And upon this and no other principle did the convention in 1688 assemble. The vacancy of the throne was precedent to their meeting without any royal summons, not a consequence of it. They did not assemble without writ, and then make the throne vacant; but, the throne being previously vacant by the king's abdication, they assembled without writ, as they must do if they assembled at all. Had the throne been full, their meeting would not have been regular; but, as it was really empty, such meeting became absolutely necessary. And accordingly it is declared by statute 1 W. & M. II. c. 1. that this convention was really the two houses of parliament, notwithstanding the want of writs or other defects of form. So that, notwithstanding these two capital exceptions, which were justifiable only on a principle of necessity, (and each of which, by the way, induced a revolution in the government), the rule laid down is in general certain, that the king only can convoke a parliament.

And this, by the ancient statutes of the realm, he is bound to do every year, or oftener, if need be. Not that he is, or ever was, obliged by these statutes to call a new parliament every year; but only to permit a parliament to sit annually for the redress of grievances, and dispatch of business, if need be. These last words are so loose and vague, that such of our monarchs as were inclined to govern without parliaments, neglected the convoking them, sometimes for a very considerable period, under pretence that there was no need of them. But, to remedy this, by the statute 16 Car. II. c. 1. it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most. And by the statute 1 W. & M. II. c. 2. it is declared to be one of the rights of the people, that for redress of all grievances, and for the amending, strengthening, and preserving the laws, parliaments ought to be held frequently. And this indefinite frequency is again reduced to a certainty by statute 6 W. & M. c. 2. which enacts, as the statute of Charles the second had done before, that a new parliament shall be called within three years after the determination of the former.

II. *The constituent parts of a parliament are*, the king's majesty, sitting there in his royal political capacity, and the three estates of the realm; the lords spiritual, the lords temporal, (who sit together with the king in one house), and the commons, who sit by themselves in another. And the king and these three estates together form the great corporation or body politic of the kingdom, of which the king is said to be *caput, principium, et finis*. For upon their coming together the king meets them, either in person or by representation; without which there can be no beginning of a parliament; and he also has alone the power of dissolving them.

It is highly necessary for preserving the balance of the constitution, that the executive power should be a branch, though not the whole, of the legislature. The

total union of them, we have seen, would be productive of tyranny; the total disjunction of them, for the present, would in the end produce the same effects, by causing that union against which it seems to provide. The legislature would soon become tyrannical, by making continual encroachments, and gradually assuming to itself the rights of the executive power. Thus the long parliament of Charles the first, while it acted in a constitutional manner, with the royal concurrence, redressed many heavy grievances and established many salutary laws. But when the two houses assumed the power of legislation, in exclusion of the royal authority, they soon after assumed likewise the reins of administration; and, in consequence of these united powers, overturned both church and state, and established a worse oppression than any they pretended to remedy. To hinder therefore any such encroachments, the king is himself a part of the parliament; and as this is the reason of his being so, very properly therefore the share of legislation which the constitution has placed in the crown, consists in the power of rejecting, rather than resolving; this being sufficient to answer the end proposed. For we may apply to the royal negative, in this instance, what Cicero observes of the negative of the Roman tribunes, that the crown has not any power of doing wrong, but merely of preventing wrong from being done. The crown cannot begin of itself any alterations in the present established law; but it may approve or disapprove of the alterations suggested and consented to by the two houses. The legislature therefore cannot abridge the executive power of any rights which it now has by law, without its own consent; since the law must perpetually stand as it now does, unless all the powers will agree to alter it. And herein indeed consists the true excellence of the British government, that all the parts of it form a mutual check upon each other. In the legislature, the people are a check upon the nobility, and the nobility a check upon the people, by the mutual privilege of rejecting what the other has resolved; while the king is a check upon both, which preserves the executive power from encroachments. And this very executive power is again checked and kept within due bounds by the two houses, through the privilege they have of inquiring into, impeaching, and punishing the conduct (not indeed of the king, which would destroy his constitutional independence; but, which is more beneficial to the public) of his evil and pernicious counsellors. Thus every branch of our civil polity supports and is supported, regulates and is regulated, by the rest: for the two houses naturally drawing in two directions of opposite interest, and the prerogative in another still different from them both, they mutually keep each other from exceeding their proper limits; while the whole is prevented from separation, and artificially connected together by the mixed nature of the crown, which is a part of the legislative, and the sole executive magistrate. Like three distinct powers in mechanics, they jointly impel the machine of government in a direction different from what either, acting by itself, would have done; but at the same time in a direction partaking of each, and formed out of all; a direction which constitutes the true line of the liberty and happiness of the community.

Parliament.

Having already considered these constituent parts of the sovereign power, or parliament, each in a separate view, under the articles KING, LORDS, and COMMONS, to which the reader is referred, we proceed,

III. To examine the laws and customs relating to parliament, united together and considered as one aggregate body. The power and jurisdiction of parliament, says Sir Edward Coke, is so transcendent and absolute, that it cannot be confined, either for causes or persons, within any bounds. And of this high court he adds, it may be truly said, *Si antiquitatem spectes, est vetustissima; si dignitatem, est honoratissima; si jurisdictionem, est capacissima*. It hath sovereign and uncontrollable authority in making, confirming, enlarging, restraining, abrogating, repealing, reviving, and expounding of laws, concerning matters of all possible denominations, ecclesiastical or temporal, civil, military, maritime, or criminal: this being the place where that absolute despotic power, which must in all governments reside somewhere, is entrusted by the constitution of these kingdoms. All mischiefs and grievances, operations and remedies, that transcend the ordinary course of the laws, are within the reach of this extraordinary tribunal. It can regulate or new-model the succession to the crown; as was done in the reign of Henry VIII. and William III. It can alter the established religion of the land; as was done in a variety of instances, in the reigns of king Henry VIII. and his three children. It can change and create afresh even the constitution of the kingdom and of parliaments themselves; as was done by the act of union, and the several statutes for triennial and septennial elections. It can, in short, do every thing that is not naturally impossible; and therefore some have not scrupled to call its power, by a figure rather too bold, the *omnipotence of parliament*. True it is, that what the parliament doth, no authority upon earth can undo. So that it is a matter most essential to the liberties of this kingdom, that such members be delegated to this important trust as are most eminent for their probity, their fortitude, and their knowledge; for it was a known apothegm of the great lord treasurer Burleigh, "That England could never be ruined but by a parliament;" and, as Sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in the kingdom, if by any means a misgovernment should any way fall upon it, the subjects of this kingdom are left without all manner of remedy. To the same purpose the president Montesquieu, though we trust too hastily, presages, that as Rome, Sparta, and Carthage, have lost their liberty and perished; so the constitution of England will in time lose its liberty, will perish: it will perish whenever the legislative power shall become more corrupt than the executive.

It must be owned that Mr. Locke, and other theoretical writers, have held, that "there remains still inherent in the people a supreme power to remove or alter the legislative, when they find the legislative act contrary to the trust reposed in them; for when such trust is abused, it is thereby forfeited, and devolves to those who gave it." But however just this conclusion may be in theory, we cannot adopt it, nor argue from it, under any dispensation of government at present actually existing. For this devolution of power,

to the people at large, includes in it a dissolution of Parliament. the whole form of government established by that people; reduces all the members to their original state of equality; and by annihilating the sovereign power, repeals all positive laws whatsoever before enacted. No human laws will therefore suppose a case, which at once must destroy all law, and compel men to build afresh upon a new foundation; nor will they make provision for so desperate an event, as must render all legal provisions ineffectual. So long therefore as the English constitution lasts, we may venture to affirm, that the power of parliament is absolute and without control.

In order to prevent the mischiefs that might arise, by placing this extensive authority in hands that are either incapable or else improper to manage it, it is provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be 21 years of age. This is also expressly declared by statute 7 & 8 W. III. c. 25: with regard to the house of commons, doubts have arisen, from some contradictory adjudications, whether or no a minor was incapacitated from sitting in that house. It is also enacted by statute 7 Jac. I. c. 6. that no member be permitted to enter the house of commons till he hath taken the oath of allegiance before the lord steward or his deputy: and by 30 Car. II. st. 2. and 1 Geo. I. c. 13. that no member shall vote or sit in either house till he hath, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, and subscribed and repeated the declaration against transubstantiation, and invocation of saints, and the sacrifice of the mass. Aliens, unless naturalized, were likewise by the law of parliament incapable to serve therein: and now it is enacted, by statute 12 & 13 W. III. c. 2. that no alien, even though he be naturalized, shall be capable of being a member of either house of parliament. And there are not only these standing incapacities; but if any person is made a peer by the king, or elected to serve in the house of commons by the people, yet may the respective houses, upon complaint of any crime in such person, and proof thereof, adjudge him disabled and incapable to sit as a member: and this by the law and custom of parliament.

For as every court of justice hath laws and customs for its direction, some the civil and canon, some the common law, others their own peculiar laws and customs; so the high court of parliament hath also its own peculiar law, called the *lex et consuetudo parliamenti*; a law which Sir Edward Coke observes is *ab omnibus querenda, a multis ignorata, a paucis cognita*. It will not therefore be expected that we should enter into the examination of this law with any degree of minuteness; since, as the same learned author assures us, it is much better to be learned out of the rolls of parliament and other records, and by precedents and continual experience, than can be expressed by any one man. It will be sufficient to observe, that the whole of the law and custom of parliament has its original from this one maxim, "That whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere." Hence, for instance, the lords will not suffer the commons to interfere in settling the election of a peer of Scotland; the commons

commons will not allow the lords to judge of the election of a burgess; nor will either house permit the subordinate courts of law to examine the merits of either case. But the maxims upon which they proceed, together with the method of proceeding, rest entirely in the breast of the parliament itself; and are not defined and ascertained by any particular stated laws.

The privileges of parliament are likewise very large and indefinite; and therefore, when, in 3<sup>rd</sup> Hen. VI. the house of lords propounded a question to the judges concerning them, the chief justice, Sir John Fortescue, in the name of his brethren, declared, "That they ought not to make answer to that question; for it hath not been used aforetime, that the justices should in any wise determine the privileges of the high court of parliament; for it is so high and mighty in its nature, that it may make law; and that which is law, it may make no law; and the determination and knowledge of that privilege belongs to the lords of parliament, and not to the justices." Privilege of parliament was principally established, in order to protect its members not only from being molested by their fellow-subjects, but also more especially from being oppressed by the power of the crown. If therefore all the privileges of parliament were once to be set down and ascertained, and no privilege to be allowed but what was so defined and determined, it were easy for the executive power to devise some new case, not within the line of privilege, and under pretence thereof to harass any refractory member, and violate the freedom of parliament. The dignity and independence of the two houses are therefore in great measure preserved by keeping their privileges indefinite. Some, however, of the more notorious privileges of the members of either house, are privilege of speech, of person, of their domestics, and of their lands and goods. As to the first, privilege of speech, it is declared by the statute 1 W. & M. II. 2. c. 2. as one of the liberties of the people, "That the freedom of speech, and debates, and proceedings in parliament, ought not to be impeached or questioned in any court or place out of parliament." And this freedom of speech is particularly demanded of the king in person, by the speaker of the house of commons, at the opening of every new parliament. So likewise are the other privileges, of person, servants, lands, and goods; which are immunities as ancient as Edward the Confessor: in whose laws we find this precept, *Ad synodos venientibus, sine summoniti sint, sine per se quid agendum habuerint sit summa pax*; and so too in the old Gothic constitutions, *Extenditur hæc pax et securitas ad quatuordecim dies, convocato regni senatu*. This included formerly not only privilege from illegal violence, but also from legal arrests and seizures by process from the courts of law. And still to assault by violence a member of either house, or his menial servants, is a high contempt of parliament, and there punished with the utmost severity. It has likewise peculiar penalties annexed to it in the courts of law by the statutes 5 Hen. IV. c. 6. and 11 Hen. VI. c. 11. Neither can any member of either house be arrested and taken into custody without a breach of the privilege of parliament.

But all other privileges which derogate from the common law are now at an end, save only as to the freedom of the member's person; which in a peer (by

the privilege of peerage) is for ever sacred and inviolable; and in a commoner (by the privilege of parliament) for forty days after every prorogation, and forty days before the next appointed meeting; which is now in effect as long as the parliament subsists, it seldom being prorogued for more than eighty days at a time. As to all other privileges which obstruct the ordinary course of justice, they were restrained by the statutes 12 W. III. c. 3. 2 & 3 Ann. c. 18. and 11 Geo. II. c. 24. and are now totally abolished by statute 10 G. III. c. 50.; which enacts, that any suit may at any time be brought against any peer or member of parliament, their servants, or any other person entitled to privilege of parliament; which shall not be impeached or delayed by pretence of any such privilege, except that the person of a member of the house of commons shall not thereby be subjected to any arrest or imprisonment. Likewise, for the benefit of commerce, it is provided by statute 4 Geo. III. c. 33. that any trader, having privilege of parliament, may be served with legal process for any just debt, (to the amount of 100l.); and unless he makes satisfaction within two months, it shall be deemed an act of bankruptcy; and that commissions of bankrupt may be issued against such privileged traders in like manner as against any other.

The only way by which courts of justice could anciently take cognizance of privilege of parliament was by writ of privilege, in the nature of a *superfedeas*, to deliver the party out of custody when arrested in a civil suit. For when a letter was written by the speaker to the judges, to stay proceedings against a privileged person, they rejected it as contrary to their oath of office. But since the statute 12 Will. III. c. 3. which enacts, that no privileged person shall be subject to arrest or imprisonment, it hath been held, that such arrest is irregular *ab initio*, and that the party may be discharged upon motion. It is to be observed, that there is no precedent of any such writ of privilege, but only in civil suits; and that the statute of 1 Jac. I. c. 13. and that of king William, (which remedy some inconveniences arising from privilege of parliament), speak only of civil actions. And therefore the claim of privilege hath been usually guarded with an exception as to the case of indictable crimes; or, as it hath been frequently expressed, of treason, felony, and breach (or surty) of the peace. Whereby it seems to have been understood, that no privilege was allowable to the members, their families, or servants, in any crime whatsoever; for all crimes are treated by the law as being *contra pacem domini regis*. And instances have not been wanting, wherein privileged persons have been convicted of misdemeanors, and committed, or prosecuted to outlawry, even in the middle of a session; which proceeding has afterwards received the sanction and approbation of parliament. To which may be added, that a few years ago, the case of writing and publishing seditious libels was resolved by both houses not to be entitled to privilege; and that the reasons upon which that case proceeded, extended equally to every indictable offence. So that the chief, if not the only, privilege of parliament, in such cases, seems to be the right of receiving immediate information of the imprisonment or detention of any member, with the reason for which he is detained: a practice that is daily used upon the slightest military accusations, preparatory to a trial by a court

Parliament court-martial; and which is recognized by the several temporary statutes for suspending the *habeas corpus* act: whereby it is provided, that no member of either house shall be detained, till the matter of which he stands suspected be first communicated to the house of which he is a member, and the consent of the said house obtained for his commitment or detaining. But yet the usage has uniformly been, ever since the Revolution, that the communication has been subsequent to the arrest.

These are the general heads of the laws and customs relating to parliament, considered as one aggregate body. The laws and customs relating to each branch in particular being explained under the articles already referred to, *viz.* KING, LORDS, and COMMONS, we should proceed, IV. To the method of making laws; which is much the same in both houses. But for this, too, we have to refer the reader to the article BILL; and shall only observe in this place, that, for dispatch of business, each house of parliament has its speaker. The speaker of the house of lords, whose office it is to preside there, and manage the formality of business, is the lord chancellor, or keeper of the king's great seal, or any other appointed by the king's commission: and if none be so appointed, the house of lords (it is said) may elect. The speaker of the house of commons is chosen by the house; but must be approved by the king. And herein the usage of the two houses differs, that the speaker of the house of commons cannot give his opinion or argue any question in the house; but the speaker of the house of lords, if a lord of parliament, may. In each house the act of the majority binds the whole; and this majority is declared by votes openly and publicly given; not, as at Venice, and many other senatorial assemblies, privately, or by ballot. This latter method may be serviceable, to prevent intrigues and unconstitutional combinations; but is impossible to be practised with us, at least in the house of commons, where every member's conduct is subject to the future censure of his constituents, and therefore should be openly submitted to their inspection.

V. There remains only, in the last place, to add a word or two concerning the manner in which parliaments may be *adjourned*, *prorogued*, or *dissolved*.

An *adjournment* is no more than a continuance of the session from one day to another; as the word itself signifies: and this is done by the authority of each house separately every day; and sometimes for a fortnight or a month together, as at Christmas or Easter, or upon other particular occasions. But the adjournment of one house is no adjournment of the other. It hath also been usual, when his Majesty hath signified his pleasure that both or either of the houses should adjourn themselves to a certain day, to obey the king's pleasure so signified, and to adjourn accordingly. Otherwise, besides the indecorum of a refusal, a prorogation would assuredly follow; which would often be very inconvenient to both public and private business. For prorogation puts an end to the session; and then such bills as are only begun and not perfected, must be resumed *de novo*, (if at all), in a subsequent session; whereas, after an adjournment, all things continue in the same state as at the time of the adjournment made, and may be proceeded on without any fresh commencement.

A *prorogation* is the continuance of the parliament from one session to another; as an adjournment is a continuance of the session from day to day. This is done by the royal authority, expressed either by the lord chancellor in his Majesty's presence, or by commission from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time; it not being a prorogation of the house of lords or commons, but of the parliament. The session is never understood to be at an end until a prorogation; though, unless some act be passed, or some judgment given in parliament, it is in truth no session at all. And formerly the usage was, for the king to give the royal assent to all such bills as he approved at the end of every session, and then to prorogue the parliament, though sometimes only for a day or two; after which all business then depending in the houses was to be begun again. Which custom obtained so strongly, that it once became a question, Whether giving the royal assent to a single bill did not of course put an end to the session? And though it was then resolved in the negative, yet the notion was so deeply rooted, that the statute 1 Car. I. c. 7. was passed to declare, that the king's assent to that and some other acts should not put an end to the session; and even so late as the reign of Charles II. we find a proviso frequently tacked to a bill, that his Majesty's assent thereto should not determine the session of parliament. But it now seems to be allowed, that a prorogation must be expressly made, in order to determine the session. And if at the time of an actual rebellion, or imminent danger of invasion, the parliament shall be separated by adjournment or prorogation, the king is empowered to call them together by proclamation, with 14 days notice of the time appointed for their reassembling.

A *dissolution* is the civil death of the parliament; and this may be effected three ways: 1. By the king's will, expressed either in person or by representation. For as the king has the sole right of convening the parliament, so also it is a branch of the royal prerogative, that he may (whenever he pleases) prorogue the parliament for a time, or put a final period to its existence. If nothing had a right to prorogue or dissolve a parliament but itself, it might happen to become perpetual. And this would be extremely dangerous, if at any time it should attempt to encroach upon the executive power; as was fatally experienced by the unfortunate king Charles I.; who, having unadvisedly passed an act to continue the parliament then in being till such time as it should please to dissolve itself, at last fell a sacrifice to that inordinate power which he himself had consented to give them. It is therefore extremely necessary that the crown should be empowered to regulate the duration of these assemblies, under the limitations which the English constitution has prescribed: so that, on the one hand, they may frequently and regularly come together for the dispatch of business and redress of grievances; and may not, on the other, even with the consent of the crown, be continued to an inconvenient or unconstitutional length.

2. A parliament may be dissolved by the demise of the crown. This dissolution formerly happened immediately upon the death of the reigning sovereign; for he being considered in law as the head of the parliament, (*caput, principium, et finis*), that falling, the whole

Parliament, whole body was held to be extinct. But the calling of a new parliament immediately on the inauguration of the successor being found inconvenient, and dangers being apprehended from having no parliament in being in case of a disputed succession, it was enacted by the statutes 7 & 8 W. III. c. 15. and 6 Ann. c. 7. that the parliament in being shall continue for six months after the death of any king or queen, unless sooner prorogued or dissolved by the successor: that if the parliament be, at the time of the king's death, separated by adjournment or prorogation, it shall notwithstanding assemble immediately: and that if no parliament is then in being, the members of the last parliament shall assemble, and be again a parliament.

3. Lastly, a parliament may be dissolved or expire by length of time. For if either the legislative body were perpetual, or might last for the life of the prince who convened them as formerly, and were so to be supplied, by occasionally filling the vacancies with new representatives; in these cases, if it were once corrupted, the evil would be past all remedy; but when different bodies succeed each other, if the people see cause to disapprove of the present, they may rectify its faults in the next. A legislative assembly also, which is sure to be separated again, (whereby its members will themselves become private men, and subject to the full extent of the laws which they have enacted for others), will think themselves bound, in interest as well as duty, to make only such laws as are good. The utmost extent of time that the same parliament was allowed to sit, by the statute 6 W. & M. c. 3. was three years; after the expiration of which, reckoning from the return of the first summons, the parliament was to have no longer continuance. But by the statute 1 Geo. I. st. 2. c. 38. (in order, professedly, to prevent the great and continued expences of frequent elections, and the violent heats and animosities consequent thereupon, and for the peace and security of the government then just recovering from the late rebellion), this term was prolonged to seven years; and, what alone is an instance of the vast authority of parliament, the very same house that was chosen for three years, enacted its own continuance for seven. So that, as our constitution now stands, the parliament must expire, or die a natural death, at the end of every seventh year, if not sooner dissolved by the royal prerogative.

We shall conclude this article with an account of some general forms not taken notice of under any of the above heads.

In the house of lords, the princes of the blood sit by themselves on the sides of the throne; at the wall, on the king's right hand, the two archbishops sit by themselves on a form. Below them, the bishops of London, Durham, and Winchester, and all the other bishops, sit according to the priority of their consecration. On the king's left hand the lord-treasurer, lord president, and lord privy-seal, sit upon forms above all dukes, except the royal blood; then the dukes, marquesses, and earls, according to their creation. Across the room are wool-facks, continued from an ancient custom; and the chancellor, or keeper, being of course the speaker of the house of lords, sits on the first wool-fack before the throne, with the great seal or mace lying by him; below these are forms for the viscounts and barons. On the other wool facks

are seated the judges, masters in chancery, and king's Parliament council, who are only to give their advice in points of law: but they all stand up till the king gives them leave to sit.

The commons sit promiscuously; only the speaker has a chair at the upper end of the house, and the clerk and his assistant sit at a table near him.

When a member of the house of commons speaks, he stands up uncovered, and directs his speech to the speaker only. If what he says be answered by another, he is not allowed to reply the same day, unless personal reflections have been cast upon him: but when the commons, in order to have a greater freedom of debate, have resolved themselves into a committee of the whole house, every member may speak to a question as often as he thinks necessary. In the house of lords they vote, beginning at the pulpit, or lowest baron, and so up orderly to the highest, every one answering, *Content* or *Not content*. In the house of commons they vote by *yeas* and *nays*; and if it be dubious which are the greater number, the house divides. If the question be about bringing anything into the house, the *yeas* go out; but if it be about any thing the house already has, the *nays* go out. In all divisions the speaker appoints four tellers, two of each opinion. In a committee of the whole house, they divide by changing sides, the *yeas* taking the right and the *nays* the left of the chair; and then there are but two tellers. If a bill pass one house, and the other demur to it, a conference is demanded in the painted chamber, where certain members are deputed from each house; and here the lords sit covered, and the commons stand bare, and debate the case. If they disagree, the affair is null; but if they agree, this, with the other bills that have passed both houses, is brought down to the king in the house of lords, who comes thither clothed in his royal robes; before him the clerk of the parliament reads the title of each bill, and as he reads, the clerk of the crown pronounces the royal assent or dissent. If it be a public bill, the royal assent is given in these words, *Le roy le veut*, "The king will have it so;" if private, *Soi fait comme il est désiré*, "Let the request be complied with: if the king refuses the bill, the answer is, *Le roy s'aviseira*, "The king will think of it;" and if it be a money-bill, the answer is, *Le roy remercie ses loyaux sujets, accepte leur benevolence, & aussi le veut*: "The king thanks his loyal subjects, accepts their benevolence, and therefore grants his consent."

*High Court of PARLIAMENT*, is the supreme court in the kingdom, not only for the making, but also for the execution, of laws; by the trial of great and enormous offenders, whether lords or commons, in the method of parliamentary impeachment. As for acts of parliament to attain particular persons of treason or felony, or to inflict pains and penalties, beyond or contrary to the common law, to serve a special purpose, we speak not of them; being to all intents and purposes new laws, made *pro re nata*, and by no means an execution of such as are already in being. But an impeachment before the lords by the commons of Great Britain, in parliament, is a prosecution of the already known and established law, and has been frequently put in practice; being a presentment to the most high and supreme court of criminal jurisdiction by the most solemn grand inquest of the whole kingdom.

Parliament. dom. A commoner cannot, however, be impeached before the lords for any capital offence, but only for high misdemeanors; a peer may be impeached for any crime. And they usually (in case of an impeachment of a peer for treason) address the crown to appoint a lord high steward, for the greater dignity and regularity of their proceedings; which high steward was formerly elected by the peers themselves, though he was generally commissioned by the king; but it hath of late years been strenuously maintained, that the appointment of a high steward in such cases is not indispensably necessary, but that the house may proceed without one. The articles of impeachment are a kind of bills of indictment, found by the house of commons, and afterwards tried by the lords; who are in cases of misdemeanors considered not only as their own peers, but as the peers of the whole nation. This is a custom derived to us from the constitution of the ancient Germans; who in their great councils sometimes tried capital accusations relating to the public: *Licet apud concilium accusare quoque, et discrimen capitis intendere.* And it has a peculiar propriety in the English constitution; which has much improved upon the ancient model imported hither from the continent. For though in general the union of the legislative and judicial powers ought to be most carefully avoided, yet it may happen that a subject, intrusted with the administration of public affairs, may infringe the rights of the people, and be guilty of such crimes as the ordinary magistrate either dares not or cannot punish. Of these the representatives of the people, or house of commons, cannot properly judge; because their constituents are the parties injured, and can therefore only impeach. But before what court shall this impeachment be tried? Not before the ordinary tribunals, which would naturally be swayed by the authority of so powerful an accuser. Reason therefore will suggest, that this branch of the legislature, which represents the people, must bring its charge before the other branch, which consists of the nobility, who have neither the same interests, nor the same passions, as popular assemblies. This is a vast superiority which the constitution of this island enjoys over those of the Grecian or Roman republics; where the people were at the same time both judges and accusers. It is proper that the nobility should judge, to insure justice to the accused; as it is proper that the people should accuse, to insure justice to the commonwealth. And therefore, among other extraordinary circumstances attending the authority of this court, there is one of a very singular nature, which was insisted on by the house of commons in the case of the earl of Danby in the reign of Charles II. and is now enacted by statute 12 & 13 W. III. c. 2. that no pardon under the great seal shall be pleadable to an impeachment by the commons of Great Britain in parliament.

PARLIAMENTS of France, are sovereign courts established by the king, finally to determine all disputes between particular persons, and to pronounce on appeals from sentences given by inferior judges. There are ten of these parliaments in France, of which that of Paris is the chief, its privileges and jurisdiction being of the greatest extent. It consists of six chambers, v. z. the grand chamber, where causes of audiences are pleaded; and five chambers of inquest, where processes

are adjudged in writing. This parliament enjoys the privileges of verifying and registering the king's arrests or edicts, without which those edicts are of little or no value.

PARLIAMENT of Sweden, consists of four estates, with the king at their head: These estates are, 1. The nobility and representatives of the gentry; with whom the colonels, lieutenant-colonels, majors, and captains of every regiment, sit and vote. 2. The clergy; one of which body is elected from every rural deanry of ten parishes; who, with the bishops and superintendents, amount to about two hundred. 3. The burghers, elected by the magistrates and council of every corporation as their representatives, of whom there are four for Stockholm, and two for every other town, amounting in the whole to about an hundred and fifty. 4. The peasants, chosen by the peasants out of every district; who choose one of their own rank, and not a gentleman, to represent them: these amount to about two hundred and fifty.

All these generally meet at Stockholm: and after the state-affairs have been represented to them from the throne, they separate, and sit in four several chambers or houses, in each of which affairs are carried on by majority of votes; and every chamber has a negative in the passing any law.

PARMA, an ancient, rich, populous, and handsome town of Italy, capital of the duchy of the same name, with a citadel, a bishop's see, and an university. It has a magnificent cathedral, and the largest opera-house in Europe, which has seats for 8000 people; but as it required a vast number of candles, which occasioned great expence, they have contrived another which has room for 2000 spectators. The dome and the church of St John are painted by the famous Corregio, who was a native of this place. Don Carlos, king of the two Sicilies, carried away the library to Naples, which contained 18,000 volumes, and a very valuable cabinet of curiosities, as also the rich collection of medals. The citadel, which is very near the city, is built in the same taste as that at Antwerp. In 1734 there was a bloody battle fought here; and in 1741, by the treaty of Aix-la-Chapelle, the duchies of Parma, Placentia, and Guastalla, were given to Don Philip, brother to Don Carlos above-mentioned. It is 30 miles south-east of Cremona, and 30 south-east of Milan. E. Long. 10. 51. N. Lat. 44. 50.

PARMA, the duchy of a province of Italy, bounded on the north by the Po; on the north-east, by the Mantuan; on the east, by the duchy of Modena; on the south, by Tuscany; and on the west, by the duchy of Placentia. The air is very wholesome, on which account the inhabitants live to a great age. The soil is very fertile in corn, wine, oil, and hemp; the pastures feed a great number of cattle, and the cheese was in very high esteem. Here are considerable mines of copper and silver, and plenty of truffes, which many are very fond of.

PARMEGIANO, a celebrated painter, whose true name was Francesco Mazzuoli; but he received the former from the city of Parma, where he was born, in 1504. He was brought up under his two uncles, and was an eminent painter when but sixteen years of age. He was famous all over Italy at nineteen; and

Parnassus  
||  
Patonoma-  
fia.

at twenty-three performed such wonders, that when the general of the emperor Charles V. took Rome by storm, some of the common soldiers having, in sacking the town, broke into his apartments, found him intent upon his work, and were instantly so struck with the beauty of his pieces, that instead of involving him in the plunder and destruction in which they were then employed, they resolved to protect him from all manner of violence; which they actually performed. His works are distinguished by the beauty of the colouring, the invention, and drawing. His figures are spirited and graceful, particularly with respect to the choice of attitude, and in their dresses. He also excelled in music, in which he much delighted. His principal works are at Parma, where he lived for several years in great reputation; till unhappily he involved himself in ruin, by spending a considerable part of his time and fortune in search of the philosopher's stone; and died poor in 1540.

There are extant many valuable prints made by this master, not only in chiaro oscuro, but also in etching with aqua-fortis, of which he is said to be the inventor, or at least the first who practised the art of etching in Italy.

**PARNASSIA**, genus of Parnassus; a genus of the tetragynia order, belonging to the pentandria class of plants. There is but one species, having a stalk about a foot high, angular, and often a little twisted, bearing a single white flower at top. The flowers are very beautifully streaked with yellow; so that though it is a common plant, growing naturally in moist pastures, it is frequently admitted into gardens.

**PARNASSUS**, (Strabo, Pindar, Virgil), a mountain of Phocis, near Delphi, and the mounts Cithæron and Helicon, with two tops, (Ovid, Lucan); the one called *Cirrho*, sacred to Apollo; and the other, *Nisa*, sacred to Bacchus, (Juvenal). It was covered with bay trees, (Virgil); and originally called *Larnassus*, from Deucalion's larnax or ark, thither conveyed by the flood, (Stephanus, Scholiast on Apollonius); after the flood, *Parnassus*; from Har Nahas, changing the *h* into *p*, the hill of divination or augury, Peuceurus; the oracle of Delphi standing at its foot.

**PARNELL** (Dr Thomas), a very ingenious divine and poet in the early part of this century. He was archdeacon of Clogher, and the intimate friend of Mr Pope; who published his works, with an elegant copy of commendatory verses prefixed. He died in 1718, aged 39.

**PARODY**, a popular maxim, adage, or proverb.

**PARODY**, is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule, to another; or in turning a serious work into a burlesque, by affecting to observe as near as possible the same rhymes, words, and cadences.

**PAROLE**, in a military sense, the promise made by a prisoner of war, when he has leave to go any where, of returning at a time appointed, if not exchanged.

**PAROLE**, means also a word given out every day in orders by the commanding officer, both in camp and garrison, in order to know friends for enemies.

**PARONOMASIA**, in rhetoric, a pun; or a fi-

VOL. VIII.

1

gure whereby words nearly alike in sound, but of very different meanings, are affectedly or designedly used. See ORATORY, n° 76.

**PAROS**, (anc. geog.), an island of the Ægean sea, one of the Cyclades, with a strong cognominal town, 38 miles distant from Delos, (Pliny, Nepos). Anciently called *Padye* and *Minoa*, (Pliny); also *Demetrias*, *Zacynthus*, *Hyria*, *Hylessa*, and *Cabarnis*, (Nicaur). The country of Archilochus, the Iambic poet, (Strabo). An island famous for its white marble, (Virgil, Horace, Ovid), called *lychnites*, because dug with lamps, (Pliny).

**PAROTIDES**, in anatomy. See there, n° 391.

**PAROXYSM**, in medicine, the severe fit of a disease, under which it grows higher or exasperated; as of the gout, &c.

**PARR** (Catharine), was the eldest daughter of Sir Thomas Parr of Kendall. She was first married to John Nevil, lord Latmyer; after whose death she so captivated her amorous sovereign, that he raised her to the throne. The royal nuptials were solemnized at Hampton Court on the 12th of July 1543. Being religiously disposed, she was, in the early part of her life, a zealous observer of the Romish rites and ceremonies; but, in the dawning of the Reformation, she became as zealous a promoter of the Lutheran doctrine; yet with such prudence and circumspection as her perilous situation required. Nevertheless, we are told, that she was in great danger of falling a sacrifice to the Popish faction, the chief of whom was bishop Gardiner: he drew up articles against her, and prevailed on the king to sign a warrant to remove her to the Tower. This warrant was, however, accidentally dropped, and immediately conveyed to her majesty. What her apprehensions must have been on this occasion, may be easily imagined. She knew the monarch, and she could not help recollecting the fate of his former queens. A sudden illness was the natural consequence. The news of her indisposition brought the king to her apartment. He was lavish in expressions of affection, and sent her a physician. His majesty being soon after also somewhat indisposed, she prudently returned the visit; with which the king seemed pleased, and began to talk with her on religious subjects, proposing certain questions, concerning which he wanted her opinion. She answered, that such profound speculations were not suited to her sex; that it belonged to the husband to choose principles for his wife; the wife's duty was, in all cases, to adopt implicitly the sentiments of her husband: and as to herself, it was doubly her duty, being blessed with a husband who was qualified, by his judgment and learning, not only to choose principles for his own family, but for the most wife and knowing of every nation. "Not so, by St Mary," replied the king; "you are now become a doctor, Kate, and better fitted to give than receive instruction." She meekly replied, that she was sensible how little she was entitled to these praises; that though she usually declined not any conversation, however sublime, when proposed by his Majesty, she well knew that her conceptions could serve to no other purpose than to give him a little momentary amusement; that she found the conversation a little apt to languish when not revived by some opposition, and

PAROS  
||  
Parr.

she had ventured sometimes to feign a contrariety of sentiments, in order to give him the pleasure of refuting her; and that she also proposed, by this innocent artifice, to engage him into topics whence she had observed by frequent experience, that she reaped profit and instruction. "And is it so, sweetheart?" replied the king, "then we are perfect friends again." He embraced her with great affection, and sent her away with assurances of his protection and kindness.

The time being now come when she was to be sent to the Tower, the king, walking in the garden, sent for the queen, and met her with great good humour; when lo the chancellor, with forty of the guards, approached. He fell upon his knees, and spoke softly with the king, who called him knave, arrant knave, beast, fool, and commanded him instantly to depart. Henry then returned to the queen, who ventured to intercede for the chancellor: "Ah poor soul!" said the king, "thou little knowest how evil he deserveth this grace at thy hands. Of my word, sweetheart, he hath been toward thee an arrant knave; and so let him go." The king died in January 1547, just three years and a half after his marriage with this second Catharine; who in a short time was again espoused to Sir Thomas Seymour lord-admiral of England; for, in September 1548, he died in childbirth. The historians of this period generally insinuate, that she was poisoned by her husband, to make way for his marriage with the lady Elizabeth.

That Catharine Parr was beautiful, is beyond a doubt: that she was pious and learned, is evident from her writings: and that her prudence and sagacity were not inferior to her other accomplishments, may be concluded from her holding up the passion of a capricious tyrant as a shield against her enemies; and that at the latter end of his days, when his passions were enfeebled by age, and his peevish austerity increased by disease. She wrote, 1. *Queen Catharine Parr's lamentation of a sinner, bewailing the ignorance of her blind life*; Lond. 8vo, 1548, 1563. 2. *Prayers or meditations, wherein the mynd is stirred patiently to suffice all afflictions here, to set at nought the vaine prosperitie of this worlde, and always to long for the everlastynge felicitye*. Collected out of holy works, by the most virtuous and gracious princeesse Katharine, queene of Englande, France, and Irelande. Printed by John Wayland, 1545, 4to.—1561, 12mo. 3. *Other Meditations, Prayers, Letters, &c.* unpublished.

PARR (Thomas), or *Old Parr*, a remarkable Englishman, who lived in the reigns of ten kings and queens; married a second wife when he was 120, and had a child by her. See *LONGEVITY*.

PARRELS, in a ship, are frames made of trucks, ribs, and ropes, which having both their ends fastened to the yards, are so contrived as to go round about the masts, that the yards by their means may go up and down upon the mast. These also, with the breast-ropes, fasten the yards to the masts.

PARRHESIA. See *ORATORY*, n° 88.

PARRICIDE, the murder of one's parents or children. By the Roman law, it was punished in a much severer manner than any other kind of homicide. After being scourged, the delinquents were sewed up

in a leathern sack, with a live dog, a cock, a viper, and an ape, and so cast into the sea. Solon, it is true, in his laws, made none against parricide; apprehending it impossible that one should be guilty of so unnatural a barbarity. And the Persians, according to Herodotus, entertained the same notion, when they adjudged all persons who killed their reputed parents to be ballards. And upon some such reason as this must we account for the omission of an exemplary punishment for this crime in our English laws; which treat it no otherwise than as simple murder, unless the child was also the servant of the parent.

For though the breach of natural relation is unobscured, yet the breach of civil or ecclesiastical connections, when coupled with murder, denominates it a new offence; no less than a species of treason called *parva proditio*, or *petit treason*: which, however, is nothing else but an aggravated degree of murder; although, on account of the violation of private allegiance, it is stigmatized as an inferior species of treason. And thus, in the ancient Gothic constitution, we find the breach both of natural and civil relations ranked in the same class with crimes against the state and sovereign.

PARSLEY, in botany. See *APIUM*.

PARSNEF, in botany. See *PASTINACA*.

PARSON and VICAR. A parson, *persona ecclesiæ*, is one that hath full possession of all the rights of a parochial church. He is called parson, *persona*, because by his person the church, which is an invisible body, is represented; and he is in himself a body corporate, in order to protect and defend the rights of the church (which he personates) by a perpetual succession. He is sometimes called the *rector* or *governor* of the church: but the appellation of *parson* (however it may be depreciated by familiar, clownish, and indiscriminate use) is the most legal, most beneficial, and most honourable title that a parish-priest can enjoy; because such a one (Sir Edward Coke observes) and he only, is said *vicem seu personam ecclesiæ gerere*. A parson has, during his life, the freehold in himself of the parsonage-house, the glebe, the tithes, and other dues. But these are sometimes appropriated; that is to say, the benefice is perpetually annexed to some spiritual corporation, either sole or aggregate, being the patron of the living; whom the law esteems equally capable of providing for the service of the church as any single private clergyman.\*

The appropriating corporations, or religious houses, were wont to depute one of their own body to perform divine service, and administer the sacraments, in those parishes of which the society was thus the parson. This officiating minister was in reality no more than a curate, deputy, or viceregent of the appropriator, and therefore called *vicarius*, or "vicar." His stipend was at the discretion of the appropriator, who was, however, bound of common right to find somebody, *qui illi de temporalibus, episcopo de spiritualibus, debeat respondere*. But this was done in so scandalous a manner, and the parishes suffered so much by the neglect of the appropriators, that the legislature was forced to interpose: and accordingly it is enacted, by statute 15 Ric. II. c. 6. that in all appropriations of churches

Blackston's  
Comment.

article Ap-  
propriation.

Parson. churches the diocesan bishop shall ordain (in proportion to the value of the church) a competent sum to be distributed among the poor parishioners annually; and that the vicarage shall be sufficiently endowed. It seems the parish were frequently sufferers, not only by the want of divine service, but also by withholding those aims for which, among other purposes, the payment of tithes was originally imposed: and therefore in this act a pension is directed to be distributed among the poor parochians, as well as a sufficient stipend to the vicar. But he, being liable to be removed at the pleasure of the appropriator, was not likely to insist too rigidly on the legal sufficiency of the stipend; and therefore, by statute 4 Hen. IV. c. 12. it is ordained, that the vicar shall be a secular person, not a member of any religious house; that he shall be vicar perpetual, not removable at the caprice of the monastery; and that he shall be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary; for these three express purposes, to do divine service, to inform the people, and to keep hospitality. The endowments, in consequence of these statutes, have usually been by a portion of the glebe or land belonging to the parsonage, and a particular share of the tithes, which the appropriators found it most troublesome to collect, and which are therefore generally called *prizes*, or *small tithes*; the greater, or predial tithes, being still reserved to their own use. But one and the same rule was not observed in the endowment of all vicarages. Hence some are more liberally, and some more scantily, endowed: and hence the tithes of many things, as wood in particular, are in some parishes rectorial, and in some vicarial tithes.

The distinction therefore of a parson and vicar is this: The parson has for the most part the whole right to all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, entitled to the best part of the profits, to whom he is in effect perpetual curate, with a standing salary. Though in some places the vicarage has been considerably augmented by a large share of the great tithes; which augmentations were greatly assisted by the statute 27 Car. II. c. 8. enacted in favour of poor vicars and curates, which rendered such temporary augmentations (when made by the appropriators) perpetual.

The method of becoming a parson or vicar is much the same. To both there are four requisites necessary; holy orders, presentation, institution, and induction. The method of conferring the holy orders of deacon and priest, according to the liturgy and canons, is foreign to the present purpose; any farther than as they are necessary requisites to make a complete parson or vicar. By common law, a deacon, of any age, might be instituted and inducted to a parsonage or vicarage: but it was ordained, by statute 13 Eliz. c. 12. that no person under twenty-three years of age, and in deacon's orders, should be presented to any benefice with cure; and if he were not ordained priest within one year after his induction, he should be *ipso facto* deprived: and now, by statute 13 and 14 Car. II. c. 4. no person is capable to be admitted to any benefice, unless he hath been first ordained a priest; and then he is, in the language of the law, a clerk in orders. But if he obtains orders, or a licence to preach, by money or corrupt practices, (which seems to be the

true, though not the common, notion of simony), the person giving such orders forfeits 40*l.* and the person receiving, 10*l.* and is incapable of any ecclesiastical preferment for seven years after.

Any clerk may be presented to a parsonage or vicarage; that is, the patron, to whom the advowson of the church belongs, may offer his clerk to the bishop of the diocese to be instituted. But when he is presented, the bishop may refuse him upon many accounts. As, 1. If the patron is excommunicated, and remains in contempt 40 days; or, 2. If the clerk be unfit: which unfitness is of several kinds. First, with regard to his person; as if he be a bastard, an outlaw, an excommunicate, an alien, under age, or the like. Next, with regard to his faith or morals; as for any particular heresy, or vice that is *malum in se*; but if the bishop alleges only in general, as that he is *schismaticus in veteratur*, or objects a fault that is *malum prohibitum* merely, as haunting taverns, playing at unlawful games, or the like, it is not good cause of refusal. Or, lastly, the clerk may be unfit to discharge the pastoral office for want of learning. In any of which cases, the bishop may refuse the clerk. In case the refusal is for heresy, schism, inability of learning, or other matter of ecclesiastical cognizance, there the bishop must give notice to the patron of such his cause of refusal, who being usually a layman, is not supposed to have knowledge of it; else he cannot present by lapse; but if the cause be temporal, there he is not bound to give notice.

If an action at law be brought by the patron against the bishop for refusing his clerk, the bishop must assign the cause. If the cause be of a temporal nature, and the fact admitted, (as, for instance, outlawry), the judges of the king's courts must determine its validity, or whether it be sufficient cause of refusal: but if the fact be denied, it must be determined by a jury. If the cause be of a spiritual nature, (as heresy, particularly alleged), the fact, if denied, shall also be determined by a jury: and if the fact be admitted or found, the court, upon consultation and advice of learned divines, shall decide its sufficiency. If the cause be want of learning, the bishop need not specify in what points the clerk is deficient, but only allege that he is deficient; for the statute 9 Edw. II. li. 1. c. 13. is express, that the examination of the fitness of a person presented to a benefice belongs to the ecclesiastical judge. But because it would be nugatory in this case to demand the reason of refusal from the ordinary, if the patron were bound to abide by his determination, who has already pronounced his clerk unfit; therefore if the bishop returns the clerk to be *minus sufficiens in literatura*, the court shall write to the metropolitan to re-examine him, and certify his qualifications; which certificate of the archbishop is final.

If the bishop hath no objections, but admits the patron's presentation, the clerk so admitted is next to be instituted by him; which is a kind of investiture of the spiritual part of the benefice; for by institution, the care of the souls of the parish is committed to the charge of the clerk. When a vicar is instituted, he (besides the usual forms) takes, if required by the bishop, an oath of perpetual residence; for the maxim of law is, that *vicarius non habet vicarium*: and as the non-residence of the appropriators was the cause of the perpetual

tual establishment of vicarages, the law judges it very improper for them to defeat the end of their constitution, and by absence to create the very mischief which they were appointed to remedy; especially as, if any profits are to arise from putting in a curate and living at a distance from the parish, the appropriator, who is the real parson, has undoubtedly the elder title to them. When the ordinary is also the patron, and confers the living, the presentation and institution are one and the same act, and are called a *collation to a benefice*. By institution or collation the church is full, so that there can be no fresh presentation till another vacancy, at least in the case of a common patron; but the church is not full against the king till induction: nay, even if a clerk is instituted upon the king's presentation, the crown may revoke it before induction, and present another clerk. Upon institution also the clerk may enter on the parsonage-house and glebe, and take the tithes; but he cannot grant or let them, or bring an action for them, till induction. See INDUCTION.

For the rights of a parson or vicar, in his tithes and ecclesiastical dues, see TITHES. As to his duties, they are so numerous, that it is impracticable to recite them here with any tolerable conciseness or accuracy; but the reader who has occasion may consult *Bp Gibson's Codex*, and *Burn's Ecclesiastical Law*. We shall therefore only just mention the article of residence, upon the supposition of which the law does style every parochial minister an incumbent. By statute 21 Hen. VIII. c. 13. persons willingly absenting themselves from their benefices, for one month together, or two months in the year, incur a penalty of 5 l. to the king, and 5 l. to any person that will sue for the same; except chaplains to the king, or others therein mentioned, during their attendance in the household of such as retain them: and also except all heads of houses, magistrates, and professors in the universities, and all students under forty years of age residing there, *bona fide*, for study. Legal residence is not only in the parish, but also in the parsonage-house; for it hath been resolved, that the statute intended residence, not only for serving the cure and for hospitality, but also for maintaining the house, that the successor also may keep hospitality there.

We have seen that there is but one way whereby one may become a parson or vicar: there are many ways by which one may cease to be so. 1. By death. 2. By cession, in taking another benefice; for by statute 21 Hen. VIII. c. 13. if any one having a benefice of 8 l. *per annum*, or upwards, in the king's books, (according to the present valuation), accepts any other, the first shall be adjudged void, unless he obtains a dispensation; which no one is entitled to have but the chaplains of the king and others therein mentioned, the brethren and sons of lords and knights, and doctors and bachelors of divinity and law, admitted by the universities of this realm. And a vacancy thus made for want of a dispensation, is called *cessum*. 3. By consecration; for, as was mentioned before, when a clerk is promoted to a bishopric, all his other preferments are void the instant that he is consecrated. But there is a method, by the favour of the crown, of holding such livings in *commendam*. *Commenda*, or *ecclesia commendata*, is a living commended by the crown

to the care of a clerk, to hold till a proper pastor is provided for it. This may be temporary for one, two, or three years, or perpetual, being a kind of dispensation to avoid the vacancy of the living, and is called a *commenda retinere*. There is also a *commenda recipere*, which is to take a benefice *de novo* in the bishop's own gift, or the gift of some other patron consenting to the same; and this is the same to him as institution and induction are to another clerk. 4. By resignation. But this is of no avail till accepted by the ordinary, into whose hands the resignation must be made. 5. By deprivation, either by canonical censures, or in pursuance of divers penal statutes, which declare the benefice void, for some nonconformance or neglect, or else some malefiance or crime: as for simony; for maintaining any doctrine in derogation of the king's supremacy, or of the thirty-nine articles, or of the book of common-prayer; for neglecting after institution to read the liturgy and articles in the church, or make the declarations against popery, or take the abjuration-oath; for using any other form of prayer than the liturgy of the church of England; or for absenting himself 60 days in one year from a benefice belonging to a popish patron, to which the clerk was presented by either of the universities: in all which, and similar cases, the benefice is *ipso facto* void, without any formal sentence of deprivation.

PARSONAGE, a rectory, or parish-church, endowed with a glebe, house, lands, tithes, &c. for the maintenance of a minister, with cure of souls within such parish. See PARSON.

PARSONS, or PERSONS, (Robert), an eminent writer of the church of Rome, was born at Nether-Storey, near Bridgewater, in Somersetshire, in 1546, and educated at Balliol college, Oxford, where he distinguished himself as a zealous Protestant and an acute disputant; but being charged by the society with incontinency and embezzling the college money, he went to Flanders, and declared himself a Catholic. After travelling to several other places, he effected the establishment of the English seminary at Rome, and procured father Allen to be chosen rector of it. He himself was appointed the head of the mission to England, in order to dethrone Queen Elizabeth, and if possible extirpate the Protestant religion. He accordingly came over to this kingdom in 1580, and took some bold steps towards accomplishing his purpose, in which he concealed himself with great art, travelling about the country to gentlemen's houses, disguised in the habit, sometimes of a soldier, sometimes of a gentleman, and at other times like a minister or an apothecary; but father Campian being seized and committed to prison, our author escaped out of England for fear of the same fate, and went to Rome, where he was made rector of the English seminary. He had long entertained the most sanguine hopes of converting to the popish faith the young king of Scots, which he considered as the best and most effectual means of bringing over his subjects to the same religious principles; but finding it impossible to succeed in his design, he published, in 1594, his celebrated book, under the feigned name of *Deleman*, in order to overthrow, as far as lay in his power, the title of that prince to the crown of England. He died at Rome in 1610, and was buried in the chapel of the English college;

Part  
Parthia.

Parthia.

college. Besides the book already mentioned, he wrote, 1. A defence of the Catholic hierarchy. 2. The liturgy of the sacrament of the mass. 3. A memorial for the Reformation; and several other tracts.

PART, a portion of some whole, considered as divided or divisible.

*Aliquot* PART, is a quantity which, being repeated any number of times, becomes equal to an integer. Thus 6 is an aliquot part of 24, and 5 an aliquot part of 30, &c.

*Aliquant* PART, is a quantity which, being repeated any number of times, becomes always either greater or less than the whole. Thus 5 is an aliquant part of 17, and 9 an aliquant part of 10, &c.

The aliquant part is resolvable into aliquot parts. Thus 15, an aliquant part of 20, is resolvable into 10 $\frac{1}{2}$ , and 5 a fourth part of the same.

PARTS of *speech*, in grammar, are all the sorts of words which can enter the composition of a discourse. See GRAMMAR.

PARTIERRE, in gardening, a level division of ground, which for the most part faces the south, or best front of a house, and is generally furnished with ever-greens, flowers, &c. There are two kinds of these, the plain ones and the parterres of embroidery.

Plain parterres are most valuable in England, because of the firmness of the English grass turf, which is superior to that of any other part of the world; and the parterres of embroidery are cut into shell and scroll work, with alleys between them. An oblong, or long square, is accounted the most proper figure for a parterre; and a parterre should indeed be always twice as long as it is broad, because, according to the known laws of perspective, a long square always sinks to a square; and an exact square always appears less than it really is. As to the breadth of a parterre, it is to be proportionable to the front of the house; but less than 100 feet in breadth is too little.

There should be on each side the parterre a terrace-walk raised for view, and the flat of the parterre between the terraces should never be more than 300 feet, at the utmost, in breadth, and about 140 feet in width, with twice and a half that in length, is esteemed a very good size and proportion.

PARTHIA, a celebrated empire of antiquity, bounded on the west by Media, on the north by Hyrcania, on the east by Aria, on the south by Carmania the desert; surrounded on every side by mountains, which still serve as a boundary, though its name is now changed, having obtained that of *Eyrac* or *Arak*; and, to distinguish it from Chaldaea, that of *Eyrac Agami*. By Ptolemy it is divided into five districts, viz. Camisine, or Gamisene, Parthyene, Choroane, Atticene, and Tabiene. The ancient geographers enumerate a great many cities in this country. Ptolemy in particular reckons 25 large cities; and it certainly must have been very populous, since we have accounts of 2000 villages, besides a number of cities, in this district being destroyed by earthquakes. Its capital was named *Hecatempolis*, from the circumstance of its having 100 gates. It was a noble and magnificent place; and, according to some, it still remains under the name of *Ispahan*, the capital of the present Persian empire.

Parthia is by some supposed to have been first peo-

pled by the Phetri or Pathri, often mentioned in scripture, and will have the Parthians to be descended from Pathrusim the son of Misraim. But however true this Whence may be with regard to the ancient inhabitants, yet it is certain, that those Parthians who were so famous in history, descended from the Scythians, though from what tribe we are not certainly informed.

The history of the ancient Parthians is totally lost. All that we know about them is, that they were first subject to the Medes, afterwards to the Persians, and lastly to Alexander the Great. After his death the province fell to Seleucus Nicator, and was held by him and his successors till the reign of Antiochus Theus, about the year 250 before Christ. At this time the Parthians revolted, and chose one Arsaces for their king. The immediate cause of this revolt was the lewdness of Agathocles, to whom Antiochus had committed the care of all the provinces beyond the Euphrates. This man made an infamous attempt on Tetricides, a youth of great beauty; which so enraged his brother Arsaces, that he excited his countrymen to revolt; and before Antiochus had leisure to attend to the rebellion, it became too powerful to be crushed. Seleucus Callinicus, the successor of Antiochus Theus, attempted to reduce Arsaces; but the latter having had so much time to strengthen himself, defeated, and drove his antagonist out of the country. Seleucus, however, in a short time, undertook another expedition against Arsaces; but was still more unfortunate than he had been in the former, being not only defeated in a great battle, but taken prisoner, and died in captivity. The day on which Arsaces gained this victory was ever after observed among the Parthians as an extraordinary festival. Arsaces being thus fully established in his new kingdom, reduced Hyrcania, and some other provinces under his power; and was at last killed in a battle against Arearathes IV. king of Cappadocia. From this prince all the other kings of Parthia took the surname of *Arsaces*, as those of Egypt did that of *Ptolemy* from Ptolemy Soter.

Arsaces I. was succeeded by his son Arsaces II. who, entering Media, made himself master of that country, while Antiochus the Great was engaged in a war with Ptolemy Euergetes king of Egypt. Antiochus, however, was no sooner disengaged from that war, than he marched with all his forces against Arsaces, and at first drove him quite out of Media. But he soon returned with an army of 100,000 foot and 20,000 horse, with which he put a stop to the further progress of Antiochus; and a treaty was soon after concluded, in which it was agreed, that Arsaces should remain master of Parthia and Hyrcania, upon condition of his assisting him in his wars with other nations.

Arsaces II. was succeeded by his son Ariapatus, who reigned 15 years, and left three sons, Phrahiates, Mithridates, and Artabanus. Phrahiates, the eldest, succeeded to the throne, and reduced under his subjection the Mardi, who had never been conquered by any but Alexander the Great. After him, his brother Mithridates was invested with the regal dignity. He reduced the Bactrians, Medes, Persians, Elymians, and over-ran in a manner all the east, penetrating beyond the boundaries of Alexander's conquests. Demetrius Nicator, who then reigned in Syria, endeavoured

Parthia. vowed to recover those provinces; but his army was entirely destroyed, and himself taken prisoner, in which state he remained till his death; after which victory Mithridates made himself master of Babylonia and Mesopotamia, so that he now commanded all the provinces from between the Euphrates and the Ganges.

5  
Antiochus  
Sidetes de-  
stroyed with  
his whole  
army.

Mithridates died in the 37th year of his reign, and left the throne to his son Phrahabes II. who was scarce settled in his kingdom, when Antiochus Sidetes marched against him at the head of a numerous army, under pretence of delivering his brother Demetrius, who was still in captivity. Phrahabes was defeated in three pitched battles, in consequence of which he lost all the countries conquered by his father, and was reduced within the limits of the ancient Parthian kingdom. Antiochus did not; however, long enjoy his good fortune; for his army, on account of their number, amounting to no fewer than 400,000, being obliged to separate to such distances as prevented them, in case of any sudden attack, from joining together, the inhabitants, whom they had most cruelly oppressed, taking advantage of this separation, conspired with the Parthians to destroy them. This was accordingly executed; and the vast army of Antiochus, with the monarch himself, were slaughtered in one day, scarce a single person escaping to carry the news to Syria. Phrahabes, elated with this success, proposed to invade Syria; but in the mean time, happening to quarrel with the Scythians, he was by them cut off with his whole army, and was succeeded by his uncle Artabanus.

6  
Alliance  
concluded  
with the  
Romans.

The new king enjoyed his dignity but a very short time, being, a few days after his accession, killed in another battle with the Scythians. He was succeeded by Pacorus I. who entered into an alliance with the Romans; and he by Phrahabes III. This monarch took under his protection Tigranes the son of Tigranes the Great, king of Armenia, gave him his daughter in marriage, and invaded the kingdom with a design to place the son on the throne of Armenia; but on the approach of Pompey he thought proper to retire, and soon after solemnly renewed the treaty with the Romans.

7  
Cræsus re-  
solves on a  
war with the  
Parthians.

Phrahabes was murdered by his children Mithridates and Orodes; and soon after, the former was put to death by his brother, who thus became sole master of the Parthian empire. In his reign happened the memorable war with the Romans under Cræsus. This was occasioned not by any breach of treaty on the side of the Parthians, but through the shameful avarice of Cræsus. The whole Roman empire at that time had been divided between Cæsar, Pompey, and Cræsus; and by virtue of that partition, the eastern provinces had fallen to the lot of Cræsus. No sooner was he invested with this dignity, than he resolved to carry the war into Parthia, in order to enrich himself with the spoils of that people, who were then looked upon to be very wealthy. Some of the tribunes opposed him, as the Parthians had religiously observed the treaty; but Cræsus having, by the assistance of Pompey, carried every thing before him, left Rome in the year 55 B. C. and pursued his march to Brundisium, where he immediately embarked his troops, though the wind blew very high; and after a difficult passage, where

he lost many of his ships, he reached the ports of Galatia.

Parthia.

8

From Galatia Cræsus hastened to Syria, and passing through Judea, plundered the temple of Jerusalem in his way. He then marched with as great expedition as he could to the river Euphrates, which he crossed on a bridge of boats; and, entering the Parthian dominions, began hostilities. As the enemy had not expected an invasion, they were quite unprepared for resistance, and therefore Cræsus over-ran all Mesopotamia; and if he had taken advantage of the consternation which the Parthians were in, might have also reduced Babylonia. But instead of this, early in the autumn, he repassed the Euphrates, leaving only 7000 foot and 1000 horse to garrison the places he had reduced; and putting his army into winter-quarters in Syria, gave himself totally up to his favourite passion of amassing money.

Early in the spring, the Roman general drew his forces out of their winter-quarters, in order to pursue the war with vigour; but, during the winter, Orodes had collected a very numerous army, and was well prepared to oppose him. Before he entered upon action, however, the Parthian monarch sent ambassadors to Cræsus, in order to expostulate with him on his injustice in attacking an ally of the Roman empire; but Cræsus, without attending to what they said, only returned for answer, that "they should have his answer at Seleucia."

Orodes, finding that a war was not to be avoided, divided his army into two bodies. One he commanded in person, and marched towards Armenia, in order to oppose the king of that country, who had raised a considerable army to assist the Romans. The other he sent into Mesopotamia, under the command of Surena or Surenas, a most experienced general, by whose conduct all the cities which Cræsus had reduced were disheartened. On this some Roman soldiers who made their escape, and fled to the camp of Cræsus, filled the minds of his army with terror at the accounts of the number, power, and strength of the enemy. They told their fellow-soldiers, that the Parthians were very numerous, brave, and well disciplined; that it was impossible to overtake them when they fled, or escape them when they pursued; that their defensive weapons were proof against the Roman darts, and their offensive weapons so sharp, that no buckler was proof against them, &c. Cræsus looked upon all this only as the effects of cowardice; but the common foldiers, and even many of the chief officers, were so disheartened, that Cræsus, the same who afterwards conspired against Cæsar, and most of the legionary tribunes, advised Cræsus to suspend his march, and consider better of the enterprise before he proceeded farther in it. But Cræsus obstinately persisted in his former resolution, being encouraged by the arrival of Artabazus king of Armenia, who brought with him 6000 horse, and promised to send 10,000 cuirassiers and 30,000 foot, whenever he should stand in need of them. At the same time, he advised him by no means to march his army through the plains of Mesopotamia, but to take his route over the mountains of Armenia. He told him, that as Armenia was a mountainous country, the enemy's cavalry, in which their main strength consisted, would there be entirely ufe-

9  
His soldiers  
were disheart-  
ened.

Parthia.

Parthia.

useless; and besides, his army would there be plentifully supplied with all manner of necessaries: whereas, if he marched by the way of Mesopotamia, he would be perpetually harassed by the Parthian horse, and frequently be obliged to lead his army thro' sandy deserts, where he would be distressed for want of water and all other provisions. This salutary advice, however, was rejected, and Crassus entered Mesopotamia with an army of about 40,000 men.

The Romans had no sooner crossed the Euphrates, than Crassus advised his general to advance to some of those towns in which the garrisons yet remained, in order to halt and refresh his troops; or if he did not choose to follow this advice, he said that his best way would be to march along the banks of the Euphrates to Seleucia; as by this method he would prevent the Parthians from surrounding him, at the same time that he would be plentifully supplied with provisions from his ships. Of this advice Crassus seemed to approve; but was dissuaded by Abgarus king of Edessa, whom the Romans took for an ally, but who was in reality a traitor sent by Surenas to bring about the destruction of the Roman army.

TO  
Betrayed by  
Abgarus  
king of E-  
dessa.

Under the conduct of this faithless guide, the Romans entered a vast green plain divided by many rivulets. Their march proved very easy through this fine country; but the farther they advanced, the worse the roads became, inasmuch, that they were at last obliged to climb up rocky mountains, which brought them to a dry and sandy plain, where they could neither find food to satisfy their hunger, nor water to quench their thirst. Abgarus then began to be suspected by the tribunes and other officers, who earnestly intreated Crassus not to follow him any longer, but to retreat to the mountains; at the same time an express arrived from Artabazus, acquainting the Roman general that Orodes had invaded his dominions with a great army, and that he was obliged to keep his troops at home, in order to defend his own dominions. The same messenger advised Crassus in his master's name to avoid by all means the barren plains, where his army would certainly perish with hunger and fatigue, and by all means to approach Armenia, that they might join their forces against the common enemy. But all was to no purpose; Crassus, instead of hearkening either to the advice of the king or his own officers, first flew into a violent passion with the messengers of Artabazus, and then told his troops, that they were not to expect the delights of Campania in the most remote parts of the world.

Thus they continued their march for some days cross a desert, the very sight of which was sufficient to throw them into the utmost despair; for they could not perceive, either near them or at a distance, the least tree, plant, or brook, not so much as an hill, or a single blade of grass; nothing was to be seen all around them, but huge heaps of burning sand. The Romans had scarcely got thro' this desert, when word was brought them by their scouts, that a numerous army of Parthians was advancing full march to attack them; for Abgarus, under pretence of going out on parties, had often conferred with Surenas, and concerted measures with him for destroying the Roman army. Upon this advice, which occasioned great confusion in the camp, the Romans being quite exhausted and ti-

red out with their long and troublesome march, Crassus drew up his men in battalia, following at first the advice of Cassius, who was for extending the infantry as wide as possible, that they might take up the more ground, and by that means prevent the enemy from surrounding them; but Abgarus assuring the proconsul, that the Parthian forces were not so numerous as was represented, he changed this disposition, and believing only the man who betrayed him, drew up his troops in a square, which faced every way, and had on each side 12 cohorts in front. Near each cohort, he placed a troop of horse to support them, that they might charge with the greater security and boldness. Thus the whole army looked more like one phalanx, than troops drawn up in manipuli, with spaces between them, after the Roman manner. The general himself commanded in the centre, his son in the left wing, and Cassius in the right.

In this order they advanced to the banks of a small river called the *Balsifus*, the sight of which was very pleasing to the soldiers, who were much harassed with drought and excessive heat. Most of the officers were for encamping on the banks of this river, or rather rivulet, to give the troops time to refresh themselves after the fatigues of so long and painful a march; and, in the mean time, to procure certain intelligence of the number and disposition of the Parthian army; but Crassus, suffering himself to be hurried on by the inconsiderate ardour of his son, and the horse he commanded, only allowed the legions to take a meal standing; and before this could be done by all, he ordered them to advance, not slowly, and halting now and then, after the Roman manner, but as fast as they could move, till they came in sight of the enemy, who, contrary to their expectation, did not appear either so numerous or so terrible as they had been represented; but this was a stratagem of Surenas, who had concealed his men in convenient places, ordering them to cover their arms, lest their brightness should betray them, and, starting up at the first signal, to attack the enemy on all sides. The stratagem had the desired effect; for Surenas no sooner gave the signal, than the Parthians, rising as it were out of the ground, with dreadful cries, and a most frightful noise, advanced against the Romans, who were greatly surprised and dismayed at that sight; and much more so, when the Parthians, throwing off the covering of their arms, appeared in shining cuirasses, and helmets of burnished steel, finely mounted on horses covered all over with armour of the same metal. At their head appeared young Surenas, in a rich dress, and was the first who charged the enemy, endeavouring, with his pikemen, to break through the first ranks of the Roman army; but finding it too close and impenetrable, the cohorts supporting each other, he fell back, and retired in a seeming confusion: but the Romans were much surprised when they saw themselves suddenly surrounded on all sides, and galled with continual showers of arrows. Crassus ordered his light-armed foot and archers to advance, and charge the enemy; but they were soon repulsed, and forced to cover themselves behind the heavy-armed foot. Then the Parthian horse, advancing near the Romans, discharged showers of arrows upon them, every one of which did execution, the legionaries being drawn up in such close

11  
The battle  
of Carthar.

Parthia.

close order, that it was impossible for the enemy to miss their aim. As their arrows were of an extraordinary weight, and discharged with incredible force and impetuosity, nothing was proof against them. The two wings advanced in good order to repulse them, but to no effect; for the Parthians shot their arrows with as great dexterity when their backs were turned, as when they faced the enemy; so that the Romans, whether they kept their ground, or pursued the flying enemy, were equally annoyed with their fatal arrows.

The Romans, as long as they had any hopes that the Parthians, after having spent their arrows; would either betake themselves to flight, or engage them hand to hand, stood their ground with great resolution and intrepidity; but when they observed, that there were a great many camels in their rear, loaded with arrows, and that those who emptied their quivers wheeled about to fill them anew, they began to lose courage, and loudly to complain of their general for suffering them thus to stand still, and serve only as a butt to the enemy's arrows, which, they well saw, would not be exhausted till they were all killed to a man. Hereupon Crassus ordered his son to advance, at all adventures, and attack the enemy with 1300 horse, 500 archers, and 8 cohorts. But the Parthians no sooner saw this choice body (for it was the flower of the army) marching up against them, but they wheeled about, and betook themselves, according to their custom, to flight. Hereupon young Crassus, crying out as loud as he could, *They fly before us*, pushed on full speed after them, not doubting but he should gain a complete victory; but, when he was at a great distance from the main body of the Roman army, he perceived his mistake; for those who before had fled, facing about, charged him with incredible fury. Young Crassus ordered his troops to halt, hoping that the enemy, upon seeing their small number, would not be afraid to come to a close fight; but herein he was likewise greatly disappointed; for the Parthians, contenting themselves to oppose his front with their heavy-armed horse, surrounded him on all sides; and, keeping at a distance, discharged incessant showers of arrows upon the unfortunate Romans, thus surrounded and pent up. The Parthian cavalry, in wheeling about, raised so thick a dust, that the Romans could scarce see one another, much less the enemy: nevertheless, they found themselves wounded, with arrows, tho' they could not perceive whence they came. In a short time, the place where they stood was all strown with dead bodies.

Some of the unhappy Romans finding their entrails torn, and many overcome by the exquisite torments they suffered, rolled themselves on the sand with the arrows in their bodies, and expired in that manner. Others endeavouring to tear out by force the bearded points of the arrows, only made the wounds the larger and increased their pain. Most of them died in this manner; and those who outlived their companions were no more in a condition to act; for when young Crassus exhorted them to march up to the enemy, some flung their wounded bodies, others their hands nailed to their bucklers, and some their feet pierced through and pinned to the ground: so that it was equally impossible for them either to attack the enemy

Parthia.

or defend themselves. The young commander, therefore, leaving his infantry to the mercy of the enemy, advanced at the head of the cavalry against their heavy-armed horse. The thousand Gauls whom he had brought with him from the west, charged the enemy with incredible boldness and vigour; but their lances did little execution on men armed with cuirasses, and horses covered with tried armour: however, they behaved with great resolution; for some of them taking hold of the enemies spears, and closing with them, threw them off their horses on the ground, where they lay without being able to stir, by reason of the great weight of their armour; others dismounting, crept under the enemy's horses, and thrusting their swords into their bellies, made them throw their riders. Thus the brave Gauls fought, tho' greatly harrassed with heat and thirst, which they were not accustomed to bear, till most of their horses were killed, and their commander dangerously wounded. They then thought it advisable to retire to their infantry, which they no sooner joined, than the Parthians invested them anew, making a most dreadful havoc of them with their arrows. In this desperate condition, Crassus, spying a rising ground at a small distance, led the remains of his detachment thither, with a design to defend himself in the best manner he could, till succours should be sent him from his father. The Parthians pursued him; and having surrounded him in his new post, continued showering arrows upon his men, till most of them were either killed or disabled, without being able to make use of their arms, or give the enemy proofs of their valour.

Young Crassus had two Greeks with him, who had settled in the city of Carhræ. These, touched with compassion, at seeing so brave a man reduced to such straits, pressed him to retire with them to the neighbouring city of Ichne, which had declared for the Romans; but the young Roman rejected their proposal with indignation, telling them, that he would rather die a thousand times than abandon so many valiant men, who sacrificed their lives for his sake. Having returned this answer to his two Greek friends, he embraced and dismissed them, giving them leave to retire and shift for themselves in the best manner they could. As for himself, having now lost all hopes of being relieved, and seeing most of his men and friends killed round him, he gave way to his grief; and, not being able to make use of his arm, which was shot <sup>13</sup> thro' with a large barbed arrow, he presented his of young Crassus. He put an end to his unhappy life. His example was followed by Censorius, a senator, by Megabacchus, an experienced and brave officer, and by most of the nobility who served under him. Five hundred common soldiers were taken prisoners, and the rest cut in pieces.

The Parthians, having thus cut off or taken the whole detachment commanded by young Crassus, marched without delay against his father, who, upon the first advice that the enemy fled before his son, and were closely pursued by him, had taken heart, the more because those who had remained to make head against him, seemed to abate much of their ardour, the greatest part of them having marched with the rest against his son. Wherefore, having encouraged his troops,

Parthia.

Parthia.

troops, he had retired to a small hill in his rear, to wait there till his son returned from the pursuit. Young Crassus had dispatched frequent expresses to his father, to acquaint him with the danger he was in; but they had fallen into the enemy's hands, and been by them put to the sword: only the last, who had escaped with great difficulty, arrived safe, and informed him that his son was lost if he did not send him an immediate and powerful reinforcement. This news threw Crassus into the utmost consternation; a thousand affecting thoughts rose in his mind, and disturbed his reason to such a degree, that he scarce knew what he was doing. However, the desire he had of saving his son, and so many brave Romans who were under his command, made him immediately decamp, and march to their assistance; but he was not gone far before he was met by the Parthians, who, with loud shouts, and songs of victory, gave, at a distance, the unhappy father notice of his misfortune. They had cut off young Crassus's head, and, having fixed it on the point of a lance, were advancing full speed to fall on the father. As they drew near, Crassus was struck with that dismal and affecting sight; but, on this occasion, behaved like an hero: for tho' he was under the deepest concern, he had the presence of mind to stifle his grief, for fear of discouraging the army, and to cry out to the dismayed troops, "This misfortune is entirely mine; the loss of one man cannot affect the victory. Let us charge, let us fight like Romans: if you have any compassion for a father who has just now lost a son whose valour you admired, let it appear in your rage and resentment against these insulting barbarians." Thus Crassus strove to reanimate his troops; but his efforts were unsuccessful: their courage was quite sunk, as appeared from the faint and languishing shout which they raised, according to custom, before the action. When the signal was given, the Parthians, keeping to their old way of fighting, discharged clouds of arrows on the legionaries, without drawing near them; which did such dreadful execution, that many of the Romans, to avoid the arrows, which occasioned a long and painful death, threw themselves, like men in despair, on the enemy's heavy-armed horse, seeking from their spears a more quick and easy kind of death. Thus the Parthians continued playing them incessantly with their arrows till night, when they left the field of battle, crying out, that they would allow the father one night to lament the death of his son.

<sup>14</sup>  
Distress of  
Crassus.

This was a melancholy night for the Romans. Crassus kept himself concealed from the soldiery, lying not in the general's tent, but in the open air, and on the bare ground, with his head wrapped up in his paludamentum or military cloak: and was, in that forlorn condition, says Plutarch, a great example to the vulgar, of the infallibility of fortune; to the wife, a still greater of the pernicious effects of avarice, temerity, and ambition. Octavius, one of his lieutenants, and Cassius, approached him, and endeavoured to raise him up and console him: but, seeing him quite sunk under the weight of his affliction, and deaf to all comfort, they summoned a council of war, composed of all the chief officers; wherein it was unanimously resolved, that they should decamp before break of day, and retire, without sound of trumpet, to the neigh-

VOL. VIII.

I

bouring city of Carrhæ, which was held by a Roman garrison. Agreeable to this resolution, they began their march as soon as the council broke up; which produced dreadful outcries among the sick and wounded, who, perceiving that they were to be abandoned to the mercy of the enemy, filled the camp with their complaints and lamentations: but their cries and tears, though very affecting, did not stop the march of the others, which, indeed, was very slow, to give the stragglers time to come up. There were only 300 light horse, under the command of one Ægnatius, who pursued their march, without stopping. These arriving at Carrhæ about midnight, Ægnatius, calling to the centinels on the walls, desired them to acquaint Coponius, governor of the place, that Crassus had fought a great battle with the Parthians; and, without saying a word more, or letting them know who he was, continued his march with all possible expedition to the bridge of Zeugma; which he passed, and by that means saved his troops, but was much blamed for abandoning his general.

However, the message sent to Coponius was of some temporary service to Crassus. For that commander, wisely conjecturing, from the manner in which the unknown person had given him that intelligence, that some misfortune had befallen Crassus, immediately ordered his garrison to stand to their arms; and, marching out, met Crassus, and conducted him and his army into the city: for the Parthians, tho' informed of his flight, did not offer to pursue him, observing therein the superstitious custom which obtained among them and the Persians, not to fight in the night; but, when it was day, they entered the Roman camp, and, having put all the wounded, to the number of 4000, to the sword, dispersed their cavalry all over the plain, in pursuit of the fugitives. One of Crassus's lieutenants, named *Vargunteius*, having separated in the night from the main body of the army, with four cohorts, missed his way, and was overtaken by the enemy; at whose approach he withdrew to a neighbouring hill, where he defended himself with great valour, till all his men were killed, except 20, who made their way through the enemy sword in hand, and got safe to Carrhæ: but *Vargunteius* himself lost his life on this occasion.

15

In the mean time Surenas, not knowing whether Surenas Crassus and Cassius had retired to Carrhæ, or chosen pretends to a different route; in order to be informed of the truth, he condescends to confer with Crassus. and take his measures accordingly, dispatched a messenger, who spoke the Roman language, to the city of Carrhæ, enjoining him to approach the walls, and acquaint Crassus himself, or Cassius, that the Parthian general was inclined to enter into a treaty with them, and demanded a conference. Both the proconsul and his quaestor Cassius spoke from the walls with the messenger; and, accepting the proposal with great joy, desired that the time and place for an interview might be immediately agreed upon. The messenger withdrew, promising to return quickly with an answer from Surenas: but that general no sooner understood that Crassus and Cassius were in Carrhæ, than he marched thither with his whole army; and, having invested the place, acquainted the Romans, that, if they expected any favourable terms, they must deliver up Crassus and Cassius to him in chains. Hereupon a council of the

33 F

chief

Parthia.

chief officers being summoned, it was thought expedient to retire from Carrhæ that very night, and seek for another asylum. It was of the utmost importance, that none of the inhabitants of Carrhæ should be acquainted with their design till the time of its execution; but Crassus, whose whole conduct evidently shewed that he was blinded, as Dio Cassius observes, by some divinity, imparted the whole matter in confidence to one Andromachus, choosing him for his guide, and relying judiciously on the fidelity of a man whom he scarce knew. Andromachus immediately acquainted Surenas with the design of the Romans; promising at the same time, as the Parthians did not engage in the night, to manage matters so, that they should not get out of his reach before day-break. Pursuant to his promise, he led them through many windings and turnings, till he brought them into deep marshy grounds, where the infantry were up to the knees in mire. Then Cassius, suspecting that their guide had led them into those bogs with no good design, refused to follow him any longer; and, returning to Carrhæ, took his route towards Syria, which he reached with 500 horse. Octavius, with 5000 men under his command, being conducted by trusty guides, gained the mountains called by Plutarch and Appian *Sinnaci*, and there intrenched himself before break of day.

As for Crassus, he was still entangled in the marshes, when Surenas, at the rising of the sun, overtook him, and invested him with his cavalry. The proconsul had with him four cohorts, and a small body of horse; and with these he gained, in spite of all opposition, the summit of another hill within 12 furlongs of Octavius; who, seeing the danger that threatened his general, flew to his assistance, first with a small number of his men, but was soon followed by all the rest, who, being ashamed of their cowardice, quitted their post, tho' very safe, and, charging the Parthians with great fury, disengaged Crassus, and obliged the enemy to abandon the hill. Upon the retreat of the enemy, they formed themselves into an hollow square; and placing Crassus in the middle, made a kind of rampart round him with their bucklers, resolutely protesting, that none of the enemy's arrows should touch their general's body, till they were all killed fighting in his defence. Surenas, loth to let so fine a prey escape, surrounded the hill, as if he designed to make a new attack: but, finding his Parthians very backward, and not doubting but the Romans, when night came on, would pursue their march, and get out of his reach, he had recourse again to artifice; and declared before some prisoners, whom he soon after set at liberty, that he was inclined to treat with the proconsul of a peace; and that it was better to come to a reconciliation with Rome, than to sow the seeds of an eternal war, by shedding the blood of one of her generals.

Agreeable to this declaration, Surenas, as soon as the prisoners were released, advanced towards the hill where the Romans were posted, attended only by some of his officers, and, with his bow unbent, and open arms, invited Crassus to an interview. So sudden a change seemed very suspicious to the proconsul; who therefore declined the interview, till he was forced, by his own soldiers, to intrust his life with an enemy

whose treachery they had all experienced; for the legionaries flocking round him, not only abused him in an outrageous manner, but even menaced him if he did not accept of the proposals made him by the Parthian general. Seeing, therefore, that his troops were ready to mutiny, he began to advance, without arms or guards, towards the enemy, after having called the gods and his officers to witness the violence his troops offered him; and intreated all who were present, but especially Octavius and Petronius, two of the chief commanders, for the honour of Rome their common mother, not to mention, after his death, the shameful behaviour of the Roman legionaries. Octavius and Petronius could not resolve to let him go alone; but attended him down the hill, as did likewise some legionaries, keeping at a distance. Crassus was met at the foot of the hill by two Greeks; who, dismounting from their horses, saluted him with great respect; and desired him, in the Greek tongue, to send some of his attendants, who might satisfy him, that Surenas, and those who were with him, came without arms. Hereupon Crassus sent two brothers, of the Rofcian family; but Surenas, having caused them to be seized, advanced to the foot of the hill, mounted on a fine horse, and attended by the chief officers of his army. Crassus, who waited for the return of his two messengers, was surprised to see himself prevented by Surenas in person, when he least expected it. The Parthian general, perceiving, as he approached Crassus, that he was on foot, cried out, in a seeming surprise, "What do I see? a Roman general on foot, and we on horseback! Let an horse be brought for him immediately." "You need not be surprised, (replied Crassus;) we are come only to an interview, each after the custom of his country." "Very well, (answered Surenas;) there shall be henceforth a lasting peace between king Orodes and the people of Rome: but we must sign the articles of it on the banks of the Euphrates; for you Romans do not always remember your conventions." Crassus would have sent fort an horse: but a very stately one, with a golden bit, and richly caparisoned, was brought to him by a Parthian; which Surenas presenting to him, "Accept this horse from my hands, (said he,) which I give you in the name of my master king Orodes." He had scarce uttered these words, when some of the king's officers, taking Crassus by the middle, set him upon the horse, which they began to whip with great violence before them in order to make him quicken his pace. Octavius, offended at this insult, took the horse by the bridle; Petronius, and the few Romans who were present, seconded him, and flocking all round Crassus, stopped his horse. The Parthians endeavoured to repulse them, and clear the way for the proconsul; whereupon they began to juggle and push one another with great tumult and disorder. At last, Octavius, drawing his sword, killed one of the king's grooms; but, at the same time, another coming behind Octavius, with one blow laid him dead at his feet. Both Crassus. <sup>17</sup>  
parties fought with great resolution, the Parthians striving to carry off Crassus, and the Romans to rescue him out of their hands. In this scuffle most of the Romans who came to the conference were killed; and, among the rest, Crassus himself, but whether by a Roman or a Parthian is uncertain.

Parthia.

Parthia.

Upon his death, the rest of the army either surrendered to the enemy, or, dispersing in the night, were pursued, and put to the sword. The Romans lost in this campaign at least 30,000 men; of which 20,000 were killed, and 10,000 taken prisoners.

When the battle of Carrhae was fought, king Orodes was in Armenia, where he had made peace with Artabazus. While the two kings were solemnizing their new alliance with expensive and public feasts, Syllaces, or Syllaces, a Parthian officer, whom Surenas had sent with the news of his late victory, and the head of Crassus as a proof of it, arrived in the capital of Armenia. The transports of joy which Orodes felt at this sight, and these news, are not to be expressed; and the lords of both kingdoms, who attended their sovereigns, raised loud and repeated shouts of joy. Syllaces was ordered to give a more particular and distinct account of that memorable action: which when he had done, Orodes commanded melted gold to be poured into Crassus's mouth; reproaching him thereby with avarice, which had been always his predominant passion.

<sup>18</sup> Surenas put victory; for Orodes, jealous of his power and authority among the Parthians, soon after caused him to be put to death. Pacorus, the king's favourite son, was put at the head of the army; and, agreeable to his father's directions, invaded Syria: but he was driven out from thence with great loss by Cicero and Cassius, the only general who survived the defeat of Crassus. After this we find no mention of the Parthians, till the time of the civil war between Cæsar and Pompey, when the latter sent ambassadors to solicit succour against his rival. This Orodes was willing to grant, upon condition that Syria was delivered up to him: but as Pompey would not consent to such a proposal, the succours were not only denied, but, after the battle of Pharsalia, he put Lucius Hirius in irons, whom Pompey had again sent to ask assistance, or at least to desire leave to shelter himself in the Parthian dominions.

<sup>19</sup> War commenced against the Parthians by Mark Anthony.

Cæsar is said to have meditated a war against the Parthians, which in all probability would have proved fatal to them. His death delivered them from this danger. But, not long after, the eastern provinces, being grievously oppressed by Mark Anthony, rose up in arms; and having killed the tax-gatherers, invited the Parthians to join them, and drive out the Romans. They very readily accepted the invitation, and crossed the Euphrates with a powerful army under the command of Pacorus and Labienus a Roman general of Pompey's party. At first they met with great success, over-ran all Asia Minor, and reduced all the countries as far as the Hellespont and the Egean Sea, subduing likewise Phœnicia, Syria, and even Judæa. They did not however long enjoy their new conquests: for being elated with their victories, and despising the enemy, they engaged Ventidius, Anthony's lieutenant, before Labienus had time to join them, and were utterly defeated. This so disheartened Labienus's army, that they all abandoned him; and he himself, being thus obliged to wander from place to place in disguise, was at last taken and put to death at Cyprus. Ventidius pursuing his advantage, gained several other victories;

and at last entirely defeated the Parthian army under Pacorus, cutting almost the whole of them in pieces, and the prince himself among the rest. He did not, however, pursue this last victory as he might have done; being afraid of giving umbrage to Anthony, who had already become jealous of the great honour gained by his lieutenant. He therefore contented himself with reducing those places in Syria and Phœnicia which the Parthians had taken in the beginning of the war, until Anthony arrived to take the command of the army upon himself.

Orodes was almost distracted with grief on receiving the dreadful news of the loss of his army and the death of his favourite son. However, when time had restored the use of his faculties, he appointed Phrahates, the eldest, but the most wicked, of all his children, to succeed him in the kingdom, admitting him at the same time to a share of the sovereign authority with himself. The consequence of this was, that Phrahates very soon attempted to poison his father with hemlock. But this, contrary to expectation, proving a cure for the dropsy which an excess of grief had brought upon the king, the unnatural son had him stifled in bed; and soon after not only murdered all his own brethren, who were 30 in number, but cut off all the rest of the royal family, not sparing even his own eldest son, left the discontented Parthians should place him, as he was already of age, on the throne.

Many of the chief lords of Parthia, being intimidated by the cruelty of Phrahates, retired into foreign countries; and among these was one Monæses, a person of great distinction, as well as skill and experience in war. This man, having fled to Anthony, soon gained his confidence, and was by him easily prevailed upon to engage in a war against his countrymen. But Phrahates, justly dreading the consequences of such a person's defection, sent a solemn embassy to invite him home on such terms as he should think fit to accept: which greatly provoked Anthony; though he did not hinder him from returning, lest others should thereby be discouraged from coming over to him. He therefore dismissed him with great civility, sending ambassadors at the same time to Phrahates to treat of a peace. Thus he hoped to divert the Parthian monarch's attention from making the necessary preparations for war, and that he should be able to fall upon him in the spring when he was in no condition to make resistance. But herein he was greatly disappointed; for, on his arrival at the Euphrates, which he intended to pass, and enter the Parthian dominions on that side, he found all the passes so well guarded, that he thought proper to enter Media, with a design first to reduce that country, and then to enter Parthia.

This plan had been suggested to him by Artabazus king of Armenia, who in the end betrayed him; for, instead of conducting the army the straight way from Zeugma on the Euphrates, to the Araxes which parted Media from Armenia, and which was about 500 miles distant from the place whence he first set out, Artabazus led them over rocks and mountains so far about, that the army had marched above 1000 miles before they reached the borders of Media, where they intended to begin the war. Thus they were not only greatly fatigued, but had not sufficient time, the year being far spent, to put in execution the design on

Parthia.

Anthony king of Armenia, who in the end betrayed him; for, instead of conducting the army the straight way from Zeugma on the Euphrates, to the Araxes which parted Media from Armenia, and which was about 500 miles distant from the place whence he first set out, Artabazus led them over rocks and mountains so far about, that the army had marched above 1000 miles before they reached the borders of Media, where they intended to begin the war. Thus they were not only greatly fatigued, but had not sufficient time, the year being far spent, to put in execution the design on

Parthia. which they had come. However, as Anthony was impatient to get back to Cleopatra, he left behind him most of the baggage of the army, and 300 waggon loads loaded with battering rams and other military engines for sieges; appointing Statianus, one of his lieutenants, with a body of 10,000 men, to guard them, and to bring them, by slower marches, after the army. With the rest of the forces he marched more than 300 miles before the rest, without allowing his men any respite till he arrived at Praespa, or Phrahata, the capital of Media, which he immediately invested. But the Parthians, well knowing that he could not make any progress without his military machines, passed by his army, in order to attack Statianus; which they did with such success, that the body commanded by him were all to a man cut off, and all their military engines taken, among which was a battering ram 80 feet long.

Anthony, notwithstanding this disaster, continued the siege of Praespa; but was daily harassed by sallies of the garrison from within, and the enemy's army without. At last he began to think of a retreat when his provisions were almost exhausted, finding it impossible to become master of the city. But as he was to march 300 miles through the enemy's country, he thought proper first to send ambassadors to the Parthian monarch, acquainting him that the Roman people were willing to allow him a peace, provided he would restore the standards and prisoners taken at Carrhae. Phraates received the ambassadors, sitting on a golden throne; and, after having bitterly inveighed against the avarice and unbounded ambition of the Romans, told them that he would not part with the standards and prisoners; but that, if Antony would immediately raise the siege of Praespa, he would suffer him to retire unmolested.

Anthony, who was reduced to great straits, no sooner received this answer, than he broke up the siege, and marched towards Armenia. However, Phraates was not so good as his word; for the Romans were attacked by the enemy no fewer than 18 times on their march, and were thrice in the utmost danger of being cut off. A famine also raged in the Roman army; upon which they began to desert to the enemy; and indeed Anthony would probably have been left by himself, had not the Parthians, in a very cruel as well as impolitic manner, murdered all those who fled to them in sight of the rest. At last, after having lost 32,000 men, and being reduced to such despair that he was with difficulty prevented from laying violent hands on himself, he reached the river Araxes; when his men, finding themselves out of the reach of the enemy, fell down on the ground, and kissed it with tears of joy.

Anthony was no sooner gone, than the kings of Media and Parthia quarrelled about the booty they had taken; and after various contests, Phraates reduced all Media and Armenia. After this, being elated with his conquests, he oppressed his subjects in such a cruel and tyrannical manner, that a civil war took place; in which the competitors were alternately driven out and restored, till the year 50, when one Vologeses, the son of Gotarzes, a former king, became peaceable possessor of the throne. He carried on some wars against the Romans, but with very indifferent success, and at

last gladly consented to a renewal of the ancient treaties with that powerful people.

From this time the Parthian history affords nothing remarkable till the reign of the emperor Trajan; when the Parthian king, by name *Coldroes*, infringed the treaty with Rome, by driving out the king of Armenia. Upon this Trajan, who was glad of any pretence to quarrel with the Parthians, immediately hastened into Armenia. His arrival there was so sudden and unexpected, that he reduced almost the whole country without opposition; and took prisoner Parthamaspis, the king whom the Parthians had set up. After this he entered Mesopotamia, took the city of Nisibis, and reduced to a Roman province the whole of that wealthy country.

Early in the spring of the following year, Trajan, who had kept his winter-quarters in Syria, took the field again; but was warmly opposed by Coldroes. He found him encamped on the banks of the Euphrates, with a design to dispute his passage: which he did with such vigour, that the emperor, after having several times attempted to ford that river, and been always repulsed with great slaughter, was obliged to cause boats to be built on the neighbouring mountains, which he privately conveyed from thence on carriages to the water-side; and having in the night-time formed a bridge with them, he passed his army the next day; but not without great loss and danger, the Parthians harassing his men the whole time with incessant showers of arrows, which did great execution. Having gained the opposite bank, he advanced boldly into Assyria, the Parthians flying every where before him, and made himself master of Arbela. Thence he pursued his march; subduing, with incredible rapidity, countries where the Roman standard had never been displayed before. Babylonia, or the province of Babylon, voluntarily submitted to him. The city itself was, after a vigorous resistance, taken by storm; by which means he became master of all Chaldaea and Assyria, the two richest provinces of the Parthian empire. From Babylon he marched to Ctesiphon, the metropolis of the Parthian monarchy; which he besieged, and at last reduced. But as to the particulars of these great conquests, we are quite in the dark; this expedition, however glorious to the Roman name, being rather hinted at, than described, by the writers of those times. While Trajan was thus making war in the heart of the enemy's country, Coldroes, having recruited his army, marched into Mesopotamia, with a design to recover that country, and cut off all communication between the Roman army and Syria. On his arrival in that province, the inhabitants flocked to him from all parts; and most of the cities, driving out the garrisons left by Trajan, opened their gates to him. Hereupon the emperor detached Lucius and Maximus, two of his chief commanders, into Mesopotamia, to keep such cities in awe as had not revolted, and to open a communication with Syria. Maximus was met by Coldroes; and having ventured a battle, his army was entirely defeated, and himself killed. But Lucius being joined by Emicius and Clarius, two other commanders sent by Trajan with fresh supplies, gained considerable advantages over the enemy, and retook the cities of Nisibis and Seleucia, which had revolted.

And now Trajan, seeing himself possessed of all the

belk

Parthia.

best and most fruitful provinces of the Parthian empire; but at the same time being well apprised that he could not, without a vast expence, maintain his conquests, nor keep in subjection so fierce and warlike a people at such a distance from Italy; resolved to set over them a king of his own choosing, who should hold the crown of him and his successors, and acknowledge them as his lords and sovereigns. With this view he repaired to Ctesiphon; and having there assembled the chief men of the nation, he crowned one of the royal family, by name *Parthaspates*, king of Parthia, obliging all who were prelent to pay him their allegiance. He chose *Parthaspates*, because that prince had joined him at his first entering the Parthian dominions, conducted him with great fidelity, and shown on all occasions an extraordinary attachment to the Romans. Thus the Parthians were at last subdued, and their kingdom made tributary to Rome. But they did not long continue in this state of subjection: for they no sooner heard of Trajan's death, which happened shortly after, than, taking up arms, they drove *Parthaspates* from the throne; and, recalling *Cosdroes*, who had retired into the country of the *Hyracians*, openly revolted from Rome. *Adrian*, who was then commander in chief of all the forces in the east, and soon after acknowledged emperor by the army, did not care, though he was at that time in Syria with a very numerous army, to engage in a new war with the Parthians; but contented himself with preserving the ancient limits of the empire, without any ambitious prospects of further conquests. Therefore, in the beginning of his reign, he abandoned those provinces beyond the Euphrates which Trajan had conquered; withdrew the Roman garrisons from Mesopotamia; and, for the greater safety of other places, made the Euphrates the boundary of and barrier in those parts, posting his legions along the banks of that river.

*Cosdroes* died after a long reign, and was succeeded by his eldest son *Vologeses*: in whose reign the Alani breaking into Media, then subject to the Parthians, committed there great devastations; but were prevailed upon, with rich presents sent them by *Vologeses*, to abandon that kingdom, and return home. Upon their retreat, *Vologeses*, having no enemy to contend with at home, fell unexpectedly upon Armenia; surprised the legions there; and having cut them all in pieces to a man, entered Syria; defeated with great slaughter *Artabianus* Cornelianus, governor of that province; and advanced, without opposition, to the neighbourhood of Antioch; putting every where the Romans, and those who favoured them, to the sword. Hereupon the emperor *Verus*, by the advice of his colleague *Antoninus* surnamed the *Philosopher*, leaving Rome, hastened into Syria: and having driven the Parthians out of that province, ordered *Statius Priscus* to invade Armenia; and *Cassius*, with *Martius Verus*, to enter the Parthian territories, and carry the war into the enemy's country. *Priscus* made himself master of *Artaxata*; and in one campaign drove the Parthians, though not without great loss on his side, quite out of Armenia. *Cassius*, on the other hand, having, in several encounters, defeated *Vologeses*, who had an army of 400,000 men under his command, reduced, in four years time, all those provinces which

had formerly submitted to Trajan, took *Seleucia*, burnt and plundered the famous cities of Babylon and Ctesiphon, with the stately palaces of the Parthian monarchs, and struck terror into the most remote provinces of that great empire. On his return, he lost above half the number of his forces by sickness and famine; so that, after all, the Romans, as *Spartianus* observes, had no great reason to boast of their victories and conquests.

However, *Verus*, who had never stirred during the whole time of the war from Antioch and Damascus, took upon him the lofty titles of *Parthicus* and *Armenicus*, as if he had acquired them jolly in the midst of his pleasures and debaucheries. After the revolt and death of *Cassius*, *Antoninus* the Philosopher repaired into Syria to settle the affairs of that province. On his arrival there, he was met by ambassadors from *Vologeses*; who having recovered most of the provinces subdued by *Cassius*, and being unwilling either to part with them or engage in a new war, solicited the emperor to confirm him in the possession of them, promising to hold them of him, and to acknowledge the sovereignty of Rome. To these terms *Antoninus* readily agreed, and a peace was accordingly concluded between the two empires; which *Vologeses* did not long enjoy, being soon after carried off by a distemper, and not murdered by his own subjects, as we read in *Constantinus Manassés*, who calls him *Belgeses*.

Upon his death, *Vologeses* III. the son of his brother *Sanatruces*, and grandson of *Cosdroes*, was raised to the throne. He sided with *Niger* against the emperor *Severus*: who thereupon, having settled matters at home, marched with all his forces against him; and advancing to the city of Ctesiphon, whither he had retired, laid close siege to that metropolis. *Vologeses* made a most gallant defence; but the city, after a long siege, and much bloodshed on both sides, was at length taken by assault. The king's treasures, with his wives and children, fell into the emperor's hands; but *Vologeses* himself had the good luck to make his escape; which was a great disappointment to *Severus*, who immediately dispatched an express to acquaint the senate with the success that had attended him in his expedition against the only nation that was then formidable to Rome. But he had no sooner crossed the Euphrates, than *Vologeses* recovered all the provinces, except Mesopotamia, which he had reduced. These expeditions were chargeable to the Romans, and cost them much blood, without reaping any advantages from them; for as they had not sufficient forces to keep in awe the provinces they had subdued, the inhabitants, greatly attached to the family of *Artaces*, never failed to return to their ancient obedience as soon as the Roman armies were withdrawn. *Vologeses* was soon after engaged in a war still more troublesome and destructive, with his brother *Artabanus*, who, encouraged by some of the discontented nobles, attempted to rob him of the crown, and place it on his own head. *Vologeses* gained several victories over his brother and rebellious subjects; but died before he could restore the empire to its former tranquillity.

*Artabanus*, who had a numerous army at his devotion, did not meet with any opposition in seizing the throne, vacant by the death of his brother, though

Parthia.

Tiridates had a better title to it, as being his elder brother. He had scarce settled the affairs of his kingdom, when the emperor Caracalla, desirous to signalize himself, as several of his predecessors had done, by some memorable exploit against the Parthians, sent a solemn embassy to him, desiring his daughter in marriage. Artabanus, overjoyed at this proposal, which he thought would be attended with a lasting peace between the two empires, received the ambassadors with all possible marks of honour, and readily complied with their request. Soon after, Caracalla sent a second embassy, to acquaint the king that he was coming to solemnise the nuptials; whereupon Artabanus went to meet him, attended with the chief of the nobility and his best troops, all unarmed, and in most pompous habits: but this peaceable train no sooner approached the Roman army, than the soldiers, on a signal given them, falling upon the king's retinue, made a most terrible slaughter of the unarmed multitude; Artabanus himself escaping with great difficulty. The treacherous Caracalla, having gained by this exploit great booty, and, as he thought, no less glory, wrote a long and boasting letter to the senate, assuming the title of *Parthicus* for this piece of treachery; as he had before that of *Germanicus*, for murdering, in like manner, some of the German nobility.

29  
Infamous  
treachery of  
the emperor  
Caracalla.

Artabanus, resolving to make the Romans pay dear for their inhuman and barbarous treachery, raised the most numerous army that had ever been known in Parthia, crossed the Euphrates, and entered Syria, putting all to fire and sword. But, Caracalla being murdered before this invasion, Macrinus, who had succeeded him, met the Parthians at the head of a mighty army, composed of many legions, and all the auxiliaries of the states of Asia. The two armies no sooner came in sight of each other, but they engaged with the utmost fury. The battle continued two days; both Romans and Parthians fighting so obstinately, that night only parted them, without any apparent advantage on either side; though both retired, when night had put an end to the contest, crying, Victory, victory. The field of battle was covered all over with dead bodies, there being already above 40,000 killed, including both Romans and Parthians: nevertheless Artabanus was heard to say, that the battle was only begun, and that he would continue it till either the Parthians or Romans were all to a man cut in pieces. But Macrinus, being well apprised that the king came highly enraged against Caracalla in particular, and dreading the consequences which would attend the destruction of his army, sent an herald to Artabanus, acquainting him with the death of Caracalla, and proposing an alliance between the two empires. The king, understanding that his great enemy was dead, readily embraced the proposals of peace and amity, upon condition that all the prisoners who had been taken by the treachery of Caracalla should be immediately restored, and a large sum of money paid him to defray the expences of the war.

These affairs being performed without delay or hesitation, Artabanus returned into Parthia, and Macrinus to Antioch.

As Artabanus lost on this occasion the flower of his army, Artaxerxes, a Persian of mean descent,

but of great courage and experience in war, revolting from the Parthians, prevailed on his countrymen to join him, and attempt the recovery of the sovereign power, which he said they had been unjustly deprived of, first by the Macedonians, and afterwards by the Parthians their vassals. Artabanus, upon the news of this revolt, marched with the whole strength of his kingdom to suppress it; but being met by Artaxerxes at the head of a no less powerful army, a bloody battle ensued, which is said to have lasted three days. At length the Parthians, though they behaved with the utmost bravery, and fought like men in despair, were forced to yield to the Persians, who were commanded by a more experienced leader. Most of their troops were cut off in the flight; and the king himself was taken prisoner, and soon after put to death by Artaxerxes's order. The Parthians, having lost in this fatal engagement both their king and their army, were forced to submit to the conqueror, and become vassals to a nation which had been subject to them for the space of 475 years.

For an account of the manners, customs, &c. of the ancient Parthians, see the article PERSIA.

PARTI, PARTIE, *Party*, or *Parted*, in heraldry, is applied to a shield or escutcheon, denoting it divided or marked out into partitions.

*Parti per pale*, is when the shield is divided perpendicularly into two halves, by a cut in the middle from top to bottom.

*Parti per fess*, is when the cut is across the middle, from side to side.

*Parti per bend dexter*, is when the cut comes from the upper corner of the shield on the right hand, and descends athwart to the opposite lower corner.

*Parti per bend sinister*, is when the cut, coming from the upper left corner, descends across to the opposite lower one.

All these partitions, according to M. de la Colombe, have their origin from the cuts and bruises that have appeared on shields after engagements; and, being proofs of the dangers to which the bearers had been exposed, they gained them esteem: for which reason they were transmitted to posterity, and became arms and marks of honour to their future families.

PARTICIPLE, in grammar, an adjective formed of a verb; so called, because it participates partly of the properties of a noun, and partly of those of a verb. See GRAMMAR.

PARTICLE, in physiology, the minute part of a body, an assemblage of which constitutes all natural bodies.

PARTICLE, in grammar, a denomination for all those small words that tie or unite others, or that express the modes or manners of words. See GRAMMER.

PARTISAN, in the art of war, a person dextrous in commanding a party; who, knowing the country well, is employed in getting intelligence, or surprising the enemy's convoy, &c. The word also means an officer sent out upon a party, with the command of a body of light troops, generally under the appellation of the *partisans* corps. It is also necessary that this corps should be composed of infantry, light-horse, and hussars.

**PARTNERSHIP**, is a contract among two or more persons, to carry on a certain business, at their joint expence, and share the gain or loss which arises from it. Of this there are four kinds.

I. Occasional joint trade, where two or more merchants agree to employ a certain sum in trade, and divide the gain or loss so soon as the adventure is brought to an issue. This kind of contract being generally private, the parties concerned are not liable for each other. If one of them purchase goods on trust, the furnisher, who grants the credit through confidence in him alone, has no recourse, in case of his insolvency, against the other partners. They are only answerable for the share of the adventure that belongs to the insolvent partner.

If it be proposed to carry the adventure further than originally agreed on, any partner may withdraw his interest; and, if it cannot be separated from the others, may insist that the whole shall be brought to an issue.

II. Standing companies, which are generally established by written contract between the parties, where the stock, the firm, duration, the division of the gain or loss, and other circumstances, are inserted.

All the partners are generally authorized to sign by the firm of the company, though this privilege may be confined to some of them by particular agreement. The firm ought only to be subscribed at the place where the copartnership is established. If a partner has occasion, when absent, to write a letter relating to their affairs, he subscribes his own name on account of the company. When the same partners carry on business at different places, they generally choose different firms for each. The signature of each partner is generally sent to new correspondents; and, when a partner is admitted, although there be no alteration in the firm, his signature is transmitted, with an intimation of the change in the copartnership, to all their correspondents. Houses that have been long established, often retain the old firm, though all the original partners be dead or withdrawn.

The powers of each partner are, in general, discretionary; but they ought not to act, in matters of importance, without consulting together, when there is an opportunity. No partner is liable to make good the loss arising from his judging wrong in a case where he had authority to act. If he exceeds his power, and the event prove unsuccessful, he must bear the loss; but, if it prove successful, the gain belongs to the company: yet, if he acquiesces in the company immediately of what he has done, they must either acquiesce therein, or leave him the chance of gain, as well as the risk of loss.

All debts contracted under the firm of the company are binding on the whole partners, though the money was borrowed by one of them for his private use, without the consent of the rest. And, if a partner exceeds his power, the others are nevertheless obliged to implement his engagements; tho' they may render him responsible for his misbehaviour.

Although the sums to be advanced by the partners be limited by the contract, if there be a necessity for raising more money to answer emergencies or pay the debts of the company, the partners must furnish what is necessary, in proportion to their shares.

A debt to a company is not cancelled by the private debts of the partner; and, when a partner becomes insolvent, the company is not bound for his debts beyond the extent of his share.

The debts of the company are preferable, on the company's effects, to the private debts of the partners.

Partnership is generally dissolved by the death of a partner: yet, when there are more partners than two, it may, by agreement, subsist among the survivors. Sometimes it is stipulated, that, in case of the death of a partner, his place shall be supplied by his son, or some other person confederated on. The contract ought to specify the time and manner in which the surviving partners shall reckon with the executors of the deceased for his share of the stock, and a reasonable time allowed for that purpose.

When partnership is dissolved, there are often outstanding debts that cannot be recovered for a long time, and effects that cannot easily be disposed on. The partnership, though dissolved in other respects, still subsists for the management of their outstanding affairs; and the money arising from them is divided among the partners, or their representatives, when it is recovered. But, as this may protract the final settlement of the company's affairs to a very inconvenient length, other methods are sometimes used to bring them to a conclusion, either in consequence of the original contract, or by agreement at the time of dissolution. Sometimes the debts and effects are sold by auction; sometimes they are divided among the partners; and, when there are two partners, one divides them into shares, as equal as possible, and the other chooses either share he thinks best.

If a partner withdraws, he continues responsible for his former partners till it be publicly known that he hath done so. A deed of separation, registered at a public office, is sufficient presumption of such notoriety.

III. Companies, where the business is conducted by officers. There are many companies of this kind in Britain, chiefly established for purposes which require a larger capital than private merchants can command. The laws with respect to these companies, when not confirmed by public authority, are the same as the former, but the articles of their agreement usually very different. The capital is confederated on; and divided into a certain number of shares, whereof each partner may hold one or more, but is generally restricted to a certain number. Any partner may transfer his share; and the company must admit his assignee as a partner. The death of the partners has no effect on the company. No partner can act personally in the affairs of the company: but the execution of their business is intrusted to officers, for whom they are responsible; and, when the partners are numerous, the superintendency of the officers is committed to directors chosen annually, or at other appointed times, by the partners.

IV. Companies incorporated by authority. A royal charter is necessary to enable a company to hold lands, to have a common seal, and enjoy the other privileges of a corporation. A charter is sometimes procured, in order to limit the risk of the partners: for, in every private company, the partners are liable for the

**Partridge.** the debts, without limitation ; in incorporated societies, they are only liable for their shares in the stock of the society. The incorporation of societies is sometimes authorised by act of parliament ; but this high authority is not necessary, unless for conferring exclusive privileges.

**PARTRIDGE**, in ornithology. See **TETRAO**.

The partridge is so valuable at the table, that a great many ways of taking it have been invented by sportsmen, all of which succeed from the natural folly and timidity of the animal.

The places partridges delight in most are corn-fields, especially whilst the corn grows, for under that cover they shelter and breed : neither are those places unfrequented by them when the corn is cut down, by reason of the grain they find there, especially in wheat-stubble, the height of which they delight in, being to them as a covert or shelter. When the wheat-stubble is much trodden by men or beasts, they then betake themselves to the barley-stubble, provided it be fresh and untrodden ; and they will, in the furrows, amongst the clots, branches, and long grass, hide both themselves and coveys, which are sometimes 20 in number ; nay, 30 in a covey.

When the winter-season is arrived, and the stubble-fields are ploughed up, or over-soiled with cattle, partridges resort into the upland meadows, and lodge in the dead-grass, or fog under hedges, amongst mole-hills, or under the roots of trees ; sometimes they resort to coppices and under-woods, especially if any corn-fields are adjacent, or where there is grown broom, brakes, fern, &c.

In the harvest-time, when every field is full of men and cattle, in the day-time they are found in the fallow-fields which are next adjoining to the corn-fields, where they lie lurking till evening or morning, and then they feed among the sheaves of corn.

When their haunts are known, according to the situation of the country and season of the year, the next care must be to find them out in their haunts, which is done several ways. Some do it by the eye only ; and this art can never be taught, but learned by frequent experience, the colour of the birds being so like that of the earth at a distance, that no eye but a very conversant one could distinguish them. When they are once seen, the business is to keep the eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a person almost tread upon them ; though if the person stands still to eye them, they will rise immediately, though they be at a considerable distance.

Another method of discovering them, is by going to their haunts very early in the morning, or at the close of the evening, which is called the *ducking-time*. The noise of the cock-partridge is to be attended to at this time, and is very loud and earnest. The hen will soon come up to the cock after her making the noise, which she does by way of answer ; and when they are got together, their chattering will discover them. Thus they may always be found at these times. But there is a yet better method of finding this bird, which is by the *call*. The business, in order to have success in this way, is carefully to learn the notes of the partridge, and be able to imitate all the several sounds. When perfect in this, the person is to go to

the haunts morning and evening, and placing himself in some place where he can see the birds without being seen by them, he is to listen to their calling ; and when they are heard, he is to answer in the same notes, doubling again as they do : by continuing this, they may be brought so near, that the person lying down on his back may count their whole number. Having in this manner found where the birds are, the next care is to catch them.

They are so foolish, that it is extremely easy to take them in *nets*. In order to this, there needs no more than the going out, provided with two or three nets, with meshes somewhat smaller than those of the pheasant nets, and walking round about the covey, a net is to be fixed so as to draw over them, on pulling a line at a distance. All this may be easily done ; for so long as the sportsman continues moving about, and does not fix his eye too intently upon them, they will let him come near enough to fix the net, without moving. If they lie so straggling, that one net will not cover them, then two or three must be fixed in the same manner. The sportsman may then draw the nets over them, and they will often lie still with the nets upon them till he comes up to fright them ; then they will rise, and be entangled in the net.

A second method of taking them is with *bird-lime*. this is done by means of wheat-straws. These must be large, and cut off between knot and knot ; they must be well lined with the best and strongest bird-lime, and the sportsman must carry a great number out with him. Having found a field where there are partridges, he is to call ; and if they answer, he is then to stick up the limed straws in rows across two or three lands, and going backward, call again to them, leading them on in the road where the straws are : they will follow one another like a flock of chickens, and come out to the call ; and will in their way run upon the straws, and liming themselves they will daub one another by crowding together, so that very few of them will be able to escape.

But there is yet a pleasanter way of taking them than this, that is, by *driving* of them. In order to this, an engine is to be made of canvas stuffed with straw, to represent a horse ; this horse and nets are to be taken to the haunts of the partridges, and the nets being placed slanting or slopewise in the lower part of the field, the sportsman is to take the wind in his back and get above them, driving them downwards ; his face is to be covered with something green or blue, and placing the horse before him, he is to go towards them slowly and gently ; and by this means they will be raised on their legs, but not on their wings, and will run before the horse into the nets. If in the way they go into a wrong path, the horse is to be moved to face them ; and they will be thus driven back again, and driven every way the sportsman pleases.

**PARTURITION**, the art of bringing forth, or being delivered of, young. See **MIDWIFERY**.

**PARTY**, in a military sense, a small number of men, horse, or foot, sent upon any kind of duty ; as into an enemy's country to pillage, to take prisoners, and to oblige the country to come under contribution. Parties are often sent out to view the roads and ways, get intelligence, seek forage ; to reconnoitre, or amuse the enemy upon a march : they are also frequently sent upon

**Partridge**  
||  
**Party.**

Parulides, upon the flanks of an army or regiment, to discover the enemy if near, and prevent surprise or ambuscade.

PARULIDES, in surgery, tumours and inflammations of the gums, commonly called *gum-balls*. They are to be treated with discutients like other inflammatory tumours.

PARUS, or TITMOUSE, in ornithology, a genus belonging to the order of passerines. The bill is very entire, covered at the basis with hairs; the tongue is truncated and hairy. There are 14 species; of which the most remarkable are,

1. The cristatus, or crested titmouse, weighs 13 pennyweight; the bill is black, with a spot of the same colour above it; all the upper part of the body gray; the neck and under parts are white, with a faint tincture of red, which is deepest just below the wings. The legs are of a lead colour. It erects its crown feathers into a crest. It inhabits the warm parts of North America; and frequents forest-trees, feeding upon insects.

2. The major, or great titmouse, has the head and throat black, the cheeks white, the back of a green colour, the belly yellowish green, divided in the middle by a bed of black which extends to the vent; the rump of a bluish grey, the legs of a lead colour, the toes divided to the very origin, and the back-toe very large and strong. This species sometimes visits our gardens; but for the most part inhabits woods, where it builds in hollow trees, laying about ten eggs. It feeds on insects, which it finds in the bark of trees. In the spring they do a great deal of mischief by picking off the tender buds of the fruit-trees. Like woodpeckers, they are perpetually running up and down the bodies of trees in quest of food. This bird has three cheerful notes, which it begins to utter in the month of February.

3. The *cæruleus*, or blue titmouse, is a very beautiful bird. The bill is short and dusky; the crown of the head of a fine blue; from the bill to the eyes is a black line; the forehead and cheeks white; the back, of a yellowish green; the lower side of the body yellow; the wings and tail blue, the former marked transversely with a white bar; the legs of a lead colour. They frequent gardens; and do great injury to fruit-trees, by bruising the tender buds in search of the insects which lie under them. It breeds in holes of walls, and lays 12 or 14 eggs.

4. The *virginianus*, or yellow rump, is found in Virginia; and is distinguished by a yellow spot on its rump. All the rest of the feathers are brown, with a slight tincture of green. It runs about the bodies of trees; and feeds on insects, which it pecks from the crevices of the bark.

5. The *caudatus*, or long-tailed titmouse, is about five inches and a quarter in length, and seven inches in breadth. The bill is black, very thick and convex, differing from all others of this genus. The top of the head, from the bill to the hind part, is white, mixed with a few dark-grey feathers: this bed of white is entirely surrounded with a broad stroke of black; which rising on each side of the upper mandible, passes over each eye, unites at the hind part of the head, and continues along the middle of the back to the rump. The feathers on each side of this black stroke are of a purplish red, as are those immediately incumbent

on the tail. The tail is the longest, in proportion to the bulk, of any British bird, being in length three inches, the form not unlike that of a magpie, consisting of 12 feathers of unequal lengths, the middlemost the longest, those on each side growing gradually shorter. These birds are often seen passing through our gardens, going from one tree to another, as if in their road to some other place, never making any halt. They make their nests with great elegance, of an oval shape, and about eight inches deep, having near the upper end a hole for admission. The external materials are mosses and lichens curiously interwoven with wool. On the inside it is very warmly lined with a thick bed of feathers. The female lays from 10 to 17 eggs. The young follow their parents the whole winter; and, from the flimsiness of their bodies, and great length of tail, appear, while flying, like as many darts cutting the air.

6. The *biarmicus*, or bearded titmouse, has a short, strong, and very convex bill, of a box colour; the head of a fine grey; the clin and throat white; the middle of the breast flesh-coloured; the sides and thighs of a pale orange; the hind part of the neck and back of orange bay; the tail is two inches and three quarters long; the legs of a deep shining black. The female wants the flesh-colour on the breast, and a triangular tuft of black feathers on each side the bill which adorn the male. They are found in marshy places.

PASCAL (BLAISE), one of the greatest geniuses and best writers France has produced, was born at Clermont in Auvergne, in the year 1623. His father, Stephen Pascal, born in 1588, and of an ancient family, was president of the court of aids in his province: he was a very learned man, an able mathematician, and a friend of Des Cartes. Having an extraordinary tenderness for this child, his only son, he quitted his office in his province, and went and settled at Paris in 1631, that he might be quite at leisure for the instruction of him; and Blaise never had any master but his father. From his infancy he gave proofs of a very extraordinary capacity: for he desired to know the reason of every thing; and when good reasons were not given him, he would seek for better; nor would he ever yield his assent but upon such as appeared to him well grounded. There was room to fear, that with such a cast of mind he would fall into free thinking, or at least into heterodoxy; yet he was always very far from any thing of this nature.

What is told of his manner of learning the mathematics, as well as the progress he quickly made in that science, seems almost miraculous. His father, perceiving in him an extraordinary inclination to reasoning, was afraid lest the knowledge of the mathematics would hinder his learning the languages. He kept him therefore as much as he could from all notions of geometry, locked up all his books of that kind, and refrained even from speaking of it in his presence. He could not, however, make his son refrain from musing upon proportions; and one day surprised him at work with charcoal upon his chamber-floor, and in the midst of figures. He asked him what he was doing? I am searching, says Pascal, for such a thing; which was just the 32d proposition of the first book of Euclid. He asked him then how he came to think of this? It was, says Pascal, because I have found out such

another thing : and to go going backward, and using the names of *bar* and *round*, he came at length to the definitions and axioms he had formed to himself. Does it not seem miraculous, that a boy should work his way into the heart of a mathematical book, without ever having seen that or any other book upon the subject, or knowing any thing of the terms? Yet we are assured of the truth of this by Madam Perier, and several other writers, the credit of whose testimony cannot reasonably be questioned. He had, from henceforward, full liberty to indulge his genius in mathematical pursuits. He understood Euclid's Elements as soon as he cast his eyes upon them : and this was not strange ; for, as we have seen, he understood them before. At 16 years of age he wrote a treatise of conic sections, which was accounted by the most learned a mighty effort of genius ; and therefore it is no wonder that Des Cartes, who had been in Holland a long time, should, upon reading it, choose to believe, that Mr Pascal, the father, was the real author of it. At nineteen, he contrived an admirable arithmetical machine, which was esteemed a very wonderful thing : and at twenty-three, having seen the Torricellian experiment, he invented and tried a great number of other new experiments.

After he had laboured abundantly in mathematical and philosophical disquisitions, he forsook those studies and all human learning at once ; and determined to know nothing, as it were, for the future, but Jesus Christ and him crucified. He was not 24 years of age, when the reading some pious books had put him upon taking this holy resolution ; and he became as great a devotee as any age has produced. Mr Pascal now gave himself up entirely to a state of prayer and mortification. He had always in his thoughts these great maxims, of renouncing all pleasure and all superfluity ; and this he practised with rigour even in his illnesses, to which he was frequently subject, being of a very invalid habit of body : for instance, when his sickness obliged him to feed somewhat delicately, he took great care not to relish or taste what he eat. He had no violent affection for those he loved ; he thought it sinful, since a man possesses a heart which belongs only to God. He found fault with some discourses of his sister, which the thought very innocent ; as if she had said upon occasion, that she had seen a beautiful woman, he would be angry, and tell her, that she might raise bad thoughts in footmen and young people. He frequently wore an iron girdle full of points next to his skin ; and when any vain thought came into his head, or when he took particular pleasure in any thing, he gave himself some blows with his elbow, to redouble the prickings, and to recall himself to his duty.

Though Mr Pascal had thus abstracted himself from the world, yet he could not forbear paying some attention to what was doing in it ; and he even interested himself in the contest between the Jesuits and the Jansenists. The Jesuits, though they had the popes and kings on their side, were yet decry'd by the people, who brought up afresh against them the assassination of Henry the Great, and all the old stories that were likely to make them odious. Pascal went farther ; and by his *Lettres Provinciales*, published in 1656, under the name of *Louis de Montalte*, made them

the subject of ridicule. " These letters," says Voltaire, " may be considered as a model of eloquence and humour. The best comedies of Moliere have not more wit than the first part of these letters ; and the sublimity of the latter part of them is equal to any thing in Bossuet. It is true, indeed, that the whole book was built upon a false foundation ; for the extravagant notions of a few Spanish and Flemish Jesuits were artfully ascribed to the whole society. Many absurdities might likewise have been discovered among the Dominican and Franciscan casuists : but this would not have answered the purpose ; for the whole rillery was to be levelled only at the Jesuits. These letters were intended to prove, that the Jesuits had formed a design to corrupt mankind ; a design which no sect or society ever had, or can have " Voltaire calls Pascal the first of their satyrists ; for Despreaux, says he, must be considered as only the second. In another place, speaking of this work of Pascal, he says, that " examples of all the various species of eloquence are to be found in it. Though it has been now written almost 100 years, yet not a single word occurs in it, favouring of that vicissitude to which living languages are so subject. Here then we are to fix the epocha when our language may be said to have assumed a settled form. The bishop of Lucon, son of the celebrated Buffy, told me, that asking one day the bishop of Meaux what work he would covet most to be the author of, supposing his own performances set aside, Bossuet replied, The Provincial Letters." These letters have been translated into all languages, and printed over and over again. Some have said, that there were decrees of formal condemnation against them ; and also that Pascal himself, in his last illness, detested them, and repented of having been a Jansenist : but both these particulars are false and without foundation. Father Daniel was supposed to be the anonymous author of a piece against them, intitled, *The Dialogues of Cleander and Eudoxus*.

Mr Pascal died at Paris the 19th of August 1662, aged 39 years. He had been some time about a work against atheists and infidels, but did not live long enough to digest the materials he had collected. What was found among his papers was published under the title of *Pensées*, &c. or *Thoughts upon religion and other subjects*, and has been much admired. After his death appeared also two other little tracts ; one of which is intitled, *The equilibrium of fluids* ; and the other, *The weight of the mass of air*.

To conclude, Mr Pascal was, all things considered, a man of a most singular composition ; or, as Mr Bayle says, " a paradoxical individuum of the human kind."

PASCHAL, something belonging to the passover, or Easter. See PASSOVER and EASTER.

PASIPHAE, in fabulous history, the daughter of Apollo, and the wife of Minos, king of Crete, by whom she had Androgeos, Ariadne, and Phaedra. She conceived a violent passion for a bull ; and had by him the Minotaur, which was kept in the labyrinth, where it was killed by Theseus.

PASQUIN, a mutilated statue at Rome, in a corner of the palace of the Ursini. It takes its name from a cobbler of that city called *Pasquin*, famous for his sneers and gibes, and who diverted himself by passing his jokes on all that went through that street.

After

**Pasquinade** After his death, as they were digging up the pavement before his door, they found in the earth the statue of an ancient gladiator, well cut, but maimed and half-spoiled: this they set up in the place where it was found, and by common consent named it *Pasquin*. Since that time all satires are attributed to that figure; and are either put into its mouth, or patted upon it, as if they were written by Pasquin redivivus; and these are addressed by Pasquin to Marforio, another statue at Rome. When Marforio is attacked, Pasquin comes to his assistance; and, when Pasquin is attacked, Marforio assists him in his turn: that is, the people make the statues speak just what they please.

**PASQUINADE**, a satirical libel fastened to the statue of Pasquin: these are commonly short, witty, and pointed; and from hence the term has been applied to all lampoons of the same cast.

**PASS**, or **PASSADE**, in fencing; an advance, or leap forward upon the enemy. Of these there are several kinds; as passes within, above, beneath, to the right, the left, and passes under the line, &c. The measure of the pass is when the swords are so near as that they may touch one another.

**Pass**, in a military sense, a strait and difficult passage, which shuts up the entrance into a country.

**Pass-Parole**, in military affairs, a command given at the head of an army, and thence communicated to the rear, by passing it from mouth to mouth.

**PASSADE**, in the manege, is a turn or course of a horse backwards or forwards on the same spot of ground. Hence there are several sorts of passades, according to the different ways of turning, in order to part or return upon the same tread, which is called *closing the passade*; as the passade of one time, the passade of five times, and the raised or high passades, into which the demolvits are made into curvets. See **HORSEMANSHIP**.

*North-west PASSAGE.* } See **POLE**.

*North-east PASSAGE.* }

**Right of PASSAGE**, in commerce, is an imposition or duty exacted by some princes, either by land or sea, in certain close and narrow places in their territories, on all vessels and carriages, and even sometimes on persons or passengers coming in or going out of ports, &c. The most celebrated passage of this kind in Europe is the Sound; the dues for passing which strait belong to the king of Denmark, and are paid at Elsenore or Cronenburg.

**PASSANT**, in herald, a term applied to a lion or other animal in a shield, appearing to walk leisurely: for most beasts, except lions, the *trippant* is frequently used instead of *passant*.

**PASSAU**, an ancient, handsome, and celebrated town of Germany, in lower Bavaria, with a bishop's see and fort. The houses are well built, and the cathedral is thought to be the finest in all Germany. It is divided into four parts, three of which are fortified; but the other is only a suburb, and has nothing but an old castle in which the bishop generally resides. It is situated at the confluence of the rivers Inn and Ilitz, in E. Long. 13. 34. N. Lat. 48. 26.

**PASSAU**, a bishopric of Germany, lying between Lower Bavaria, Austria, and Bohemia. It extends

not above 20 miles where largest; and has no considerable place, except the capital which is of the same name.

**Pasflorat**  
**Passions.**

**PASSERAT** (John), a celebrated professor of eloquence in the royal college of Paris, and one of the politest writers of his time, was born at Troyes in the province of Champagne, in 1534. He spent three years in studying the law under the famous Cujacius at Bourges, where he became professor of eloquence in 1572. He was an indefatigable student, passing frequently whole days without eating a morsel; yet to an extraordinary erudition he joined an uncommon politeness of manners and pleantry, having nothing of the mere scholar except the gown and hood. He gained the esteem of the kings Charles IX. Henry III. and of all the men of wit and learning in his time. He died in 1602, and left several admired works behind him.

**PASSERES**, the name of a class of birds. See **ZOOLOGY**.

**PASSIONS**, in moral philosophy, are certain motions of the soul, which make it pursue what appears to be good, and avoid whatever threatens evil. See **METAPHYSICS**, n° 31, 32.

On the just regulation and subordination of the passions depends in a great measure the happiness of mankind. See **MORAL Philosophy**, n° 6, 17, 31, 32, 68, 212.

**PASSIONS and Emotions**, difference between them. See **EMOTIONS and Passions**.

*External Signs of Emotions and Passions*. So intimately connected are the soul and body, that every agitation in the former produces a visible effect upon the latter. There is, at the same time, a wonderful uniformity in that operation; each class of emotions and passions being invariably attended with an external appearance peculiar to itself. These external appearances, or signs, may not improperly be considered as a natural language, expressing to all beholders emotions and passions as they arise in the heart. Hope, fear, joy, grief, are displayed externally: the character of a man can be read in his face; and beauty, which makes so deep an impression, is known to result, not so much from regular features and a fine complexion, as from good-nature, goodness, sprightliness, sweetness, or other mental quality, expressed upon the countenance. Though perfect skill in that language be rare, yet what is generally known is sufficient for the ordinary purposes of life. But by what means we come to understand the language, is a point of some intricacy. It cannot be by sight merely; for upon the most attentive inspection of the human visage, all that can be discerned are figure, colour, and motion, which, singly or combined, never can represent a passion, nor a sentiment: the external sign is indeed visible; but to understand its meaning, we must be able to connect it with the passion that causes it, an operation far beyond the reach of eye-sight. Where then is the instructor to be found that can unveil this secret connection? If we apply to experience, it is yielded, that from long and diligent observation, we may gather, in some measure, in what manner those we are acquainted with express their passions externally: but with respect to strangers, we are left in the dark; and yet we are not

puzzled about the meaning of these external expressions in a stranger, more than in a bosom-companion. Further, had we no other means but experience for understanding the external signs of passion, we could not expect any uniformity nor any degree of skill in the bulk of individuals: yet matters are so much better ordered, that the external expressions of passion form a language understood by all, by the young as well as the old, by the ignorant as well as the learned: We talk of the plain and legible characters of that language; for undoubtedly we are much indebted to experience, in deciphering the dark and more delicate expressions. Where then shall we apply for a solution of this intricate problem, which seems to penetrate deep into human nature? Undoubtedly if the meaning of external signs be not derived to us from sight, nor from experience, there is no remaining source whence it can be derived but from nature.

Elements of Criticism.

We may then venture to pronounce, with some degree of confidence, that man is provided by nature with a sense or faculty that lays open to him every passion by means of its external expressions. And we cannot entertain any reasonable doubt of this, when we reflect, that the meaning of external signs is not hid even from infants: an infant is remarkably affected with the passions of its nurse expressed on her countenance; a smile cheers it, a frown makes it afraid: but fear cannot be without apprehending danger; and what danger can the infant apprehend, unless it be sensible that its nurse is angry? We must therefore admit, that a child can read anger in its nurse's face; of which it must be sensible intuitively, for it has no other mean of knowledge. We do not affirm, that these particulars are clearly apprehended by the child; for to produce clear and distinct perceptions, reflection and experience are requisite: but that even an infant, when afraid, must have some notion of its being in danger, is evident.

That we should be conscious intuitively of a passion from its external expressions, is conformable to the analogy of nature: the knowledge of that language is of too great importance to be left upon experience; because a foundation for uncertain and precarious, would prove a great obstacle to the formation of societies. Wisely therefore is it ordered, and agreeably to the system of Providence, that we should have nature for our instructor.

Manifold and admirable are the purposes to which the external signs of passion are made subservient by the Author of our nature.

1. The signs of internal agitation displayed externally to every spectator, tend to fix the signification of many words. The only effectual means to ascertain the meaning of any doubtful word, is an appeal to the thing it represents: and hence the ambiguity of words expressive of things that are not objects of external sense; for in that case an appeal is denied. Passion, strictly speaking, is not an object of external sense: but its external signs are; and by means of these signs, passions may be appealed to with tolerable accuracy: thus the words that denote our passions, next to those that denote external objects, have the most distinct meaning. Words signifying internal action and the more delicate feelings, are less distinct. This defect with regard to internal action, is what chiefly occa-

sions the intricacy of logic: the terms of that science are far from being sufficiently ascertained, even after much care and labour bestowed by an eminent writer\*; to whom however the world is greatly indebted, for removing a mountain of rubbish, and moulding the subject into a rational and correct form. The same defect is remarkable in criticism, which has for its object the more delicate feelings; the terms that denote these feelings being not more distinct than those of logic.

2. Society among individuals is greatly promoted by that universal language. Looks and gestures give direct access to the heart; and lead us to select, with tolerable accuracy, the persons who are worthy of our confidence. It is surprising how quickly, and for the most part how correctly, we judge of character from external appearance.

3. After social intercourse is commenced, these external signs, which diffuse through a whole assembly the feelings of each individual, contribute above all other means to improve the social affections. Language, no doubt, is the most comprehensive vehicle for communicating emotions: but in expedition, as well as in power of conviction, it falls short of the signs under consideration; the involuntary signs especially, which are incapable of deceit. Where the countenance, the tones, the gestures, the actions, join with the words in communicating emotions, these united have a force irresistible: thus all the pleasant emotions of the human heart, with all the social and virtuous affections, are, by means of these external signs, not only perceived, but felt. By this admirable contrivance, conversation becomes that lively and animating amusement, without which life would at best be insipid: one joyful countenance spreads cheerfulness instantaneously through a multitude of spectators.

4. Disocial passions, being hurtful by prompting violence and mischief, are noted by the most conspicuous external signs, in order to put us upon our guard: thus anger and revenge, especially when sudden, display themselves on the countenance in legible character. The external signs, again, of every passion that threatens danger, raise in us the passion of fear: which frequently operating without reason or reflection, moves us by a sudden impulse to avoid the impending danger.

5. These external signs are remarkably subservient to morality. A painful passion, being accompanied with disagreeable external signs, must produce in every spectator a painful emotion: but then, if the passion be social, the emotion it produces is attractive, and connects the spectator with the person who suffers. Disocial passions only, are productive of repulsive emotions, involving the spectator's aversion, and frequently his indignation. This artful contrivance makes us cling to the virtuous, and abhor the wicked.

6. Of all the external signs of passion, those of affliction or distress are the most illustrious with respect to a final cause, and deservedly merit a place of distinction. They are illustrious by the singularity of their contrivance; and also by inspiring sympathy, a passion to which human society is indebted for its greatest blessing, that of providing relief for the distressed. A subject so interesting, deserves a leisurely and attentive examination. The conformity of the nature

Locke.

ture of man to his external circumstances, is in every particular wonderful: his nature makes him prone to society; and society is necessary to his well-being, because in a solitary state he is a helpless being, destitute of support, and in his distresses destitute of relief: but mental support, the shining attribute of society, is of too great moment to be left dependent upon cool reason; it is ordered more wisely, and with greater conformity to the analogy of nature, that it should be enforced even instinctively by the passion of sympathy. Here sympathy makes a capital figure; and contributes, more than any other means, to make life easy and comfortable. But however essential the sympathy of others may be to our well-being, one beforehand would not readily conceive how it could be raised by external signs of distress: for considering the analogy of nature, if these signs be agreeable, they must give birth to a pleasant emotion leading every beholder to be pleased with human woes: if disagreeable, as they undoubtedly are, ought they not naturally to repel the spectator from them, in order to be relieved from pain? Such would be the reasoning beforehand; and such would be the effect were man purely a selfish being. But the benevolence of our nature gives a very different direction to the painful passion of sympathy, and to the desire involved in it: instead of avoiding distress, we fly to it in order to afford relief; and our sympathy cannot be otherwise gratified but by giving all the succour in our power. Thus external signs of distress, though disagreeable, are attractive: and the sympathy they inspire is a powerful cause, impelling us to afford relief even to a stranger, as if he were our friend or relation.

It is a noted observation, that the deepest tragedies are the most crowded: which in an overly view will be thought an unaccountable bias in human nature. Love of novelty, desire of occupation, beauty of action, make us fond of theatrical representations; and when once engaged, we must follow the story to the conclusion, whatever distress it may create. But we generally become wise by experience; and when we foresee what pain we shall suffer during the course of the representation, is it not surprising that persons of reflection do not avoid such spectacles altogether? And yet one who has scarce recovered from the distress of a deep tragedy, resolves coolly and deliberately to go to the very next, without the slightest obstruction from self-love. The whole mystery is explained by a single observation: That sympathy, though painful, is attractive; and attaches us to an object in distress, instead of prompting us to fly from it. And by this curious mechanism it is, that persons of any degree of sensibility are attracted by affliction still more than by joy.

To conclude: the external signs of passion are a strong indication, that man, by his very constitution, is framed to be open and sincere. A child, in all things obedient to the impulses of nature, hides none of its emotions; the savage and clown, who have no guide but pure nature, expose their hearts to view, by giving way to all the natural signs. And even when men learn to dissemble their sentiments, and when behaviour degenerates into art, there still remain checks, that keep dissimulation within bounds, and prevent a great part of its mischievous effects: the total suppression of the

voluntary signs during any vivid passion, begets the utmost uneasiness, which cannot be endured for any considerable time: this operation becomes indeed less painful by habit; but luckily the involuntary signs cannot, by any effort, be suppressed nor even dissembled. An absolute hypocrisy, by which the character is concealed and a fictitious one assumed, is made impracticable; and nature has thereby prevented much harm to society. We may pronounce, therefore, that Nature, herself sincere and candid, intends that mankind should preserve the same character, by cultivating simplicity and truth, and banishing every sort of dissimulation that tends to mischief.

*Influence of PASSION with respect to our Perceptions, Opinions, and Belief.* So intimately are our perceptions, passions, and actions, connected, it would be wonderful if they should have no mutual influence. That our actions are too much influenced by passion, is a known truth; but it is not less certain, though not so well known, that passion hath also an influence upon our perceptions, opinions, and belief. For example, the opinions we form of men and things are generally directed by affection: An advice given by a man of figure hath great weight; the same advice from one in a low condition is despised or neglected: a man of courage under-rates danger; and to the indolent the slightest obstacle appears unformidable.

There is no truth more universally known, than that tranquility and sedateness are the proper state of mind for accurate perception and cool deliberation; and for that reason, we never regard the opinion even of the wisest man, when we discover prejudice or passion behind the curtain. Passion hath such influence over us, as to give a false light to all its objects. Agreeable passions prepossess the mind in favour of their objects; and disagreeable passions, not less against their objects: A woman is all perfection in her lover's opinion, while in the eye of a rival beauty she is awkward and disagreeable: when the passion of love is gone, beauty vanishes with it;—nothing left of that gentle motion, that sprightly conversation, those numberless graces, which formerly, in the lover's opinion, charmed all hearts. To a zealot every one of his own sect is a saint, while the most upright of a different sect are to him children of perdition: the talent of speaking in a friend, is more regarded than prudent conduct in any other. Nor will this surprise any one acquainted with the world; our opinions, the result frequently of various and complicated views, are commonly so slight and wavering, as readily to be susceptible of a bias from passion.

With that natural bias another circumstance concurs, to give passion an undue influence on our opinions and belief; and that is a strong tendency in our nature to justify our passions as well as our actions, not to others only, but even to ourselves. That tendency is peculiarly remarkable with respect to disagreeable passions: by its influence, objects are magnified or lessened, circumstances supplied or suppressed, every thing coloured and disguised, to answer the end of justification. Hence the foundation of self-deceit, where a man imposes upon himself innocently, and even without suspicion of a bias.

We proceed to illustrate the foregoing observations by proper examples.

Gratitude,

*Elements of Criticism,*  
vol. i. p. 152  
&c.

Gratitude, when warm, is often exerted upon the children of the benefactor; especially where he is removed out of reach by death or absence. The passion in this case being exerted for the sake of the benefactor, requires no peculiar excellence in his children: but the practice of doing good to these children produces affection for them, which never fails to advance them in our esteem. By such means, strong connections of affection are often formed among individuals, upon the slight foundation now mentioned.

Envy is a passion, which, being altogether unjustifiable, cannot be excused but by disguising it under some plausible name. At the same time, no passion is more eager than envy, to give its object a disagreeable appearance: it magnifies every bad quality, and fixes on the most humbling circumstances:

*Cassius.* I cannot tell what you and other men Think of this life; but for my single self, I had as lief not be, as live to be In awe of such a thing as I myself. I was born free as Cæsar, so were you; We both have fed as well; and we can both Endure the winter's cold as well as he. For once, upon a raw and gusty day, The troubled Tyber chasing with his shores, Cæsar says to me, 'Dar't thou, Cassius, now Leap in with me into this angry flood, And swim to yonder point?'—Upon the word, Accounted as I was, I plunged in, And bid him follow; so indeed he did. The torrent roar'd, and we did buffet it With lusty sinews; throwing it aside, And stemming it with hearts of controversy. But ere we could arrive the point propos'd, Cæsar cry'd, 'Help me, Cassius, or I sink.' I, as Æneas, our great ancestor, Did from the flames of Troy upon his shoulder The old Anchises bear; so from the waves of Tyber Did I the tired Cæsar; and this man Is now become a god; and Cassius is A wretched creature, and must bend his body If Cæsar carelessly but nod on him. He had a fever when he was in Spain; And when the fit was on him, I did mark How he did shake. 'Tis true, this god did shake; His coward lips did from his colour fly; And that same eye whose bend doth awe the world, Did lose its lustre; I did hear him groan; Ay, and that tongue of his, that bade the Romans Mark him, and write his speeches in their books, Alas! it cry'd—'Give me some drink, Titinius,—As a sick girl. Ye gods, it doth amaze me, A man of such a feeble temper should So get the start of the majestic world, And bear the palm alone. *Julius Cæsar, act 1. sc. 3.*

Gloster, inflamed with resentment against his son Edgar, could even force himself into a momentary conviction that they were not related:

O strange fasten'd villain!  
Would he deny his letter?—I never got him.

*King Lear, act 2. sc. 3.*

When by great sensibility of heart, or other means, grief becomes immoderate, the mind, in order to justify itself, is prone to magnify the cause; and if the

real cause admit not of being magnified, the mind seeks a cause for its grief in imagined future events:

*Buffy.* Madam, your Majesty is much too sad:  
You promis'd, when you parted with the king,  
To lay aside self-harming heaviness,  
And entertain a cheerful disposition.

*Queen.* To please the king, I did; to please myself, I cannot do it. Yet I know no cause  
Why I should welcome such a guest as grief;  
Save bidding farewell to so sweet a guest  
As my sweet Richard: yet again, methinks,  
Some unborn sorrow, ripe in Fortune's womb,  
Is coming tow'rd me: and my inward soul  
With something trembles, yet at nothing grieves,  
More than with parting from my lord the king.

*Richard II. act 2. sc. 5.*

Repentment at first is vented on the relations of the offender, in order to punish him; but as repentment, when so outrageous, is contrary to conscience, the mind, to justify its passion, is disposed to paint these relations in the blackest colours; and it comes at last to be convinced, that they ought to be punished for their own demerits.

Anger raised by an accidental stroke upon a tender part of the body, is sometimes vented upon the undesigning cause. But as the passion in that case is absurd, and as there can be no solid gratification in punishing the innocent, the mind, prone to justify as well as to gratify its passion, deludes itself into a conviction of the action's being voluntary. The conviction, however, is but momentary; the first reflection shows it to be erroneous: and the passion vanisheth almost instantaneously with the conviction. But anger, the most violent of all passions, has still greater influence: it sometimes forces the mind to personify a flock or a stone if it happen to occasion bodily pain, and even to believe it a voluntary agent, in order to be a proper object of resentment. And that we have really a momentary conviction of its being a voluntary agent, must be evident from considering, that without such conviction the passion can neither be justified nor gratified: the imagination can give no aid; for a flock or a stone imagined sensible, cannot be an object of punishment, if the mind be conscious that it is an imagination merely without any reality. Of such personification, involving a conviction of reality, there is one illustrious instance. When the first bridge of boats over the Hellepont was destroyed by a storm, Xerxes fell into a transport of rage, so excessive, that he commanded the sea to be punished with 300 stripes; and a pair of fetters to be thrown into it, enjoining the following words to be pronounced: "O thou salt and bitter water! thy master hath condemned thee to this punishment for offending him without cause; and is lib. 7. resolved to pass over thee in despite of thy insolence: with reason all men neglect to sacrifice to thee, because thou art both disagreeable and treacherous."

Shakespeare exhibits beautiful examples of the irregular influence of passion in making us believe things to be otherwise than they are. King Lear, in his distress, personifies the rain, wind, and thunder; and in order to justify his resentment, believes them to be taking part with his daughters:

*Lear.* Rumble thy bellyfull, spit fire, spout rain!

Not

Nor rain, wind, thunder, fire, are my daughters.  
 I tax not you, ye elements, with unkindness;  
 I never gave you kingdoms, call'd you children;  
 You owe me no subscription. Then let fall  
 Your horrible pleasure.—Here I stand, your brave;  
 A poor, infirm, weak, and despis'd old man!  
 But yet I call you fervile ministers,  
 That have with two pernicious daughters join'd  
 Your high-engender'd battles, 'gainst a head  
 So old and white as this. Oh! oh! 'tis foul!

*Act 3. sc. 2.*

King Richard, full of indignation against his favourite  
 horse for carrying Bolingbroke, is led into the con-  
 viction of his being rational:

*Groom.* O, how it yearn'd my heart, when I beheld  
 In London streets, that coronation-day,  
 When Bolingbroke rode on Roan Barbary,  
 That horse that thou so often hast bestrid,  
 That horse that I so carefully have dress'd.

*K. Rich.* Rode he on Barbary? tell me, gentle friend,  
 How went he under him?

*Groom.* So proudly as he had disdain'd the ground.  
*K. Rich.* So proud that Bolingbroke was on his back!  
 That jade had eat bread from my royal hand.  
 This hand hath made him proud with clapping him.  
 Would he not stumble? would he not fall down,  
 (Since pride must have a fall), and break the neck  
 Of that proud man that did usurp his back?

*Richard II. act 5. sc. 11.*

Hamlet, swelled with indignation at his mother's se-  
 cond marriage, was strongly inclined to lessen the time  
 of her widowhood, the shortness of the time being a  
 violent circumstance against her; and he deludes him-  
 self by degrees into the opinion of an interval shorter  
 than the real one:

*Hamlet.* ————— That it should come to this!  
 But two months dead! nay, not so much; not two—  
 So excellent a king, that was, to this,  
 Hyperion to a satyr: so loving to my mother,  
 That he permitted not the wind of heav'n  
 Visit her face too roughly. Heav'n and earth!  
 Must I remember—why, she would hang on him,  
 As if increase of appetite had grown  
 By what it fed on: yea, within a month—  
 Let me not think—Faintly, thy name is *Woman*!  
 A little month! or ere those shoes were old,  
 With which she follow'd my poor father's body,  
 Like Niobe, all tears—why she, ev'n she—  
 (O heav'n!) a beast, that wants discourse of reason,  
 Wou'd have mourn'd longer! married with mine uncle,  
 My father's brother; but no more like my father,  
 Than I to Hercules. Within a month!—  
 Ere yet the salt of most unrighteous tears  
 Had left the flushing in her gauled eyes,  
 She married—Oh, most wicked speed! to post  
 With such dexterity to incestuous sheets!  
 It is not, nor it cannot come to good.  
 But break, my heart, for I must hold my tongue.

*Act 1. sc. 3.*

The power of passion to falsify the computation of  
 time is remarkable in this instance; because time, which  
 hath an accurate measure, is less obsequious to our de-  
 sires and wishes, than objects which have no precise

standard of less or more.

Good news are greedily swallowed upon very slender  
 evidence; our wishes magnify the probability of  
 the event, as well as the veracity of the relater; and  
 we believe as certain, what at best is doubtful:

Quel, che l'huom vede, amor li fa invisibile  
 E l'invisibil fa veder amore.  
 Questo creduto fu, che 'l miser suole  
 Dar facile credenza a' quel, che vuole.

*Orland. Furisf. cant. 1. st. 56.*

For the same reason, bad news gain also credit upon  
 the slightest evidence: fear, if once alarmed, has the  
 same effect with hope, to magnify every circumstance  
 that tends to conviction. Shakespeare, who shows  
 more knowledge of human nature than any of our phi-  
 losophers, hath in his Cymbeline represented this bias  
 of the mind; for he makes the person who alone was  
 affected with the bad news, yield to evidence that did  
 not convince any of his companions. And Othello is  
 convinced of his wife's infidelity from circumstances  
 too slight to move any person less interested.

If the news interest us in so low a degree as to give  
 place to reason, the effect will not be altogether the  
 same: judging of the probability or improbability of  
 the story, the mind settles in a rational conviction ei-  
 ther that it is true or not. But even in that case, the  
 mind is not allowed to rest in that degree of convic-  
 tion which is produced by rational evidence: if the  
 news be in any degree favourable, our belief is raised  
 by hope to an improper height; and if unfavourable,  
 by fear.

This observation holds equally with respect to fu-  
 ture events: if a future event be either much wished  
 or dreaded, the mind never fails to augment the proba-  
 bility beyond truth.

That easiness of belief with respect to wonders and  
 prodigies, even the most absurd and ridiculous, is a  
 strange phenomenon; because nothing can be more  
 evident than the following proposition, That the more  
 singular any event is, the more evidence is required to  
 produce belief: a familiar event daily occurring, being  
 in itself extremely probable, finds ready credit, and  
 therefore is vouched by the slightest evidence; but to  
 overcome the improbability of a strange and rare event,  
 contrary to the course of nature, the very strongest  
 evidence is required. It is certain, however, that  
 wonders and prodigies are swallowed by the vulgar,  
 upon evidence that would not be sufficient to ascer-  
 tain the most familiar occurrence. It has been re-  
 ceeded difficult to explain that irregular bias of mind;  
 but we are now made acquainted with the influence of  
 passion upon opinion and belief: a story of ghouls or  
 fairies, told with an air of gravity and truth, raiseth  
 an emotion of wonder, and perhaps of dread; and  
 these emotions imposing on a weak mind, impress  
 upon it a thorough conviction contrary to reason.

Opinion and belief are influenced by propensity as  
 well as by passion. An innate propensity is all we have  
 to convince us that the operations of nature are uni-  
 form: influenced by that propensity, we often rashly  
 think, that good or bad weather will never have an  
 end; and in natural philosophy, writers, influenced  
 by the same propensity, stretch commonly their ana-  
 logical reasonings beyond just bounds.

Opinion

Opinion and belief are influenced by affection as well as by propensity. The noted story of a fine lady and a curate viewing the moon through a telescope, is a pleasant illustration: "I perceive," says the lady, "two shadows inclining to each other; they are certainly two happy lovers:" "Not at all," replies the curate, "they are two steeples of a cathedral."

*Language of Passion.* Among the particulars that compose the social part of our nature, a propensity to communicate our opinions, our emotions, and every thing that affects us, is remarkable. Bad fortune and injustice affect us greatly; and of these we are so prone to complain, that if we have no friend nor acquaintance to take part in our sufferings, we sometimes utter our complaints aloud, even where there are none to listen.

But this propensity operates not in every state of mind. A man immoderately grieved, seeks to afflict himself, rejecting all consolation: immoderate grief accordingly is mute; complaining is struggling for consolation.

It is the wretch's comfort still to have  
Some small reserve of near and inward wo,  
Some unsuspected hoard of inward grief,  
Which they unseen may wail, and weep, and mourn,  
And glutton-like alone devour.

*Mourning Bride, act 1. sc. 1.*

When grief subsides, it then, and no sooner, finds a tongue: we complain, because complaining is an effort to disburden the mind of its distress. This observation is finely illustrated by a story which Herodotus records, *b. 3.* Cambyfes, when he conquered Egypt, made Plammenitus the king prisoner; and for trying his constancy, ordered his daughter to be dressed in the habit of a slave, and to be employ'd in bringing water from the river; his son also was led to execution with a halter about his neck. The Egyptians vented their sorrow in tears and lamentations: Plammenitus only, with a downcast eye, remained silent. Afterward meeting one of his companions, a man advanced in years, who, being plundered of all, was begging alms, he wept bitterly, calling him by his name. Cambyfes, struck with wonder, demanded an answer to the following question: "Plammenitus, thy master Cambyfes is desirous to know, why, after thou hadst seen thy daughter so ignominiously treated, and thy son led to execution, without exclaiming or weeping, thou shouldst be so highly concerned for a poor man, no way related to thee?" Plammenitus returned the following answer: "Son of Cyrus, the calamities of my family are too great to leave me the power of weeping; but the misfortunes of a companion, reduced in his old age to want of bread, is a fit subject for lamentation."

Surprise and terror are silent passions, for a different reason: they agitate the mind so violently, as for a time to suspend the exercise of its faculties, and among others the faculty of speech.

Love and revenge, when immoderate, are not more loquacious than immoderate grief. But when these passions become moderate, they set the tongue free, and, like moderate grief, become loquacious. Moderate love, when unsuccessful, is vented in complaints; when successful, is full of joy expressed by words and gestures.

As no passion hath any long uninterrupted existence, nor beats always with an equal pulse, the language suggested by passion is not only unequal but frequently interrupted: and even during an uninterrupted fit of passion, we only express in words the more capital sentiments. In familiar conversation, one who vents every single thought, is justly branded with the character of *loquacity*; because sensible people express no thoughts but what make some figure: in the same manner, we are only disposed to express the strongest impulses of passion, especially when it returns with impetuosity after interruption.

It is elsewhere observed \*, that the sentiments ought to be tuned to the passion, and the language to both. Elevated sentiments require elevated language: tender sentiments ought to be clothed in words that are soft and flowing: when the mind is depressed with any passion, the sentiments must be expressed in words that are humble, not low. Words being intimately connected with the ideas they represent, the greatest harmony is required between them: to express, for example, an humble sentiment in high-sounding words, is disagreeable by a discordant mixture of feelings; and the discord is not less when elevated sentiments are dressed in low words:

Verfibus exponi tragicis res comica non vult.

Indignatur item privatis ac prope focco

Dignis carminibus narrari cœna Thyœæ.

*Horat. Ars poet. l. 89.*

This, however, excludes not figurative expression, which, within moderate bounds, communicates to the sentiment an agreeable elevation. We are sensible of an effect directly opposite, where figurative expression is indulged beyond a just measure: the opposition between the expression and the sentiment makes the discord appear greater than it is in reality.

At the same time, figures are not equally the language of every passion: pleasant emotions, which elevate or swell the mind, vent themselves in strong epithets and figurative expression; but humbling and dispiriting passions affect to speak plain:

Et tragicus plerumque dolet sermone pedestri  
Telephus et Peleus: cum pauper et exul uterque;  
Projicit ampullas et sequepedalia verba,  
Si curat cor spectantis tetigisse querela.

*Horat. Ars poet. 95.*

Figurative expression, being the work of an enlivened imagination, cannot be the language of anguish or distress. Otway, sensible of this, has painted a scene of distress in colours finely adapted to the subject: there is scarce a figure in it, except a short and natural simile with which the speech is introduced. Belvidera talking to her father of her husband:

Think you saw what pail at our last parting;  
Think you beheld him like a raging lion,  
Pacing the earth, and tearing up his steps,  
Fate in his eyes, and roaring with the pain  
Of burning fury; think you saw his one hand  
Fix'd on my throat, while the extended other  
Grasp'd a keen threatening dagger: oh, 'twas thus  
We last embrac'd, when, trembling with revenge,  
He dragg'd me to the ground, and at my bosom  
Presented horrid death; cry'd out, My friends!

Where

\* See the article *Sensiments*.

Where are my friends? I swore, wept, rag'd, threaten'd,  
For he yet lov'd, and that dear love prefer'd me [lov'd;  
To this last trial of a father's pity.  
I fear not death, but cannot bear a thought  
That that dear hand should do th' unfriendly office.  
If I was ever then your care, now hear me;  
Fly to the senate, save the promis'd lives  
Of his dear friends, ere mine be made the sacrifice.

*Venice prefer'd, act 5.*

To preserve the forensid resemblance between words  
and their meaning, the sentiments of active and hurrying  
passions ought to be dress'd in words where syllables  
prevail that are pronounced short or fast; for  
these make an impression of hurry and precipitation.  
Emotions, on the other hand, that rest upon their  
objects, are best express'd by words where syllables  
prevail that are pronounced long or slow. A person  
affected with melancholy, has a languid and slow train  
of perceptions. The expression best suited to that state  
of mind, is where words, not only of long, but of  
many syllables, abound in the composition; and for  
that reason, nothing can be finer than the following  
passage:

In those deep solitudes, and awful cells,  
Where heav'nly-pensive Contemplation dwells,  
And ever-musing Melancholy reigns.

*POPE, Eloisa to Abelard.*

To preserve the same resemblance, another circum-  
stance is requisite, that the language, like the emotion,  
be rough or smooth, broken or uniform. Calm  
and sweet emotions are best express'd by words that  
glide softly: surprise, fear, and other turbulent pas-  
sions, require an expression both rough and broken.

It cannot have escap'd any diligent inquirer in na-  
ture, that in the hurry of passion, one generally ex-  
presses that thing first which is most at heart; which is  
beautifully done in the following passage.

Me, me; adsum qui feci: in me convertite ferrum,  
O Rutuli, mea fraus omnis. *Æneid. ix. 427.*

Passion has often the effect of redoubling words,  
the better to make them express the strong conception  
of the mind. This is finely imitated in the following  
examples.

Thou sun, said I, fair light!  
And thou enlighten'd earth, so fresh and gay!  
Ye hills and dales, ye rivers, woods, and plains!  
Ye that live, and move, fair creatures! tell,  
Tell, if ye saw, how came I thus, how here.—

*Paradise Lost, b. viii. 273.*

Both have sinn'd! but thou  
Against God only; I, 'gainst God and thee:  
And to the place of judgment will return;  
'Twere with my cries importune Heaven, that all  
The sentence, from thy head remov'd, may light  
On me, sole cause to thee of all this woe;  
Me! me! only just object of his ire.

*Paradise Lost, b. x. 930.*

1. In general, the language of violent passion ought  
to be broken and interrupted. Soliloquies ought to be  
so in a peculiar manner: language is intended by na-  
ture for society: and a man when alone, though he  
always clothes his thoughts in words, seldom gives his

words utterance, unless when prompted by some strong  
emotion; and even then by starts and intervals only.  
Shakespeare's soliloquies may be justly established as a  
model; for it is not easy to conceive any model more  
perfect. Of his many incomparable soliloquies, the two  
following only shall be quoted, being different in their  
manner.

*Hamlet.* Oh, that this too, too solid flesh would  
Thaw, and resolve itself into a dew! [melt,  
Or that the Everlasting had not fix'd  
His canon 'gainst self-slaughter! O God! O God!  
How weary, stale, flat, and unprofitable  
Seem to me all the uses of this world!  
Fie on't! O fie! 'tis an unweeded garden,  
That grows to seed: things rank and gross in nature  
Possess it merely.—That it should come to this!  
But two months dead! nay, not so much; not two—  
So excellent a king, that was, to this,  
Hyperion to a satyr: so loving to my mother,  
That he permitted not the winds of heav'n  
Visit her face too roughly. Heav'n and earth!  
Must I remember—why, he would hang on him,  
As if increase of appetite had grown  
By what it fed on: yet, within a month—  
Let me not think—Frailty, thy name is Woman!  
A little month! or ere those shoes were old,  
With which the follow'd my poor father's body,  
Like Niobe, all tears—why she, ev'n she—  
(O heav'n! a beast, that wants discourse of reason,  
Would have mourn'd longer—) married with mine  
uncle,

My father's brother; but no more like my father,  
Than I to Hercules. Within a month!—  
Ere yet the salt of most unrighteous tears  
Had left the flushing in her galled eyes,  
She married.—Oh, most wicked speed, to post  
With such dexterity to incestuous sheets!  
It is not, nor it cannot come to good.  
But break, my heart, for I must hold my tongue

*Hamlet, act 1. sc. 3.*

"Ford. Hum! ha! is this a vision? is this a dream?  
"do I sleep? Mr Ford, awake; awake, Mr Ford;  
"there's a hole made in your best coat, Mr Ford;  
"this 'tis to be married! this 'tis to have linen and  
"buck baskets? Well, I will proclaim myself what  
"I am; I will now take the leacher; he is at my  
"house; he cannot 'scape me; 'tis impossible he  
"should; he cannot creep into a half-penny purse,  
"nor into a pepper-box. But left the devil that  
"guides him should aid him, I will search impossible  
"places; tho' what I am I cannot avoid, yet to be  
"what I would not, shall not make me tame."

*Merry Wives of Windsor, act 3. sc. last.*

These soliloquies are accurate and bold copies of na-  
ture: in a passionate soliloquy one begins with think-  
ing aloud; and the strongest feelings only, are ex-  
press'd; as the speaker warms, he begins to imagine  
one listening, and gradually slides into a connected dis-  
course.

How far distant are soliloquies generally from these  
models? So far indeed as to give disgust instead of  
pleasure. The first scene of Iphigenia in Tauris dis-  
covers that princess, in a soliloquy, gravely reporting  
to herself her own history. There is the same impro-

propriety in the first scene of *Alceſtes*, and in the other introductions of Euripides, almost without exception. Nothing can be more ridiculous: it puts one in mind of a most curious device in Gothic paintings, that of making every figure explain itself by a written label issuing from its mouth. The description which a parasite, in the eunuch of Terence (*act* 2. *ſc.* 2.) gives of himself, makes a sprightly soliloquy: but it is not consistent with the rules of propriety; for no man, in his ordinary state of mind and upon a familiar subject, ever thinks of talking aloud to himself. The same objection lies against a soliloquy in the *Adelphi* of the same author, (*act* 1. *ſc.* 1.) The soliloquy which makes the third scene act third of his *Heicyra*, is insufferable; for there Pamphilus, soberly and circumstantially, relates to himself an adventure which had happened to him a moment before.

Cornelle is unhappy in his soliloquies: Take for a specimen the first scene of *Cinna*.

Racine is extremely faulty in the same respect. His soliloquies are regular harangues, a chain completed in every link, without interruption or interval: that of Antiochus in Berenice (*act* 1. *ſc.* 2.) resembles a regular pleading, where the parties *pro* and *con* display their arguments at full length. The following soliloquies are equally faulty: *Bajazet*, *act* 3. *ſc.* 7; *Mithridate*, *act* 3. *ſc.* 4. and *act* 4. *ſc.* 5; *Iphigenia*, *act* 4. *ſc.* 8.

Soliloquies upon lively or interesting subjects, but without any turbulence of passion, may be carried on in a continued chain of thought. If, for example, the nature and sprightliness of the subject prompt a man to speak his thoughts in the form of a dialogue, the expression must be carried on without break or interruption, as in a dialogue between two persons; which justifies Falstaff's soliloquy upon honour:

"What need I be so forward with Death, that calls not on me? Well, 'tis no matter, Honour pricks me on. But how if Honour prick me off, when I come on? how then? Can Honour set a leg? No. Or an arm? No. Or take away the grief of a wound? No. Honour hath no skill in surgery then? No. What is Honour? A word.—What is that word *ho. pour*?" Air; a trim reckoning.—Who hath it? He that dy'd a Wednesday. Doth he feel it? No. Doth he hear it? No. Is it insensible then? Yea, to the dead. But will it not live with the living? No. Why? Detraction will not suffer it. Therefore I'll none of it; honour is a mere scutcheon: and so ends my catechism.

*First Part, Henry IV. act* 5. *ſc.* 2.

And even without dialogue, a continued discourse may be justified, where a man reasons in a soliloquy upon an important subject; for if in such a case it be at all excusable to think aloud, it is necessary that the reasoning be carried on in a chain; which justifies that admirable soliloquy in *Hamlet* upon life and immortality, being a serene meditation upon the most interesting of all subjects. And the same consideration will justify the soliloquy that introduces the 5th act of Addison's *Cato*.

2. Language ought not to be elevated above the tone of the sentiment.

*Zara*. Swift as occasion, I

Myself will fly; and earlier than the morn  
Wake thee to freedom. Now 'tis late; and yet  
Some news few minutes past arriv'd, which seem'd  
To shake the temper of the king—Who knows  
What racking cares disease a monarch's bed?  
Or love, that late at night still lights his lamp,  
And strikes his rays through dusk, and folded lids,  
Forbidding rest, may stretch his eyes awake,  
And force their balls abroad at this dead hour.  
I'll try.

*Mourning Bride, act* 3. *ſc.* 4.

The language here is undoubtedly too pompous and laboured for describing so simple a circumstance as absence of sleep. In the following passage, the tone of the language, warm and plaintive, is well suited to the passion, which is recent grief: but every one will be sensible, that in the last couplet save one the tone is changed, and the mind suddenly elevated to be let fall as suddenly in the last couplet:

Il déteste à jamais sa coupable victoire,  
Il renonce à la cour, aux humains, à la gloire;  
Et se fuyant lui-même, au milieu des déserts,  
Il va cacher sa peine au bout de l'univers;  
Là, fait que le soleil rendit le jour au monde,  
Soit qu'il finit sa course au vaste sein de l'onde,  
Sa voix faisoit redire aux échos attendris,  
Le nom, le triste nom, de son malheureux fils.

*Henriade, chant*. viii. 229.

3. Light and airy language is unsuitable to a severe passion.

Imagery and figurative expression are discordant, in the highest degree, with the agony of a mother, who is deprived of two hopeful sons by a brutal murder. Therefore the following passage is undoubtedly in a bad taste:

*Queen*. Ah, my poor princes! ah, my tender babes!  
My unblown flowers, new appearing sweets!  
If yet your gentle souls fly in the air,  
And be not fixt in doom perpetual,  
Hover about me with your airy wings,  
And hear your mother's lamentation.

*Richard III. act* 4. *ſc.* 4.

Again,

*K. Philip*. You are as fond of grief as of your child.  
*Constance*. Grief fills the room up of my absent child,  
Lies in his bed, walks up and down with me,  
Puts on his pretty looks, repeats his words,  
Remembers me of all his gracious parts,  
Stuffs out his vacant garment with his form;  
Then have I reason to be fond of grief.

*King John, act* 3. *ſc.* 9.

4. Thoughts that turn upon the expression instead of the subject, commonly called a *play of words*, being low and childish, are unworthy of any composition, whether gay or serious, that pretends to any degree of elevation.

In the *Amynta* of Tasso, the lover falls into a mere play of words, demanding how he who had lost himself, could find a mistress. And for the same reason, the following passage in Corneille has been generally condemned:

*Chimene*. Mon pere est mort, Elvire, et la première épée  
Dont s'est armée Rodrigue a sa trame coupée.

*Pléurez*

Pleurez, pleurez, mes yeux, et fondez-vous en eau,  
La moitié de ma vie a mis l'autre au tombeau,  
Et m'oblige à venger, après ce coup funeste,  
Celle que je n'ai plus, sur celle que me reste.

*Cid, act 3. sc. 3.*

To die is to be banish'd from myself:  
And Sylvia is myself: banish'd from her,  
Is self from self; a deadly banishment?

*Two Gentlemen of Verona, act 3. sc. 3.*

*Countess.* I pray thee, Lady, have a better cheer:  
If thou engross'st all the griefs as thine,  
Thou robb'st me of a moiety.

*All's well that ends well, act 3. sc. 3.*

*K. Henry.* O my poor kingdom, sick with civil  
blows!

When that my care could not with-hold thy riots,  
What wilt thou do when riot is thy care?  
O, thou wilt be a wilderness again,  
Peopled with wolves, thy old inhabitants.

*Second Part, Henry IV. act 4. sc. 11.*

Cruda Amarilli, che col nome ancora  
D'amar, ah! lasso, amaramente infigni.

*Pastor Fido, act 1. sc. 2.*

Antony, speaking of Julius Cæsar:

O world! thou wast the forest of this hart;  
And this, indeed, O world, the heart of thee.  
How like a deer, stricken by many princes,  
Dost thou here lie!

*Julius Cæsar, act 3. sc. 3.*

Playing with the sound of words, which is still  
worse than a pun, is the meanest of all conceits. But  
Shakespeare, when he descends to a play of words,  
is not always in the wrong; for it is done sometimes  
to denote a peculiar character, as in the following  
passage:

*K. Philip.* What say'st thou, boy? look in the  
lady's face.

*Lewis.* I do, my Lord, and in her eye I find  
A wonder, or a wond'rous miracle;  
The shadow of myself form'd in her eye;  
Which being but the shadow of your son,  
Becomes a fun, and makes your son a shadow.  
I do protest, I never lov'd myself  
Till now infixed I beheld myself  
Drawn in the flat'ring table of her eye.

*Faulconbridge.* Drawn in the flat'ring table of  
her eye!

Hang'd in the frowning wrinkle of her brow!  
And quarter'd in her heart! he doth spy  
Himself Love's traitor: this is pity now,  
That hang'd, and drawn, and quarter'd, there  
should be,

In such a love so vile a lout as he.

*King John, act 2. sc. 5.*

A jingle of words is the lowest species of that low  
wit; which is scarce sufferable in any case, and least of  
all in an heroic poem: and yet Milton in some instances  
has descended to that puerility:

And brought into the world a world of wo.

— Begirt th' Almighty throne

Befeeching or beseeging—

Which tempted our attempt—

At one slight bound high overleap'd all bound.

With a shout  
Loud as from numbers without number.

5. One should think it unnecessary to enter a caveat  
against an expression that has no meaning, or no distinct  
meaning; and yet somewhat of that kind may  
be found even among good writers.

*Sebastian.* I beg no pity for this mould'ring clay.  
For if you give it burial, there it takes  
Possession of your earth:

If burnt and scatter'd in the air; the winds  
That throw my dust, diffuse my royalty,  
And spread me o'er your clime; for where one atom  
Of mine shall light, know there Sebastian reigns.

*DRYDEN, Don Sebastian king of Portugal, act 1.*

*Cleopatra.* Now; what news, my Charmion?  
Will he be kind? and will he not forsake me?  
Am I to live or die? nay, do I live?  
Or am I dead? for when he gave his answer,  
Fate took the word, and then I liv'd or dy'd.

*DRYDEN, All for love, act 2.*

If she be coy, and scorn my noble fire,  
If her chill heart I cannot move;  
Why, I'll enjoy the very love,  
And make a mistress of my own desire.

*COWLEY, poem inscribed, "The Request."*

His whole poem, inscribed, *My picture*, is a jargon  
of the same kind.

'Tis he, they cry, by whom  
Not men, but war itself is overcome.

*Indian Queen.*

Such empty expressions are finely ridiculed in the *Re-  
bearfal*.

Was't not unjust to ravish hence her breath,  
And in life's stead to leave us nought but death?

*Act 4. sc. 1.*

PASSIONS, in *Medicine*, make one of the non-  
naturals, and produce very sensible effects. Joy, anger,  
and fear, are the principal. In the two first, the  
spirits are hurried with too great vivacity; whereas,  
in fear or dread, they are as it were curbed and con-  
centrated: whence we may conclude, that they have a  
very bad effect upon health; and therefore it will be  
best to keep them within bounds as much as possible,  
and to preserve an inward serenity, calmness, and tran-  
quillity.

PASSIONS, in *Painting*, are the external expressions  
of the different dispositions and affections of the mind;  
but particularly their different effects upon the several  
features of the face: for though the arms, and indeed  
every part of the body\*, serve likewise, by their  
quick, languid, and variously diversified motions, to  
express the passions of the soul; yet, in painting, this  
difference is most conspicuous in the face. See *PAINT-  
ING*, n° 15. and *DRAWING*, art. 9.

In sorrow, joy, love, shame, and compassion, the  
eyes swell all of a sudden, are covered with a super-  
abundant moisture, and drop tears; and, in grief espe-  
cially, the corners of the mouth hang down, the eye-  
lids are half shut, and the pupil of the eye is elevated  
and half covered; and all the other muscles of the face  
are relaxed, so that the visage appears longer than or-  
dinary.

Passion  
Passport.

In fear, terror, fright, and horror, the eye-brows are greatly elevated: the eye-lids are expanded as wide as possible, so as to discover the white of the eye; and the pupil is depressed, and half covered by the lower eye-lid: the hair stands on end: the mouth is at the same time wide open; and the lips are so far drawn back, that the teeth both of the upper and under jaw appear.

Contempt is expressed by raising one side of the upper lip, so as to discover the teeth, whilst the other side has a movement like that in laughter; the eye, on that side where the teeth appear, is half shut, whilst the other remains open; however, both the pupils are depressed.

In jealousy, envy, hatred, and malice, the eye-brows are knit; and, in laughter, all the parts agree, tending as it were towards the centre of the face. See Plates XC. XCVIII.

PASSION-Flower. See PASSIFLORA.

PASSION-Week, the week immediately preceding the festival of Easter: so called, because in that week our Saviour's passion and death happened. The Thursday of this week is called *Maunday Thursday*; the Friday, *Good Friday*; and the Saturday, the *Great Sabbath*.

PASSIVE, in general, denotes something that suffers the action of another, called an *agent* or *active power*. In grammar, the verb or word that expresses this passion is termed a *passive verb*: which, in the learned languages, has a peculiar termination; as *amor, doceor*, &c. in Latin; that is, an *r* is added to the actives *amo, doceo*: and, in the Greek, the inflection is made by changing *ω* into *ουαι*; as *τιςτις τιμωμαι*, &c. But, in the modern languages, the passive inflection is performed by means of auxiliary verbs, joined to the participle passive; as, "I am praised," in Latin *laudor*, and in Greek *τιμωμαι*; or, "I am loved," in Latin *amor*, and in Greek *φιλομαι*. Thus it appears, that the auxiliary verb *I am*, serves to form the passives of English verbs: and the same holds of the French; as, *Je suis loué*, "I am praised;" *J'ai été loué*, "I have been praised," &c.

PASSIVE TITLE, in Scots law. See LAW, Part III. N° clxxx. 30.

PASSOVER, a solemn festival of the Jews, celebrated on the 14th day of the month next after the vernal equinox, and instituted in commemoration of their coming out of Egypt; because, on the night before their departure, the destroying angel, who put to death the first-born of the Egyptians, passed over the houses of the Hebrews, which were sprinkled with the blood of a lamb. The whole transaction is related in the xiiith chapter of Exodus.

PASSPORT, or *Pass*, a licence or writing obtained from a prince or governor, granting permission and a safe-conduct to pass through his territories without molestation. Also a permission granted by any state to navigate in some particular sea, without hindrance or molestation from it. It contains the name of the vessel, and that of the master, together with her tonnage and the number of her crew, certifying that she belongs to the subjects of a particular state, and requiring all persons at peace with that state to suffer her to proceed on her voyage without interruption.

PASTEBOARD, a kind of thick paper, formed of several single sheets pasted one upon another. The chief use of pasteboard is for binding books, making letter-cases, &c.

PASTER of a Horse, in the menage, is the distance betwixt the joint next the foot and the coronet of the hoof. This part should be short, especially in middle-sized horses; because long pasterns are weak, and cannot so well endure travelling.

PASTER-Joint, the joint next a horse's foot.

PASTIL, or PASTEL, among painters, a kind of paste made of different colours, ground up with gum-water, in order to make CRAYONS.

PASTIL, in pharmacy, is a dry composition of sweet-smelling resins, aromatic woods, &c. sometimes burnt to clear and scent the air of a chamber.

PASTINACA, the PARSNIP, in botany, a genus of the digynia order, belonging to the pentandria class of plants. There are only two species of this genus; the principal of which is the *pastinaca sativa*, or garden-parsnip: which is an exceeding fine sculent root. It is to be propagated by sowing the seeds in February or March, in a rich mellow soil, which must be deep dug, that the roots may be able to run deep without hindrance.

It is a common practice to sow carrots at the same time, upon the same ground with the parsnips; and if the carrots are designed to be drawn young, there is no harm in it. The parsnips, when they are grown up a little, must be thinned to a foot distance, and carefully kept clear of weeds. They are finest tasted just at the season when the leaves are decayed; and such as are desirous to eat them in spring should have them taken up in autumn, and preserved in sand. When the seeds are to be sowed, some very strong and fine plants should be left four feet distance; and towards the end of August, or in the beginning of September, the seeds will be ripe: they must then be carefully gathered, and dried on a coarse cloth. They should always be sown the spring following; for they do not keep well.

PASTORAL, in general, something that relates to shepherds; hence we say, pastoral life, manners, poetry, &c.

PASTORAL Poetry. See POETRY, n° 63.

PASTRY, that branch of cookery which is chiefly taken up in making pies, pasties, cakes, &c.

Dr Cullen observes, that paste is very hard and indigestible without butter; and, even with it, is apt to produce heart-burn and accefcency. Perhaps this is increased by the burned butter, from a certain sensibility in the stomach, which occasions all empyreumatic oils to be long retained, and so turn rancelous and acid.

PASTURE, or PASTURE-Land, is that reserved for feeding cattle.

Pasture-land is of such advantage to husbandry, that many prefer it even to corn-land, because of the small hazard and labour that attends it; and as it lays the foundation for most of the profit that is expected from the arable land, because of the manure afforded by the cattle which are fed upon it. Where dung is not to be bought, as is often the case in places distant from large towns, the farmer is forced to proportion the arable to the pasture land, in such a manner, that

Pastureboard  
Pasture.

the

Patagonia.

the cattle fed on the latter may be sufficient for a supply of dung so necessary for producing the fruits of the former.

**PATAGONIA**, a country of South America, comprehending all that country extending from Chili and Paraguay to the utmost extremity of South America; that is, from 35° almost to 54° of latitude: being surrounded by the countries just mentioned, the South and North Seas, and the Straits of Magellan, which separate it from the island called *Terra del Fuego*, and extend about 116 leagues in length from sea to sea, but only from half a league to three or four in breadth.

This country had the name of *Terra Magellanica*, from Ferdinand Magellan, a Portuguese officer in the service of the Catholic king, who is reported to have sailed through the straits that also bear his name, from the North to the South Sea, in the year 1510.

The lofty mountains of the Andes, which are covered with snow a great part of the year, traversing the country from north to south, the air is said to be much colder than in the north under the same parallels of latitude. Towards the north, it is said to be covered with wood, and stored with an inexhaustible fund of large timber; whereas, to the southward, not so much as a single tree fit for any mechanical purpose is to be seen: yet there is good pasture, and incredible numbers of wild horned cattle and horses, which were first brought hither by the Spaniards, and have increased amazingly. Fresh water, we are told by some writers, is very scarce; but if that were really the case, it is difficult to conceive how the present inhabitants, and such multitudes of cattle, could subsist. The east coast is mostly low land, with few or no good harbours: one of the best is Port St Julian.

Patagonia is inhabited by a variety of Indian tribes; as the Patagons, from which the country takes its name; the Pampas, the Coscares, &c. of whom we know very little. Only it appears, from the accounts of former voyagers, lately confirmed by commodore Byron and his crew, and the testimonies of other navigators, that some of them are of a gigantic stature, and clothed with skins; but it would seem that there are others who go almost quite naked, notwithstanding the inclemency of the climate. Some of them also, that live about the Straits, if we may credit the navigators who have passed that way into the South Sea, are perfect savages: but those with whom commodore Byron and his people conversed, are represented as of a more gentle humane disposition; only, like other savages, they live on fish and game, and what the earth produces spontaneously.

The Spaniards once built a fort upon the Straits, and left a garrison in it, to prevent any other European nation passing that way into the South Sea: but most of the men perished by famine, whence the place obtained the name of *Port Famine*; and no people have attempted to plant colonies here ever since.

About the middle of the Strait is a promontory called *Cape Froward*, which is the most southerly on the continent of South America.

On the coasts of Patagonia lie a great number of islands, or clusters of islands. On the west coast are the islands Madre de Dios, Santa Trinidad, Santa Cruz, the isles of the Chunians and Huillans, the Sarmientos, and many others; to the number of 80 in all, as some

say. Of those on the south coast, the most considerable are *Terra del Fuego*, and *Staten Land*. See these articles.

**PATAN**, a kingdom of Asia, in the East Indies, and in the peninsula of Malacca, and on the eastern coast between the kingdoms of Siam and Paha. The inhabitants are partly Mahometans and partly Gentoos; but they are all very voluptuous. The air is wholesome, though very hot; and they have no seasons but the winter and summer. The former is more properly the rainy season; and contains the months of November, December, and January. The woods are full of elephants and many wild animals. Some voyagers pretend that this country is governed by a queen, who never marries, but may have as many gallants as she pleases. They have some trade with the Chinese; and the principal town is of the same name, which is one of the strongest in these parts, having a well defended harbour.

**PATAN**, a town of Asia, and capital of a province of the same name, in the dominions of the Great Mogul; it is very little known. E. Long. 109. 0. N. Lat. 27. 30.

**PATAVINITY**, among critics, denotes a peculiarity of Livy's diction; derived from Patavium or Padua, the place of his nativity: but wherein this patavinity consists, they are by no means agreed.

**PATARA**, (Livy, Mela); the capital of Lycia, to the east of the mouth of the river Xanthus; famous for a temple and oracle of Apollo, thence called *Pataraeus*, three syllables only; but *Pataraeus*, (Horace). For the six winter months, Apollo gave answers at Patara; and for the six summer at Delos, (Virgil, Servius): these are the *Lycia Sortes* of Virgil. The town was situated in a peninsula, called *Lyciorum Chersonesus*, (Stephanus).

**PATAVIUM**, (Tacitus, Strabo); a town of the Transpadana, situate on the left or north bank of the Medoacus Minor; founded by Antenor the Trojan, (Mela, Virgil, Seneca); *Patavini*, the people, (Livy); who himself was a native, and by Asinius Pollio charged with pativinity. Now *Padua*, in the territory and to the west of Venice. E. Long. 12. 15. N. Lat. 45. 30.

**PATAY**, a town of France, in the province of Orleans, remarkable for the defeat of the English in 1429, and where Joan of Arc did wonders. E. Long. 1. 43. N. Lat. 48. 5.

**PATE**, in fortification, a kind of platform, resembling what is called an *horse's shoe*.

**PATEE**, or **PATTEE**, in heraldry, a cross small in the centre, and widening to the extremes, which are very broad.

**PATELLA**, or **KNEE-PAN**, in anatomy. See there, n° 58.

**PATELLA**, the *Limpet*, a genus of insects belonging to the order of vermes testacea. It is an animal of the snail kind; the shell consists of one conical valve without any spiral. There are 36 species; principally distinguished by peculiarities in their shells.

**PATENT**, in general, denotes something that stand open or expanded: thus a leaf is said so patent, when it stands almost at right angles with the stalk.

**PATENT**, or *Letters Patent*. See **LETTER**.  
**PATER**

Patant

Patent.

PATER NOSTER, the *Lord's Prayer*, so called from the two first words thereof in Latin.

PATER Noster, islands of Asia, in the East Indian sea, so called because of the great number of rocks, which sailors have likened to the beads with which the Papists tell their pater-noster. They abound in corn and fruits, and are very populous.

PATER PATRATUS, in Roman antiquity, an officer chosen by one of the college of *faeciales* out of their own body, to treat with an enemy on the subject of war and peace. He derived his title from a circumstance necessary to his enjoying it: for in order that he might be the more firmly interested in the fate of his country, he was to have both a father and a son living at the same time.

PATERA, among antiquaries, a goblet or vessel used by the Romans in their sacrifices; wherein they offered their consecrated meats to the gods, and where-with they made libations. See SACRIFICE and LIBATION.

The word is Latin, formed from *pateo*, "I am open;" *quid pateat*, "because it has a great aperture;" in contradistinction to bottles, &c. which have only narrow necks, or whose aperture is less than the body of the vessel.

On medals the patera is seen in the hands of several deities; and frequently in the hands of princes, to mark the sacerdotal authority joined with the imperial, &c.

Hence F. Joubert observes, that beside the patera, there is frequently an altar upon which the patera seems to be pouring its contents.

The patera was of gold, silver, marble, brass, glass, or earth; and they used to inclose it in urns with the ashes of the deceased, after it had served for the libations of the wine and liquors at the funeral.

The patera is an ornament in architecture, frequently seen in the Doric freeze, and the tympanum of arches.

PATERCULUS (Caius Velleius), an ancient Roman historian, who flourished in the reign of Tiberius Cæsar, was born in the year of Rome 735. His ancestors were illustrious for their merit and their offices. His grandfather espoused the party of Tiberius Nero, the emperor's father; but being old and infirm, and not able to accompany Nero when he retired from Naples, he ran himself through with his sword. His father was a soldier of rank, and so was Paterculus himself. He was a military tribune when Caius Cæsar, a grandson of Augustus, had an interview with the king of the Parthians, in an island of the river Euphrates, in the year 753. He commanded the cavalry in Germany under Tiberius; and accompanied that prince for nine years successfully in all his expeditions. He received honourable rewards from him; but we do not find that he was preferred to any higher dignity than the prætorship. The praises he bestows upon Sejanus give some probability to the conjecture, that he was looked upon as a friend of this favourite, and consequently that he was involved in his ruin. His death is placed by Mr Dodwell in the year of Rome 784, when he was in his 50th year.

He wrote an abridgment of the Roman history in two books, which is very curious. His purpose was only to deduce things from the foundation of Rome to the time wherein he lived, but he began his work with

things previous to that memorable æra: for, though Paterculus, the beginning of his first book is wanting, we yet find in what remains of it, an account of many cities more ancient than Rome. He promised a larger history; and no doubt would have executed it well: for during his military expeditions he had seen, as he tells us, the provinces of Thrace, Macedonia, Achaia, Asia Minor, and other more easterly regions; especially upon the shores of the Euxine sea, which had furnished his mind with much entertaining and useful knowledge. In the Abridgment which we have, many particulars are related that are no where else to be found; and this makes it the more valuable. The style of Paterculus, though miserably disguised through the carelessness of transcribers, and impossible to be restored to purity for want of manuscripts, is yet manifestly worthy of his age, which was the time of pure Latinity. The greatest excellence of this historian lies in his manner of commending and blaming those he speaks of; which he does in the finest terms and most delicate expressions. He is, however, condemned, and indeed with the greatest reason, for his partiality to the house of Augustus; and for making the most extravagant eulogies, not only upon Tiberius, but even upon his favourite Sejanus: whom, though a vile and cruel monster, Paterculus celebrates as one of the most excellent persons the Roman commonwealth had produced. Lippius, though he praises him in other respects, yet censures him most severely for his insincerity and partiality. "Velleius Paterculus (says he), raises my indignation: he represents Sejanus as endowed with all good qualities. The impudence of this historian! But we know, that he was born, and died, to the destruction of mankind. After many commendations, he concludes, that Livia was a woman more resembling the gods than men: and as to Tiberius, he thinks it a crime to speak otherwise of him than as of an immortal Jove. What sincere and honest mind can bear this? On the other hand, how artfully does he every where conceal the great qualities of Cæsar Germanicus! how obliquely does he ruin the reputation of Agrippina and others, whom Tiberius was thought to hate! In short, he is nothing but a court-prostitute. You will say, perhaps, it was unsafe to speak the truth at those times: I grant it; but if he could not write the truth, he ought not to have written lies: none are called to account for silence." La Mothe le Vayer has made a very just remark upon this occasion: "The same fault (says he) may be observed in many others, who have written the history of their own times, with a design to be published while they lived."

It is strange, that a work so elegant and worthy to be preserved, and of which, by reason of its shortness, copies might be so easily taken, should have been so near being lost. One manuscript only has had the luck to be found, as well of this author among the Latins, as of Helychius among the Greeks: in which, says a great critic of our own nation, "The faults of the scribes are found so numerous, and the defects so beyond all redress, that notwithstanding the pains of the learned and most acute critics for two whole centuries, these books still are, and are like to continue, a mere heap of errors." No ancient author but Prician makes mention of Paterculus: the moderns have done him infinitely more justice, and have illustrated him with notes and

Path  
Patmos.

Patna  
Patriarch.

and commentaries. He was first published, from the manuscript of Morbac, by Rhenanus, at Basil in 1520: afterwards by Liplius at Leyden in 1581; then by Gerard Vossius in 1630; next by Boederus at Strasburg in 1642; then by Thylus and others; and, lastly, by Peter Burman at Leyden 1719, in 8vo. To the Oxford edition in 1693, 8vo, were prefixed the *Annales Velleiani* of Mr Dodwell, which show deep learning and a great knowledge of antiquity.

**PATH**, in general, denotes the course or track marked out or run over by a body in motion.

For the path of the moon, &c. see **ASTRONOMY**, n° 147, 155.

**PATHETIC**, whatever relates to the passions, or that is proper to excite or awake them. The word comes from the Greek *πάθος*, *passion*, or *emotion*. See **PASSION**.

**PATHOGNOMONIC**, among physicians, an appellation for a symptom, or concurrence of symptoms that are inseparable from a distemper, and are found in that only, and in no other.

**PATHOLOGY**, that part of medicine which explains the nature of diseases, their causes and symptoms. See **MEDICINE**.

**PATHOS**, a Greek term, literally signifying passion.

**PATIN** (Guy), professor of physic in the royal college of Paris, was born in 1602. He made his way into the world merely by the force of his genius, being at first corrector of a printing-house. He was a man of great wit and erudition: he spoke with the gravity of a Stoic, but his expressions were very satirical. He hated bigotry, superstition, and knavery; had an upright soul, and a well-disposed heart. He was a most tender father, courteous to every body, and polite in the highest degree. He died in 1672, and did not owe his reputation to any writings published in his life-time upon physic; but his letters which appeared after his death have rendered his name very famous. He left a son mentioned in the ensuing article.

**PATIN** (Charles), who made a great figure in the world, and excelled in the knowledge of medals. He was born in Paris in 1633; and made so surprising a progress, that he maintained theses in Greek and Latin, on all parts of philosophy, in 1647. He studied the law in compliance to an uncle, and was admitted an advocate in the parliament of Paris; but could not lay aside that of physic; for which he always had an inclination. He therefore quitted the law, and devoted himself to physic; in which, after taking the doctor's degree, he applied himself to practice, with great success. He afterwards travelled into Germany, Holland, England, Switzerland, and Italy. In 1676 he was appointed professor of physic in Padua; and three years after was created a knight of St Mark. He died in that city in 1694. His works are many, and well known to the learned world. His wife too, and his daughters, were authoresses.

**PATMOS** (anc. geog.), one of the Sporades (Dionysius); 30 miles in compass (Pliny); concerning which we read very little in authors. It was rendered famous by the exile of St John and the Revelation shewed him there. It is now in the hands of the Turks. It is considerable for its harbours; but the inhabitants derive little benefit from them, because the corsairs have ob-

liged them to quit the town and retire to a hill on which St John's convent stands. This convent is a citadel, consisting of several irregular towers, and is a substantial building seated on a very steep rock. The whole island is very barren, and without wood; however, it abounds with partridges, rabbits, quails, turtles, pigeons, and snipes. All their corn does not amount to 1000 barrels in a year. It is 18 miles in circumference; and there are scarce 300 men in it: but there are above 20 women to one man, who expect that all strangers who land in the island should carry some of them away. To the memory of St John, is an hermitage on the side of a mountain, where there is a chapel not above eight paces long and five broad. Over head they threw a chink in the rock, through which they pretend that the Holy Ghost dictated to St John. E. Long. 26. 40. N. Lat. 37. 20.

**PATNA**, a town of Asia, in the dominions of the Great Mogul, and capital of a territory of the same name, to the north of the kingdom of Bengal, where the English have factories for saltpetre, borax, and raw silk. It also produces large quantities of opium. The town is large, but the houses are built at a distance from each other. It is seated in a fertile pleasant country, 400 miles east of Agra. E. Long. 85. 40. N. Lat. 25. 25.

**PATANCE**, in heraldry, is a cross, flory at the ends; from which it differs only in this, that the ends, instead of turning down like a fleur de lis, are extended somewhat in the pattee form. See **FLORY**.

**POTOMACK**, a large river of North America, in Virginia, which rises in the Alleghany mountains, separates Virginia from Maryland, and falls into Chesapeake bay. It is about seven miles broad, and is navigable for near 200 miles.

**PATRANA**, or **PASTRANA**, a town of New Castile in Spain, with the title of a duchy. It is seated between the rivers Tajo and Tajuna, in E. Lon. 0. 15.

**PATRAS**, an ancient and flourishing town of European Turkey, in the Morea, capital of a duchy, with a Greek archbishop's see. It is pretty large and populous; and the Jews, who are one third part of the inhabitants, have four synagogues. There are several handsome mosques and Greek churches. The Jews carry on a great trade in silk, leather, honey, wax, and cheese. There are cypress trees of a prodigious height, and excellent pomegranates, citrons, and oranges. It has been several times taken and retaken, and it is just now in the hands of the Turks. It is seated in E. Long. 21. 57. N. Lat. 38. 20.

**PATRICA**, a town of Italy in the territory of the church, and in the Campagna of Rome, towards the sea-coast, and eight miles east of Ostia. About a mile from this place is a hill called *Monte di Livano*, which some have thought to be the ancient *Lavinium* founded by Æneas.

**PATRES CONSCRIPTI**. See **CONSCRIPT** and **SENATOR**.

**PATRIARCH**, **PATRIARCHA**, one of those first fathers who lived towards the beginning of the world, and who became famous by their long lines of descendants. Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament; Seth, Enoch, &c. were antediluvian patriarchs.

**PATRIARCHS**, among Christians, are ecclesiastical dig-

Patriarchs

||  
Patrick.

dignitaries, or bishops, so called from their paternal authority in the church. The power of patriarchs was not the same in all, but differed according to the different customs of countries, or the pleasures of kings and councils. Thus the patriarch of Constantinople grew to be a patriarch over the patriarchs of Ephesus and Caesarea, and was called the *ecumenical and universal patriarch*; and the patriarch of Alexandria had some prerogatives which no other patriarch but himself enjoyed, such as the right of consecrating and approving every single bishop under his jurisdiction.

**PATRIARCHAL cross**, in heraldry, is that where the shaft is twice crossed; the lower arms being longer than the upper ones.

**PATRICIAN**, among the ancient Romans, a title given to the descendants of the hundred, or, according to others, of the two hundred first senators chosen by Romulus, and by him called *pateres*, "fathers."

**PATRICK** (St), the apostle of Ireland, and second bishop of that country in the 5th century. At 16 years of age he was made a slave, and continued to for six years. Then he became a disciple of St Martin of Tours, who ordained him priest, and sent him into Ireland, where he laboured successfully for 60 years in converting the inhabitants.

**PATRICK** (Simon), a very learned English bishop, was born at Gainsborough in Lincolnshire in 1626. In 1644 he was admitted into Queen's college; Cambridge, and entered into holy orders. After being for some time chaplain to Sir Walter St John, and vicar of the church at Battersea in Surrey, he was preferred to the rectory of St Paul's, Covent-garden, in London, where he continued all the time of the plague in 1665 among his parishioners, to their great comfort. In 1668 he published his *Friendly Debate* between a Conformist and a Non-conformist. This was answered by the Dissenters, whom he had much exasperated by it; but by his moderation and candour toward them afterwards, they were perfectly reconciled to him, and he brought over many of them to the communion of the established church. In 1678 he was made dean of Peterborough, where he was much beloved. In 1682, Dr Lewis de Moulins, who had been a history-professor at Oxford, and written many bitter books against the church of England, sent for Dr Patrick upon his sick-bed, and made a solemn declaration of his regret on that account, which he signed, and it was published after his death. During the reign of king James, the dean's behaviour shewed that he had nothing more at heart than the Protestant religion; for which he ventured all that was dear to him, by preaching and writing against the errors of the church of Rome. In 1687 he published a prayer composed for that difficult time, when persecution was expected by all who stood firm to their religion. The year after the Revolution, the dean was appointed bishop of Chichester, and was employed with others of the new bishops to settle the affairs of the church in Ireland. In 1691 he was translated to the see of Ely, in the room of the deposed bishop Turner. He died in 1707, after having published various works; among which the most distinguished are his *Paraphrases and Commentaries on the holy scriptures*, 3 volumes folio. These, with Louth on the proverbs, Arnold on the Apocrypha,

and Whitby on the New Testament, make a regular continued commentary in English on all the sacred books.

**PATRIMONY**, a right or estate inherited by a person from his ancestors.

The term *patrimony* has been also given to church-estates or revenues; in which sense authors still say, the patrimony of the church of Rimini, Milan, &c. The church of Rome hath patrimonies in France, Africa, Sicily, and many other countries. To create the greater respect to the estates belonging to the church, it was usual to give their patrimonies the names of the saints they held in the highest veneration: thus the estate of the church of Ravenna was called the *patrimony of St Apollinaris*; that of Milan, the *patrimony of St Ambrose*; and the estates of the Roman church were called the *patrimony of St Peter in Abruzzo*, the *patrimony of St Peter in Sicily*, and the like.

What is now called *St Peter's patrimony* is only the duchy of Castro, and the territory of Orvietto. See CASTRO, &c.

**PATRIPASSIANS**, *PATRIPASSIANI*, in church-history, a Christian sect, who appeared about the latter end of the 2d century; so called, from their ascribing the passion to the Father: for they asserted the unity of God in such a manner as to destroy all distinctions of persons, and to make the Father and Son precisely the same; in which they were followed by the Sabellians and others. The author and head of the Patripassians was Praxeas, a philosopher of Phrygia in Asia.

**PATROL**, in war, a round or march made by the guards or watch in the night-time, to observe what passes in the streets, and to secure the peace and tranquillity of a city or camp. The patrol generally consists of a body of five or six men, detached from a body on guard, and commanded by a serjeant.

They go every hour of the night, from the beating of the tattoo until the reveille: they are to walk in the streets in garriçons, and all over the camp in the field, to prevent disorders, or any number of people from assembling together: they are to see the lights in the soldiers barracks put out, and to take up all the foldiers they find out of their quarters. Sometimes patrols consist of an officer and 30 or 40 men, as well infantry as cavalry; but then the enemy is generally near at hand, and consequently the danger greater.

**PATRON**, among the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of master expired, that of patron began: for the Romans in giving their slaves their freedom, did not depossess themselves of all rights and privileges in them; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished.

Patron was also a name which the people of Rome gave to some great man, under whose protection they usually put themselves; paying him all kinds of honour and respect, and denominating themselves his clients; while the patron, on his side, granted them his credit and protection.

**PATRON**, in the church of Rome, a saint, whose name a person bears, or under whose protection he is put, and whom he takes particular care to invoke: or

Patrimony

||  
Patron.

Patronage. a faint, in whose name a church or order is founded.

**PATRON**, in the canon and common law, is a person, who having the advowson of a parsonage, vicarage, or the like spiritual promotion, belonging to his manor, hath, on that account, the gift and disposition of the benefice; and may present to it whenever it becomes vacant. The patron's right of disposing of a benefice, originally arises either from the patron, or his ancestors, &c. being the founders or builders of the church; from their having given lands for the maintenance thereof; or, from the church's being built on their ground; and frequently from all three together.

**PATRONAGE**, or **ADVOWSON**, a sort of incorporeal hereditament, consisting in the right of presentation to a church or ecclesiastical benefice. Advowson, *advocatio*, signifies in *clientelam recipere*, the taking into protection; and therefore is synonymous with patronage, *patronatus*: and he who has the right of advowson is called the *patron of the church*. For, when lords of manors first built churches on their own demesnes, and appointed the tithes of those manors to be paid to the officiating ministers, which before were given to the clergy in common (from whence arose the division of parishes), the lord, who thus built a church, and endowed it with glebe or land, had of common right a power annexed of nominating such minister as he pleased, (provided he were canonically qualified), to officiate in that church, of which he was the founder, endower, maintainer, or, in one word, the patron.

Advowsons are either advowsons *appendant*, or advowsons *in gross*. Lords of manors being originally the only founders, and of course the only patrons, of churches, the right of patronage or presentation, so long as it continues annexed to the possession of the manor, as some have done from the foundation of the church to this day, is called an *advowson appendant*: and it will pass, or be conveyed, together with the manor, as incident and appendant thereto, by a grant of the manor only, without adding any other words. But where the property of the advowson has been once separated from the property of the manor, by legal conveyance, it is called an *advowson in gross*, or at large, and never can be appendant any more; but is for the future annexed to the person of its owner, and not to his manor or lands.

Advowsons are also either *presentative*, *collative*, or *donative*. And advowson presentative is where the patron hath a right of presentation to the bishop or ordinary, and moreover to demand of him to institute his clerk if he finds him canonically qualified: and this is the most usual advowson. An advowson collative is where the bishop and patron are one and the same person: in which case the bishop cannot present to himself; but he does, by the one act of collation, or conferring the benefice, the whole that is done in common cases, by both presentation and institution. An advowson donative is when the king, or any subject by his licence, doth found a church or chapel, and ordains that it shall be merely in the gift or disposal of the patron; subject to his visitation only, and not to that of the ordinary; and vested absolutely in the clerk by the patron's deed of donation, without presentation, institution, or induction. This is said

to have been anciently the only way of conferring ecclesiastical benefices in England; the method of institution by the bishop not being established more early than the time of archbishop Becket in the reign of Henry II. and therefore, though pope Alexander III. in a letter to Becket, severely inveighs against the *prava consuetudo*, as he calls it, of investiture conferred by the patron only, this however shews what was then the common usage. Others contend, that the claim of the bishops to institution is as old as the first planting of Christianity in this island; and in proof of it they allege a letter from the English nobility to the pope in the reign of Henry the third, recorded by Matthew Paris, which speaks of presentation to the bishop as a thing immemorial. The truth seems to be, that, where the benefice was to be conferred on a mere layman, he was first presented to the bishop in order to receive ordination, who was at liberty to examine and refuse him: but where the clerk was already in orders, the living was usually vested in him by the sole donation of the patron; till about the middle of the 12th century, when the pope and his bishops endeavoured to introduce a kind of feudal dominion over ecclesiastical benefices, and, in consequence of that, began to claim and exercise the right of institution universally, as a species of spiritual investiture.

However this may be, if, as the law now stands, the true patron once waives this privilege of donation, and presents to the bishop, and his clerk is admitted and instituted, the advowson is now become for ever presentative, and shall never be donative any more. For these exceptions to general rules and common right, are ever looked upon by the law in an unfavourable view, and construed as strictly as possible. If therefore the patron, in whom such peculiar right resides, does once give up that right, the law, which loves uniformity, will interpret it to be done with an intention of giving it up for ever; and will therefore reduce it to the standard of other ecclesiastical livings. See further, **LAW**, Part III. N<sup>o</sup> cliv. 5.—9.

**Arms of PATRONAGE**, in heraldry, are those on the top of which are some marks of subjection and dependence: thus the city of Paris bears the fleurs de lis in chief, to shew her subjection to the king; and the cardinals, on the top of their arms, bear those of the pope, who gave them the hat, to shew that they are his creatures.

**PATRONYMIC**, among grammarians, is applied to such names of men or women as are derived from those of parents or ancestors.

Patronymics are derived, 1. From the father; as Pelides, *i. e.* Achilles the son of Peleus. 2. From the mother; as Philirides, *i. e.* Chiron the son of Philira. 3. From the grandfather on the father's side; as Æceides, *i. e.* Achilles the grandson of Æacus. 4. From the grandfather by the mother's side; as Atlantiades, *i. e.* Mercury the grandson of Atlas. And, 5. From the kings and founders of nations; as Romulides, *i. e.* the Romans from their founder king Romulus.

The termination of Greek and Latin patronymics are chiefly four, *viz.* *des*, of which we have examples above; *as*, as Thaumantias, *i. e.* Iris the daughter of Thamaus; *is*, as Atlantis, *i. e.* Elestra the daughter

Blackf.  
Comment.

Patronages.  
Patronymic

Patros  
Pavia.

of Atlas; and *ne*, as Nerine, the daughter of Nereus. Of these terminations *des* is masculine; and *as*, *is*, and *ne*, feminine: *des* and *ne* are of the first declension, *as* and *is* of the third.

PATROS, (Jeremiah, Ezekiel), appears from the context to be meant of a part of Egypt. Bochart thinks it denotes the Higher Egypt: the Septuagint translate it the country of *Pathure*; in Pliny we have the *Nomos Pathurites* in the Thebais; in Ptolemy, *Pathyris*, probably the metropolis. From the Hebrew appellation *Patros* comes the gentilitious name *Pathrystus*, Mofes.

PATRU (Oliver), a counsellor in parliament, and dean of the French academy, was born at Pairs in 1604. He had an excellent faculty both of speaking and writing. Upon his admission into the French academy in 1640, he made an oration of thanks, that gave rise to the custom of admisory speeches, which are still in use in that society. Mr de Vaugelas owns himself much indebted to him for his assistance in composing his Remarks on the French tongue, of which he was by far the greatest master in France; so that he was consulted as an oracle by all the best writers of that nation.

Patru was estimable for the qualities of his heart, as well as for those of the head: was honest, generous, sincere; and preserved a gayness of character, which no ill-fortune could alter or affect. For this famous advocate, in spite of all his great talents, lived almost in a state of indigence. The love of the belles lettres made him neglect the law; and the barren glory of being an oracle to the best French writers had more charms for him, than all the profits of the bar. Hence he became so poor, as to be reduced to the necessity of selling his books, which seemed dearer to him than his life; and would actually have sold them for an under-price, if Boileau had not generously advanced him a larger sum, with this further privilege, that he should have the use of them as long as he lived. His death was preceded by a tedious illness, during which he received a present of 500 crowns from Colbert, as a mark of the esteem which the king had for him. He died the 16th of January 1681. The prodigious care and exactness with which he touched and finished every thing he wrote, did not permit him to publish much. His miscellaneous works were printed at Paris in 1670, 4to; the third edition of which, in 1714, 4to, was augmented with several pieces. They consist of Pleadings, Orations, Letters, Lives of some of his friends, Remarks upon the French language, &c.

PAU, a handsome town of France, in the province of Gascony and territory of Bearn, with a parliament, a mint, and a castle where Henry IV. was born. It is seated on an eminence, at the foot of which runs the river Gave. W. Long. o. 29. N. Lat. 43. 15.

PAVIA, an ancient and celebrated town of Italy, in the duchy of Milan, and capital of the Pavese, with an university and bishop's see. It is defended by strong walls, large ditches, good ramparts, excellent bastions, and a bridge over the river Tassin. In the centre of the town is a strong castle, where the duke of Milan was wont to reside. There are a great number of magnificent castles, and some colleges. It was

taken by the duke of Savoy in 1706; by the French in 1733; by the French and Spaniards in 1745; but retaken by the Austrians in 1746. E. Long. 9. 5. N. Lat. 45. 10.

PAVILION, in architecture, signifies a kind of turret or building, usually insulated, and contained under a single roof; sometimes square, and sometimes in form of a dome: thus called from the resemblance of its roof to a tent.

Pavilions are sometimes also projecting pieces, in the front of a building, marking the middle thereof; sometimes the pavilion flanks a corner, in which case it is called an *angular pavilion*. The Louvre is flanked with four pavilions: the pavilions are usually higher than the rest of the building. There are pavilions built in gardens, commonly called *summer-houses*, *pleasure-houses*, &c. Some castles or forts consist only of a single pavilion.

PAVILION, in military affairs, signifies a tent raised on posts, to lodge under in the summer time.

PAVILION, is also sometimes applied to flags, colours, ensigns, standards, banners, &c.

PAVILION, in heraldry, denotes a covering in form of a tent, which invests or wraps up the armories of divers kings and sovereigns, depending only on God and their sword.

The pavilion consists of two parts; the top, which is the chapeau, or coronet; and the curtain, which makes the mantle.

None but sovereign monarchs, according to the French heralds, may bear the pavilion entire, and in all its parts. Those who are elective, or have any dependence, say the heralds, must take off the head, and retain nothing but the curtains.

PAVILIONS, among jewellers, the underfides and corners of the brilliants, lying between the girdle and the collet.

PAUL (St) the apostle, was born at Tarsus in Cilicia, of Jewish parents. He was educated at Tarsus; which, as Strabo informs us, excelled Alexandria, Athens, and Rome itself, for polite learning. Thence he was sent to Jerusalem, to study the law under Gamaliel. Here he became a Pharisee, and engaged in a violent perfection; but was wonderfully converted in his way to Damascus. After which he preached the gospel in various parts, until he was at last sent to Rome, where he is said to have converted Poppea Sabina, Nero's concubine; for which Nero being enraged against him, commanded him to be beheaded.

PAUL, first bishop of Narbonne, or Sergius Paulus the proconsul, converted and made bishop by St Paul, was descended from one of the best families of Rome. It is said the apostle called himself *Paul* from his name. The Spaniards will have him to be their apostle, which is not improbable; and it is said he died a martyr at Narbonne.

PAUL (Father), was born at Venice in 1552. He was educated by his uncle Ambrosio Morilli, and soon made great progress in learning. He was remarkable for two qualities, which seldom meet in the same person; a strong memory, and clear judgment. He took upon him the habit of the Servites in 1566. Upon entering into this order, he changed his name of *Peter Sarpi* for that of *Paul*. He was afterwards

Pavilion;  
Paul.

chaplain

chaplain to the duke of Mantua, and reader of positive and casuistical divinity and canon law in that city. So he became a perfect master of the Hebrew language and of history; but shewed the utmost contempt for judicial astrology. When weary of a court life, he returned to his convent at Venice; and so intensely applied himself to study, that he injured his health by it. He was chosen provincial of his order for the province of Venice at 26 years of age; and discharged this post with such honour, that 1759 he was appointed, with two others, to draw up new regulations and statutes for his order. This he executed with great success; and when his office of provincial was expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he is said to have made some useful discoveries. He was then chosen procurator-general of his order; and during his residence at Rome was greatly esteemed by pope Sixtus V. and contracted an intimate friendship with cardinal Bellarmine and other eminent persons. Some time after, he was accused of heresy; and brought into a series of troubles, which he supported with exemplary patience and magnanimity; till at length, growing extremely odious to the pope's party, he was assassinated, and left for dead, by five ruffians, who retired to the palace of the pope's nuncio in Venice, from whence they escaped to Ravenna or Ferrara. These circumstances discovered who were concerned in this attempt. He recovered, however, of his wounds; and retired to a place of security, where he wrote his history of the council of Trent, which he compiled principally for the sake of king James I. of England, with whom he corresponded. His name, ever since the interdict, was become famous all over Europe; and two kings made him very advantageous offers to reside in their dominions. He died as he had lived, with piety and resignation, in 1623. He was a good controversial writer, a judicious and elegant historian.

**PAULIONISTS**, in church-history, Christian heretics of the third century, disciples of Paul Samatensis bishop of Antioch, who denied Christ's divinity; maintaining, that, when we call him the Son of God, we do not therefore mean that he is truly and really God; but only that he was so perfect a man, and so superior in virtue to all others, that he had this name given him by way of eminence.

**PAULICIANS**, Christian heretics of the seventh century, disciples of one Constantine a native of Armenia, and a favourer of the errors of Manes; who, as the name *Manichee* was become odious, gave thofe of his sect the name of *Paulicians*, on the pretence that they followed only the doctrine of St Paul.

**PAVO**, the **PEACOCK**, in ornithology; a genus belonging to the order of gallinæ. The head is covered with feathers which bend backwards; the feathers of the tail are very long, and beautifully variegated with eyes of different colours. There are three species.

1. The cristatus, or common peacock of English authors, has a compressed crest and solitary spurs. It is a native of India; and we are assured, that they are still found in a wild state in the islands of Ceyland and Java. So beautiful a bird could not long be permitted to be a stranger in the more distant parts: for so early

as the days of Solomon, we find, among the articles imported in his Tarshish navies, apes and peacocks. A monarch so conversant in all branches of natural history, "who spoke of trees, from the cedar of Lebanon, even unto the hyssop that springeth out of the wall; who spoke also of beasts and of fowl," would certainly not neglect furnishing his officers with instructions for collecting every curiosity in the countries they voyaged to, which gave him a knowledge that distinguished him from all the princes of his time. *Ælian* relates, that they were brought into Greece from some barbarous country; and that they were held in such high esteem, that a male and female were valued at Athens at 1000 drachmæ, or 32 l. 5 s. 10 d. Their next step might be to Samos; where they were preserved about the temple of Juno, being the birds sacred to the goddesses: and *Gellius*, in his *Noctes Atticæ*, c. 16. commends the excellency of the Samian peacocks. It is therefore probable, that they were brought here originally for the purposes of superstition, and afterwards cultivated for the uses of luxury. We are also told, when Alexander was in India, he found vast numbers of wild ones on the banks of the Hyarotis; and was so struck with their beauty, as to appoint a severe punishment on any person that killed them.

Peacock's crests, in ancient times, were among the ornaments of the kings of England. *Ernald* de Aclent was fined to king John in 140 palfries, with fackbuts, lorains, gilt spurs, and peacock's crests, such as would be for his credit.

2. The bicalcaratas has a small crest and double spurs. It is a native of China.

3. The muticus has a sharp-pointed crest, and no spurs; the orbits of the eyes are red. It is found in Japan.

**PAVO**, in astronomy. See **ASTRONOMY**, n° 206.

**PAUREDASTYLÆ**, in natural history, the name of a genus of perfect crystals with double pyramids, and no intermediate column, composed of 12 planes, or two hexangular pyramids joined base to base.

**PAUSANIA**, in Grecian antiquity, a festival in which were solemn games, wherein nobody contended but free-born Spartans; in honour of Pausanias the Spartan general, under whom the Greeks overcame the Persians in the famous battle of Platea.

**PAUSANIAS**, a learned Greek historian and orator, in the second century, under the reign of Antoninus the philosopher, was the disciple of Herodotus Atticus. He lived for a long time in Greece; and afterwards went to Rome, where he died at a great age. He wrote an excellent Description of Greece, in ten books; in which we find not only the situation of places, but the antiquities of Greece, and every thing most curious and worthy of knowledge. *Abbé Gedin* has given a French translation of it, in 2 vols 4to.

**PAUSE**, a stop or cessation in speaking, singing, playing, or the like. One use pointing in grammar is to make proper pauses, in certain places. There is a pause in the middle of each verse; in a hemistich, it is called a *reft* or *repose*. See **POETRY**, n° 118, &c. and **READING**, n° xi.

**PAW**, in the manege. A horse is said to paw the ground, when, his leg being either tired or painful, he

Pca  
#  
Peuk,

does not rest it upon the ground, and fears to hurt himself as he walks.

PEA, in botany. See PISUM.

PEACH, in botany. See AMYGDALUS.

PEACOCK, in ornithology. See PAVO.

PEAK of DERBYSHIRE, a chain of very high mountains in the county of Derby in England, famous for the mines they contain, and for their remarkable caverns. The most remarkable of these are Pool's-hole and Elden-hole. The former is a cave at the foot of a high hill called *Coitnoss*, so narrow at the entrance that passengers are obliged to creep on all-fours; but it soon opens to a considerable height, extending to above a quarter of a mile, with a roof somewhat resembling that of an ancient cathedral. By the petrifying water continually dropping in many parts of the cave are formed a variety of curious figures and representations of the works both of nature and art. There is a column here as clear as alabaster, which is called the *Queen of Scots Pillar*, because Queen Mary is said to have proceeded thus far when she visited the cavern. If a pillar is fired by this pillar, it will make a report as loud as a cannon. Near the extremity there is a hollow in the roof, called the *Needle's eye*; in which if a candle is placed, it will represent a star in the firmament to those who are below. At a little distance from this cave is a small clear stream consisting of hot and cold water, so near each other, that the finger and thumb of the same hand may be put, the one into the hot water, and the other into the cold.

Elden-hole is a dreadful chasm in the side of a mountain; which, before the latter part of the last century, was thought to be altogether unfathomable. In the time of queen Elizabeth, a poor man was let down into it for 200 yards; but he was drawn up in a frenzy, and soon after died. In 1682, it was examined by Captain Collins, and in 1699 by Captain Sturmy, who published their accounts in the Philosophical Transactions. The latter descended by ropes fixed at the top of an old lead-ore pit, four fathoms almost perpendicular, and from thence three fathoms more obliquely, between two great rocks. At the bottom of this he found an entrance into a very spacious cavern, from whence he descended along with a miner for 25 fathoms perpendicular. At last they came to a great river or water, which he found to be 20 fathoms broad and eight fathoms deep. The miner who accompanied him, insisted that this water ebbed and flowed with the sea; but the Captain disproved this assertion by remaining in the place from three hours flood to two hours ebb, during which time there was no alteration in the height of the water. As they walked by the side of this water, they observed a hollow in the rock some feet above them. The miner went into this place, which was the mouth of another cavern; and walked for about 70 paces in it, till he just lost sight of the Captain. He then called to him, that he had found a rich mine; but immediately after came running out and crying, that he had seen an evil spirit; neither could any persuasions induce him to return. The floor of these caverns is a kind of white stone enamelled with lead ore, and the roofs are encruited with shining spar. On his return from this subterraneous journey, Captain Sturmy was seized with a

Pean  
#  
Pearce,

violet head-ach, which, after continuing four days, terminated in a fever, of which he died in a short time.

A few years ago this cavern was visited by the late Mr James Ferguson: who tells us, that it consists of two hollows one over another; but that the mouth of the lowermost is now stopped up by planks of timber laid across it, on which are a heap of stones thrown in at the upper mouth with a design to fill up the cavern entirely; which, however, will probably be never accomplished on account of its vast size.

PEAR, in heraldry, is when the field of a coat of arms is sable, and the powderings or.

PEAR, in botany. See PYRUS.

PEARCE (Dr), lord bishop of Rochester, was the son of a distiller in High Holborn. He married Miss Adams, the daughter of a distiller in the same neighbourhood, with a considerable fortune, who lived with him 52 years in the highest degree of connubial happiness. He had his education in Westminster school, where he was distinguished by his merit, and elected one of the king's scholars. In 1710, when he was 20 years old, he was elected to Trinity College, Cambridge. During the first years of his residence at the university, he sometimes amused himself with lighter compositions, some of which are inserted in the Guardian and Spectator. In 1716, he published his edition of *Cicero de Oratore*, and, at the desire of a friend, luckily dedicated it to Lord Chief Justice Parker, (afterwards Earl of Macclesfield,) to whom he was a stranger. This incident laid the foundation of his future fortune: for Lord Parker soon recommended him to Dr Bentley, master of Trinity, to be made one of the fellows; and the doctor consented to it on this condition, that his lordship would promise to *unmake* him again as soon as it lay in his power to give him a living. In 1717, Mr Pearce was ordained at the age of 27; having taken time enough, as he thought, to attain a sufficient knowledge of the sacred office. In 1718, Lord Parker was appointed chancellor, and invited Mr Pearce to live with him in his house as chaplain. In 1719, he was instituted into the rectory of Stapleford Abbots, in Essex; and in 1720, into that of St Bartholomew, behind the Royal Exchange, worth 400 l. *per annum*. In 1723, the lord chancellor presented him to St Martin's in the Fields. His Majesty, who was then at Hanover, was applied to in favour of St Claget, who was then along with him; and the doctor actually kissed hands upon the occasion: but the chancellor, upon the king's return, disputed the point, and was permitted to present Mr Pearce.—Mr Pearce soon attracted the notice and esteem of persons in the highest stations and of the greatest abilities. Beside Lord Parker, he could reckon amongst his patrons or friends, Lord Macclesfield, Mr Pulteney (afterwards Earl of Bath), archbishop Potter, Lord Hardwicke, Sir Isaac Newton, and other illustrious personages.—In 1724, the degree of doctor of divinity was conferred on him by archbishop Wake. The same year he dedicated to his patron, the Earl of Macclesfield, his edition of *Longinus on the Sublime*, with a new Latin version and notes.

When the church of St Martin's was rebuilt, Dr Pearce preached a sermon at the consecration, which he

Pearce. he afterwards printed, and accompanied with an essay on the origin and progress of temples, traced from the rude stones which were first used for altars, to the noble structure of Solomon, which he considers as the first temple completely covered. His observations on that building, which is called the *temple of Dagon*, removes part of the difficulty which presents itself in the narration of the manner in which Samson destroyed it.

The deanry of Winchester becoming vacant, Dr Pearce was appointed dean in 1739; and in the year 1744 he was elected prolocutor of the lower house of convocation for the province of Canterbury. His friends now began to think of him for the episcopal dignity; but Mr Dean's language rather declined it. However, after several difficulties had been started and removed, he consented to accept the bishoprick of Bangor, and promised Lord Hardwicke to do it with a good grace. He accordingly made proper acknowledgments of the royal goodness, and was consecrated Feb. 12. 1748. Upon the declining state of health of Dr Wilcocks, bishop of Rochester, the bishop of Bangor was several times applied to by archbishop Herring to accept of Rochester, and the deanry of Westminster, in exchange for Bangor; but the bishop then first signified his desire to obtain leave to resign and retire to a private life. His lordship, however, upon being pressed, suffered himself to be prevailed upon.—“My Lord,” said he to the Duke of Newcastle, “your grace offers these dignities to me in so generous and friendly a manner, that I promise you to accept them.” Upon the death of bishop Wilcocks he was accordingly promoted to the see of Rochester and deanry of Westminster in 1756. Bishop Sherlock died in 1761, and Lord Bath offered his interest for getting the bishop of Rochester appointed to succeed him in the diocese of London; but the bishop told his lordship, that he had determined never to be bishop of London or archbishop of Canterbury.

In the year 1763, his lordship being 73 years old, and finding himself less fit for the business of his stations as bishop and dean, informed his friend lord Bath of his intention to resign both, and live in a retired manner upon his private fortune. Lord Bath undertook to acquaint his majesty; who named a day and hour, when the bishop was admitted alone into the closet. He told the king, that he wished to have some interval between the fatigues of business and eternity; and desired his majesty to consult proper persons about the propriety and legality of his resignation. In about two months the king informed him, that Lord Mansfield saw no objection; and that Lord Northampton, who had been doubtful, on farther consideration thought that the request might be complied with. Unfortunately for the bishop, lord Bath applied for bishop Newton to succeed. This alarmed the ministry, who thought that no dignities should be obtained but through their hands. They therefore opposed the resignation; and his majesty was informed that the bishops disliked the design. His majesty sent to him again; and at a third audience told him, that he must think no more of resigning. The bishop replied, “Sir, I am all duty and submission;” and then retired.

In 1768 he obtained leave to resign the deanry; in 1773, he lost his lady; and after some months of lingering decay, he died at Little Ealing, June 29, 1774.

This eminent prelate distinguished himself in every part of his life by the virtues proper to his station. His literary abilities, and application to sacred and philological learning, appear by his works; the principal of which are, A letter to the clergy of the church of England, on occasion of the bishop of Rochester's commitment to the Tower, 2d ed. 1722. Miracles of Jesus vindicated, 1727 and 1728. A review of the text of Milton, 1733. Two letters against Dr Middleton, occasioned by the doctor's letter to Waterland, on the publication of his treatise, intitled *Scripture Vindicated*, 3d edit. 1752. And since his death, a commentary with notes on the four Evangelists and the Acts of the Apostles, together with a new translation of St Paul's first Epistle to the Corinthians, with a paraphrase and notes, have been published, with his life prefixed, from original MSS. in 2 vols 4to.

PEARCH, in ichthyology. See PERCA.

The perch affords good sport for the angler. The best time for their biting is when the spring is over, and before the heats of summer come on. At this time they are very greedy; and the angler, with good management, may take at one standing all that are in the hole, be they ever so many.

The proper baits are a minnow or young frog; but the worm called the *brandling*, well scowered, is also excellent at all times of the year. When the perch bites, he should always have a great deal of time allowed him to swallow the bait.

The perch will bite all day long, if the weather be cloudy; but the best time is from eight to ten in the morning, and from three till six in the afternoon. The perch is very abstemious in winter, and will seldom bite in this season of the year; if he does at all, it is in the middle of the day: at which time indeed all fish bite best at that season.

If the bait be a minnow, which is the bait that affords most diversion to the angler, it must be fastened to the hook alive, by putting the hook through the upper lip or back-fin; it must be kept at about mid-water, and the bait must be a quill and a cork, that the minnow alone may not be able to sink it.

The line must be of silk, and strong; and the hook armed with a small and fine wire, that if a pike should take the bait, as is not unfrequently the case, he may be taken. The way to carry the minnows or small gudgeons alive for baits is this: A tin-pot is to be provided, with holes in the lid, and filled with water; and the fish being put in this, the water is to be changed once in a quarter of an hour by the holes, without taking off the lid at any time, except when the bait is to be taken out.

A small casting-net, made for these little fish, should be taken out with the perch-tackle; and one or two casts of this will take baits enough for the day, without any farther trouble. When the bait is a frog, the hook is to be fastened to the upper part of the leg. The best place for the fishing for perch is in the turn of the water near some gravelly fount. A place of this kind being pitched upon, it should be baited over-night with lobworms chopped to pieces; and in the morning, on going to it, the depth is to be regularly plumbed, and then the hook is to be baited with the worm or other bait; and as it drags along, the perch will soon seize upon it.

PEARCH-

**PEARCH-Glue**, the name of a kind of glue, of remarkable strength and purity, made from the skins of pearches.

**PEARL**, in natural history, a hard, white, shining body, usually roundish, found in a testaceous fish resembling an oyster.

Pearls, though esteemed of the number of gems by our jewellers, and highly valued, not only at this time, but in all ages, proceed only from a distemper in the creature that produces them, analogous to the bezoars, and other stony concretions in several animals of other kinds.

The fish in which these are usually produced is the East-Indian pearl-oyster, as it is commonly called. Besides this shell, there are many others that are found to produce pearls; as the common oyster, the muscle, and several others; the pearls of which are often very good; but those of the true Indian berberi, or pearl-oyster, are in general superior to all. The small or seed-pearls, also called *ounce-pearls*, from their being sold by the ounce and not by tale, are vastly the most numerous and common: but, as in diamonds, among the multitudes of small ones, there are smaller numbers and larger found, so in pearls there are larger and larger kinds; but as they increase in size, they are proportionally less frequent; and this is one reason of their great price. We have Scotch pearls frequently as big as a little tare, some as big as a large pea, and some few of the size of a horse-bean; but these are usually of a bad shape, and of little value in proportion to their weight. Philip II. of Spain had a pearl perfect in its shape and colour, and of the size of a pigeon's egg. The finest, and what is called the true shape of the pearl, is a perfect round; but if pearls of a considerable size, are of the shape of a pear, as is not unfrequently the case, they are not less valued, as they serve for ear-rings and other ornaments. Their colour ought to be a pure white; and that not a dead and lifeless, but a clear and brilliant one: they must be perfectly free from any foulness, spot, or stain; and their surfaces must be naturally smooth and glossy; for they bring their natural polish with them, which art is not able to improve.

All pearls are formed of the matter of the shell, and consist of a number of coats spread with perfect regularity one over another, in the manner of the several coats of an onion, or like the several strata of the stones found in the bladders or stomachs of animals, only much thinner.

*Manner of fishing for PEARLS in the East Indies.* There are two seasons for pearl-fishing: the first is in March and April, and the last in August and September; and the more rain there falls in the year, the more plentiful are these fisheries. At the beginning of the season there are sometimes 250 barks on the banks; the larger barks have two divers, and the smaller one. As soon as the barks arrive at the place where the fish lie, and have cast anchor, each diver binds a stone, six inches thick and a foot long, under his body; which serves him as ballast, prevents his being driven away by the motion of the water, and enables him to walk more steadily under the waves. They also tie another very heavy stone to one foot, by which they are very speedily sent to the bottom of the sea; and as the oysters are usually firmly fastened to

the rocks, they arm their hands with leather mittens, to prevent their being wounded in pulling them violently off; but this task some perform with an iron rake. In the last place, each diver carries down with him a large net in the manner of a sack, tied to his neck by a long cord, the other end of which is fastened to the side of the bark. This net is to hold the oysters gathered from the rock; and the cord is to pull up the diver when his bag is full, or he wants air.

In this equipage he sometimes precipitates himself sixty feet under water; and as he has no time to lose, he no sooner arrives at the bottom, than he begins to run from side to side, tearing up all the oysters he meets with, and cramming them into his budget.

At whatever depth the divers are, the light is so great, that they easily see whatever passes in the sea; and, to their great consternation, sometimes perceive monstrous fishes, from which all their address in muddying the water, &c. will not always save them, but they unhappily become their prey: and of all the dangers of the fishery, this is one of the greatest and most usual. The best divers will keep under water near half an hour, and the rest do not stay less than a quarter. During this time they hold their breath without the use of oils or any other liquors; only acquiring the habit by long practice. When they find themselves straitened, they pull the rope to which the bag is fastened, and hold fast by it with both hands; when those in the bark, taking the signal, heave them up into the air, and unload them of their fish; which is sometimes 500 oysters, and sometimes not above 50. Some of the divers need a moment's respite to recover breath; others jump in again instantly, continuing this violent exercise without intermission for several hours.

On the shore they unload their barks, and lay their oysters in an infinite number of little pits dug in the sand four or five feet square, raising heaps of sand over them to the height of a man; and in this condition they are left till the rain, wind, and sun, have obliged them to open, which soon kills them: upon this the flesh rots and dries, and the pearls, thus disengaged, fall into the pit, on their taking out the shells. After clearing the pits of the grosser filth, they sift the sand several times in order to find the pearl; but, whatever care they take, they always lose a great many. After cleaning and drying the pearls, they are passed through a kind of sieve, according to their sizes; the smallest are then sold as seed-pearls, and the rest put up to auction, and sold to the highest bidder.

*Artificial PEARLS.* Attempts have been made to take out stains from pearls, and to render the foul opaque-coloured ones equal in lustre to the oriental. Abundance of processes are given for this purpose in books of secrets and travels; but they are very far from answering what is expected from them. Pearls may be cleaned indeed from any external foulness by washing and rubbing them with a little Venice soap and warm water, or with ground rice and salt, with starch and powder-blue, plaster of Paris, coral, white vitriol and tartar, cuttle-bone, pumice-stone, and other similar substances; but a stain that reaches deep into

Pearl  
Peat.

into the substance of the pearls is impossible to be taken out. Nor can a number of small pearls be united into a mass similar to an entire natural one, as some pretend.

There are, however, methods of making artificial pearls, in such manner as to be with difficulty distinguished from the best oriental. The ingredient used for this purpose was long kept a secret; but is now discovered to be a fine scale-like substance found upon the under side of the scales of the blay or bleak fish. The scales, taken off in the usual manner, are washed and rubbed with fresh parcels of fair water, and the several liquors suffered to settle: the water being then poured off, the pearly matter remains at the bottom, of the consistence of oil, called by the French *essence d'orient*. A little of this is dropped into a hollow bead of bluish glass, and shaken about so as to line the internal surface; after which the cavity is filled up with wax, to give solidity and weight. Pearls made in this manner are distinguishable from the natural only by their having fewer blemishes.

*Mother-of-PEARL* is the shell, not of the pearl oyster, but of another sea-fish of the oyster kind. This shell, on the inside, is extremely smooth, and of the whiteness and water of pearl itself: it has also the same lustre on the outside after the external laminae have been taken off by aquafortis and the lapidary's mill. Mother of pearl is used in inlaid works, and in several toys, as snuff-boxes, &c.

PEARSON (John), a very learned English bishop in the 17th century, was born at Snoring in 1613. After his education at Eton and Cambridge, he entered into holy orders in 1639, and was the same year collated to the prebend of Netherhaven in the church of Sarum. In 1640 he was appointed chaplain to the lord keeper Finch, and by him presented to the living of Torrington in Suffolk. In 1650 he was made minister of St Clement's, East-cheap, in London. In 1657, he and Mr Gunning had a dispute with two Roman Catholics, upon the subject of schism; a very unfair account of which was printed at Paris in 1658. Some time after, he published his *Exposition of the Creed*, and several other works. After various preferments, he was advanced in 1672 to the see of Chester; where he died, in 1686.

PEAT, a kind of turf used for fuel in several countries. See CHEMISTRY, n° 516.

There are very considerable differences in peat, proceeding perhaps wholly from different mineral admixtures; for the substance of the peat is plainly of vegetable origin, whence it is found to answer for the smelting of ores, and the reduction of metallic calces, nearly in the same manner as the coals of wood. Some sorts yield in burning a very disagreeable smell, which extends to a great distance; whilst others are inoffensive. Some burn into grey or white, and others into red ferruginous ashes. The ashes yield, on elixation, a small quantity of alkaline salt, with sometimes one and sometimes another salt of the neutral kind.

The smoke of peat does not preserve or harden flesh like that of wood; and the foot, into which it condenses, is more disposed to liquefy in moist weather. On distilling peat in close vessels, there arises a clear insipid phlegm, an acid liquor, which is succeeded by an alkaline one, and a dark coloured oil. The oil has a

very pungent taste; and an empyreumatic smell, less fetid than that of animal substances, more so than that of mineral bitumens: it congeals in the cold into a pitchy mass, which liquefies in a small heat: it readily catches fire from a candle, but burns less vehemently than other oils, and immediately goes out upon removing the external flame: it dissolves almost totally in rectified spirit of wine into a dark brownish red liquor.

PEBBLES, the name of a genus of fossils, distinguished from the flints and homochroa by their having a variety of colours. These are defined to be stones composed of a crystalline matter debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations, usually formed by incrustation round a central nucleus, but sometimes the effect of a simple concretion; and veined like the agates, by the disposition which the motion of the fluid they were formed in gave their differently coloured substances.

The variety of pebbles is so great, that an hasty describer would be apt to make almost as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred as accidental varieties. When we find the same colours, or those resulting from a mixture of the same, such as nature frequently makes in a number of stones, we shall easily be able to determine that these are all of them the same species, though of different appearances; and that whether the matter be disposed of in one or two, or in 20 crusts, laid regularly round a nucleus; or thrown irregularly, without a nucleus, into irregular lines; or lastly, if blended into an uniform mass.

These are the three states in which every pebble is found; for if it has been naturally and regularly formed by incrustation round a certain nucleus, we find that always the same in the same species, and the crusts not less regular and certain. If the whole has been more hastily formed, and the result only of one simple concretion, if that has happened while its different substances were all moist and thin, they have blended together and made a mixed mass of the joint colour of them all. But if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. These are the natural differences of all the pebbles; and having regard to these in the several variegations, all the known pebbles may be reduced to 34 species.

PECCANT, in medicine, a term used for those humours of the body which offend either by their quantity or quality.

PECCARY, or TAJACU, in zoology; a species of Suis.

PECK, a measure of capacity, four of which make a bushel.

PECORA, in zoology, the fifth order of the class mammalia, in the Linnean system. See ZOOLOGY.

PECTEN, the SCALLOP, a genus of shell-fish, the characters of which are these: The animal is a tethys; the shell bivalve and unequal; the hinge toothless, having a small ovated hollow. This shell-fish is one of the spinners, having the power of spinning threads like the muscle

Peat  
Pecten.

Pectoral  
||  
Peculiar.

muscle: but they are much shorter and coarser than even those of that fish; so that they can never be wrought into any kind of work like the longer and finer threads of the pinna marina. The use of the threads which are spun by the scallop is to fix the creature to any solid body near its shell. All these proceed, as in the muscle, from one common trunk. It is an evident proof that the fish has a power of fixing itself at pleasure to any solid body by means of these threads, that after storms the scallops are often found tuffed upon rocks, where there were none the day before; and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner with the muscle; only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter. The most remarkable species of this genus is,

The *maximus*, or great scallop, with 14 rays, very prominent and broad; striated lengthwise above and below. These grow to a large size; are found in beds by themselves; are dredged up, and barrelled for sale. The ancients say that they have a power of removing themselves from place to place by vast springs or leaps. This shell was called by the Greeks *πτερυγία*, by the Latins *peten*; and was used by both as a food. When dressed with pepper and cummin, it was taken medicinally.

The scallop was commonly worn by pilgrims on their hat, or the cape of their coat, as a mark that they had crossed the sea in their way to the Holy Land, or some distant object of devotion.

PECTORAL, an epithet for medicines good in diseases of the breast and lungs.

PECTORALIS, in anatomy. See there, *Table of the Muscles*.

PECULATE, in civil law, the crime of embezzling the public money, by a person intrusted with the receipt, management, or custody thereof. This term is also used by civilians for a theft, whether the thing be public, fiscal, sacred, or religious.

PECULIAR, in the canon law, signifies a particular parish or church that has jurisdiction within itself for granting probates of wills and administrations, exempt from the ordinary or bishop's courts. The king's chapel is a royal peculiar, exempt from all spiritual jurisdiction, and reserved to the visitation and immediate government of the king himself. There is likewise the archbishop's peculiar; for it is an ancient privilege of the see of Canterbury, that wherever any manors or advowsons belong to it, they forthwith become exempt from the ordinary, and are reputed peculiars: there are 57 such peculiars in the see of Canterbury.

Besides these, there are some peculiars belonging to deans, chapters, and prebendaries, which are only exempted from the jurisdiction of the archdeacon: these are derived from the bishop, who may visit them, and to whom there lies an appeal.

PECULIARS (*Court of*), is a branch of, and annexed to, the court of ARCHES. It has a jurisdiction over all those parishes dispersed through the province of Canterbury in the midst of other dioceses, which are exempt from the ordinary's jurisdiction, and subject to the metropolitan only. All ecclesiastical causes, arising within these peculiar or exempt jurisdictions, are originally

cognizable by this court; from which an appeal lay formerly to the pope, but now by the stat. 25 H. VIII. c. 19. to the king in chancery.

PECULIUM, the stock or estate which a person, in the power of another, as a slave, may acquire by his industry.

In the Romish church, peculium denotes the goods which each religious reserves and posses to himself.

PEDALS, the largest pipes of an organ, so called because played and stopped with the foot. The pedals are made square, and of wood; they are usually 13 in number. They are of modern invention, and serve to carry the sounds of an octave deeper than the rest. See ORGAN.

PEDAGOGUE, or PEDAGOGUE, a tutor or master, to whom is committed the discipline and direction of a scholar, to be instructed in grammar and other arts. The word is formed from the Greek *παιδαγωγός*, *pædagogos*, *dulcor*, "leader of boys."

M. Fleury observes, that the Greeks gave the name *pedagogus* to slaves appointed to attend their children, lead them, and teach them to walk, &c. The Romans gave the same denomination to the slaves who were intrusted with the care and instruction of their children.

PEDANT, a school-master, or pedagogue, who professes to instruct and govern youth, teach them the humanities, and the arts. See PEDAGOGUE.

PEDANT is also used for a rough, unpolished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations.

Dacier defines a pedant, a person who has more reading than good sense. See PEDANTRY.

Pedants are people ever armed with quibbles and syllogisms; breathe nothing but disputation and chancery, and pursue a propolition to the last limits of logic.

Malebranche describes a pedant as a man full of false erudition, who makes a parade of his knowledge, and is ever quoting some Greek or Latin author, or hunting back to a remote etymology.

St Evremont says, that to paint the folly of a pedant, we must represent him as turning all conversation to some one science or subject he is best acquainted withal.

There are pedants of all conditions, and all robes. Wicquefort says, an ambassador, always attentive to formalities and decorums, is nothing else but a political pedant.

PEDANTRY, or PEDANTISM, the quality or manner of a pedant. See PEDANT.

To swell up little and low things, to make a vain show of science, to heap up Greek and Latin without judgment, to tear those to pieces who differ from us about a passage in Suetonius or the etymology of a word, to stir up all the world against a man for not admiring Cicero enough, to be interested for the reputation of an ancient as if he were our next of kin, is what we properly call *pedantry*.

PEDARIAN, in Roman antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the house.

PEDERASTS, the same with SODOMITES.

PEDESTAL, in architecture, the lowest part of an

Peculium  
||  
Pedestal.

**Pedicle, Pediculus.** an order of columns, being that part which sustains the column, and serves it as a foot or stand. See COLUMN.

**PEDICLE**, among botanists, that part of a stalk which immediately sustains the leaf of a flower or a fruit, and is commonly called a *footstalk*.

**PEDICULUS**, the Louse, in zoology, a genus of insects belonging to the order of aptera. It has six feet, two eyes, and a sort of sting in the mouth; the feelers are as long as the thorax; and the belly is depressed and sublobated.

Many animals both of the quadruped and flying kinds are subject to lice; but these are of peculiar species on each animal, and are not at all like those which infest the human body. Nay, even insects are infested with vermin which feed on and torment them. Several kinds of beetles are subject to lice; but particularly that kind called thence the *lousy beetle*. The lice on this are very numerous, and will not be shook off. The earwig is often infested with lice, just at the setting on of its head: these are white, and shining like mites, but they are much smaller; they are round-backed, flat belliced, and have long legs, particularly the foremost pair. Snails of all kinds, but especially the large naked sorts, are very subject to lice; which are continually seen running about them, and devouring them. Numbers of little red lice, with a very small head, and in shape resembling a tortoise, are often seen about the legs of spiders, and they never leave the animal while he lives; but if he is killed, they almost instantly forsake him. A sort of whitish lice is found on humble-bees: they are also found upon ants; and fishes are not less subject to them than other animals.

Kircher tells us, that he found lice also on flies, and M. de la Hire has given a curious account of the creature which he found on the common fly. Having occasion to view a living fly with the microscope, he observed on its head, back, and shoulders, a great number of small animals crawling very nimbly about, and often climbing up the hairs which grow at the origin of the fly's legs. He with a fine needle took up one of these, and placed it before the microscope used to view the animalcules in fluids. It had eight legs; four on each side. These were not placed very distant from each other; but the four towards the head were separated by a small space from the four towards the tail. The feet were of a particular structure, being composed of several fingers, as it were, and fitted for taking fast hold of any thing; but the two nearest the head were also more remarkable in this particular than those near the tail; the extremities of the legs for a little way above the feet were dry and void of flesh like the legs of birds, but above this part they appeared plump and fleshy. It had two small horns upon its head, formed of several hairs arranged closely together; and there were some other clusters of hairs by the side of these horns, but they had not the same figure; and towards the origin of the hinder legs there were two other such clusters of hairs which took their origin at the middle of the back. The whole creature was of a bright yellowish red; the legs, and all the body, except a large spot in the centre, were perfectly transparent. In size, he computed it to be about  $\frac{1}{1000}$ th part of the head of the fly; and he observes, that such kind of vermin are rarely found on flies.

The louse which infests the human body makes a very curious appearance through a microscope. It has such a transparent shell or skin, that we are able to discover more of what passes within its body than in most other living creatures. It has naturally three divisions, the head, the breast, and the tail part. In the head appear two fine black eyes, with a horn that has five joints, and is surrounded with hairs standing before each eye; and from the end of the nose or snout there is a pointed projecting part, which serves as a sheath or case to a piercer or sucker, which the creature thrusts into the skin to draw out the blood and humours which are its destined food; for it has no mouth that opens in the common way. This piercer or sucker is judged to be 700 times smaller than a hair, and is contained in another case within the first, and can be drawn in or thrust out at pleasure. The breast is very beautifully marked in the middle; the skin is transparent, and full of little pits; and from the under part of it proceed six legs, each having five joints, and their skin all the way resembling shagreen, except at the ends where it is smoother. Each leg is terminated by two claws, which are hooked, and are of an unequal length and size. These it uses as we would a thumb and middle finger; and there are hairs between these claws as well as all over the legs. On the back part of the tail there may be discovered some ring-like divisions, and a sort of marks which look like the strokes of a rod on the human skin; the belly looks like shagreen, and towards the lower end it is very clear, and full of pits: at the extremity of the tail there are two semicircular parts all covered over with hairs, which serve to conceal the anus. When the louse moves its legs, the motion of the muscles, which all unite in an oblong dark spot in the middle of the breast, may be distinguished perfectly, and so may the motion of the muscles of the head when it moves its horns. We may likewise see the various ramifications of the veins and arteries, which are white, with the pulse regularly beating in the arteries. But the most surprising of all the sights is the peristaltic motion of the guts, which is continued all the way from the stomach down to the anus.

If one of these creatures, when hungry, be placed on the back of the hand, it will thrust its sucker into the skin, and the blood which it sucks may be seen passing in a fine stream to the fore-part of the head; where, falling into a roundish cavity, it passes again in a fine stream to another circular receptacle in the middle of the head; from thence it runs thro' a small vessel to the breast, and then to a gut which reaches to the hinder part of the body, where in a curve it turns again a little upward; in the breast and gut the blood is moved without intermission, with a great force; especially in the gut, where it occasions such a contraction of the gut as is very surprising. In the upper part of the crooked ascending gut above-mentioned, the propelled blood stands still, and seems to undergo a separation, some of it becoming clear and watery, while other black particles are pushed forward to the anus. If a louse is placed on its back, two bloody darkish spots appear; the larger in the middle of the body, the lesser towards the tail; the motions of which are followed by the pulsation of the dark bloody spot, in or over which the white bladder

*Pediculus*. seems to lie. This motion of the systole and diastole is best seen when the creature begins to grow weak; and on pricking the white bladder, which seems to be the heart, the creature instantly dies. The lower dark spot is supposed to be the excrement in the gut.

Lice have been supposed to be hermaphrodites: but this is erroneous; for Mr Liewenhoeck observed, that the males have stings in their tails, which the females have not. And he supposes the smarting pain, which those creatures sometimes give, to be owing to their stinging with these stings when made uneasy by pressure or otherwise. He says, that he felt little or no pain from their suckers, though six of them were feeding on his hand at once.

In order to know the true history and manner of breeding of these creatures, Mr Liewenhoeck put two female lice into a black stocking, which he wore night and day. He found on examination that, in six days one of them had laid above 50 eggs; and, upon dissecting it, he found as many yet remaining in the ovary: whence he concludes, that in 12 days it would have laid 100 eggs. These eggs naturally hatch in six days, and would then probably have produced 50 males, and as many females; and these females coming to their full growth in 18 days, might each of them be supposed after 12 days more to lay 100 eggs; which eggs, in six days more, might produce a young brood of 5000; so that in eight weeks, one louse may see 5000 of its own descendants.

Signior Rhedi, who has more attentively observed these animals than any other author, has given several engravings of the different species of lice found on different animals. Men, he observes, are subject to two kinds; the common louse, and the crab-louse. He observes also, that the size of the lice is not at all proportioned to that of the animal which they infest; since the starling has them as large as the swan.

Some kinds of constitutions are more apt to breed lice than others; and in some places of different degrees of heat, they are certain to be destroyed upon people who in other climates are over-run with them. It is an observation of Ovidio, that the Spanish sailors, who are generally much afflicted with lice, always lose them in a certain degree of latitude in their voyage to the East Indies, and have them again on their returning to the same degree. This is not only true of the Spaniards, but of all other people who make the same voyage; for though they set out ever so lousy, they have not one of those creatures by the time they come to the tropic. And in the Indies there is no such thing as a louse about the body, though the people be ever so nasty. The sailors continue free from these creatures till their return; but in going back, they usually begin to be lousy after they arrive at the latitude of the Madeira islands. The extreme sweats, which the working people naturally fall into, between the latitude of Madeira and the Indies, drown and destroy the lice; and have the same effect as the rubbing over the lousy heads of children with butter and oil. The sweat, in these hot climates, is not rank as in Europe, and therefore it is not apt to breed lice; but where people return into latitudes where they sweat rank again, their nastiness subjects them to the same visitations of these vermin as before. The people in general in the Indies are very subject to lice in their

heads, tho' free from them on their bodies. The reason of this is, that their heads sweat less than their bodies, and they take no care to comb and clean them. The Spanish negroes wash their heads thoroughly once every week with soap, to prevent their being lousy. The makes them escape much better than the other negroes who are slaves there; for the lice grow so numerous in their heads, that they often eat large holes in them.

**PEDILUVIUM, or BATHING of the FEET.** The uses of warm bathing in general, and of the pediluvium in particular, are so little understood, that they are often preposterously used, and sometimes as injudiciously abstained from.

In the Edinburgh medical essays, we find an ingenious author's opinion of the warm pediluvium, notwithstanding that of Borelli, Boerhaave, and Hoffman, to the contrary, to be, That, the legs becoming warmer than before, the blood in them is warmed: this blood rarifying, distends the vessels; and in circulating imparts a great degree of warmth to the rest of the mass; and as there is a portion of it constantly passing through the legs, and acquiring new heat there, which heat is in the course of circulation communicated to the rest of the blood, the whole mass rarifying, occupies a larger space, and of consequence circulates with greater force. The volume of the blood being thus increased, every vessel is distended, and every part of the body feels the effects of it; the distant parts a little later than those first heated. The benefit obtained by a warm pediluvium is generally attributed to its making a derivation into the parts immersed, and a revulsion from those affected, because they are relieved; but the cure is performed by the direct contrary method of operating, viz. by a greater force of circulation through the parts affected, removing what was stagnant or moving too sluggishly there. Warm bathing is of no service where there is an irresolvable obstruction, though, by its taking off from a spasm in general, it may seem to give a moment's ease: nor does it draw from the distant parts, but often hurts by pushing against matter that will not yield with a stronger impetus of circulation than the stretched and diseased vessels can bear: so that where there is any suspicion of scirrhus, warm bathing of any sort should never be used. On the other hand, where obstructions are not of long standing, and the impacted matter is not obstinate, warm baths may be of great use to resolve them quickly. In recent colds, with slight humoral peripneumonies, they are frequently an immediate cure. This they effect by increasing the force of the circulation, opening the skin, and driving freely through the lungs that lentor which stagnated or moved slowly in them. As thus conducing to the resolution of obstructions, they may be considered as short and safe fevers; and in using them we imitate nature, which by a fever often carries off an obstructing cause of a chronic ailment. Borelli, Boerhaave, and Hoffman, are all of opinion, that the warm pediluvium acts by deriving a larger quantity of blood into the parts immersed. But arguments must give way to facts: the experiments related in the Medical Essays seem to prove to a demonstration, that the warm pediluvium acts by rarifying the blood.

A warm pediluvium, when rightly tempered, may be used

Pediment  
Peebles.

used as a safe cordial, by which circulation can be roused, or a gentle fever raised; with this advantage over the cordials and sudorifics, that the effect of them may be taken off at pleasure.

Pediluvia are sometimes used in the small-pox; but Dr Stevenson thinks their frequent tumultuous operations render that suspected, and at best of very doubtful effect; and he therefore prefers Monsr. Martin of Lausanne's method of bathing the skin, not only of the legs, but of the whole body, with a soft cloth dipped in warm water, every four hours, till the eruption; by which means the pustules may become universally higher, and consequently more safe.

PEDIMENT. See ARCHITECTURE, n° 77.

PEDLAR, a travelling foot-trader. See HAWKER.

Among the British and French the pedlars are despised; but it is otherwise in certain countries. In Spanish America, the business is so profitable, that it is thought by no means dishonourable; and there are many gentlemen in Old Spain, who, when their circumstances are declining, send their sons to the Indies to retrieve their fortunes in this way. Almost all the commodities of Europe are distributed through the southern continent of America by means of these pedlars. They come from Panama to Paita by sea; and in the road from the port last mentioned, they make Peura their first voyage to Lima. Some take the road through Caxamalá; others through Truxillo, along shore from Lima. They take their passage back to Panama by sea, and perhaps take with them a little cargo of brandy. At Panama they again stock themselves with European goods, returning by sea to Paita, where they are put on shore; there they hire mules and load them, the Indians going with them in order to lead them back. Their travelling expenses are next to nothing; for the Indians are brought under such subjection, that they find lodging for them, and provender for their mules, frequently thinking it an honour done them for their guests to accept of this for nothing, unless the stranger now and then, out of generosity or compassion, makes a small recompence.

In Poland, where there are few or no manufactures, almost all the merchandize is carried on by pedlars, who are said to be generally Scotsmen, and who, in the reign of king Charles II. are said to have amounted to no fewer than 53,000.

PEDUNCLE, in botany. See PEDICLE.

PEEBLES, or TWEEDALE, a county of Scotland, extending 25 miles in length, and 18 in breadth. It is bounded on the east by Etrick Forest, on the south by Annandale, on the west by Clydesdale, and on the north by Mid Lothian. Tweedale is a hilly country, well watered with the Tweed, the Yarrow, and a great number of smaller streams that fertilize the valleys, which produce good harvests of oats and barley, with some proportion of wheat. All the rivers of any consequence abound with trout and salmon. The lake called *West-Water Loch* swarms with a prodigious number of eels. In the month of August, when the west wind blows, they tumble into the river Yarrow in such shoals, that the people who wade in to catch them run the risk of being overturned. There is another lake on the borders of Annandale, called *Loch-*

*gennet*, which forms a cataract over a precipice 250 paces high: here the water falls with such a momentum as to kill the fish underneath. About the middle of this country is the hill or mountain of Braidalb, from the top of which the sea may be seen on each side of the island. Tweedale abounds with limestone and freestone. The hills are generally as green as the downs in Suffex, and feed innumerable flocks of sheep, that yield great quantities of excellent wool. The country is well shaded with woods and plantations, abounds with all the necessaries of life, and is adorned with many fine seats and populous villages. The earls of March were hereditary sheriffs of Tweedale, which bestows the title of *marquis* on a branch of the ancient house of Hay, earls of Errol, and hereditary high constables of Scotland. The family of Tweedale is, by the female side, descended from the famous Simon de Fraser, proprietor of great part of this country, who had a great share in obtaining the triple victory at Rossin. The chief, and indeed the only town of consequence in Tweedale, is PEEBLES, a small inconsiderable royal borough, and seat of a presbytery, pleasantly situated on the banks of the Tweed, over which there is at this place a stately stone bridge of five arches. In the neighbourhood of Peebles, near the village of Romana, on the river Lene, we see the vestiges of two Roman castella, or stationary forts; and a great many terraces on the neighbouring hills, which perhaps have served as itinerary encampments. In the shire of Tweedale there are many ancient and honourable families of the gentry. Among these, Douglas of Cavers, who was hereditary sheriff of the county, still preserves the standard and the iron mace of the gallant lord Douglas, who fell in the battle of Otterburn, just as his troops had defeated and taken Henry Percy, surnamed *Hottspur*. In the churchyard of Drumelzier, belonging to an ancient branch of the Hay-family, the famous Merlin is supposed to lie buried. There was an old traditional prophecy, that the two kingdoms should be united, when the waters of the Tweed and the Pafel should meet at his grave. Accordingly, the country people observe that this meeting happened in consequence of an inundation at the accession of James VI. to the crown of England.

PEEK, in the sea-language, is a word used in various senses. Thus the anchor is said to be a-peek, when the ship being about to weigh comes over her anchor in such a manner that the cable hangs perpendicularly between the haufe and the anchor.

To have a-peek is to bring the peek so as that the anchor may hang a-peek. A ship is said to ride a-peek, when lying with her main and fore yards hoisted up, one end of her yards is brought down to the shrouds, and the other raised up an end; which is chiefly done when the lies in rivers, lest other ships falling foul of the yards should break them. Riding a-broad peek, denotes much the same, excepting that the yards are only raised to half the height.

Peek is also used for a room in the hold, extending from the bits forward to the stem: in this room men of war keep their powder, and merchant-men their victuals.

PEER, in general, signifies an equal, or one of the same rank and station: hence in the acts of some coun-

Peebles  
Peer.

Peer.

cils, we find these words, *with the consent of our peers, bishops, abbots, &c.* Afterwards the same term was applied to the vassals or tenants of the same lord, who were called *peers*, because they were all equal in condition, and obliged to serve and attend him in his courts; and *peers in fiefs*, because they all held fiefs of the same lord.

The term *peers* is now applied to those who are imprisoned in an inquest upon a person for convicting or acquitting him of any offence laid to his charge: and the reason why the jury is so called, is because by the common law and the custom of this kingdom, every person is to be tried by his peers or equals; a lord by the lords, and a commoner by commoners. See the article JURY.

*PEER of the Realm*, a noble lord who has a seat and vote in the House of Lords, which is also called the *House of Peers*.

These lords are called *peers*, because though there is a distinction of degrees in our nobility, yet in public actions they are equal, as in their votes in parliament, and in trying any nobleman or other person impeached by the commons, &c. See PARLIAMENT.

*House of PEERS*, or *House of Lords*, forms one of the three estates of parliament. See LORDS and PARLIAMENT.

In a judicative capacity, the house of peers is the supreme court of the kingdom, having at present no original jurisdiction over causes, but only upon appeals and writs of error; to rectify any injustice or mistake of the law committed by the courts below. To this authority they succeeded of course upon the dissolution of the *Aula Regia*. For as the barons of parliament were constituent members of that court, and the rest of its jurisdiction was dealt out to other tribunals, over which the great officers who accompanied those barons were respectively delegated to preside, it followed, that the right of receiving appeals, and superintending all other jurisdictions, still remained in that noble assembly, from which every other great court was derived. They are therefore in all cases the last resort, from whose judgment no farther appeal is permitted; but every subordinate tribunal must conform to their determinations: The law reposing an entire confidence in the honour and conscience of the noble persons who compose this important assembly, that they will make themselves masters of those questions upon which they undertake to decide; since upon their decision all property must finally depend. See LORDS.

*PEERS of France*, are twelve great lords of that kingdom; of which six are dukes and six counts; and of these, six are ecclesiastics and six laymen: thus the archbishop of Rheims, and the bishop of Laon and Langres, are dukes and peers; and the bishops of Chalons on the Marne, Noyons, and Beauvais, are counts and peers. The dukes of Burgundy, Normandy, and Aquitaine, are lay peers and dukes; and the counts of Flanders, Champagne, and Toulouse, lay peers and counts. These peers still assist at the coronation of kings, either in person or by their representatives, where each performs the functions attached to his respective dignity: but as the fix lay peerages are all at present united to the crown, except that of the count of Flanders, six lords of the first quality are chosen to represent them: but the eccle-

siastical peers usually assist in person. At present the title of peer is bestowed on every lord whose estate is erected into a peerage; the number of which is uncertain, as it depends entirely on the king.

*PEERESS*, a woman who is noble by descent, creation, or marriage.

If a peeress, by descent or creation, marries a person under the degree of nobility, she still continues noble: but if she obtains that dignity only by marriage, she loses it, on her afterwards marrying a commoner; yet by the courtesy of England, she always retains the title of her nobility.

*PEWIT*, in ornithology. See LARUS.

*PEGASUS*, among the poets, a horse imagined to have wings; being that whereon Bellerophon was fabled to be mounted when he engaged the chimera. See CHIMERA.

The opening of the fountain Hippocrene on mount Helicon, is ascribed to a blow of Pegasus's hoof. It was feigned to have flown away to heaven, where it became a constellation. Hence

*Pegasus*, in astronomy, the name of a constellation of the northern hemisphere, in form of a flying horse. See ASTRONOMY, n° 206.

*PEGU*, a very considerable kingdom of Asia, beyond the Ganges. The country properly so called is but about 350 miles in length from north to south, and as much in breadth from east to west. It is bounded, on the north by the kingdoms of Arrakan and Ava; on the east, by the Upper and Lower Siam; on the south, by part of Siam and the sea; and on the west, by the sea and part of Arrakan. Considered in a larger sense however, as augmented by the conquests of its Barma kings, it extends as far north as the province of Yunnan in China, comprehending almost all the farther peninsula of India.

The kingdom of Pegu is said to have been founded about 1100 years ago. Its first king was a seaman; concerning whom and his successors we know nothing till the discovery of the East Indies by the Portuguese in the beginning of the 16th century. In 1518 the throne of Pegu was possessed by one Bressagukan, with whom Antony Correa the Portuguese ambassador solemnly concluded a peace in 1519. This monarch was possessed of a very large and rich empire, nine kingdoms being in subjection to him, whose revenues amounted to three millions of gold. We hear no farther account of his transactions after the conclusion of the treaty with the Portuguese. In 1539 he was murdered on the following occasion: Among other princes who were his tributaries was Para Mandara, king of the Barmas. These people inhabited the high lands called *Pangavirau*, to the northward of the kingdom of Pegu. Their prince, by one of the terms of his vassalage, was obliged to furnish the king of Pegu with 30,000 Barmas, to labour in his mines and other public works. As the king used frequently to go and see how his works went forward, and in these journeys took along with him none but his women, the Barmas observing these visits frequently repeated, formed a design of robbing the queen and all the concubines of their jewels; and pursuant to this design, the next time the king visited the works, they murdered him, and having stripped the ladies fled to their own country.

Peerefs

Pegu.

By this enormity all Pegu was thrown into confusion : but, instead of revenging the death of their king, the people divided every where into factions ; so that Dacha Rupi, the lawful heir to the crown, found himself unable to maintain his authority. Of these commotions, the king of the Barmas taking the advantage, not only shook off the yoke, but formed a design of conquering the kingdom of Pegu itself. With this view he invaded the country with an army of more than a million of foot, and 5000 elephants ; besides a great fleet which he sent down the river Ava towards Bagou, or Pegu, the capital of the empire ; while he himself marched thither by land. Just at this time Ferdinand de Mirales arrived at Pegu from Goa with a large galleon richly laden on account of the king of Portugal. As soon as Dacha Rupi heard of his coming, he sent to desire his assistance against the enemy. This he obtained by great presents and promises : and Mirales, setting out in a galliot, joined the king's ships. Had the numbers been any thing near an equality, the superior skill of Mirales would undoubtedly have gained the victory : But the fleet of the Barmas covered the whole river though as large as the Ganges, while that of Dacha Rupi could scarce be observed in comparison with them. Mirales did every thing that man could do, and even held out alone after the natives had deserted him ; but at last, oppressed and overwhelmed with numbers, he was killed, with all his men.

Thus Para Mandara became master of all Pegu ; after which he attacked the tributary kingdoms. In 1544 he besieged Martavan, the capital of a kingdom of the same name, then very great and flourishing. The land-forces which he brought against it consisted of 700,000 men, while by sea he attacked it with a fleet of 1700 sail ; 100 of which were large galleys, and in them 700 Portuguese commanded by John Cayero, who had the reputation of being a valiant and experienced officer. The siege, however, continued seven months, during which time the Barmas lost 120,000 men ; but at last the besieged king, finding himself straitened for want of provisions, and unable to withstand so great a power, offered terms of capitulation. The besiegers would admit of no terms, upon which the distressed king applied to the Portuguese in the service of his enemy ; for by their assistance he doubted not to be able to drive away the Barmas. Accordingly he sent one Seixas to Cayero, intreating him to receive himself, his family, and treasure, on board the four ships he had under his command ; offering, on that condition, to give half his riches to the king of Portugal, to become his vassal, and pay such tribute as should be agreed upon. Cayero consulted the principal officers, and in their presence asked Seixas what he thought the treasure might amount to. Seixas answered, that out of what he had seen, for he had not seen all, two ships might be loaded with gold, and four or five with silver. This proposal was too advantageous to be slighted ; but the rest of the officers envying the great fortune which Cayero would make, threatened to discover the whole to the king of Barma if he did not reject it. The unhappy king of Martavan had now no other resource but to set fire to the city, make a folly, and die honourably with the few men he had with him : but

even here he was disappointed ; for by the desertion of 4000 of his troops the enemy were apprised of his design, and prevented it. Thus betrayed, he capitulated with the Barma king for his own life and the lives of his wife and children, with leave to end his days in retirement. All this was readily granted, but the conqueror intended to perform no part of his promise. The city was plundered and burnt, by which above 60,000 persons perished, while at least an equal number were carried into slavery. Six thousand cannon were found in the place ; 100,000 quintals of pepper, and an equal quantity of other spices. The day after this destruction, 21 gibbets were erected on an hill adjoining to the city ; on which the queen, her children and ladies, were executed, by hanging them up alive by the feet : however, the queen expired with anguish before she suffered such a cruel indignity. The king, with 50 of his chief lords, was cast into the sea, with stones about their necks. This monstrous cruelty so provoked the tyrant's soldiers, that they mutined, and he was in no small danger of suffering for it : however, he found means to pacify them ; after which he proceeded to besiege Prom, the capital of another kingdom. Here he increased his army to 900,000 men. The queen by whom it was governed offered to submit to be his vassal ; but nothing would satisfy the Barma monarch less than her surrender at discretion, and putting all her treasure into his hands. This she, who knew his perfidy, refused to do ; on which the city was fiercely assaulted, but greatly to the disadvantage of the Barmas, who lost near 100,000 men. However, the city was at last betrayed to him, when Mandara behaved with his usual cruelty. Two thousand children were slain, and their bodies cut in pieces and thrown to the elephants ; the queen was stripped naked, publicly whipped, and then tortured till she died ; the young king was tied to her dead body, and both together cast into a river, as were also 300 other people of quality.

While the tyrant was employed in fortifying the city, he was informed, that the prince of Ava had sailed down the river Queytor with 400 rowing vessels having 30,000 soldiers on board ; but that, hearing of the queen's disaster, he stopped at Mcletay a strong fortress about 12 leagues north of Prom, where he waited to be joined by his father the king of Ava with 80,000 men. On this news the Barma king sent his foster-brother Chaumigrem along the river-side with 200,000 men, while he himself followed with 100,000 more. The prince in this emergency burnt his barks, forming a vanguard of the mariners ; and, putting his small army in the best position he could, expected the enemy. A most desperate engagement ensued, in which only 800 of the prince's army were left, and 115,000 out of 200,000 Barmas who opposed him were killed. The 800 Avas retired into the fort : but Mandara coming up soon after, and being enraged at the terrible havoc made in his army, attacked the fortress most violently for seven days ; at the end of which time, the 800, finding themselves unable to hold out any longer, rushed out in a dark and rainy night, in order to sell their lives at as dear a rate as possible. This last effort was so extremely violent, that they broke through the enemy's troops in several places, and even pressed so hard on the king himself that he was forced to jump  
into

into the river. However, they were at last all cut off, but not before they had destroyed 12,000 of their enemies.

Mandara having thus become master of the fort, commanded it to be immediately repaired; and failed up the river to the port of Ava, about a league from the capital, where he burnt between 2000 and 3000 vessels, and lost in the intercept about 8000 men. The city itself he did not think proper to invest, as it had been newly fortified, was defended by a numerous garrison, and an army of 80,000 men was advancing to its relief. The king also, apprehensive of Mandara's power, had implored the protection of the emperor Siam; offering to become his tributary on condition that he would assist him with his forces in recovering the city of Prom. To this the emperor readily assented; which news greatly alarmed the Barma monarch, so that he dispatched ambassadors to the Kalaminhm or sovereign of a large territory adjacent, requesting him to divert the emperor from his purpose. On the ambassadors return from this court it appeared that the treaty had already taken effect; but as the season was not yet arrived for invading Ava, Chaumigren the king's foster-brother was sent with 150,000 men to reduce Sembali or Savadi the capital of a small kingdom about 130 leagues north-east from Pagu. The general, however, failed in his attempt; and afterwards endeavouring to revenge himself on a town in the neighbourhood, he was surprized by the enemy and put to flight.

In the mean time the empire of Siam fell into great distractions; the king together with the heir to the crown were murdered by the queen, who had fallen in love with an officer, whom she married after her husband's death. However, both of them were soon after killed at an entertainment; and the crown was given to a natural brother of the late king, but a coward and a tyrant. On this Mandara resolved to invade the country; and, his principal courtiers concurring in the scheme, he collected an army of 800,000 men, with no fewer than 20,000 elephants. In this army were 1000 Portuguese, commanded by one James Suarez, who already had a pension of 200,000 ducats a-year from the king of Pegu, with the title of his brother, and governor of the kingdom. With this formidable army he set out in April 1548. His first achievement was the taking of a fortress on the borders of the enemy's country; before which, being several times repulsed, and having lost 3000 of his men, he revenged himself by putting all the women to the sword. He next besieged the capital of itself; but though the siege was continued for five months, during which time the most violent attacks were made upon it, the assailants were constantly repulsed with great loss. However, it was still resolved to continue the siege; and a mound of earth was raised, on which were placed 40 pieces of cannon ready to batter it anew, when, in October, advice was received of a rebellion having broke out in Pegu.

The person who headed the rebels on the present occasion was Shoripam Shay, near akin to the former monarch slain twelve years before. He was a religious person, of great understanding, and esteemed a saint. As he was a famous preacher, he made a sermon, in which he set forth the tyranny of the Barmas in such a manner, that he was immediately taken out

of the pulpit and proclaimed king by the people, who, as a token of sovereignty, gave him the title of *Shemindoo*. The first act of sovereignty which he exerted was to cut in pieces 15,000 Barmas, and seize on the treasure: and so agreeable was this change of government to all ranks of people, that in three weeks time all the strong-holds of Pegu fell into his hands.

On this news the king immediately raised the siege in which he was engaged, and in 17 days got to Martavan. Here he was informed, that Shemindoo had posted 500,000 men in different places, in order to intercept his passage; at the same time that he had the mortification to find 50,000 of his best troops deserted. To prevent a greater desertion, after 14 days stay, he departed from Martavan, and soon met Shemindoo at the head of 600,000 men. A desperate engagement followed; in which Shemindoo was entirely defeated, with the loss of 300,000 men. Of the Barma troops were slain 60,000; among whom were 280 Portuguese.

The morning after this victory, the tyrant marched to the city; the inhabitants of which surrendered, on condition of having their lives and effects spared. The kingdom being thus again brought under his subjection, his next step was to punish the principal persons concerned in the rebellion: their heads he cut off; and confiscated their estates, which amounted to no less than ten millions of gold. Others say, that he put all without distinction to the sword, excepting only 12,000, who took shelter in James Suarez's house; that alone affording an asylum from the general slaughter. The plunder was incredible, Suarez alone getting three millions. All these cruelties, however, were insufficient to secure the allegiance of the tyrant's subjects: for in less than three months news was brought that the city of Martavan had revolted; and that the governor had not only declared for Shemindoo, but murdered 2000 Barmas. Mandara then summoned all the lords of the kingdom to meet him with their force, within 15 days, at a place called *Mouchau*, not far from his capital, whither he himself went with 300 men, to wait their arrival. But in the mean time he received intelligence that the shemin or governor of Zatan, a city of some consequence, had submitted to Shemindoo, and also lent him a large sum of gold. The shemin was immediately sent for in order to be put to death: but he, suspecting Mandara's design, excused himself by pretending sickness; after which, having consulted with his friends, he drew together about 600 men; and having with these privately advanced to the place where the king was, he killed him, with the few attendants that were about him at the time. The guards in the court being alarmed with the noise, a skirmish ensued with the shemin's men, in which about 800 were slain on both sides, most of them Barmas. The shemin then retreated to a place called *Pontel*; whither the people of the country, hearing of the death of the king, who was universally hated, resorted to him. When he had assembled about 5000 men, he returned to seek the troops which the late king had with him; and finding them dispersed in several places, easily killed them all. With the Barmas were slain 80 out of 300 Portuguese. The remainder surrendered, with Suarez their leader; and were spared, on condition of their remaining

Pegu. remaining in the service of the shemin.

The shemin now finding his forces daily increase, assumed the title of king; and, to render himself the more popular, gave out, that he would exterminate the Barmas so effectually, as not to leave one in all the kingdom. It happened, however, that one of those who were with the late king at the time he was murdered, escaped the general slaughter; and, swimming over the river, informed Chaumigrem of the king's death. He had with him 180,000 men, all of them natives of Pegu, excepting 30,000 Barmas. He knew very well, that if the natives had known that the king was dead, he and all his Barmas would have instantly been put to the sword. Pretending therefore that he had received orders to put garrisons into several places, Chaumigrem dispatched all the natives into different parts; and thus got rid of those whom he had so much cause to fear. As soon as they were marched, he turned back upon the capital, and seized the king's treasure, together with all the arms and ammunition. He then set fire to the magazines, arsenals, palace, some of whose apartments were ciled with gold, and 2000 rowing vessels which were on the river. Then, destroying all the artillery, he fled with the 30,000 Barmas to his own country, being pursued in vain by the natives of Pegu.

Thus the shemin of Zatan was left in quiet possession of the kingdom; but, by his repeated acts of tyranny and cruelty, he so disgusted his subjects, that many fled to foreign countries, while others went over to Shemindoo, who began now to gather strength again. In the mean time, James Suarez, the Portuguese whom we have often mentioned, lost his life by attempting to ravish a young woman of distinction; the shemin being unable to protect him, and obliged to give him up to the mob, who stoned him to death. The shemin himself did not long survive him; for, being grown intolerable by his oppressions, most of his followers abandoned him, and he was besieged in his capital by Shemindoo with an army of 200,000 men, and soon after slain in a rally: so that Shemindoo now seemed to be fully established in the throne. But in the mean time Chaumigrem, the foster-brother to the deceased king, hearing that Pegu was very ill provided with the means of defence, invaded the kingdom with an army of 300,000 men. Shemindoo met him with three times their number; but his men, being all natives of Pegu, were inferior in strength, notwithstanding their numbers, to the enemy. The consequence was, that Shemindoo was defeated with prodigious slaughter, and Chaumigrem caused himself to be proclaimed king of Pegu. Shortly after, Shemindoo himself was taken; and, after being treated with the utmost of cruelty, was beheaded.

The history of Chaumigrem is very imperfect. However, we know that he was a very great conqueror, and not at all inferior in cruelty to his predecessors. He reduced the empire of Siam and Arrakan, and died in 1583; being succeeded by his son named *Pranjinsko*, then about 50 years of age. When this prince ascended the throne, the kingdom of Pegu was in its greatest height of grandeur; but by his tyranny and obliquity he lost all that his father had gained. He died in 1599, and after his death the kingdom of Pegu became subject to Arrakan; nor have we any farther distinct hi-

story of it.

The air of Pegu is very healthy, and presently recovers sick strangers. The soil also is very rich and fertile in corn, rice, fruit, and roots; being enriched by the inundations of the river Pegu, which are almost incredible, extending above 30 leagues beyond its channel. It produces also good timber of several kinds. The country abounds with elephants, buffaloes, goats, hogs, and other animals, particularly game; and deer is so plenty in September and October, that one may be bought for three or four pence: they are very fleshy, but have no fat. There is store of good poultry; the cocks are vastly large, and the hens very beautiful. As for fish, there are many sorts, and well tasted. In Pegu are found mines, not only of gold, iron, tin, and lead, or rather a kind of copper, or mixture of copper and lead, but also of rubies, diamonds, and sapphires. The rubies are the best in the world; but the diamonds are small, and only found in the claws of poultry and pheasants. Besides, only one family has the privilege of felling them; and none dare open the ground to dig for them. The rubies are found in a mountain in the province of Kablan, or Kapelan, between the city of Pegu and the port of Sirian.

The inhabitants are of an olive, or rather a tawny complexion. The women are branded by some travellers, as having shoo off all modesty, on account of their exposing some parts of their bodies which ought to be concealed from sight. Some also tell us, that the men wear bells, which at a certain age, *viz.* 25 or 30, or, according to others, when they are capable of making use of women, are inserted on each side the virile member between the skin and the flesh, which is opened for that purpose, and healed in seven or eight days. The Peguers may be ranked among the most superstitious of all mankind. They maintain and worship crocodiles; and will drink nothing but the waters of the ditches where those monstrous animals harbour. By thus exposing themselves to the manifest hazard of their lives, they have frequently the misfortune to be devoured. They have five principal festivals in the year, called *sapants*, which they celebrate with extraordinary magnificence. In one of them the king and queen make a pilgrimage about 12 leagues from the city, riding on a triumphal car, so richly adorned with jewels, that it may be said without an hyperbole, that they carry about with them the value of a kingdom. This prince is extremely rich; and has in the chapel of his palace, idols of inestimable value, some of them being of massy gold and silver, and adorned with all sorts of precious stones. The talapoins, or priests of this country, have no possessions; but such is the respect paid them by the people, that they are never known to want. They preach to them every Monday, not to commit murder; to take from no person any thing belonging to him; to do no hurt; to give no offence; to avoid impurity and superstition; but above all, not to worship the devil: but these discourses have no effect in the least respect. The people, attached to manichæism, believe, that all good comes from God, that the devil is the author of all the evil that happens to men; and that therefore they ought to worship him, that he may not afflict them. This is a common notion among the Indian idolaters.

The inhabitants of Pegu are accused by some authors with

Pegu.

with being slovenly in their houses, and nasty in their diet, on account of their seasoning their victuals with fido, a composition made of stinking fish, reduced to a consistency like mustard, so nauseous and offensive, that none but themselves can endure the smell of it. Balbi says, he could sooner bear the scent of stinking carrion; and yet with this they season their rice, and other soups, instead of oil or butter. As they have no wheat in this country, their bread is rice made into cakes. Their common drink is water, or a liquor distilled from coccat-nut water.

The men here, as in most eastern countries, buy their wives, or pay their parents a dowry for them. They have an odd custom; which is to offer their daughters to strangers, and hire them out for a time: some say they hire out their wives in the same manner. These marriages for a term are well regulated, and often prove very beneficial to the occasional husband. Most of the foreigners who trade hither, marry a wife for the time of their stay. In case of a separation, the father is obliged to take care of the boys, and the mother of the girls. We are told that no woman is looked upon the worse, but rather the better, for having had several European husbands: nay, we are told, that no person of fashion in Pegu, from the gentleman to the king, will marry a maiden, till some acquaintance or stranger has had the first night's lodging with her.

In Pegu, the inheritance of all land is in the king: he is likewise the heir of all his subjects who die without issue; but in case they have children, two-thirds go to them, and the rest to his majesty.

When a person falls sick, we are told that they generally make a vow to the devil, from whom they believe all evil comes. Then a scaffold is built, and victuals are spread on the top of it to solace Old Nic, and render him propitious. This feast is accompanied with lighted candles and music; and the whole is managed by an undertaker called the *devil's father*.

The commodities exported from this country are gold, silver, rubies, musk, benjamin, long-pepper, tin, lead, copper; lakka, or gum-lac, whereof they make hard wax; rice; rice-wine; and some sugar-canes, of which they would have plenty, but that the elephants eat them. It may be observed, that under the name of *rubies*, the Peguers comprise topazes, sapphires, amethysts, and other stones; which they distinguish by saying the blue, the violet, and the yellow rubies. The true ruby is red, transparent, or sparkling, inclining near the surface, to the violet of the amethyst. Cotton cloths from Bengal and Coromandel, with some striped silks, are best for the Pegu market, and silver of any sort will go off there; for the king, in return for his eight and a half *per cent.* duty on it, allows the merchants to melt it down, and put what copper alloy they please in it. They wear none of our European commodities in Pegu but hats and ribbons. The gentry will give extravagant prices for fine beaver hats, which they wear without any coats. They are no less fond of ribbons flowered with gold and silver, which they wear round their hats.

As to the religion of the Peguers, it is the same at bottom with that which prevails over the rest of India and Tibet; only varies in dress somewhat in different countries, according to the humour or interest of the priests. They hold the existence of one supreme God,

of whom they make no image; but they have many inferior created gods, whose images are set up in the temples for the laity to worship. Not content with these, we are told they worship the devil also. Many are seen to run about the streets every morning, with rice in one hand and a torch in the other, crying aloud, that they are going to give the devil his breakfast, that he may not hurt them all the day. Besides the manichean doctrine of two principles, one the author of good, and the other of evil, from whence their worshipping the devil has its rise, they believe an eternal succession of worlds without creation. The Peguers hold the doctrine of the Metempsychosis, or transmigration of the human soul, which, after passing through the bodies of various animals, shall attain to the perfection and felicity of their gods; which in effect is no other than a state of annihilation. They have a strong opinion of the sanctity of apes and crocodiles, inasmuch that they believe the persons to be perfectly happy that are devoured by them. Their temples are of a conic form, and some of them a quarter of a mile round. They observe a great many festivals, some of which are called *Japan*. The images of their inferior gods are in a sitting posture, with their legs across, and toes of equal length: their arms and hands very small in proportion to their bodies; their faces longer than human; their ears long, and the lapets very thick. The congregation bow to them when they come in and when they go out; and that is all the worship which they pay to them. The priests of Pegu, called *talapouts*, are a sort of mediant friars. They observe celibacy; and eat but once a-day; living in the woods, in a sort of nests or cages built on the tops of trees for fear of the tygers. They preach frequently, lead very innocent lives, and are very hospitable and humane.

The king of Pegu's revenues arise chiefly from the rent of lands, of which he is the sole proprietor. Another branch of it are the duties paid for the commodities imported or exported. In a word, he is judged the richest monarch in the world, next to the emperor of China.

PEINE FORT ET DURE, (Lat. *poena fortis et dura*), signifies a special punishment inflicted on those who, being arraigned of felony, refuse to put themselves on the ordinary trial, but stubbornly stand mute; it is vulgarly called *pressing to death*. See ARRANGMENT.

PEIRCE (James), an eminent dissenting minister, was born at Wapping, in London, in the year 1674, and was educated at Utrecht and Leyden; after which he spent some time at Oxford, in order to enjoy the benefit of frequenting the Bodleian library. He then for two years preached the Sunday-evening's lecture at the meeting-house in Miles-Lane, London, and then settled at Cambridge. In 1713, he was removed to a congregation at Exeter, where he continued till the year 1718: when the Calvinists among the dissenters proposing a subscription to articles of faith to be signed by all the dissenting ministers in the kingdom, several articles were proposed to him and Mr John Hallet, another dissenting minister at Exeter, in order to their subscribing them, they both refused, imagining this proceeding of their dissenting brethren to be an unworthy impolition on religious liberty and private judgment; for which they were ejected from their congregation. Upon this, a new meeting was opened

Pekin. for them at Exeter, of which Mr Pierce continued minister till his death, in 1726. He was a man of the strictest virtue, exemplary piety, and great learning. He wrote, 1. *Exercitatio philosophica de Homemeria Anaxagorea.* 2. Thirteen pieces on the Controversy between the Church of England and the Dissenters. 3. Ten pieces on the Controversy about the Ejection at Exeter. 4. Six pieces on the Doctrine of the Trinity. 5. A Paraphrase and Notes on the Epistles of St Paul to the Colossians, Philippians, and Hebrews. 6. An Essay in favour of giving the Eucharist to Children. 7. Fourteen Sermons.

PEKIN, the capital city of the empire of China in Asia, where the emperor generally resides. It is an exact square, and divided into two parts; namely, that which contains the emperor's palace, which is in the new city, or the Tartars city, because it is inhabited by Tartars ever since they conquered this empire; the other, called the *Old City*, is inhabited by the Chinese. The circuit of both these together is 52 Chinese paces, each of which contains 240 geometrical paces. The gates of this city are high and well arched, supporting buildings of nine stories high; the lowest of which is for the soldiers when they come off guard. The gates are nine in number; and before each is an open space, which serves for a parade. The streets are as straight as a line, most of which are three miles in length, and about 120 feet wide, with shops on both sides; but the houses are poorly built, and have only a ground-floor. It is surprising to see what numbers of people there are in the streets, and not one woman among them; there is always a great confusion, occasioned by the vast numbers of horses, camels, mules, asses, waggons, carts, and chairs, without reckoning the several mobs which gather about jugglers, ballad-singers, and the like. Persons of distinction have always a horseman, who goes before them to clear the way. All the riches and merchandises of the empire are continually pouring into this city. There are always hackney-horses and chairs in various parts, which stand ready to be hired for a trifle; and the owners of them know every street and house where any considerable person lives. All the great streets are guarded by soldiers, who patrol night and day with swords by their sides, and whips in their hands, to chastise those who make any disturbance, or take them into custody. The little streets have lattice-gates at their entrance into the great streets, which are shut up at nights, and guarded by soldiers, who suffer no assemblies in the streets at that time, and examine all that pass along. The emperor's palace is of vast extent, and surrounded by a brick wall, with pavilions at each corner, encompassed by galleries supported by columns. But it would be endless to give an account of the different apartments, with their ornaments and furniture, as well as of the different magazines, and rich commodities kept therein; not to mention the supreme courts of justice, which are six in number, and are only to be controuled by the emperor and the grand council. Those who have computed the compass of this city a different way, observe, that it is 20 miles in circumference, and that the number of inhabitants is at least 2,000,000; that the walls are so high that they cover the town, and are broad enough for several horsemen to ride a breast;

and there are strong towers a bow-shot distant from each other. The walls of the emperor's palace, including that and the gardens, are about two miles in length; and the architecture of the structures entirely different from that of the Europeans, for they are covered with tiles of a shining beautiful yellow. The temples and the towers of this city are so numerous, that it is difficult to count them. The country about it is plain, but sandy, and not very fruitful; yet provisions of all kinds are exceeding plentiful, they being, as well as the merchandises, brought from other parts by means of canals cut from the rivers, and always crowded with vessels of different sizes. An earthquake which happened here in 1731 buried above 100,000 persons in the ruins of the houses, which were thrown down. E. Long. 116. 41. N. Lat. 39. 54.

PELAGIANS, a Christian sect who appeared about the fifth or end of the fourth century. They maintained the following doctrines. 1. That Adam was by nature mortal, and whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That new-born infants are in the same situation with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty, being sufficient, &c. The founder of this sect was

PELAGIUS, a native of Great Britain; but whether of England, Scotland, or Wales, is as uncertain as it is immaterial. He was born towards the close of the fourth century, and educated in the monastery of Banchor, in Wales, of which he became a monk, and afterwards abbot. In the early part of his life he went over to France, and thence to Rome, where he had the infolence to promulgate certain opinions somewhat different from those of the infallible church. His morals being irreproachable, he gained many disciples; and the dreadful hereby made so rapid a progress, that, for the salvation of souls, it became necessary for the pope to exert his power. Pelagius, to avoid the danger, in the year 409, passed over to Sicily, attended by his friend and pupil Celestius. In 411 they landed in Africa, continued some time at Hippo, and were present at the famous conference between the Catholics and Donatists which was held at Carthage in 412. From thence they travelled to Egypt; and from Egypt, in 415, to Palestine, where they were graciously received by John bishop of Jerusalem. In the same year, Pelagius was cited to appear before a council of seventeen bishops, held at Diospolis. They were satisfied with his creed, and absolved him of heresy. The African bishops, however, being displeased with their proceedings, appealed to the Roman pontiff: he first approved, and afterwards condemned the opinions of Pelagius, who, with his pupil Celestius, was publicly excommunicated; and all the bishops who refused to subscribe the condemnation of the Pelagian heresy were immediately deprived. What became of him after this period, is entirely un-

Pelagians,  
Pelagius.

**Pelafgi** known; but it seems very probable that he retired to  
**Pelican.** Panchor, and died abbot of that monastery. He  
 wrote, 1. *Expositio in epist. Paulinas* lib. xiv.  
 2. *Epistola ad Demetriadem de virginitate*. 3. *Ex-*  
*planationis symboli ad Damasum*. 4. *Epistole ad vidua-*  
*am dua*. 5. *De libero arbitrio*. These and many  
 other fragments are scattered among the works of St  
 Jerom. They are also collected by Garnerius, and  
 published in *Append. op. Mercatoris*, p. 373. *Cave*.

**PELASGL**. See **PELASGIOTIS**.

**PELASGIA**, (Pliny); the ancient name of *Lef-*  
*bos*; so called from the Pelafgi, its first inhabitants,  
 (Diodorus Siculus). Also the ancient name of *Pelo-*  
*ponnesus*, from Pelafgius, a native of the country,  
 (Nicolaus Damascenus, Ephorus).

**PELASGICUM**, (Pausanias, Pliny); the north  
 wall of Athens; so called from the builders, the Pe-  
 lasgi. There was an execration pronounced on any  
 that should build houses under this wall; because the  
 Pelafgi, while dwelling there, entered into a conspira-  
 cy against the Athenians, (Thucydides).

**PELASGIOTIS**, a third part of Thessaly, (Stra-  
 bo); so called from a very ancient people, the Pelaf-  
 gi, called *Pelafgiotæ*, (Ptolemy); who formerly, to-  
 gether with the Æolians, occupied Thessaly, and  
 thence that part was called *Pelafgicum Argos*; besides  
 many other parts of Greece. Their name *Pelafgi*, or  
*Pelargi*, denoting storms, was given them from their  
 wandering roving life, (Strabo). The poets extend  
 the appellation to Greeks in general. *Pelafgus*, the  
 epithet. Some of the inhabitants of Crete were called  
*Pelafgi*, (Homer); who thus also calls the neigh-  
 bouring people to the Cilicians in Troas. The Pe-  
 lasgi were originally of Arcadia, (Hesiod); but Æs-  
 chylus makes Argos, near Mycenæ, their country.  
 The Pelafgiotis was situate between Pieria and Mace-  
 donia to the north and west, Thessaliotis to the south,  
 and Magnesia to the east, (Strabo, Pliny).

**PELE**, (Stephanus); two towns of this name in  
 Thessaly; the one subject to Eurypylus, the other to  
 Achilleus; both extinct. *Peleus* the gentilitious name,  
 id.

**PELETHRONIUM**, (Nicander and Scholiast);  
 a town of Thessaly, situate in a flowery part of mount  
 Pelios; and hence the appellation *throna*, signifying  
 flowers. *Pelethronii*, the people, (Virgil); the *Lapi-*  
*thæ* so called, who first broke horses. Lucan says  
 the Centaurs were natives of that place; to whom Vir-  
 gil assigns mount Othrys. Most authors, however,  
 ascribe the breaking of horses to the Centaurs. Some  
 make the Lapithæ and Centaurs the same; others a  
 different people; allowed however to be both of Thes-  
 saly. Their story is greatly involved in fable.

**PELICAN**, in ornithology. See **PELICANUS**.

**PELICAN**, in chemistry, is a glass alembic con-  
 sisting of one piece. It has a tubulated capital, from  
 which two opposite and crooked beaks pass out, and  
 enter again at the belly of the cucurbit. This vessel  
 has been contrived for a continued distillation and co-  
 habitation, which chemists call *circulation*. The volatile  
 parts of substances put into this vessel rise into the ca-  
 pital, and are obliged to return through the crooked  
 beaks into the cucurbit; and this without interruption,  
 or luting and unluting the vessels.

Although the pelican seems to be a very convenient

instrument, it is nevertheless little used, and even Pelicanus.  
 much neglected at present; either because the modern  
 chemists have not so much patience as the ancient che-  
 mists had for making long experiments; or because  
 they find that two matresses, the mouth of one of  
 which is inserted into the mouth of the other, produce  
 the same effect.

**PELICANUS**, in ornithology, a genus belonging  
 to the order of anseres. The bill is straight, without  
 teeth, and crooked at the point; the face is naked,  
 and the feet are palmated. There are eight species,  
 principally distinguished by the shape of their tails.  
 The most remarkable are,

1. The carbo, or corvora, sometimes exceeds seven  
 pounds in weight; the length three feet four; the  
 extent four feet two; the bill dusky, five inches long,  
 destitute of nostrils; the base of the lower mandible is  
 covered with a naked yellow skin, that extends under  
 the chin, and forms a sort of pouch; a loose skin of  
 the same colour reaches from the upper mandible round  
 the eyes and angles of the mouth; the head and neck  
 are of a sooty blackness; but under the chin of the  
 male the feathers are white: and the head in that sex  
 is adorned with a short loose pendant crest; in some  
 the crest and hind-part of the head are streaked with  
 white. The coverts of the wings, the scapulars, and  
 the back, are of a deep green, edged with black, and  
 glossed with blue; the quill-feathers and tail dusky;  
 the legs are short, strong, and black; the middle claw  
 serrated on the inside; the irides are of a light ash-  
 colour.

These birds occupy the highest parts of the cliffs  
 that impend over the sea: they make their nests of  
 sticks, sea-tang, grafs, &c. and lay six or seven white  
 eggs of an oblong form. In winter they disperse a-  
 long the shores, and visit the fresh waters, where they  
 make great havoc among the fish. They are remarka-  
 bly voracious, having a most sudden digestion, pro-  
 moted by the infinite quantity of small worms that fill  
 their intestines. The corvora has the rankest and  
 most disagreeable smell of any bird, even when alive.  
 Its form is disagreeable; its voice hoarse and croaking,  
 and its qualities base. These birds, however, have  
 been trained to fish like falcons to fowl. Whitelock  
 tells us, that he had a cast of them manned like hawks,  
 and which would come to hand. He took much plea-  
 sure in them; and relates, that the best he had  
 was one presented him by Mr Wood, master of the  
 corvorants to Charles I. It is well known that the  
 Chinese make great use of these birds, or a congen-  
 erous sort, in fishing; and that not for amusement, but  
 profit.

2. The graculus, or shag, called in the north of  
 England the *crane*, is much inferior in size to the cor-  
 vorant: the length is 27 inches; the breadth three  
 feet six; the weight three pounds three quarters. The  
 bill is four inches long, and more slender than that of  
 the preceding: the head is adorned with a crest two  
 inches long, pointing backward; the whole plumage  
 of the upper part of this bird is of a fine and very shi-  
 ning green; the edge of the feathers a purplish black;  
 but the lower part of the back, the head, and neck,  
 wholly green; the belly is dusky; the tail of a dusky  
 hue, tinged with green; the legs are black, and like  
 those of the corvorant.

Both.

Both these kinds agree in their manners, and breed in the same places; and, what is very strange in webbed-footed birds, will perch and build in trees: both swim with their head quite erect, and are very difficult to be shot; for, like the grebes and divers, as soon as they see the flash of the gun, they pop under water, and never rise but at a considerable distance.

3. The bassanus, gannet, or solan goose, weighs seven pounds; the length is three feet one inch; the breadth six feet two inches. The bill is six inches long, straight almost to the point, where it inclines down; and the sides are irregularly jagged, that it may hold its prey with more security: about an inch from the base of the upper mandible is a sharp process pointing forward; it has no nostrils; but in their place a long furrow, that reaches almost to the end of the bill: the whole is of a dirty white, tinged with ash-colour. The tongue is very small, and placed low in the mouth; a naked skin of a fine blue surrounds the eyes, which are of a pale yellow, and are full of vivacity: this bird is remarkable for the quickness of its sight. Martin tells us, that *solan* is derived from an Irish word expressive of that quality.

From the corner of the mouth is a narrow slip of black bare skin, that extends to the hind-part of the head; beneath the chin is another, that, like the pouch of the Pelican, is dilatable, and of size sufficient to contain five or six entire herrings; which in the breeding season it carries at once to its mate or young.

The young birds, during the first year, differ greatly in colour from the old ones; being of a dusky hue, speckled with numerous triangular white spots; and at that time resemble in colours the speckled diver. Each bird, if left undisturbed, would only lay one egg in the year; but if that be taken away, they will lay another; if that is also taken, then a third; but never more than that season. Their egg is white, and rather less than that of the common goose; the nest is large, and formed of any thing the bird finds floating on the water, such as grass, sea-plants, shavings, &c. These birds frequent the Isle of Alisa, in the frith of Clyde; the rocks adjacent to St Kilda; the Stack of Soulikery, near the Orkneys; the Skelig Isles, off the coasts of Kerry, Ireland; and the Bass Isle, in the frith of Edinburgh: the multitudes that inhabit these places are prodigious. Dr Harvey's elegant account of the latter will serve to give some idea of the numbers of these, and of the other birds that annually migrate to that little spot.

"There is a small island, called by the Scotch *Bass Island*, not more than a mile in circumference; the surface is almost wholly covered during the months of May and June with nests, eggs, and young birds; so that it is scarcely possible to walk without treading on them: and the flocks of birds in sight are so prodigious, as to darken the air like clouds; and their noise is such, that you cannot without difficulty hear your next neighbour's voice. If you look down upon the sea from the top of the precipice, you will see it on every side covered with infinite numbers of birds of different kinds, swimming and hunting for their prey: if in sailing round the island you survey the hanging cliffs, you may see in every crag or fissure of the broken rocks innumerable birds of various sorts and sizes, more than the stars of heaven when viewed in a serene

night: if from afar you see the distant flocks, either flying to or from the island, you would imagine them to be a vast swarm of bees."

Nor do the rocks of St Kilda seem to be less frequented by these birds; for Martin assures us, that the inhabitants of that small island consume annually no less than 22,600 young birds of this species, besides an amazing quantity of their eggs, these being their principal support throughout the year: they preserve both eggs and fowls in pyramidal stone-buildings, covering them with turf-ashes to preserve them from moisture. This is a dear-bought food, earned at the hazard of their lives, either by climbing the most difficult and narrow paths, where (to appearance) they can barely cling, and that too at an amazing height over the raging sea; or else, being lowered down from above, they collect their annual provision, thus hanging in midway air; placing their whole dependence on the uncertain footing of one person, who holds the rope by which they are suspended at the top of the precipice. The young birds are a favourite dish with the North Britons in general: during the season, they are constantly brought from the Bass Isle to Edinburgh, sold at 20d. a-piece, are roasted, and served up a little before dinner as a whet.

The gannets are birds of passage. Their first appearance in these islands is in March; their continuance there till August or September, according as the inhabitants take or leave their first egg; but, in general, the time of breeding, and that of their departure, seems to coincide with the arrival of the herring, and the migration of that fish (which is their principal food) out of those seas. It is probable that these birds attend the herring and pilchard during their whole circuit round the British islands; the appearance of the former being always esteemed by the fishermen as a sure preface of the approach of the latter. It migrates in quest of food as far south as the mouth of the Tagus, being frequently seen off Lisbon during the month of September, plunging for sardines, fish resembling, if not the same with our pilchard.

In the month of August Mr Pennant has observed in Cathness their northern migrations: he has seen them passing the whole day in flocks, from five to fifteen in each: in calm weather they fly high; in storms they fly low and near the shore; but never cross over the land, even when a bay with promontories intervenes, but follow, at an equal distance, the course of the bay, and regularly double every cape. Many of the parties made a sort of halt for the sake of fishing: they soared to a vast height, then darting headlong into the sea, made the water foam and spring up with the violence of their descent; after which they pursued their route. Our author inquired whether they ever were observed to return southward in the spring, but was answered in the negative; so it appears that they annually encircle the whole island.

They are well known on most of the coasts of England, but not by the name of the *Solan goose*. In Cornwall and in Ireland they are called *gannets*; by the Welsh, *gan*. Mr Ray supposed the Cornish gannet to be a species of large gull: a very excusable mistake; for during his six months residence in Cornwall, he never had an opportunity of seeing that bird, except flying; and in the air it has the appearance of

Pelicanus. a gull. On that supposition he gave our skua the title of *cataracla*, a name borrowed from Aristotle, and which admirably expresses the rapid descent of this bird on its prey. Mr Moyle first detected this mistake; and the Rev. Dr William Borlase, by presenting us with a fine specimen of this bird, confirms the opinion of Mr Moyle; at the same time giving the following natural history of the bird.

"The gannet comes on the coasts of Cornwall in the latter end of summer, or beginning of autumn; hovering over the shoals of pilchards that come down to us through St George's Channel from the northern seas. The gannet seldom comes near the land, but is constant to its prey, a sure sign to the fishermen that the pilchards are on the coasts; and when the pilchards retire, generally about the end of November, the gannets are seen no more. The bird now sent was killed at Chandour, near Mountbay, Sept. 30. 1762, after a long struggle with a water-spaniel, assisted by the boatmen; for it was strong and pugnacious. The person who took it observed that it had a transparent membrane under the eye-lid, with which it covered at pleasure the whole eye, without obscuring the sight or shutting the eye-lid; a gracious provision for the security of the eyes of so weighty a creature, whose method of taking its prey is by darting headlong on it from a height of 150 feet or more into the water. About four years ago, one of these birds flying over Penzance, (a thing that rarely happens), and seeing some pilchards lie on a fir-plank, in a cellar used for curing fish, darted itself down with such violence, that it struck its bill quite through the board, (about an inch and a quarter thick), and broke its neck."

These birds are sometimes taken at sea by a deception of the like kind. The fishermen fasten a pilchard to a board, and leave it floating; which inviting bait deceives the unwary gannet to its own destruction.

In the *Cataracla* of Juba may be found many characters of this bird: he says, that the bill is toothed; that its eyes are fiery; and that its colour is white: and in the very name is expressed its furious descent on its prey. The rest of his accounts favour of fable.—We are uncertain whether the gannet breeds in any other parts of Europe besides our own islands; except (as Mr Ray suspects, the fula, described in Claudius's *Exotics*, which breeds in Ferroc Isles) be the same bird.

4. The fula, or booby, is somewhat less than a goose; the basis of the bill yellow, and of bare feathers; the eyes of a light-grey colour; the lower part of the bill of a light brown. The colours of the body are brown and white; but varied so in different individuals, that they cannot be described by them. Their wings are very long; their legs and feet pale yellow, shaped like those of corvorants. They frequent the Bahama islands, where they breed all months in the year, laying one, two, or three eggs on the bare rock. While young, they are covered with a white down, and continue so till they are almost ready to fly. They feed on fish like the rest of this genus; but have a very troublesome enemy of the man of war bird, which lives on the spoils obtained from other sea-birds, particularly the booby. As soon as this rapacious enemy perceives that the booby has taken a

fish, he flies furiously at him, upon which the former dives to avoid the blow; but as he cannot swallow his prey below water, he is soon obliged to come up again with the fish in his bill as before, when he suffers a new assault; nor does his enemy cease to persecute him till he lets go the fish, which the other immediately carries off.

5. The great booby, by Linnæus called *pelicanus* *Balsani pufus*, frequents the rivers and sea-coasts of Florida, pursuing and devouring fishes like others of the genus. Mr Catesby informs us, that he has several times found them disabled, and sometimes dead, on the shore; whence he thinks that they meet with sharks or other voracious fishes, which destroy them. The bird is about the size of a goose; the head and neck remarkably prominent; the back of a brown colour; the belly dusky white; the feet black, and shaped like those of a corvorant; the head elegantly spotted with white; the wings extend six feet when spread. Both this species and the last have a joint in the upper mandible of the bill, by which they can raise it considerably from the lower one without opening the mouth.

6. The onocrotalus, or pelican of Asia, Africa, and America; though Linnæus thinks that the pelican of America may possibly be a distinct variety. This creature, in Africa, is much larger in the body than a swan, and somewhat of the same shape and colour. Its four toes are all webbed together; and its neck in some measure resembles that of a swan; but that singularity in which it differs from all other birds is in the bill and the great pouch underneath. This enormous bill is 15 inches from the point to the opening of the mouth, which is a good way back behind the eyes. At the base the bill is somewhat greenish, but varies towards the end, being of a reddish blue. It is very thick in the beginning, but tapers off to the end, where it hooks downwards. The under-chap is still more extraordinary; for to the lower edges of it hang a bag, reaching the whole length of the bill to the neck, which is said to be capable of containing 15 quarts of water. This bag the bird has a power of wrinkling up into the hollow of the under-chap; but by opening the bill, and putting one's hand down into the bag, it may be distended at pleasure. The skin of which it is formed will then be seen of a bluish ash-colour, with many fibres and veins running over its surface. It is not covered with feathers, but a short downy substance as smooth and as soft as satin, and is attached all along the under edges of the chap, to be fixed backward to the neck of the bird by proper ligaments, and reaches near half way down. When this bag is empty it is not seen; but when the bird has fished with success, it is then incredible to what an extent it is often seen dilated. For the first thing the pelican does in fishing is to fill up the bag; and then it returns to digest its burden at leisure. When the bill is opened to its widest extent, a person may run his head into the bird's mouth, and conceal it in this monstrous pouch, thus adapted for very singular purposes. Yet this is nothing to what Ruyfch assures us, who avers that a man has been seen to hide his whole leg, boot and all, in the monstrous jaws of one of these animals. At first appearance this would seem impossible, as the sides of the under chap, from which the bag depends, are

*Fig. 2.*

PELICANUS

*Fig. 1.*

*Fig. 3.*

PENTAGRAPH

*Pelicanus.* not above an inch asunder when the bird's bill is first opened; but then they are capable of great separation; and it must necessarily be so, as the bird preys upon large fishes, and hides them by dozens in its pouch. Tertre affirms, that it will hide as many fish as will serve 60 hungry men for a meal.

The pelican was once also known in Europe, particularly in Russia; but it seems to have deserted our coasts. This is the bird of which so many fabulous accounts have been propagated; such as its feeding its young with its own blood, and its carrying a provision of water for them in its great reservoir in the desert. But the absurdity of the first account answers itself; and as for the latter, the pelican uses its bag for very different purposes than that of filling it with water.

Its amazing pouch may be considered as analogous to the crop in other birds; with this difference, that as theirs lies at the bottom of the gullet, so this is placed at the top. Thus, as pigeons and other birds macerate their food for their young in their crops, and then supply them; so the pelican supplies its young by a more ready contrivance, and macerates their food in its bill, or stores it for its own particular sustenance.

The ancients were particularly fond of giving this bird admirable qualities and parental affections: struck, perhaps, with its extraordinary figure, they were willing to supply it with as extraordinary appetites; and having found it with a large reservoir, they were pleased with turning it to the most tender and parental uses. But the truth is, the pelican is a very heavy, sluggish, voracious bird, and very ill fitted to take those flights, or to make those cautious provisions for a distant time, which we have been told they do.

The pelican, says Labat, has strong wings, furnished with thick plumage of an ash-colour, as are the rest of the feathers over the whole body. Its eyes are very small, when compared to the size of its head; there is a sadness in its countenance, and its whole air is melancholy. It is as dull and reluctant in its motions as the flamingo is sprightly and active. It is slow of flight; and when it rises to fly, performs it with difficulty and labour. Nothing, as it would seem, but the spur of necessity could make these birds change their situation, or induce them to ascend into the air: but they must either starve or fly.

They are torpid and inactive to the last degree, so that nothing can exceed their indolence but their gluttony; it is only from the stimulations of hunger that they are excited to labour; for otherwise they would continue always in fixed repose. When they have raised themselves about 30 or 40 feet above the surface of the sea, they turn their head with one eye downwards, and continue to fly in that posture. As soon as they perceive a fish sufficiently near the surface, they dart down upon it with the swiftness of an arrow, seize it with unerring certainty, and store it up in their pouch. They then rise again, though not without great labour, and continue hovering and fishing, with their head on one side as before.

This work they continue with great effort and industry till their bag is full, and then they fly to land to devour and digest at leisure the fruits of their industry. This, however, it would appear, they are not long performing; for towards night they have another hun-

gry call; and they again reluctantly go to labour. At night, when their fishing is over, and the toil of the day crowned with success, these lazy birds retire a little way from the shore; and, though with the webbed feet and clumsy figure of a goose, they will be contented to perch nowhere but upon trees among the light and airy tenants of the forest. There they take their repose for the night; and often spend a great part of the day, except such times as they are fishing, sitting in dismal solemnity, and, as it would seem, half asleep. Their attitude is with the head resting upon their great bag, and that resting upon their breast. There they remain without motion, or once changing their situation, till the calls of hunger break their repose, and till they find it indispensibly necessary to fill their magazine for a fresh meal. Thus their life is spent between sleeping and eating; and our author adds, that they are as foul as they are voracious, as they are every moment voiding excrements in heaps as large as one's fist.

The same indolent habits seem to attend them even in preparing for incubation, and defending their young when excluded. The female makes no preparation for her nest, nor seems to choose any place in preference to lay in; but drops her eggs on the bare ground to the number of five or six, and there continues to hatch them. Attached to the place, without any desire of defending her eggs or her young, she tamely sits and suffers them to be taken from under her. Now and then she ventures to peck, or to cry out when a person offers to beat her off.

She feeds her young with fish macerated for some time in her bag; and when they cry flies off for a new supply. Labat tells us, that he took two of these when very young, and tied them by the leg to a post stuck into the ground, where he had the pleasure of seeing the old one for several days come to feed them, remaining with them the greatest part of the day, and spending the night on the branch of a tree that hung over them. By these means they were all three become so familiar, that they suffered themselves to be handled; and the young ones very kindly accepted whatever fish he offered them. These they always put first into their bag, and then swallowed at their leisure.

It seems, however, that they are but disagreeable and useless domestics; their gluttony can scarcely be satisfied; their flesh smells very rancid; and tastes a thousand times worse than it smells. The native Americans kill vast numbers; not to eat, for they are not fit even for the banquet of a savage; but to convert their large bags into purses and tobacco-pouches. They bestow no small pains in dressing the skin with salt and ashes, rubbing it well with oil, and then forming it to their purpose. It thus becomes so soft and pliant, that the Spanish women sometimes adorn it with gold and embroidery to make work-bags of.

Yet, with all the seeming hebetude of this bird, it is not entirely incapable of instruction in a domestic state. Father Raymond assures us, that he has seen one so tame and well educated among the native Americans, that it would go off in the morning at the word of command, and return before night to its master, with its great paunch distended with plunder; a part of which the savages would make it disgorge, and

Pelion,  
Pella.

and a part they would permit it to reserve for itself.

"The pelican," as Faber relates, "is not destitute of other qualifications. One of those which was brought alive to the duke of Bavaria's court, where it lived 40 years, seemed to be possessed of very uncommon sensations. It was much delighted in the company and conversation of men, and in music both vocal and instrumental; for it would willingly stand," says he, "by those that sung or sounded the trumpet; and stretching out its head, and turning its ear to the music, listened very attentively to its harmony, though its own voice was little pleasanter than the braying of an ass." Gesner tells us, that the emperor Maximilian had a tame pelican which lived for above 80 years, and that always attended his army on their march. It was one of the largest of the kind, and had a daily allowance by the emperor's orders. As another proof of the great age to which the pelican lives, Aldrovandus makes mention of one of these birds that was kept several years at Mechlin, and was verily believed to be 50 years old.—We often see these birds at our fairs about town.

PELION, (Diodorus Siculus, &c.) *Pelios, mons* understood, (Mela, Virg., Horace, Seneca), a mountain of Thessaly near Ossa, and hanging over the Sinus Pelagicus, or Pagaficus; its top covered with pines, the sides with oaks, (Ovid). Said also to abound in wild ash, (Val. Flaccus). From this mountain was cut the spear of Achilles, called *pelias*; which none but himself could wield, (Homer). Dicaarchus, Aristotle's scholar, found this mountain 1250 paces higher than any other of Thessaly, (Pliny). *Pelios*, Cicero; *Peliacus*, (Catullus), the epithet.

PELLA, (anc. geog.) a town situate on the confines of Emathia, a district of Macedonia, (Ptolemy); and therefore Herodotus allots it to Bottiaea, a maritime district on the Sinus Thermaicus. It was the royal residence, situate on an eminence, verging to the south-west, encompassed with unpassable marshes summer and winter: in which, next the town, a citadel like an island rises, placed on a bank or dam, a prodigious work, both supporting the wall and securing it from any hurt by means of the circumfluent water. At a distance, it seems close to the town, but is separated from it by the Ludias, running by the walls, and joined to it by a bridge, (Livy): distant from the sea 120 stadia, the Ludias being so far navigable, (Strabo). Mela calls the town *Pelle*, though most Greek authors write *Pella*. The birth-place of Philip, who enlarged it; and afterwards of Alexander, (Strabo, Mela). Continued to be the royal residence down to Perfes, (Livy). Called *Pella Colonia*, (Pliny); *Colonia Julia Augusta*, (Coin). It afterwards came to decline, with but few and mean inhabitants, (Lucian). It is now called *τη Παλαίσιον*, the *Little Palace*, (Holstenius). *Pelleus*, both the gentilitial name and the epithet, (Lucian, Juvenal, Martial).—Another PELLA, (Polybius, Pliny); a town of the Decapolis, on the other side the Jordan; abounding in water, like its cognominal town in Macedonia; built by the Macedonians, (Strabo); by Seleucus, (Eusebius); anciently called *Butir*, (Stephanus); *Apamea*, (Strabo); situate 35 miles to the north-east of Gerasa, (Ptolemy). Thither the Christians, just before the siege of Jerusalem by Titus, were divinely admonished to fly, (Euse-

bius). It was the utmost boundary of the Perææ, or Transjordan country, to the north, (Josephus).

PELLETIER (JAMES), a doctor of physic, and an eminent mathematician, was born in 1517. He was an excellent Latin and French poet, a good orator, physician, and grammarian. He wrote, *Oeuvres Poétiques, Commentaires Latins sur Euclide, &c.*

PELLETS, in heraldry, those roundels that are black; called also *ogresses* and *gunstones*, and by the French *torceaux de sable*.

PELLICLE, among physicians, denotes a thin film or fragment of a membrane. Among chemists it signifies a thin surface of crystals uniformly spread over a saline liquor evaporated to a certain degree.

PELLISON, or PELLISON FONTANIER, (Paul), one of the finest geniuses of the 17th century, was the son of James Pellison counsellor at Caftres. He was born at Beziers in 1624, and educated in the Protestant religion. He studied with success the Latin, Greek, French, Spanish, and Italian tongues, and applied himself to the reading the best authors in these languages; after which he studied the law at Caftres with reputation. In 1652 he purchased the post of secretary to the king; and, five years after, became first deputy to M. Fouquet. He suffered by the disgrace of that minister; and in 1661 was confined in the Bastille; from whence he was not discharged till four years after. During his confinement he applied himself to the study of controversy; and in 1670 abjured the Protestant religion. Lewis XIV. bestowed upon him an annual pension of 2000 crowns; and he likewise enjoyed several posts. In 1676 he had the abbey of Giment, and some years after the priory of St Orens at Auch. He died in 1693. His principal works are, 1. The History of the French Academy. 2. Reflections on religious Disputes, &c. in 4 vols 12m°. 3. The History of Lewis XIV. 4. Historical Letters and Miscellanies, in 3 vols 12mo.

PELOPONNESUS, (Dionysius); a large peninsula, to the south of the rest of Greece; called, as it were, *Pelopis nefus* or *insula*, though properly not an island, but a peninsula; yet wanting but little to be one, viz. the isthmus of Corinth, ending in a point like the leaf of the Platane or plane-tree. Anciently called *Apia* and *Pelafgia*; a peninsula second to no other country for nobleness; situate between two seas, the Egean and Ionian, and resembling a platane-leaf, on account of its angular recesses or bays, (Pliny, Strabo, Mela). Strabo adds from Homer, that one of its ancient names was *Argos*, with the epithet *Achaicum*, to distinguish it from Thessaly, called *Pelafgicum*. Divided into six parts; namely, Argolis, Laconia, Messenia, Elis, Achaia, and Arcadia, (Mela). Now called the *Morea*.

PELOPS, in fabulous history, the son of Tantalus king of Phrygia, went into Elis, where he married Hippodamia the daughter of Oenomaus king of that country; and became so powerful, that all the territory which lies beyond the Isthmus, and composes a considerable part of Greece, was called *Peloponnesus*, that is, the *island of Pelops*, from his name, and the word *Nessus*.

PELUSIUM, (anc. geogr.); a noble and strong city of Egypt, without the Delta, distant 20 stadia from the sea; situate amidst marshes; and hence its name

Pelletier  
||  
Pelusium.

Pelvis  
Pen.

name and its strength. Called the *key* or *inlet* of *Egypt*, (Diodorus, Hirtius); which being taken, the rest of Egypt lay quite open and exposed to an enemy. Called *Sin*, (Ezekiel). *Pelygiacus*, the epithet, (Virgil, Diodorus). From its ruins arose Damietta. E. Long. 32° N. Lat. 31°.

PELVIS, in anatomy. See there, n° 38.—41.

PEMBROKE, (Mary Countess of). See HERBERT.

PEMBROKESHIRE, a county of Wales, bounded on all sides by the Irish sea, except on the east, where it joins to Caermarthenshire, and on the north-east to Cardiganshire. It lies the nearest to Ireland of any county in Wales. Its length is 26 miles, its breadth 20, and its circumference 93; within which it contains about 420,000 acres, 145 parishes, 7 hundreds, 1 city, 9 market-towns, 2 forests, and about 26,000 inhabitants. This county lies in the diocese of St David's, and sends three members to parliament, viz. one for the shire, one for Haverfordwest, and one for the town of Pembroke.

The air of Pembrokehire, considering its situation, is good; but it is in general better the farther from the sea. As there are but few mountains, the soil is generally fruitful, especially on the sea-coasts; nor are its mountains altogether unprofitable, but produce pasture sufficient to maintain great numbers of sheep and goats. Its other commodities are corn, cattle, pit-coal, marble, fish, and fowl. Among these last are falcons, called here *peregrins*. The inhabitants of this county make a very pleasant durable fire of culm, which is the dust of coal made up into balls, with a third part of mud. The county is well watered by the rivers Clethy, Doulgedy, Cledhew, and Teive; which last parts it from Cardiganshire. There is a division of the county styled *Rhos* in the Welsh, by which is meant a large green plain. This is inhabited by the descendants of the Flemings, placed there by Henry I. to curb the Welsh, who were never able to expel them, though they often attempted it. On the coasts of this county, as well as on those of Glamorganshire and the Severn Sea, is found the *lactuca marina* of Cambden, being a marine plant or weed, which, when dressed in a certain manner, is eaten by the inhabitants, and called *laver*, or *black butter*.

PEN, a little instrument, usually formed of a quill, serving to write withal.

Pens are also sometimes made of silver, brass, or iron.

*Dutch Pens*, are made of quills that have passed thro' hot ashes, to take off the grosser fat and moisture, and render them more transparent.

*Fountain Pen*, is a pen made of silver, brass, &c. contrived to contain a considerable quantity of ink, and let it flow out by gentle degrees, so as to supply the writer a long time without being under the necessity of taking fresh ink.

The fountain-pen is composed of several pieces, as in Plate CCXXXII. fig. 3. where the middle piece F carries the pen, which is screwed into the inside of a little pipe, which again is folded to another pipe of the same bigness as the lid G; in which lid is folded a male screw, for screwing on the cover, as also for stopping a little hole at the place, and hindering the ink from passing through it. At the other end of the

piece F is a little pipe, on the outside of which the top-cover H may be screwed. In the cover there goes a port-crayon, which is to be screwed into the last-mentioned pipe, in order to stop the end of the pipe, into which the ink is to be poured by a funnel. To use the pen, the cover G must be taken off, and the pen a little shaken, to make the ink run more freely.

PEN, or *Penstock*. See PENSTOCK.

PENANCE, a punishment, either voluntary or imposed by authority, for the faults a person has committed. Penance is one of the seven sacraments of the Romish church. Besides fasting, alms, abstinence, and the like, which are the general conditions of penance, there are others of a more particular kind; as the repeating a certain number of ave-maries, paternosters, and credos, wearing a hair-shirt, and giving one's self a certain number of stripes. In Italy and Spain it is usual to see Christians almost naked, loaded with chains and a cross, and lashing themselves at every step.

PENATES, in Roman antiquity, a kind of tutelar deities, either of countries or particular houses; in which last sense they differed in nothing from the lares. See LARES.

The penates were properly the tutelar gods of the Trojans, and were only adopted by the Romans, who gave them the title of *penates*.

PENCIL, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials; the larger sorts are made of boars bristles, the thick ends of which are bound to a stick, bigger or less, according to the uses they are designed for: these, when large, are called *brushes*. The finer sorts of pencils are made of camels, badgers, and squirrels hair, and of the down of swans; these are tied at the upper end with a piece of strong thread, and inclosed in the barrel of a quill.

All good pencils, on being drawn between the lips, come to a fine point.

PENCIL, is also an instrument used in drawing, writing, &c. made of long pieces of black-lead, or red-chalk, placed in a groove cut in a slip of cedar; on which other pieces of cedar being glued, the whole is planed round, and one of the ends being cut to a point, it is fit for use.

Black-lead in fine powder, stirred into melted sulphur, unites with it so uniformly, and in such quantity, in virtue perhaps of its abounding with sulphur, that though the compound remains fluid enough to be poured into moulds, it looks nearly like the coarser sorts of black-lead itself. Probably the way which prince Rupert is said to have had, mentioned in the third volume of Dr Birch's History of the Royal Society, of making black-lead run like a metal in a mould, so as to serve for black-lead again, consisting in mixing with it sulphur or sulphureous bodies.

On this principle the German black-lead pencils are said to be made; and many of those which are hawked about by certain persons among us are prepared in the same manner: their melting or softening, when held in a candle, or applied to a red-hot iron, and yielding a bluish flame, with a strong smell like that of burning brimstone, betrays their composition; for black-lead itself yields no smell or fume, and suffers no

Pen  
Pencil.

Pendant # Pendulum. apparent alteration in that heat. Pencils made with such additions are of a very bad kind; they are hard, brittle, and do not cast or make a mark freely either on paper or wood, rather cutting or scratching them than leaving a coloured stroke.

The true English pencils (which Vogel in his mineral system, and some other foreign writers, imagine to be prepared also by melting the black-lead with some additional substances, and casting it into a mould) are formed of black-lead alone, sawed into slips, which are fitted into a groove made in a piece of wood, and another slip of wood glued over them: the softest wood, as cedar, is made choice of, that the pencil may be the easier cut; and a part at one end, too short to be conveniently used after the rest has been worn and cut away, is left unfilled with the black-lead, that there may be no waste of so valuable a commodity. These pencils are greatly preferable to the others, though seldom so perfect as could be wished, being accompanied with some degree of the same inconveniences, and being very unequal in their quality, on account of different sorts of the mineral being fraudulently joined together in one pencil, the fore-part being commonly pretty good, and the rest of an inferior kind. Some, to avoid these imperfections, take the finer pieces of black-lead itself, which they saw into slips, and fix for use in port-crayons: this is doubtless the surest way of obtaining black-lead crayons, whose goodness can be depended on.

PENDANT, an ornament hanging at the ear, frequently composed of diamonds, pearls, and other jewels.

PENDANTS, in heraldry, parts hanging down from the label, to the number of three, four, five, or six at most, resembling the drops in the Doric freeze. When they are more than three, they must be specified in blazoning.

PENDANTS of a Ship, are those streamers, or long colours, which are split and divided into two parts, ending in points, and hung at the head of masts, or at the yard-arm ends.

PENDULOUS, a term applied to any thing that bends or hangs downwards.

PENDULUM, in mechanics, denotes any heavy body, so suspended as that it may vibrate or swing, backwards and forwards, about some fixed point, by the force of gravity.

The vibrations of a pendulum are called its *oscillations*.

Plate CCXXXII. A pendulum, therefore, is any body, B, (fig. 2. n° 1.) suspended upon, and moving about, a fixed point, A, as a centre.

The nature of a pendulum consists in the following particulars: 1. The times of the vibrations of a pendulum, in very small arches, are all equal. 2. The velocity of the bob, in the lowest point, will be nearly as the length of the chord of the arch which it describes in the descent. 3. The times of vibration in different pendulums, AB, AC, are as the square roots of the times of their vibrations. 4. The time of one vibration is to the time of the descent, through half the length of the pendulum, as the circumference of a circle to its diameter. 5. Whence the length of a pendulum, vibrating seconds, will be found 39.2 inches nearly; and that of an half-second pendulum

9.8 inches. 6. An uniform homogeneous body BG, (ibid. n° 2.) as a rod, staff, &c. which is one-third part longer than a pendulum AD, will vibrate in the same time with it.

From these properties of the pendulum we may discern its use as an universal chronometer, or regulator of time, as it is used in clocks, and such like machines. By this instrument also we can measure the distance of a ship, by measuring the interval of time between the fire and the sound of the gun; also the distance of a cloud, by numbering the seconds or half-seconds between the lightning and thunder. Thus, suppose between the lightning and thunder, we number 10 seconds; then, because sound passes through 1142 feet in one second, we have the distance of the cloud equal to 11420 feet. Again, the height of any room, or other object, may be measured by a pendulum vibrating from the top thereof. Thus, suppose a pendulum from the height of a room vibrates once in three seconds; then say, as 1 is to the square of 3, viz. 9, so is 39.2 to 352.8 feet, the height required. Lastly, By the pendulum we discover the different force of gravity on diverse parts of the earth's surface; and thence the true figure of the earth.

When pendulums were first applied to clocks, they were made very short: and, the arches of the circle being large, the time of vibration through different arches could not in that case be equal; to effect which, the pendulum was contrived to vibrate in the arch of a cycloid, by making it play between two semi-cycloids, CB, CD, (ibid. n° 3.) whereby it describes the cycloid BE, AD; the property of which curve is, that a body vibrating in it will describe all its arches, great or small, in equal times.

In all that has been hitherto said, the power of gravity has been supposed constantly the same. But if the said power varies, the lengths of pendulums must vary in the same proportion, in order that they may vibrate in equal times; for we have shewn, that the ratio of the times of vibration and descent through half the lengths is given, and consequently the times of vibration and descent through the whole length is given: But the times of vibration are supposed equal, therefore the times of descent through the lengths of the pendulum are equal. But bodies descending thro' unequal spaces, in equal times, are impelled by powers that are as the spaces described, that is, the powers of gravity are as the lengths of the pendulums.

The greatest inconvenience attending this most useful instrument is, that it is constantly liable to an alteration of its length, from the effects of heat and cold, which very sensibly expand and contract all metalline bodies.

To remedy this inconvenience, the common method is by applying the bob of the pendulum with a screw; so that it may be at any time made longer or shorter, according as the bob is screwed downwards or upwards, and thereby the time of its vibrations keeps always the same. Again, if a glass or metalline tube, uniform throughout, filled with quicksilver, and 58.8 inches long, were applied to a clock, it would vibrate seconds for  $39.2\frac{1}{2}$  of 58.8; and such a pendulum admits of a twofold expansion and contraction, viz. one of the metal and the other of the mercury; and these will be at the same time contrary, and therefore will

cor-

**Pendulum.** correct each other. For by what we have shewn, the metal will extend in length with heat, and so the pendulum will vibrate slower on that account. The mercury also will expand with heat; and since by this expansion it must extend the length of the column upward, and consequently raise the centre of oscillation; so that by this means its distance from the point of suspension will be shortened, and therefore the pendulum on this account will vibrate quicker: wherefore, if the circumstances of the tube and mercury are skilfully adjusted, the time of the clock might by this means, for a long course of time, continue the same, without any sensible gain or loss.

This is the invention of the late ingenious Mr Graham, in the year 1721, who made a clock of this sort, and compared it with one of the best of the common sort for three years together, and found the errors of the former but about  $\frac{1}{3}$  part of the latter; of which the reader may see a farther account in Phil. Trans. n° 393. It is what is now called *Mr Graham's quicksilver pendulum*.

In the 47th volume of the Phil. Trans. Mr Short gives us an account of other inventions to remedy the same inconvenience. Mr John Harrison of Barrow, in Lincolnshire, famous for his invention of a clock to find the difference of longitude at sea, without having the least knowledge of what Mr Graham had done before him, made several experiments upon wires of different metals, in order to find their different degrees of expansion and contraction. He thought, that by a proper combination of wires of two different metals, differing considerably in their expansion and contraction, he might be enabled to keep the centre of oscillation of a pendulum always at the same distance from the point of suspension. In consequence of these experiments, he made a pendulum consisting of one steel-wire, at the end of which is the bob or weight; and on each side of this wire, four wires, alternately brass and steel, so disposed and contrived as to raise the pendulum by the same quantity that it is lengthened by heat, and to let down the pendulum in the same proportion as it is raised by cold.

Mr Harrison, in his first machine for measuring time at sea, likewise applied this combination of wires of brass and steel, to prevent any alterations by heat and cold. And in the two machines or clocks he has since made for the same purpose, a like method of guarding against the irregularities arising from this cause is used.

Mr Graham also made a pendulum consisting of three bars, one of steel between two of brass; and the steel bar acted upon a lever, so as to raise the pendulum, when lengthened by heat, and to let it down, when shortened by cold; but he found this clock liable to sudden starts and jerks in its motion.

The ingenious Mr Ellicott, in the same volume of the Transactions, describes a pendulum of his invention, composed of brass and iron, with the method of applying it, so as to avoid the many jerks to which the machine might be liable.

But besides the irregularities arising from heat and cold, pendulum-clocks are liable to others from friction and foulness; to obviate which, Mr Harrison has several excellent contrivances, whereby his clocks are

almost entirely free from friction, and never need to be cleaned.

**PENELOPE**, in fabulous history, the daughter of Icarus, married Ulysses, by whom she had Telemachus. During the absence of Ulysses, who was gone to the siege of Troy, and who staid 20 years from his dominions, several princes, charmed with Penelope's beauty, told her that Ulysses was dead, offered to marry her, and pressed her to declare in their favour. She promised compliance on condition they would give her time to finish a piece of tapestry she was weaving; but at the same time she undid in the night what she had done in the day, and by this artifice eluded their importunity till Ulysses's return.

**PENESTICA**, (Antonine), a town of the Helvetii, situated between the Lacus Lanfonius and Salodurum; called *Penitifica* by Peutinger. Thought now to be *Biel*, (Cluverius); the capital of a small territory in Switzerland.

**PENEUS**, (Strabo); a river running through the middle of Thessaly, from west to east, into the Sinus Thermaicus, between Olympus and Ossa, near Tempe of Thessaly, rising in mount Pindus, (Ovid, Val. Flaccus).

**PENETRALE**, in Roman antiquity, properly denoted the *chapel*, consecrated to the penates or household gods.

**PENICILLUS**, among surgeons, is used for a tent to be put into wounds or ulcers.

**PENINSULA**, in geography, a portion or extent of land joining to the continent by a narrow neck or isthmus, the rest being encompassed with water. See Plate CXVI.

**PENIS**, in anatomy. See there, n° 371, o.

**PENITENTS**, an appellation given to certain fraternities of penitents distinguished by the different shape and colour of their habits. These are secular societies, who have their rules, statutes, and churches, and make public processions under their particular crosses or banners. Of these there are more than a hundred, the most considerable of which are as follows: the white penitents, of which there are several different sorts at Rome, the most ancient of which was constituted in 1264: the brethren of this fraternity every year give portions to a certain number of young girls, in order to their being married: their habit is a kind of white sackcloth, and on the shoulder is a circle, in the middle of which is a red and white cross. Black penitents, the most considerable of which are the brethren of mercy, instituted in 1488, by some Florentines, in order to assist criminals during their imprisonment, and at the time of their death: on the day of execution, they walk in procession before them, singing the seven penitential psalms and the litanies; and after they are dead, they take them down from the gibbet and bury them: their habit is black sackcloth. There are others whose business it is to bury such persons as are found dead in the streets: these wear a death's head on one side of their habit. There are also blue, grey, red, green, and violet penitents; all which are remarkable for little else besides the different colours of their habits.

Mabillon tells us, that at Turin there are a set of penitents kept in pay to walk through the streets in pro-

cession, and cut their shoulders with whips, &c.  
PENITENTIAL, an ecclesiastical book retained among the Romanists; in which is prescribed what relates to the imposition of penance and the reconciliation of penitents. See Penance.

There are various penitentials, as the Roman penitential, that of the venerable Bede, that of pope Gregory III. &c.

PENITENTIARY, in the ancient Christian church, a name given to certain presbyters or priests, appointed in every church to receive the private confessions of the people, in order to facilitate public discipline, by acquainting them what sins were to be expiated by public penance, and to appoint private penance for such private crimes as were not proper to be publicly censured.

PENITENTIARY, at the court of Rome, is an office in which are examined and delivered out the secret bulls, graces, or dispensations relating to cases of conscience, confessions, &c.

PENITENTIARY, is also an officer, in some cathedrals, vested with power from the bishop to absolve, in cases reserved to him. The pope has at present his grand penitentiary, who is a cardinal, and the chief of the other penitentiary priests established in the church of Rome, who consult him in all difficult cases. He presides in the penitentiary, dispatches dispensations, absolutions, &c. and has under him a regent and 24 professors, or advocates of the sacred penitentiary.

PENN (Sir William), was born at Bristol in 1621, and inclined from his youth to maritime affairs. He was made captain at 21 years of age, rear-admiral of Ireland at 23, vice-admiral of Ireland at 25, admiral to the Straights at 29, vice-admiral of England at 31, and general in the first Dutch war at 32. Whence returning in 1655, he was chosen representative for the town of Weymouth; and in 1660 was made commissioner of the admiralty and navy, governor of the town and fort of Kinsale, vice-admiral of Munster, and a member of that provincial council. In 1664 he was chosen great captain-commander under the duke of York, and distinguished himself in an engagement against the Dutch fleet; after which he took leave of the sea, but continued in his other employments till 1669. He died in 1670.

PENN (William), an eminent writer among the Quakers, and the planter and legislator of Pennsylvania, was the son of the above Sir William Penn, and was born at London in 1644. In 1660, he was entered a gentleman commoner of Christ-Church, in Oxford; but having before received an impression from the preaching of one Thomas Loc a Quaker, withdrew with some other students from the national worship, and held private meetings, where they preached and prayed amongst themselves. This giving great offence to the heads of the college, Mr Penn, though but 16 years of age, was fined for nonconformity; and continuing his religious exercises, was at length expelled his college. Upon his return home, he was, on the same account, treated with great severity by his father, who at last turned him out of doors; but his resentment afterwards abating, he sent him to France in company with some persons of quality; where he continued a considerable time, and returned not only well skilled in the French language, but a polite and accomplished

Penn.

gentleman. About the year 1666, his father committed to his care a considerable estate in Ireland. Being found in one of the Quakers meetings in Cork, he, with many others, was thrown into prison; but on his writing to the earl of Orrery, was soon discharged. However, his father being informed he still adhered to his opinions, sent for him to England, and finding him inflexible to all his arguments, turned him out of doors a second time. About the year 1668, he became a public preacher among the Quakers; and that year was committed close prisoner to the Tower, where he wrote several treatises. Being discharged after seven months imprisonment, he went to Ireland, where he also preached amongst the Quakers. Returning to England, he was, in 1670, committed to Newgate for preaching in Gracechurch-street meeting-house, London; but being tried at the sessions-house in the Old Bailey, he was acquitted. In September the same year, his father died; and being perfectly reconciled to him, left him both his paternal blessing and a plentiful estate. But his persecutions were not yet at an end; for, in 1671, he was committed to Newgate for preaching at a meeting in Wheeler-street, London; and during his imprisonment, which continued six months, he also wrote several treatises. After his discharge, he went into Holland and Germany; and in the beginning of the year 1672, married and settled with his family at Rickmanworth in Hertfordshire. The same year he published several pieces; and particularly one against Reeve and Muggleton. In 1677, he again travelled into Holland and Germany in order to propagate his opinions; and had frequent conversations with the princess Elizabeth, daughter to the queen of Bohemia, and sister to the princess Sophia, mother to king Geo. I. In 1681, king Charles II. in consideration of the services of Mr Penn's father, and several debts due to him from the crown at the time of his decease, granted Mr Penn and his heirs the province lying on the west side of the river Delaware in North America, which from thence obtained the name of *Pennsylvania*. Upon this Mr Penn published a brief account of that province, with the king's patent; and proposing an easy purchase of lands, and good terms of settlement for such as were inclined to remove thither, many went over. These having made and improved their plantations to good advantage, the governor, in order to secure the planters from the native Indians, appointed commissioners to purchase the land he had received from the king of the native Indians, and concluded a peace with them. The city of Philadelphia was planned and built; and he himself drew up the fundamental constitutions of Pennsylvania in 24 articles. In 1681, he was elected a member of the Royal Society; and the next year he embarked for Pennsylvania, where he continued about two years, and returned to England in August 1684. Upon the accession of king James to the throne, he was taken into a great degree of favour with his Majesty, which exposed him to the imputation of being a Papist; but from which he fully vindicated himself. However, upon the Revolution, he was examined before the council, in 1688, and obliged to give security for his appearance on the first day of next term, which was afterwards continued. He was several times discharged and examined; and at length warrants being issued out against him, he was obliged to conceal himself

Penni.

self for two or three years. Being at last permitted to appear before the king and council, he represented his innocence so effectually that he was acquitted. In August 1699, he, with his wife and family, embarked for Pennsylvania; whence he returned in 1701, in order to vindicate his proprietary right, which had been attacked during his absence. Upon queen Anne's accession to the crown, he was in great favour with her, and was often at court. But, in 1707, he was involved in a lawsuit with the executors of a person who had been formerly his steward; and, though many thought him aggrieved, the court of chancery did not think proper to relieve him; upon which account he was obliged to live within the rules of the Fleet for several months, till the matter in dispute was accommodated. He died in 1718. Mr Penn's friendly and pacific manner of treating the Indians produced in them an extraordinary love for him and his people; so that they have maintained a perfect amity with the English in Pennsylvania ever since. He was the greatest bulwark of the Quakers; in whose defence he wrote numberless pieces. Besides the above works, he wrote a great number of others; the most esteemed of which are, 1. His Primitive Christianity revived. 2. His defence of a paper, intitled *Gospel Truths, against the Exceptions of the Bishop of Cork*. 3. His *Persuasive to Moderation*. 4. His *Good Advice to the Church of England, Roman Catholic, and Protestant dissenters*. 5. The *Sandy Foundation shaken*. 6. *No Cross, no Crown*. 7. The great *Cafe of Liberty of Conscience debated*. 8. The *Christian Quaker* and his *Testimony stated and vindicated*. 9. A *Discourse of the general Rule of Faith and Practice, and Judge of Controversy*. 10. *England's Present Interest considered*. 11. An *Address to Protestants*. 12. His *Reflections and Maxims*. 13. His *Advice to his Children*. 14. His *Rise and Progress of the People called Quakers*. 15. A *Treatise on Oaths*. Most of these have passed several editions, some of them many. The letters between William Penn and Dr Tillotson, and William Penn and William Popple, Esq; together with Penn's letters to the princess Elizabeth of the Rhine and the countess of Hornes, as also one to his wife on his going to Pennsylvania, are inserted in his works, which were first collected and published in 2 vols folio; and the parts since selected and abridged into 1 vol. folio, are very much and deservedly admired for the good sense they contain.

PENNI (Giovanni Francisco), born at Florence in 1488, was the disciple of Raphael, who observing his genius and integrity, intrusted his domestic concerns entirely to his management; by which means he got the appellation of *il fattore*, or the "steward," which he retained ever after. The genius of Penni was universal; but his greatest pleasure was in painting landscapes and buildings: he was an excellent designer, and coloured extremely well in oil, distemper, and fresco. He painted portraits in an exquisite style, and had such happy natural talents, that Raphael left him heir to his fortune in partnership with Julio Romano his fellow-disciple. After Raphael's death, Penni painted many pictures at Rome, particularly in the palace of Chigi, so exactly in the style of his master, that they might not undervaluedly have been imputed to him: he finished, in conjunction with Julio and Pierino del Vaga, the

celebrated designs of the battles of Constantine, and others, which Raphael had left imperfect; but differing with them about a copy of the transfiguration, which the pope intended for the king of France, they separated. Penni went to Naples; but the air of that country disagreeing with his constitution, he died soon after in 1528. He had a brother called *Lucca Penni*, who worked at Genoa and other parts of Italy in conjunction with Pierino del Vaga, who married his sister; he went thence to England, where he worked for Henry VIII. and for several merchants; was employed by Francis I. at Fontainebleau; but at last quitted the pencil, and devoted himself to engraving.

PENNY, or PENY, in commerce, an ancient English coin, which had formerly considerable course; but is now generally dwindled into an imaginary money, or money of account. Camden derives the word from the Latin *pecunia*, "money."

The ancient English penny, penig, or pening, was the first silver coin struck in England; nay, and the only one current among our Saxon ancestors: as is agreed by Camden, Spelman, Dr Hicks, &c.

The penny was equal in weight to our three-pence; five of them made one shilling, or seiling Saxon; 30 a mark or mancuse, equal to our 7s. 6d.

Till the time of king Edw. I. the penny was struck with a cross, so deeply indented in it that it might be easily broke, and parted, on occasion, into two parts, thence called *half-pennies*; or into four, thence called *fourthings*, or *farthings*.—But that prince coined it without indenture; in lieu of which, he first struck round half-pence and farthings.

He also reduced the weight of the penny to a standard; ordering that it should weigh 32 grains of wheat, taken out of the middle of the ear.—This penny was called the *penny sterling*.—Twenty of these pence were to weigh an ounce; whence the penny became a weight as well as a coin. See *STERLING* and *PENNY-Weight*.

The penny sterling is now nigh disused as a coin; and scarce subsists, but as a money of account, containing the 12th part of a shilling, or the 140th part of a pound.

PENNY, in ancient statutes, &c. is used for all silver money.

And hence the *ward-penny*, *aver-penny*, *hundred-penny*, *titling-penny*, and *brothal-penny*.

PENNY-Weight, a Troy weight, containing 24 grains; each grain weighing a grain of wheat gathered out of the middle of the ear, well dried. The name took its rise hence, that this was anciently the weight of one of our ancient silver pennies. See *PENNY*.

Twenty of these penny-weights make an ounce Troy. PENRITH, an ancient town of the county of Cumberland in England, seated under a hill called *Penrith-Fell*, near the rivers Eimont and Lowther. It is a great thoroughfare for travellers; but has little other trade except tanning, and a small manufacture of checks. Formerly it had a castle, but it is now in ruins. In the church-yard is a monument of great antiquity, consisting of two stone-pillars 11 feet 6 inches high, and five in circumference in the lower part, which is rounded; the upper is square, and tapers to a point; in the square part is some fret-work, and the relieve of a cross; and on the interior side of one is the faint representation of some animal. Both these stones are mortified at their

Penny.  
Penrith.

Penryn lower part into a round one: they are about 15 feet  
 asunder, and the space between them is inclosed on each  
 side with two very large but thin semicircular stones;  
 so that there is left between pillar and pillar a walk of  
 two feet in breadth. Two of these lesser stones are  
 plain, the others have certain figures, at present scarce  
 intelligible. Not far from these pillars is another called  
 the *giant's thumb*, five feet eight inches high, with  
 an expanded head, perforated on both sides; from the  
 middle the stone rises again into a lesser head, round-  
 ed at top; but no part has a tendency to the figure of  
 a cross, being in no part mutilated. W. Long. 3. 16.  
 N. Lat. 54. 35.

PENRYN, a town of Cornwall in England, seated  
 on a creek of Falmouth-haven. It consists of about 300  
 houses, and the streets are broad and paved. It sends  
 two members to parliament. W. Long. 5. 35. N. Lat.  
 50. 23.

PENSACOLA, a settlement in North America,  
 situated at the mouth of a river on the gulf of Mexico.  
 It was established by the French, and ceded to Great  
 Britain in 1763; but has lately been taken by the Spaniards.  
 W. Long. 87. 20. N. Lat. 30. 22.

PENSILVANIA, one of the principal British colonies  
 in North America, had its name from the famous  
 Quaker William Penn, son of Sir William, commander  
 of the English fleet in Oliver Cromwell's time, and  
 in the beginning of Ch. II.'s reign, who obtained a  
 grant of it in the year 1679; is bounded on the east by  
 Delaware bay and river, and the Atlantic ocean; on  
 the north by the country of the Iroquois, or five nations;  
 and on the south and west by Maryland. Its  
 extent, from north to south, is about 200 miles; but  
 its breadth varies greatly, from 15, and even less, to  
 near 200.

The air in Pennsylvania is sweet and clear. The  
 fall, or autumn, begins about the 20th of October,  
 and lasts till the beginning of December, when the  
 winter sets in, which continues till March, and is  
 sometimes extremely cold and severe; but the air is  
 then generally dry and healthy. The river Delaware,  
 though very broad, is often frozen over. From  
 March to June, that is, in the spring, the weather is  
 more inconstant than in the other seasons. In the  
 months of July, August, and September, the heats  
 would be almost intolerable, if they were not mitigated  
 by frequent cool breezes. The wind, during the  
 summer, is generally south-west; but in the winter  
 blows for the most part from the north-west, over the  
 snowy frozen mountains and lakes of Canada, which  
 occasions the excessive cold during that season.

As to the face of this country, towards the coast,  
 like the adjacent colonies, it is flat, but rises gradually  
 to the Apalachian mountains on the west.

The chief rivers are three, Delaware, Sasquahanna,  
 and Skookil. The Delaware, rising in the country  
 of the Iroquois, takes its course southward; and  
 after dividing this province from that of New Jersey,  
 falls into the Atlantic ocean between the promontories  
 or capes May and Henlopen, forming at its mouth a  
 large bay, called, from the river, *Delaware Bay*.  
 This river is navigable above 200 miles. The Sasquahanna  
 rises also in the country of the Iroquois,  
 and running south through the middle of the province,  
 falls into the bay of Chesapeake, being navigable a  
 great way for large ships. The Skookil has its source

in the same country as the other two, and also runs  
 south, almost parallel to them; till at length turning  
 to the eastward, it falls into the Delaware at the city  
 of Philadelphia. It is navigable for boats above 100  
 miles. These rivers, with the numerous creeks and  
 harbours in Delaware bay, capable of containing the  
 largest fleets, are extremely favourable to the trade of  
 this province.

As to the soil, produce, and traffic of Pennsylvania,  
 we refer the reader to what has been said on these  
 heads under New-York and the JERSEYS, which is  
 equally applicable to this province; and if there is any  
 difference, it is on the side of this province. They  
 have some rice here, but no great quantities; and some  
 tobacco, but it is not equal to that of Virginia. From  
 the premiums offered by the society of arts in London,  
 it appears that the soil and climate of this province are  
 looked upon as proper for the cultivation of some species  
 of vines. The trade carried on from hence and the  
 other colonies to the French and Dutch islands  
 and Surinam, was greatly to the disadvantage of  
 Britain, and very destructive to the sugar-colonies;  
 for they take molasses, rum, and other spirits, with  
 a great many European goods, from these foreigners;  
 carrying them horses, provisions, and lumber in return,  
 without which the French could not carry on their  
 sugar-manufactures to that advantage they do.

New-York, the Jerseys, and Pennsylvania, were discovered,  
 with the rest of the continent of North America,  
 in the reign of Henry VII. by Sebastian Cabot,  
 for the crown of England; but Sir Walter Raleigh  
 was the first adventurer that attempted to plant colonies  
 on these shores, in the reign of Queen Elizabeth;  
 and, in honour of that princess, gave all the eastern  
 coast of North America the name of *Virginia*. Mr  
 Hudson, an Englishman, falling to that part of the  
 coast which lies between Virginia and New England,  
 in the beginning of the reign of James I. and being  
 about to make a settlement at the mouth of of Hudson's  
 river, the Dutch gave him a sum of money to dispose  
 of his interest in this country to them. In the year  
 1608 they began to plant it; and, by virtue of this  
 purchase, laid claim to all those countries which are  
 now denominated *New York*, *New Jersey*, and *Pennsylvania*;  
 but there remaining some part of this coast  
 which was not planted by the Hollanders, the Swedes  
 sent a fleet of ships thither, and took possession of it  
 for that crown; but the Dutch having a superior force  
 in the neighbourhood, compelled the Swedes to submit  
 to their dominion, allowing them, however, to enjoy  
 the plantations they had settled. The English not  
 admitting that either the Dutch or Swedes had any  
 right to countries first discovered and planted by a  
 subject of England, and part of them at that time  
 possessed by the subjects of Great Britain, under charter  
 from Queen Elizabeth and king James I. king  
 Charles II. during the first Dutch war in 1664, granted  
 the countries of New York, the Jerseys, and Pennsylvania,  
 of which the Dutch had usurped the possession,  
 to his brother James Duke of York; and Sir  
 Robert Carr being sent over with a squadron of men  
 of war and land-forces, and summoning the Dutch  
 governor of the city of New Amsterdam, now New  
 York, to surrender, he thought fit to obey the summons,  
 and yield that capital to the English: the rest  
 of the places in the possession of the Dutch and Swedes  
 followed.

Pennsylvania, followed his example; and these countries were confirmed to the English by the Dutch at the next treaty of peace between the two nations. The Duke of York afterwards parcelled them out to under proprietors; selling, in particular, to William Penn the elder, in 1683, the town of Newcastle, *alias* Delaware, and a district of twelve miles round the same; to whom, his heirs and assigns, by another deed of the same date, he made over all that tract of land from 12 miles south of Newcastle to the Whore-hills, otherwise called *Cape Henlopen*, now divided into the two counties of Kent and Suffex, which, with Newcastle district, are commonly known by the name of the *Three Lower counties upon Delaware River*. All the rest of the under-proprietors, some time after, surrendered their charters to the crown; whereby New York and the Jerseys became Royal governments; but Penn retained that part of the country which had been sold him by the Duke of York, together with what had been granted to him before in 1680-1, which now constitutes the province of Pennsylvania. As soon as Penn had got his patent, he began to plant the country. Those who went over from England were generally dissenters and quakers, whose religion is established by law here, but with a toleration of all other protestant sects. The Dutch and Swedes, who were settled here before Mr Penn became proprietor, choosing still to reside in this country, as they did in New York and the Jerseys, obtained the same privileges as the rest of his majesty's subjects; and their descendants are now in a manner the same people with the English, speaking their language, and being governed by their laws and customs. Mr Penn, however, not satisfied with the title granted him by king Charles II. and his brother, bought the lands also of the Indians for a valuable consideration, or what they esteemed such, (though 20 miles were purchased, at first, for less than an acre about Philadelphia would pay now), paying them in cloth, tools, and utensils, to their entire satisfaction; for they had not hands to cultivate the hundredth part of their lands, and if they could have raised a product, there was nobody to buy: the purchase, therefore, was all clear gain to them; and, by the coming of the English, their peltry trade became so profitable, that they soon found their condition much altered for the better; and are now as well clothed and fed as the European peasantry in many places.

Pennsylvania is one of the most flourishing colonies in North America, having never had any quarrel with the natives. Whenever they desire to extend their settlements, they purchase new lands of the sachems, never taking any by force; but the Indians now set a very high price upon their lands, in comparison of what they did at first, and will hardly part with them at any rate. In an estimate of the proprietary estate of the province, published above thirty years ago, we find, that the proprietaries, who alone can purchase lands here from the natives, had bought seven millions of acres for no more than 75*l*. Sterling, which the proprietaries afterwards sold at the rate of 1*l*. for every 100 acres. The Indian council at Onandago, however, disapproved of their deputies parting with so much land; and, in the year 1755, obliged the proprietaries to re-convey great part of the same to the Indians.

A dispute subsisted a long time between the proprietaries of this province and Lord Baltimore, proprietary of Maryland, about the right to certain lands; which was at last amicably adjusted, though greatly in favour of the Penns.

About the year 1704 there happened some alteration in the constitution of the province. The establishment that took place, and subsisted till the present troubles broke out, consisted of a governor, council, and assembly, each with much the same power and privileges as in the neighbouring colony of New York. The lieutenant-governor and council were appointed by the proprietors Thomas and Richard Penn, with his majesty's approbation; but if the laws enacted here were not repealed within six months after they had been presented to the king for his approbation or disallowance, they were not repealable by the crown after that time.

Pennsylvania is divided into seven counties; four of which are called the *Upper*, and three the *Lower*. Of the upper, viz. Buckingham, Philadelphia, Chester, and Lancaster, the three first are the lands included in king Charles II's grant, and designed *Pennsylvania*; the lower, viz. those of Newcastle, Kent, and Suffex, were called *Nova Belgia* before the duke of York sold them, as we observed above, to Mr Penn. The upper counties end at Marcus Hook, four miles below Chester Town, where the lower begin, and run along the coast near 100 miles. Each of these counties had a sheriff, with a quarterly and monthly session, and affizes twice a year.

PENSION, a sum of money paid annually for services or considerations already past. The yearly payment of each member to the houses of the inns of courts are likewise named *pensions*; and the yearly assembly of the society of Gray's Inn, to consult on the affairs of the house, is also called a *pension*.

PENSIONARY, or PENSIONER, a person who has an appointment, or yearly sum, payable during life, by way of acknowledgment, charged on the estate of a prince, company, or particular person.

Grand PENSIONARY, an appellation given to the first minister of the States of Holland. The grand pensionary is chairman in the assemblies of the states of that province: he proposes the matters to be consulted on; collects the votes; forms and pronounces the resolutions of the states; opens letters; confers with foreign ministers, &c. His business is also to inspect the finances, to maintain the authority of the states, and to see that the laws are observed; and he is perpetual deputy of the states-general of the United Provinces. His commission is, however, given him only for five years; after which it is deliberated whether or no it shall be renewed; but there is no instance of its being revoked; therefore death only puts an end to the functions of this important minister.

PENSIONARY, is also the first minister of the regency of each city in Holland. His office is to give his advice in affairs relating to the government, either of the state in general, or of the city in particular; and in assemblies of the states of the province, he is speaker in behalf of his city. The function, however, of these pensionaries is not every where alike; in some cities they only give their advice, and are never found in assemblies of the magistrates, except when expressly called

Pension,  
Pensionary.

**Pensioner** called thither : in others they attend constantly ; and in others they make the propositions on the part of the burgo-masters, draw up their conclusions, &c. They are called *pensionaries*, because they receive an appointment or pension.

**PENSIONER**, in general, denotes a person who receives a pension, yearly salary, or allowance. Hence, *The Band of Gentlemen-PENSIONERS*, the noblest sort of guard to the king's person, consists of 40 gentlemen, who receive a yearly pension of 100 l.

This honourable band was first instituted by king Henry VIII. and their office is to attend the king's person, with their battle-axes, to and from his chapel-royal, and to receive him in the presence-chamber, or coming out of his privy-lodgings : they are also to attend at all great solemnities, as coronations, St George's feast, public audiences of ambassadors, at the sovereign's going to parliament, &c.

They are each obliged to keep three double horses and a servant, and so are properly a troop of horse. They wait half at a time quarterly ; but on Christmas-day, Easter-day, Whitunday, &c. and on extraordinary occasions, they are all obliged to give their attendance. They have likewise the honour to carry up the sovereign's dinner on the coronation-day and St George's feast ; at which times the king or queen usually confer the honour of knighthood on two such gentlemen of the band as their captain presents.

Their arms are gilt battle-axes ; and their weapons, on horse-back, in time of war, are cuirassiers-arms, with sword and pistols. Their standard in time of war is, argent, a cross gules. Their captain is always a nobleman, who has under him a lieutenant, a standard-bearer, a clerk of the check, secretary, paymaster, and harbingers.

**PENSTOCK**, a sluice or flood-gate, serving to retain or let go at pleasure the water of a mill-pound, or the like.

**PENTACROSTIC**, in poetry, a set of verses so disposed, as that there are always five acrostics of the same name, in five divisions of each verse. See **ACROSTIC**.

**PENTÆDROSTYLA**, in natural history, the name of a genus of spars. See **SPAR**. The bodies of this genus are spars in form of Pentagonal columns, terminated by pentangular pyramids at one end, and regularly affixed at the other to some solid body.

**PENTAGON**, in geometry, a figure of five sides and five angles. See **GEOMETRY**.

In fortification, pentagon denotes a fort with five bastions.

**PENTAGRAPH**, an instrument designed for drawing figures in what proportion you please, without any skill in the art.

It consists of four brass or wooden rulers, two of them from 15 to 18 inches long, and the other two half that length. At the ends and middle of the long rulers, as also at the ends of the shorter, are holes, upon the exact fixing of which the perfection of the instrument chiefly depends. Those in the middle of the long rulers are to be at the same distance from those at the ends of the long ones, and those of the short ones so as to form a parallelogram. It is fitted together by a large pillar *a*, having at one end a screw and nut, whereby the long rulers are joined, and at the

other a little knot for the instrument to slide on : *b* is a rivet with a screw and nut, wherewith each short ruler is fastened to the middle of each long one ; *c* is a pillar, one end whereof being hollowed into a screw, has a nut fitted to it : at the other end is a worm to screw into the table when the instrument is to be used ; it joins the ends of the two short rulers : *d* is a pen or pencil screwed into a little pillar : *e* is a brass point moderately blunt, screwed likewise into a little pillar.

*Use of the Pentagraph.* 1. To copy a design in the same scale as the original. Screw the worm *c* into the table ; lay a paper under the pencil *d* now placed at *f*, and the design under the point *e* now placed at *g* ; then conducting the point over the several lines of the design, the pencil *f* will draw the same on the paper. 2. If the design is to be reduced into a half, &c. the worm must be placed at the end of the long ruler *d*, and the paper and pencil in the middle. In this situation conduct the brass point as before, and the pencil will draw its copy in the proportion required, the pencil here moving through half the length that the point does. On the contrary, if the design is to be enlarged one half, the brass point, with the design, must be placed in the middle at *c*, the pencil and paper at the end of the long ruler, and the worm at the other.

2. To enlarge and reduce in other proportions, there are holes drilled at equal distances on each ruler ; namely, all along the short ones, and half-way up the long ones, for placing of the brass point, pencil, and worm, in a right line therein ; that is, if the piece carrying the point be put in the third hole, the two other pieces must be put in its third hole. If then the point and design be placed at any hole of the short ruler, which forms the angle therewith, the copy will be less than half the original. On the contrary, if it be placed at one of the holes of that short ruler which is parallel to the long ruler, the copy will be greater than half the original. Few of these instruments will do any thing but straight lines, and many of them not even those.

**PENTAMETER**, in ancient poetry, a kind of verse, consisting of five feet, or metres, whence the name. The two first feet may be either dactyls or spondees at pleasure ; the third is always a spondee ; and the two last anapests : such is the following verse of Ovid.

1 2 3 4 5  
*Carminibus vixit, tempus in omne mori.*

A pentameter verse subjoined to an hexameter, constitutes what is called *elegiac*. See **ELEGIAC**.

**PENTANDRIA**, (from πέντε, "five," and ἀνρ, "a man or husband") ; the name of the fifth class in Linnaeus's sexual method, consisting of plants which have hermaphrodite flowers, with five stamina or male organs. See **BOTANY**, p. 1296.

**PENTAPOLIS**, (Wisdom x.) the five cities of the plain in Palestine, all destroyed by fire from heaven, except Zoar.

**PENTAPOLIS**, (Ptolemy) ; a district of Cyrenaica situate on the Mediterranean ; denominated from its five cities ; namely, *Berenice*, *Arfinoe*, *Ptolemais*, *Cyrene*, and *Apollonia*.

**PENTAPOLIS** of the *Philistines*, (Josephus) ; taking name

Pentapolis name from five principal cities, Gaza, Gath, Ascalon, Azotus, and Ekron.

||  
Pepin.

PENTAPOLIS, (Herodotus); five cities of Doris, a district of the Hither Asia; namely, Camirus, Cnidus, Cos, Jalyfus, and Lindus, (Scholiast on Theocritus).

PENTAPETALOUS, an appellation given to flowers, which consist of five petals or leaves.

PENTAPETES, in botany, a genus of the decandria order, belonging to the monodelphia class of plants. There is but one species known in the gardens of this country, viz. the phenicia, with halbert-pointed, spear-shaped, fawed leaves. It is an annual plant, a native of India, and rises to the height of two or three feet; adorned with fine scarlet flowers, consisting of one petal cut into five segments. In the centre of the flower arises a short thick column, to which adhere 15 short filamina. It is a tender plant, and must be brought up in the hot-house.

PENTATEUCH, an appellation given to the first five books of the Old Testament, viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy.

PENTATHLON, in antiquity, a general name for the five exercises performed at the Grecian games, viz. wrestling, boxing, leaping, running, and playing at the discs.

PENTECOST, a solemn festival of the Jews; so called because it was celebrated on the 50th day after the 16th of the month Nisan, which was the second day of the passover. See PASSOVER.

The feast of Pentecost was instituted in memory of the law's being given on the 50th day after the Israelites came out of Egypt. It was on the feast of Pentecost that the Holy Ghost miraculously descended on the apostles. See WHITSUNDAY.

PENTHESILEA, queen of the Amazons, succeeded Orythia, and gave proofs of her courage at the siege of Troy, where she was killed by Achilles. Pliny says that she invented the battle-ax.

PENULTIMA, or PENULTIMATE *Syllable*, in grammar, denotes the last syllable but one of a word; and hence the antipenultimate syllable is the last but two, or that immediately before the penultima.

PENUMBRA, in astronomy, a partial shade observed between the perfect shadow and the full light in an eclipse. It arises from the magnitude of the sun's body; for were he only a luminous point, the shadow would be all perfect; but, by reason of the diameter of the sun, it happens, that a place which is not illuminated by the whole body of the sun, does yet receive rays from a part thereof.

PEPIN DE HERISTAL, or LE GROS, mayor of the palace under Clovis III. Childbert, and Dagobert. The power of these mayors in France was so great, that they left the sovereign only the empty title, and in the end seized on the throne itself.

PEPIN *le Bref*, or *le Petit*, grandson to Pepin le Gros, and first king of the second race of French monarchs, was mayor of the palace to Childeric III. a weak prince: he contrived to confine him and his son Thierry in different monasteries; and then, with the assistance of Pope Stephen III. he usurped the sovereign power. He died in 768, aged 54.

PEPPER, PIPER, in natural history, an aromatic berry of a hot dry quality, chiefly used in season-

ing. We have three kinds of pepper at present used in the shops, the black, the white, and the long pepper.

Black pepper is the fruit of the piper, and is brought from the Dutch settlements in the East Indies. See PIPER.

The common white pepper is facitious, being prepared from the black in the following manner: they steep this in sea-water, exposed to the heat of the sun for several days, till the rind or outer bark loosens; they then take it out, and, when it is half dry, rub it till the rind falls off; then they dry the white fruit, and the remains of the rind blow away like chaff. A great deal of the heat of the pepper is taken off by this process, so that the white kind is more fit for many purposes than the black. However, there is a sort of native white pepper produced on a species of the same plant; which is much better than the facitious, and indeed little inferior to the black.

The long pepper is a dried fruit, of an inch or an inch and an half in length, and about the thickness of a large goose-quill: it is of a brownish grey colour, cylindrical in figure, and said to be produced on a plant of the same genus.

Pepper is principally used by us in food, to assist digestion; but the people in the East-Indies esteem it as a stomachic, and drink a strong infusion of it in water by way of giving them an appetite: they have also a way of making a fiery spirit of fermented fresh pepper, with water which they use for the same purposes. They have also a way of preserving the common and long pepper in vinegar, and eating them afterwards at meals.

Jamaica PEPPER, or Pimento. See PIMENTO.

PEPPER-Mint. See MENTHA.

PEPPER-Water, a liquor prepared in the following manner, for microscopical observations: put common black pepper, grossly powdered, into an open vessel so as to cover the bottom of it half an inch thick, and put to it rain or river-water, till it covers it an inch; shake or stir the whole well together at the first mixing, but never disturb it afterwards: let the vessel be exposed to the air uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, looking of several colours.

This is a congeries of multitudes of small animals; and being examined by the microscope, will be seen all in motion: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When disturbed, they will sometimes all dart down to the bottom; but they soon after come up to the surface again. The skin appears soonest in warm weather, and the animals grow the quickest; but in the severest cold it will succeed, unless the water freezes.

About the quantity of a pin's head of this foam, taken up on the nib of a new pen, or the tip of a hair-pencil, is to be laid on a plate of clear glass; and if applied first to the third magnifier, then to the second, and finally to the first, will shew the different animalcules it contains, of several kinds and shapes as well as sizes.

PERA, one of the suburbs of Constantinople, where

Perambulator, where ambassadors and Christians usually reside. See  
 Constantinople.

PERAMBULATOR, in surveying, an instrument for measuring distances, called also *pedometer*, *way-wiser*, and *surveying wheel*.

Plate CCL.  
 fig. 11.

It consists of a wheel AA, two feet seven inches and a half in diameter; consequently half a pole, or eight feet three inches in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, and divided into eight teeth; which, upon moving the wheel round, fall into the eight teeth of another nut C, fixed on one end of an iron-rod Q, and thus turn the rod once round in the time the wheel makes one revolution. This rod, lying along a groove in the side of the carriage of the instrument, under the dotted line, has at its other end a square hole, into which is fitted the end b of a small cylinder P. This cylinder is disposed under the dial-plate of a movement, at the end of the carriage B, in such a manner as to be moveable about its axis: its end a is cut into a perpetual screw, which falling into the 32 teeth of a wheel perpendicular thereto, upon driving the instrument forward, that wheel makes a revolution each 16th pole. On the axis of this wheel is a pinion with six teeth, which, falling into the teeth of another wheel of 60 teeth, carries it round every 160th pole, or half a mile.

This last wheel, carrying a hand or index round with it over the divisions of a dial-plate, whose outer limb is divided into 160 parts, corresponding to the 160 poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion, containing 20 teeth, which falling into the teeth of a third wheel which hath 40 teeth, drives it once round in 320 poles, or a mile. On the axis of this wheel is a pinion of 12 teeth, which, falling into the teeth of a fourth wheel having 72 teeth, drives it once round in 12 miles.

This fourth wheel, carrying another index over the inner limb of the dial-plate, divided into 12 for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as 12 miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along and observing the hands, has the same effect as dragging the chain and taking account of the chains and links.

Its advantages are its hardness and expedition; its contrivance is such, that it may be fitted to the wheel of a coach, in which state it performs its office, and measures the road without any trouble at all.

PERCA, the PERCH; a genus of fishes belonging to the order of thoracici. The head is furnished with scaly and serrated opercula; there are seven rays in the membrane of the gills; and the fins on the back are prickly. There are 38 species, principally distinguished by peculiarities in the back-fin. The most remarkable are,

1. The fluvialilis, or common perch, hath a deep body, very rough scales, and the back much arched. The colours are beautiful; the back and part of the

sides being of a deep green, marked with five broad black bars pointing downwards; the belly is white, tinged with red; the ventral fins of a fine scarlet; the anal fins and tail of the same colour, but rather paler. In a lake called *Llyn Raithlyn*, in Merionethshire in Wales, is a very singular variety of this fish: the back part is quite hunched, and the lower part of the backbone next the tail strangely distorted: in colour and other respects it resembles the common perch, which are as numerous in this lake as the deformed fish. They are not peculiar to this water; for Linnaeus takes notice of them in a lake at Fahlun in his country. It is said that they are also met with in the Thames near Marlow.

The perch was much esteemed as food by the Romans, nor is it less admired at present as a firm and delicate fish; and the Dutch are particularly fond of it when made into a dish called *water-fouchy*. It is a gregarious fish, and loves deep holes and gentle streams; is exceedingly voracious, and an eager biter: if the angler meets with a shoal of them, he is sure of taking every one.—It is a common notion that the pike will not attack this fish, on account of the spiny fins which the perch erects on its approach. This may be true of large fish; but it is well known that small perches are the most tempting bait which can be laid for the pike. The perch is very tenacious of life, and has been known to survive a journey of 60 miles in dry straw. It seldom grows to a large size, though Mr Pennant mentions one that weighed nine pounds; but this, he tells us, is very uncommon.

2. The labrax, or bass, is a very voracious, strong, and active fish. Ovid calls them *rapidi lupi*, a name continued to them by after-writers; and they are said to grow to the weight of fifteen pounds. The irides are silvery; the mouth large; the teeth are situated in the jaws, and are very small: in the roof of the mouth is a triangular rough space, and just at the gullet are two others of a roundish form. The scales are of a middling size, are very thick set, and adhere closely. The body is formed somewhat like that of a salmon. The colour of the back is dusky, tinged with blue. The belly white. In young fish the space above the side line is marked with small black spots.—It is esteemed a very delicate fish.

3. The perca marina, or sea-perch, is about a foot long; the head large and deformed; eyes great; teeth small and numerous. On the head and covers of the gills are strong spines. The colour red, with a black spot on the covers of the gills, and some transverse dusky lines on the sides. It is a fish held in some esteem at the table.

4. The cernua, or ruffe, is found in several of the English streams: it is gregarious, assembling in large shoals, and keeping in the deepest part of the water. It is of a much more slender form than the perch, and seldom exceeds six inches in length. The teeth are very small, and disposed in rows. It has only one dorsal fin, extending along the greatest part of the back: the first rays, like those of the perch, are strong, sharp, and spiny; the others soft. The body is covered with rough compact scales. The back and sides are of a dirty green, the last inclining to yellow, but both spotted with black. The dorsal fin is spotted with black; the tail marked with transverse bars.

5. The

Perca.

Perception, 5. The nilotica, or perch of the Nile, is taken about  
 Perceptive. Cairo. The flesh has a sweet and exquisite flavour,  
 and is not hard, but very white. It is one of the best  
 fishes of the Nile; and as it is of the largest size in  
 Egypt, it adorns a table if brought upon it entire and  
 well fried.

PERCEPTION, in logic, the first and most simple  
 act of the mind, whereby it perceives, or is conscious  
 of its ideas. See LOGIC, Part I. and METAPHYSICS,  
 n° 36—39. 77.

PERCEPTIVE faculty of the human mind.—Concerning this there have been very great controversies. Every one knows that there are sensations arising in our minds; but the question is what it is that perceives them, whether it is a man as a compound being of soul and body, or whether the living percipient is not a mind, or spirit alone, without a body, or else a quality only, resulting from the construction of a body without any distinct or separate spirit annexed thereto. These are difficulties probably never to be demonstrated, and we must at last be content with a probable proof only.

Man is so wonderfully made, that he seems to assign a place to every one of his sensations, and yet reason and experience tell him, that in truth they cannot exist, or be, where he is apt too hastily to judge, or suppose them to be; for as nothing can act where it is not, so the perceptive power of man cannot possibly perceive any thing without or beyond himself. It is generally agreed, that the secondary qualities of body (as they are called) do not exist external to the man, but only the primary ones; though Dr Berkeley attempted to shew that they both exist together, and that where-ever the colour was, there likewise was the extension. If this could be satisfactorily made to appear, the doctor's system would stand good for the non-existence of every thing but spirit and ideas; but it cannot, and to confine the argument to one sense alone, to wit, sight; that man perceives colour we are sure of, and therefore it must be within him, or he would act where he was not. Now if he perceived extension, that must likewise be within him too, but then he could perceive no extension larger than himself;—but as neither extension nor colour have any place assigned them in the body, surely it is not the body, or any conformation thereof, that perceives. We may then suppose that it is something else, which is joined with the body that is the percipient, which let us name *mind* or *soul*; this mind should seem to be one simple uncomposed being, otherwise it could not be conscious that successive perceptions were the affections of the same thing.

Colour, though hastily judged to be without the mind, Berkeley and Malbranche have sufficiently shewed not to be so; and that extension is so, seems also true; because it perceives none of its sensations extended, but only assigns or fixes a place for them, these of colour in particular, external to the man, although in fact they may not be without him; and this place is only determined by an operation of the mind, suggesting or supposing distance, from an experimental obstruction to the motion of some members of the body by which the touch is affected as well as the sight, and so both the tangible and visible object concluded, though too precipitately, to be in one and the same

place where the obstruction is likewise judged to be, and hence it obtained the supposition or suggestion of distance; and as we have no sensations to which we do not ascribe some distance or place, there must be place or space existing, or it could not be supposed. And therefore as nothing is perceived or suggested but what is supposed in some place, so nothing can exist but what constitutes space, or is in it, and must have some extension.

But then the mind of man surely cannot be extended beyond his body, though it often supposes an extension far beyond; and if the extension imagined was in the mind, and not a mere operation thereof, by way of supposition, it could not guess so much amiss about the extension of objects which has not been familiar to the other organs of sense, as we often find it does; for it seems to be a vulgar error to entertain a notion of the mind's judging of any distance or magnitudes from any pictures conjectured to be in the fund of the eye, or in itself: in the former case, if there be any picture in the bottom of the eye, it would judge every object in an inverse position to the body, which is contrary to experience; neither does the mind judge of any magnitude according to any such pictures, but of the real external magnitudes; and seldom errs much, unless the objects be very remote.—If the bulk of objects were judged of by the pictures in the eye, a flea or mite must judge every object very small to what a man does, because the picture will be diminished nearly as the eye is less: indeed these insects may see distinctly smaller things than man, because the objects may be brought nearer their small eyes, without throwing the focus of the rays beyond the retina, as the same distance of object would do in a larger eye, and prevent distinct vision; and it is highly probable, that these small insects cannot see objects at a great distance, unless they are much larger than what a man can see at the like distance; but then what they do see they judge to be of the same bigness that a man does; and so must every creature, let its eyes be of what dimension or number you please. It is a vague notion opticians have, who imagine that one, like a microscope lens, will magnify the picture on the retina, whereas just the contrary takes place; for when the eye is used alone, without such a lens, the shorter focus of the eye forms the picture, and the longer is at the object; but when a lens is used by way of a microscope, the object is in the shorter, and the picture at the longer focus, just contrary to the method of common vision.

So, again, if the mind was conscious of a picture in the eye, it would perceive as many objects the creature had eyes; whereas it judges of no more, let the number of eyes be as they will, than it does by the help of any other of the senses.

From all which we may conclude, that figure, extension, and motion, are not perceptible objects; but that sensations alone are such, the former being only imagined, by an operation of the mind, to exist external to it; and that if they did not so exist, the mind could not imagine any extension, figure, and motion; for there never is found any of them perceivable by it, nor any figure or motion attending a simple sensation. Indeed it is too commonly thought,

Perch  
Perfect.

that there is a shape perceived with colour, or a coloured shape; but no object appears of one simple colour to a fixed eye, but every part of the object exhibits a different degree of colour; and these degrees separate sensations, to which the mind ascribes a place, though, in fact, the colour is not in the place so judged of, but something else that gives resistance to the actions of the mind on the body; and from hence it supposes there must be something existing there which gives rise to the colour perceived by it.—It is impossible the mind should perceive the images of things within itself, unless it was equally extended with the things themselves; and if not, how can it be thought that an ideal world can exist within the mind, as some philosophers have conjectured? Surely it cannot be; but it must be only imagination that directs as to the external existence of real things. We cannot properly be said to imagine what does not or has not really existed; for let a blind man try if he can imagine colour, or a deaf man sound, and he will find himself at a loss. Father Malbranche indeed tells us, that a man may have an idea of a golden mountain that never existed; and a man may recollect the figure of a mountain which he has formerly imagined, and remember the colour of gold which he lately had a perception of, and suppose it possible they may be connected, and call this operation of his mind an idea if he pleases; but, after all his efforts, if he should happen to think of a mountain as large as Shooter's hill, he will hardly allow it to be contained in his mind.

PERCH, in land-measuring, a rod or pole of 16½ foot in length, of which 40 in length and 4 in breadth make an acre of ground. *Crompt. Jurisd.* 222. But, by the customs of several counties, there is a difference in this measure. In Staffordshire it is 24 foot; and in the forest of Sherwood 25 foot; the foot being there 18 inches long; and in Herefordshire a perch of ditching is 21 feet, the perch of walling 16½ feet, and a pole of denshiored ground is 12 feet, &c. *Skene.*

PERCHE, a territory of Orlannois in France, 35 miles long, and 30 broad; bounded on the north by Normandy; on the south, by Maine and Dunois; on the east, by Beauce; and on the west, by Maine. It takes its name from a forest, and is pretty fertile. The inhabitants carry on a pretty good trade; and the principal town is Belleme.

PERCOLATION, the same with FILTRATION. See CHEMISTRY, n° 69.

PERCUSSION, in mechanics, the impression a body makes in falling or striking upon another; or the shock of two bodies in motion.

PERDIX. See TETRAO.

PEREASLAW, a strong populous town of Poland, in the palatinate of Kiovia, situated on the river Tribecz; in E. Long. 32. 44. N. Lat. 49. 46.

PERENNIALS, or PERENNIAL FLOWERS, in botany, a term applied to those plants whose roots will abide many years, whether they retain their leaves in winter or not. Those which retain their leaves are called *evergreens*; but such as cast their leaves are named *deciduous*, or *perditols*.

PERFECT, something to which nothing is wanting, or that has all the requisites of its nature and kind.

PERFECT Cadence, in MUSIC. See CADENCE.

PERFECT *Tenses*, in grammar. See PRETERITE. Perfect Pergamum.

PERFECTION.

PERFECTION, the state or quality of a thing.

Perfection is divided, according to Chauvinus, into physical, moral, and metaphysical.

Physical or natural perfection, is that whereby a thing has all its powers and faculties, and those too in full vigour; and all its parts both principal and secondary, and those in their due proportion, constitution, &c. in which sense man is said to be perfect when he has a found mind in a found body. This perfection is by the schools frequently termed *hypotheticon*, because a thing is enabled thereby to perform all its operations.

Moral perfection is an eminent degree of virtue or moral goodness, to which men arrive by repeated acts of piety, beneficence, &c. This is usually subdivided into absolute or inherent, which is actually in him to whom we attribute it; in imputative, which exists in some other, and not in him it is attributed to.

Metaphysical, transcendental, or essential perfection, is the possession of all the essential attributes, or of all the parts necessary to the integrity of a substance; or it is that whereby a thing has or is provided of every thing belonging to its nature. This is either absolute, where all imperfection is excluded, such is the perfection of God; or *secundum quid*, and in its kind.

PERFORANS MANUS.

PERFORANS *Pedis*.

PERFORATUS MANUS.

PERFORATUS *Pedis*.

See ANATOMY, Table of the Muscles.

PERFUME, denotes either the volatile effluvia from any body affecting the organ of smelling, or the substance emitting those effluvia; in which last sense the word is most commonly used. The generality of perfumes are made up of musk, ambergris, civet, rose and cedar woods, orange-flowers, jessamines, jonquils, tuberoles, and other odoriferous flowers. Those drugs commonly called aromatics, such as storax, frankincense, benzoin, cloves, mace, &c. enter the composition of a perfume; some are also composed of aromatic herbs or leaves, as lavender, marjoram, sage, thyme, hyssop, &c.

Perfumes were anciently very much in use; but, since people are become sensible of the harm they do to the head, they are generally disused among us; however, they are still common in Spain and Italy.

PERGAMA, (Virgil), the citadel of Troy; which, because of its extraordinary height, gave name to all high buildings, (Servius). Others say the walls of Troy were called *Pergama*.

PERGAMUM, (Pliny); called also *Pergamea*, (Virgil); *Pergamia*, (Plutarch); a town of Crete, built by Agamemnon in memory of his victory, (Velleius). Here was the burying-place of Lycurgus, (Aristoxenus, quoted by Plutarch). It was situate near Cydonia, (Servius); to what point not said; but Scylax helps him out, who places the Daërynean temple of Diana, which stood near Cydonia, (Strabo), to the north of the territory of Pergamia.—Another PERGAMUM, (Pliny, Strabo); a town of Mysia, situate on the Caicus, which runs by it. It was the royal residence of Eumenes, and of the kings of the Attali, (Livy). There an ancient temple of *Æsculapius*.

Pergamus. lapis flood; an asylum, (Tacitus). The ornament of Pergamus was the royal library, vying with that of Alexandria in Egypt; the kings of Pergamus and Egypt rivaling each other in this respect, (Pliny). Strabo ascribes this rivalry to Eumenes. Plutarch reckons up 200,000 volumes in the library at Pergamus. Here the *membrane pergamenæ*, whence the name *pergament*, were invented for the use of books, (Varro, quoted by Pliny). The country of Galen, and of Orisbasius chief physician to Julian the Apostate, (Eunapius), called by some the *apt of Galen*. Here P. Scipio died, (Cicero). Attalus son of Eumenes dying without issue, bequeathed his kingdom to the Roman people, who reduced it to a province, (Strabo). Pergamene, the epithet, (Martial). Here was one of the nine *consentus juridici*, or assemblies of the *Asia Romana*, called *Pergamensis*, and the ninth in order, (Pliny); which he also calls *iurisdiclio Pergamena*.

PERGAMUS, an ancient kingdom of Asia, formed out of the ruins of the empire of Alexander the Great. It commenced about the year 283. The first sovereign was one Philetærus, an eunuch, by birth a Paphlagonian, of a mean descent, and in his youth a menial servant to Antigonus one of Alexander's captains. He afterwards served Lyfimachus king of Macedon and Thrace, who appointed him keeper of his treasures lodged in Pergamus. While he held this employment, having fallen under the displeasure of Arinoe wife to Lyfimachus, the found means to make a quarrel between him and his master; upon which Philetærus seized on the castle of Pergamus, together with the treasures entrusted to his care, amounting to 90,000 talents. At first he offered his service, together with his treasure, to Seleucus king of Syria; but both Seleucus and Lyfimachus dying soon after, he kept possession of the town and treasure all till his death; which happened 20 years after his revolt from Lyfimachus.

Philetærus left the city of Pergamus to his brother, or, according to some, to his brother's son Eumenes I.; and he, laying hold of the opportunity offered by the dissensions among the Seleucidæ, possessed himself of many strong-holds in the province of Asia; and having hired a body of Galatians, defeated Antiochus, as he was returning from a victory gained over his brother Seleucus Callinicus. By this victory he obtained possession of the greater part of Asia; however, he did not long enjoy his acquisitions; for he died next year of immoderate drinking, a vice to which he was greatly addicted.

Eumenes was succeeded by Attalus I. nephew of Philetærus, and the first who took upon him the title of king of Pergamus. He defeated the Gauls, who were desirous of settling in his territory; and, according to Livy, was the first of the Asiatic princes who refused to pay a contribution to these barbarians. When Seleucus Ceraunus was engaged in other wars, he invaded his territories, and conquered all the provinces on this side of Mount Taurus; but was soon driven out of his new acquisitions by Seleucus and his grandfather Achæus, who entering into an alliance against him, deprived him of all his newly acquired territories, and even besieged him in his capital. Upon this Attalus invited to his assistance the Gauls who had

settled in Thrace; and with their help not only obliged the enemy to raise the siege of Pergamus, but quickly recovered all the provinces he had lost. After this he invaded Ionia and the neighbouring provinces, where several cities voluntarily submitted to him. The Teians, Colophonians, with the inhabitants of Egæa and Lemnos, sent deputies declaring themselves ready to acknowledge him for their sovereign; the Carlenes, on the other side the river Lycus, opened their gates to him, having first expelled the governor set over them by Achæus. From thence he advanced to Apia, and encamping on the banks of the river Megithus, received homage from the neighbouring nations. But here the Gauls, being frightened by an eclipse of the moon, refused to proceed farther; which obliged Attalus to return to the Hellespont, where he allowed his allies to settle, giving them a large and fruitful territory, and promising that he would always assist and protect them to the utmost of his power.

Attalus having thus settled his affairs with equal honour and advantage to himself, entered into an alliance with Rome, and afterwards joined them in their war against Philip king of Macedon. Here he had the command of the Rhodian fleet; with which he not only drove the Macedonians quite out of the seas, but having landed his men, he, in conjunction with the Athenians, invaded Macedon, and obliged Philip to raise the siege of Athens, which he had greatly distressed; for which services the Athenians not only heaped on him all the favours they could, but called one of their tribes by his name; an honour they had never bestowed on any foreigner before.

Attalus, not contented with all he had yet done against Philip, attempted to form a general confederacy of the Greeks against him. But while he was haranguing the Bœotians to this purpose, and exhorting them with great vehemence to enter into an alliance with the Romans against their common enemy, he fell down speechless. However, he came to himself again, and desired to be carried by sea from Thebes to Pergamus, where he died soon after his arrival, in the 72d year of his age and 43d of his reign.

This prince was a man of great generosity, and such an enthusiast in learning and learned men, that he caused a grammarian, named *Daphidas*, to be thrown into the sea from the top of a high rock, because he spoke disrespectfully of Homer.

Attalus was succeeded by his eldest son Eumenes II. He was exceedingly attached to the Romans, inasmuch that he refused the daughter of Antiochus the Great in marriage, lest he should thus have been led into a difference with that people. He also gave notice to the Roman senate of the transactions of Ariarathes king of Cappadocia, who was making great preparations both by sea and land. Nor did Eumenes stop here; for when he saw the war about to break out between Antiochus and the Romans, he sent his brother Attalus to Rome to give information of the proceedings of Antiochus. The senate heaped honours both on Eumenes and his brother; and in the war which followed, gave the command of their fleet to the king of Pergamus in conjunction with C. Livius Salinator. The victory gained on this occasion was in a great measure owing to Eumenes, who boarded some of the enemy's

Pergamus. ships in person, and during the whole action behaved with uncommon bravery. Some time afterwards Eumenes, entering the territories of Antiochus with a body of 5000 men, ravaged all the country about Thyatira, and returned with an immense booty. But in the mean time Antiochus invading Pergamus in his turn, ravaged the whole country, and even laid siege to the capital. Attalus, the king's brother held out with a handful of men till the Achæans, who were in alliance with Eumenes, sent 1000 foot and 100 horse to his assistance. As this small body of auxiliaries were all chosen men, and commanded by an experienced officer, they behaved with such bravery that the Syrians were obliged to raise the siege. At the battle of Magnesia, too, Eumenes behaved with the greatest bravery; not only sustaining the first attack of the enemy's elephants, but driving them back again on their own troops, which put the ranks in disorder, and gave the Romans an opportunity of giving them a total defeat by attacking them opportunely with their horse. In consequence of this defeat, Antiochus was obliged to conclude a peace with the Romans on such terms as they pleased to prescribe; one of which was, that he should pay Eumenes 400 talents, and a quantity of corn, in recompence for the damage he had done him.

Eumenes now thought of obtaining some reward from the Romans equivalent to the services he had done them. Having gone to Rome, he told the senate, that he was come to beg of them that the Greek cities which had belonged to Antiochus before the commencement of the late war, might now be added to his dominions; but his demand was warmly opposed by the ambassadors from Rhodes, as well as by deputies from all the Greek cities in Asia. The senate, however, after hearing both parties, decided the matter in favour of Eumenes, adding to his dominions all the countries on this side of Mount Taurus which belonged to Antiochus; the other provinces lying between that mountain and the river Mæander, excepting Lycia and Caria, were bestowed on the Rhodians. All the cities, which had paid tribute to Attalus, were ordered to pay the same to Eumenes; but such as had been tributary to Antiochus were declared free.

Soon after this Eumenes was engaged in a war with Prusias king of Bithynia, who made war upon him by the advice of Hannibal the celebrated Carthaginian general. But Eumenes, being assisted by the Romans, defeated Prusias in an engagement by sea, and another by land; which so disheartened him, that he was ready to accept of peace on any terms. However, before the treaty was concluded, Hannibal found means to draw Philip of Macedon into the confederacy, who sent Philocrates, an old and experienced officer, with a considerable body of troops to join Prusias. Hereupon Eumenes sent his brother Attalus to Rome with a golden crown, worth 15,000 talents, to complain of Prusias for making war on the allies of the Roman people without any provocation. The senate accepted the present, and promised to adjust every thing to the satisfaction of their friend Eumenes, whom they looked upon to be the most ready ally they had in Asia. But in the mean time Prusias, having ventured another sea-fight, by a contrivance of Hannibal's, gained a complete victory. The Carthaginian commander ad-

vised him to fill a great many earthen vessels with various kinds of serpents and other poisonous reptiles, and in the heat of the fight to throw them into the enemies ships so as to break the pots and let the serpents loose. All the soldiers and seamen were commanded to attack the ship in which Eumenes was, and only to defend themselves as well as they could against the rest; and that they might be in no danger of mistaking the ship, an herald was sent before the engagement with a letter to the king. As soon as the two fleets drew near, all the ships of Prusias, singling out that of Eumenes, discharged such a quantity of serpents into it, that neither soldiers nor sailors could do their duty, but were forced to fly to the shore, lest they should fall into the enemy's hands. The other ships, after a faint resistance, followed the king's example, and were all driven ashore with great slaughter; the soldiers being no less annoyed by the stings of the serpents, than by the weapons of the enemy. The greatest part of the ships of Eumenes were burnt, several taken, and the others so much flattered, that they became quite unserviceable. The same year Prusias gained two remarkable victories over Eumenes by land, both of which were entirely owing to stratagems of Hannibal. But, while matters were thus going on to the disadvantage of Eumenes, the Romans interfered, and by their deputies not only put an end to the differences between the two kings, but prevailed on Prusias to betray Hannibal; upon which he poisoned himself, as hath been related under the article HANNIBAL.

Eumenes, being thus freed from such a dangerous enemy, engaged in a new war with the kings of Cappadocia and Pontus, in which also he proved victorious. His friendship for the Romans he carried to such a degree of enthusiasm, that he went in person to Rome to inform them of the machinations of Perseus king of Macedon. He had before quarrelled with the Rhodians, who sent ambassadors to Rome to complain of him. But as the ambassadors happened to arrive while the king himself was present in the city, the Rhodian ambassadors could not obtain any hearing, and Eumenes was dismissed with new marks of favour. This journey, however, had almost proved fatal to him; for, on his return, as he was going to perform a sacrifice at Delphi, two assassins, sent by Perseus, rolled down two great stones upon him as he entered the straits of the mountains. With one he was dangerously wounded on the head, and with the other on the shoulder. He fell with the blows from a steep place, and thus received many other bruises; so that he was carried on board his ship when it could not well be known whether he was dead or alive. His people, however, soon finding that he was still alive, conveyed him to Corinth, and from Corinth to Ægina, having caused their vessels to be carried over the Isthmus.

Eumenes remained at Ægina till his wounds were cured, which was done with such secrecy, that a report of his death was spread all over Asia, and even believed at Rome; nay, his brother Attalus was so convinced of the truth of this report, that he not only assumed the government, but even married Stratonice the wife of Eumenes. But in a short time Eumenes convinced them both of his being alive, by returning

Pergamus. to his kingdom. On the receipt of this news Attalus resigned the sovereignty in great haste, and went to meet his brother; carrying an halberd, as one of his guards. Eumenes received both him and the queen with great tenderness, nor did he ever say any thing which might tend to make them uneasy; only it is said he whispered in his brother's ear when he first saw him, "Be in no haste to marry my wife again till you are sure that I am dead."

The king being now more than ever exasperated against Perfes, joined the Romans in their war against Perfes; but during the course of it he suddenly cooled in his affection towards those allies whom he had hitherto served with so much zeal, and that to such a degree, that he admitted ambassadors from Perfes, and offered to stand neuter if he would pay him 1000 talents, and for 1500, to influence the Romans to grant him a safe and honourable peace. But these negotiations were broke off without effect, by reason of the distrust which the two kings had of one another. Eumenes could not trust Perfes unless he paid him the money beforehand; while, on the other hand, Perfes did not care to part with the money before Eumenes had performed what he promised; neither could he be induced to pay the sum in question, though the king of Pergamus offered to give hostages for the performance of his promise. What the reason of such a sudden change in the disposition of Eumenes was, is nowhere told; however, the fact is certain. The negotiations abovementioned were concealed from the Romans as long as possible; however, they soon came to be known, after which the republic began to entertain no small jealousy of their old friend, and therefore heaped favours on his brother Attalus, without taking any notice of the king himself. Eumenes had sent him to Rome to congratulate the senate on the happy issue of the war with Perfes, not thinking that his practices had been discovered. However, the senate, without taking any notice of his disaffection to Eumenes at first, entertained Attalus with the greatest magnificence; then several of the senators who visited him proceeded to acquaint him with their suspicions of the king, and desired Attalus to treat with them in his own name, assuring him, that the kingdom of Pergamus would be granted him, if he demanded it, by the senate. These speeches had at first some effect; but Attalus, being of an honest disposition, and assisted by the advice of a physician called *Stratius*, a man of great probity, resolved not to comply with their desire. When he was admitted to the senate, therefore, he first congratulated them on the happy issue of the Macedonian war, then modestly recounted his own services; and lastly, acquainted them with the motive of his journey; intreating them to send ambassadors to the Gauls, who by their authority might secure his brother from any danger of their hostilities; and he requested them also, that the two cities of *Ænus* and *Maronea* might be bestowed on himself. The senate, imagining that Attalus designed to choose some other day to sue for his brother's kingdom, not only granted all his requests, but sent him richer and more magnificent presents than they had ever done before. Upon this Attalus immediately set out on his return to Pergamus; which so provoked the senators, that they declared the cities free which they had promised to

Pergamus. Attalus; thus rendering ineffectual their promise which they were ashamed openly to revoke; and as for the Gauls, who were on all occasions ready to invade the kingdom of Pergamus, they sent ambassadors to them, with instructions to behave in such a manner as would rather tend to encourage them in their design than dissuade them from it.

Eumenes, being alarmed at those proceedings, resolved to go in person to Rome, in order to justify himself. But the senate, having already condemned him in their own minds, resolved not to hear his vindication. For this reason, as soon as they heard of his design, they made an act that no king should be permitted to enter the gates of Rome. Eumenes, however, who knew nothing of this act, set forward on his journey, and landed at Brundisium; but, no sooner did the Roman senate get intelligence of his arrival there, than they sent a quæstor acquainting him with the decree of the senate; and telling him at the same time, that if he had any business to transact with the senate, he was appointed to hear it and transmit it to them; but if not, that the king must leave Italy without delay. To this Eumenes replied, that he had no business of any consequence to transact, and that he did not stand in need of any of their assistance; and without saying a word more, went on board his ship, and returned to Pergamus.

On his return home, the Gauls, being encouraged by the cold reception which he had met with at Rome, invaded his territories, but were repulsed with great loss by the king, who afterwards invaded the dominions of Prusias, and possessed himself of several cities. This produced new complaints at Rome; and Eumenes was accused, not only by the ambassadors of Prusias, but also by those of the Gauls and many cities in Asia, of keeping a secret correspondence with Perfes king of Macedon. This last charge was confirmed by some letters which the Romans themselves had intercepted; so that Eumenes found it impossible to keep up his credit any longer at Rome, though he sent his brothers *Athenæus* and *Attalus* thither to intercede for him. The senators, in short, had conceived the most implacable hatred against him, and seemed absolutely bent on his destruction, when he died, in the 39th year of his reign, leaving his kingdom and his wife to his brother Attalus. He left one son, but he was an infant, and incapable of governing the kingdom; for which reason Eumenes chose rather to give the present possession of the crown to his brother, reserving the succession to his son, than to endanger the whole by committing the management of affairs to his son's tutors.

Attalus, in the beginning of his reign, found himself greatly distressed by Prusias king of Bithynia, who not only overthrew him in a pitched battle, but advanced to the very walls of Pergamus, ravaging the country as he marched along; and at last saved the royal city itself. The king, however, saved himself by a timely flight, and dispatched ambassadors to Rome, complaining of the bad usage of Prusias. The latter endeavoured to defend himself, and to throw the blame on Attalus. But, after a proper inquiry was made into the matter, Prusias was found to be entirely in the wrong; in consequence of which, he was at last obliged to conclude a peace with his adversary on the following

*Pergamini.* lowing terms. 1. That he should immediately deliver up to Attalus 20 ships with decks. 2. That he should pay 500 talents to Attalus within the space of 20 years. 3. That he should pay 100 talents to some of the other Asiatic nations by way of reparation for the damages they had sustained from him. And, 4. Both parties should be content with what they had before the beginning of the war.

Some time after this, Prusias having made an unnatural attempt on the life of his son Nicomedes, the latter rebelled, and, with the assistance of Attalus, drove his father from the throne, and, as is said, even murdered him in the temple of Jupiter. The Romans took no notice of these transactions, but shewed the same kindness to Attalus as formerly. The last enterprise in which we find Attalus engaged, was against Andriens the pretended son of Perles king of Macedon, where he assisted the Romans; after which he gave himself up entirely to ease and luxury, committing state affairs entirely to his ministers; and thus continued to his death, which happened in the 82d year of his age, about 138 B. C.

Attalus II. was succeeded by Attalus III. the son of Eumenes; for the late king, considering that he only held the crown as a trust for his nephew, passed by his own children in order to give to it him, tho' he appears to have been by no means worthy of it. He is said to have been deprived of his senses thro' the violence of his grief for his mother's death; and indeed, throughout his whole reign, he behaved more like a madman than any thing else. Many of his subjects of the highest quality were cut off with their wives and children, upon the most groundless suspicions; and for these executions he made use of mercenaries hired out from among the most barbarous nations. Thus he proceeded till he had cut off all the best men in the kingdom; after which he fell into a deep melancholy, imagining that the ghosts of those whom he had murdered were perpetually haunting him. On this he shut himself up in his palace, put on a mean apparel, let his hair and beard grow, and sequestered himself from all mankind. At last he withdrew from the palace, and retired into a garden, which he cultivated with his own hands, and filled with all sorts of poisonous herbs. There he used to mix with wholesome pulse, and send packets of them to such as he suspected. At last, being weary of this amusement, and living in solitude, because nobody durst approach him, he took it in his head to follow the trade of a founder, and make a brazen monument. But, while he laboured at melting and casting the brass, the heat of the sun and furnace threw him into a fever, which in seven days put an end to his tyranny, after he had sat on the throne five years.

On the death of the king, a will was found, by which he left the Roman people heirs of all his goods; upon which they seized on the kingdom, and reduced it to a province of their empire by the name of *Asia Proper*. But Ariftonicus, a son of Eumenes by an Ephesian courtesan, reckoning himself the lawful heir to the crown, could by no means be satisfied with this usurpation of the Romans, and therefore assembled a considerable army to maintain his pretensions. The people in general, having been accustomed to a monarchy, dreaded a republican form of government; in

consequence of which, they assisted Ariftonicus, and soon put him in a condition to reduce the whole kingdom. The news, however, were soon carried to Rome, and Licinius Crassus, the pontifex maximus, was sent into the east, with orders to enforce obedience to the king's will. Historians take no notice of any forces which were sent along with this commander; whence it is supposed, that he depended on assistance from the Asiatics, who were in alliance with Rome, or from the Egyptians. But when he came thither, he found both the Syrians and Egyptians so reduced, that he could not expect any assistance from them. However, he was soon supplied with troops in plenty by the kings of Pontus, Bithynia, Cappadocia, and Paphlagonia; but managed matters so ill, that he was entirely defeated and taken prisoner. Those who took him designed to carry him to Ariftonicus; but he, not able to endure the disgrace, would have laid violent hands on himself if he had not been disarmed. However, being allowed to keep a rod for managing the horse on which he sat, he struck a Thracian soldier who stood near him so violently with it, that he beat out one of his eyes; upon which the other drew his sword, and run him thro' on the spot. His head was brought to Ariftonicus, who exposed it to public view; but the body was honourably buried.

Ariftonicus had no great time to enjoy the fruits of his victory. Indeed he behaved very improperly after it; for, instead of preparing to oppose the next army, which he might have been assured the Romans would send against him, he spent his time in feasting and revelling. But he was soon roused out of his lethargy by Perpenna the new consul, who having assembled with incredible expedition the troops of the allies, came unexpectedly upon him, obliged him to venture an engagement at a disadvantage, and entirely defeated him. Ariftonicus fled to a city called *Stratonice*; but was so closely pursued by the conqueror, that the garrison, having no method of supplying themselves with provisions, delivered up their leader, as well as a philosopher named *Blesius*, who had been the companion and counsellor of Ariftonicus. The philosopher behaved with great resolution after being taken, and openly defended his siding with Ariftonicus, because he thought his cause just. He exhorted the latter to prevent the disgrace and misery of captivity by a voluntary death; but Ariftonicus, looking upon death as a greater misery than any captivity, suffered himself to be treated as his conquerors pleased.

In the mean time, a new consul, named *Manius Aquilius*, being arrived from Rome, sent a most haughty message to Perpenna, requiring him immediately to deliver up Ariftonicus as a captive belonging to his triumph when the war should be ended. With this demand Perpenna refused to comply, and his refusal had almost produced a civil war. However, this was prevented by the death of Perpenna, which happened soon after the dispute commenced. The Pergameanians, notwithstanding the defeat and captivity of their leader, still held out with such obstinacy, that Aquilius was obliged to besiege, and take by force almost every city in the kingdom. In doing this, he took a very effectual, though exceeding cruel method. Most of the cities in the kingdom had no other water than what was brought from a considerable distance in aqueducts.

**Periander** Perichorus  
Perimeter.  
 aqueducts. These Aquilinus did not demolish, but poisoned the water, which produced the greatest abhorrence of him throughout all the east. At last, however, the whole country being reduced, Aquilinus triumphed, the unhappy Aristonicus was led in chains before his chariot, and probably ended his miserable life in a dungeon. The country remained subject to the Romans while their empire lasted, but is now in the hands of the Turks. The city is half ruined, and is known by the name of *Pergamus*. It is inhabited by about 3000 Turks, and a few families of poor Christians. E. Long. 27. 27. N. Lat. 30. 3.

**PERIANDER**, tyrant of Corinth and Corcyra, was reckoned among the seven wise men of Greece; though he might rather have been reckoned among the most wicked men, since he changed the government of his country, deprived his countrymen of their liberty, usurped the sovereignty, and committed the most shocking crimes. In the beginning of his reign he behaved with mildness; but after his having sent to the tyrant of Syracuse to consult him on the safest method of government, he abandoned himself to cruelty. The latter, having heard Periander's envoys, took them into a field, and instead of answering them, pulled up before them the ears of corn which exceeded the rest in height. Periander, on being told of this action, understood what was meant by it. He first secured himself by a good guard, and then put the most powerful Corinthians to death. He abandoned himself to the most enormous crimes; committed incest with his mother, kicked to death his wife Melissa, daughter of Procles king of Epidaurus, notwithstanding her being with child; and was so enraged at Lycophron, his second son, for lamenting his mother's death, that he banished him into the island of Corcyra. Yet he passed for one of the greatest politicians of his time; and Heracles tells us, that he forbade voluptuousness; that he imposed no taxes, contenting himself with the custom arising from the sale and the import and export of commodities; that, though wicked himself, he hated the wicked, and caused all pimps to be drowned; lastly, that he established a senate, and settled the expence of its members. He died 585 B. C.

**PERIAGOGUE**, in rhetoric, is used where many things are accumulated into one period which might have been divided into several.

**PERIANTHIUM**, (from *περίανθος*, "round," and *ἄνθος*, "the flower,") the flower-cup properly so called, the most common species of calix, placed immediately under the flower, which is contained in it as in a cup. See **BOTANY**, p. 1296.

**PERICARDIUM**, in anatomy, a membranous bag filled with water, which contains the heart in man and many other animals. It is formed by a duplication of the mediastinum, or membrane which divides the thorax into two unequal parts. See **ANATOMY**, n° 382, 305, 386.

**PERICARPIMUM**, (from *περί*, "round," and *καρπός*, "fruit,") the seed-vessel; an entrail of the plant big with seeds, which it discharges when ripe. The seed-vessel is in fact the developed seed-bud, and may very properly be compared to the fecundated ovary in animals; for it does not exist till after the fertilizing of the seeds by the male-dust, and the consequent

fall of the flower. All plants, however, are not furnished with a seed-vessel; in such as are deprived of it, the receptacle or calix performs its functions by inclosing the seeds, as in a matrix, and accompanying them to perfect maturity.

**PERICHORUS**, in antiquity, a name given by the Greeks to their profane games or combats, that is, to such as were not consecrated to any of the gods.

**PERICLES**, was one of the greatest men that ever flourished in Greece. He was educated with all imaginable care; and beside other masters, he had for his tutors Zeno, Eleates, and Anaxagoras. He learned from the last of these to fear the gods without superstition, and to account for an eclipse from a natural cause. Many were unjust enough to suspect him of atheism, because he had perfectly studied the doctrine of that philosopher. He was a man of undoubted courage; and of such extraordinary eloquence, supported and improved by knowledge, that he gained almost as great an authority under a republican government as if he had been a monarch; but yet he could not escape the satirical strokes of the comic poets. His dissoluteness with the women was one of the vices with which he was chiefly charged. He died the third year of the Peloponnesian war, after long sickness, which had weakened his understanding. Aspasia, Pericles's favourite, was a learned woman of Miletus: she taught Socrates rhetoric and politics. As Pericles cared not much for his wife, he willingly gave her up to another, and married Aspasia, whom he passionately loved.

**PERICRANIUM**, in anatomy, a thick solid coat or membrane, covering the outside of the cranium or skull. See **ANATOMY**, n° 4.

**PERIGEE**, in astronomy, that point of the sun or moon's orbit wherein they are at the least distance from the earth, in which sense it stands opposed to apogee.

**PERIGRAPHE**, a word usually understood to express a careless or inaccurate delineation of any thing; but in Vesalius it is used to express the white lines or impressions that appear on the musculus rectus of the abdomen.

**PERIGEUX**, an ancient episcopal town of France, capital of the province of Perigord, seated on the river Isle, in E. Long. o. 33. N. Lat. 45. 18. It is remarkable for the ruins of the temple of Venus, and an amphitheatre.

**PERIGORD**, a province of France, which makes part of Guienne, bounded on the north by Angoumois, and a part of Marche, and on the east by Quercy and Limousin; on the south, by Agenois and Bazadais; and on the west, by Bourleadois, Angoumois, and a part of Saintonge. It is about 83 miles in length, and 60 in breadth. It abounds in iron mines, and the air is pure and healthy. Perigeux is the capital town.

**PERIHELIMUM**, in astronomy, that part of a planet or comet's orbit wherein it is in its least distance from the sun, in which sense it stands in opposition to aphelium.

**PERIMETER**, in geometry, the bounds or limits of any figure or body. The perimeters of surfaces or figures are lines; those of bodies are surfaces. In circular

Perinæum

Period.

cular figures, instead of perimeter, we say circumference, or periphery.

**PERINÆUM**, or **PERINEUM**, in anatomy, the space between the anus and the parts of generation, divided into two equal lateral divisions by a very distinct line, which is longer in males than in females.

**PERINKSKIÖLD** (John), a learned Swedish writer, born at Stregnesia in Sudermania, in 1954, studied under his father, who was professor of eloquence and poetry, and afterwards became well skilled in the antiquities of the North. He was made professor at Upsal, secretary antiquary of the king of Sweden, and counsellor of the chancery of antiquities. He died in 1720. His principal works are: 1. A history of the kings of Norway. 2. A history of the kings of the North. 3. An edition of John Meffens on the kings of Sweden, Denmark, and Norway, in 14 vols folio, &c. All Peringskiöld's works are excellent, and highly esteemed.

**PERIOD**, in astronomy, the time taken up by a star or planet in making a revolution round the sun; or the duration of its course till it return to the same part of its orbit.

The periodical times of the planets round the sun are as follow:

		seconds.	min.	hrs.	days.
Mercury	-	-	87	23	15 53
Venus	-	-	224	16	49 24
The earth	-	-	365	6	9 14
Mars	-	-	686	23	27 30
Jupiter	-	-	4332	12	20 25
Saturn	-	-	10759	6	36 26

There is a wonderful harmony between the distances of the planets from the sun, and their periods round him; the great law whereof is, that the squares of the periodical times of the primary planet, are to each other as the cubes of their distances from the sun: and likewise, the squares of the periodical times of the secondaries of any planet are to each other as the cubes of their distances from that primary. This harmony among the planets is one of the greatest confirmations of the Copernican hypothesis. See **ASTRONOMY**, n° 132.

For the periods of the moon, see **ASTRONOMY**, n° 223.

The periods of several comets are now pretty well ascertained. See **ASTRONOMY**, n° 46 *et seq.*

**PERIOD**, in chronology, denotes a revolution of a certain number of years, or a series of years, whereby, in different nations, and on different occasions, time is measured; such are the following.

**Calippic PERIOD**, a system of seventy-six years. See **CALIPPIC**.

**Dionysian PERIOD**, or **Victorian Period**, a system of 532 lune-solar and Julian years; which being elapsed, the characters of the moon fall again upon the same day and feria, and revolve in the same order, according to the opinion of the ancients.

This period is otherwise called the *great paschal cycle*, because the Christian church first used it to find the true time of the pascha or easter. The sum of these years arise by multiplying together the cycles of the fun and moon. See **ASTRONOMY**, n° 308.

**Hipparchus's PERIOD**, a system of 304 years, both

lunar and solar; which being elapsed, Hipparchus thought that the reckoning by the lunar motion would coincide again with the solar measures. This period comprehends 3760 lunar months, or 111,039 days; the sum of which arises from the multiplication of the Calippic period by 4, subtracting unity from the product.

**Julian PERIOD**. See **JULIAN**.

**PERIOD**, in grammar, denotes a small compass of discourse, containing a perfect sentence, and distinguished at the end by a point, or full stop, thus (.) ; and in members or divisions marked by commas, colons, &c.

**PERIOD**, in oratory. See there, n° 44.

**PERIODIC**, or **PERIODICAL**, something that terminates and comprehends a period; such is a periodic month; being the space of time wherein the moon dispatches her period.

**PERIOECI**, *περιοικοι*, in geography, such inhabitants of the earth as have the same latitudes, but opposite longitudes, or live under the same parallel and the same meridian, but in different semicircles of that meridian, or in opposite points of the parallel. These have the same common seasons throughout the year, and the same phenomena of the heavenly bodies; but when it is noonday with the one it is midnight with the other, there being twelve hours in an east and west direction. These are found on the globe by the hour-index, or by turning the globe half round, that is, 180 degrees either way.

**PERIOSTEUM**, or **PERIOSTIUM**, in anatomy, a nervous vascular membrane, endued with a very quick sense, immediately surrounding, in every part, both the internal and external surfaces of all the bones in the body, excepting only so much of the teeth as stand above the gums, and the peculiar places on the bones, in which the muscles are inserted. It is hence divided into the external and internal periosteum; and where it externally surrounds the bones of the skull, it is generally called the *pericranium*. See **ANATOMY**, n° 4.

**PERIPATETIC PHILOSOPHY**, that system taught and established by Aristotle, and maintained by his followers the Peripatetics, called also the *Aristotelians*. See the next article.

**PERIPATUS**, (anc. geog.) the place where Aristotle taught; a part of the Lyceum, a gymnasium at Athens, situate on the banks of the Ilissus. The reason of the appellation is, that Aristotle walked as he taught, (Cicero, Diogenes Laertius). *Peripatetici* the name of the sect or followers of Aristotle.

**PERIPETIA**, in the drama, that part of a tragedy wherein the action is turned, the plot unravelled, and the whole concludes. See **CATASTROPHE**.

**PERIPHERY**, in geometry, the circumference of a circle, ellipsis, or any other regular curvilinear figure.

**PERIPLOCA**, Virginian silk, a genus of the digynia order, belonging to the pentandria class of plants. There are four species, all of them natives of warm climates. They are perennial shrubby plants with turning branches, rising from three to 40 feet high, adorned with white and purple flowers. The seeds are inclosed in capsules filled with a soft down. Two of the species, viz. the *Græca* and *Africana*, will live in the open air in this country, and are propagated by layers;

Period.

Periploca.

Perfell  
Perjury.

layers; but the others are tender, so require to be kept in a flow.

**PERISCII**, in geography, the inhabitants of either frigid zone, between the polar circles and the poles, where the sun, when in the summer signs, moves only round about them, without setting; and consequently their shadows in the same day turn to all the points of the horizon.

**PERISTALTIC**, a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres of which the fleshy coats of the intestines are composed; by means whereof the chyle is driven into the orifices of the lacteal veins, and the feces are protruded towards the anus.

**PERISTYLE**, in ancient architecture, a building encompassed with a row of columns on the inside.

**PERITONÆUM**, in anatomy, is a thin, smooth, and lubricous membrane, investing the whole internal surface of the abdomen, and containing most of the viscera of that part as it were in a bag. See **ANATOMY**, n° 350.

**PERITROCHIUM**, in mechanics, denotes a wheel, or circle, concentric with the base of a cylinder, and moveable together with it about its axis. See **MECHANICS**.

**PERJURY**, in law, is defined by Sir Edward Coke to be a crime committed when a lawful oath is administered, in some judicial proceeding, to a person who swears wilfully, absolutely, and falsely, in a matter material to the issue or point in question. Thelaw takes no notice of any perjury but such as is committed in some court of justice having power to administer an oath; or before some magistrate or proper officer invested with a similar authority, in some proceedings relative to a civil suit or a criminal prosecution: for it esteems all other oaths unnecessary at least, and therefore will not punish the breach of them. For which reason it is much to be questioned, how far any magistrate is justifiable in taking a voluntary affidavit in any extrajudicial matter, as is now too frequent upon every petty occasion; since it is more than possible that, by such idle oaths, a man may frequently, *in foro conscientie*, incur the guilt, and at the same time evade the temporal penalties of perjury. The perjury must also be corrupt, (that is, committed *malò animò*), wilful, positive, and absolute; not upon surprise, or the like: it also must be in some point material to the question in dispute; for if it only be in some trifling collateral circumstance, to which no regard is paid, it is no more penal than in the voluntary extrajudicial oaths before-mentioned. Subornation of perjury is the offence of procuring another to take such a false oath, as constitutes perjury in the principal. The punishment of perjury and subornation, at common law, has been various. It was anciently death; afterwards banishment, or cutting out the tongue; then forfeiture of goods; and now it is fine and imprisonment, and never more to be capable of bearing testimony. But the statute 5 Eliz. c. 9. (if the offender be prosecuted thereon) inflicts the penalty of perpetual infamy, and a fine of 40*l*. on the suborner; and in default of payment, imprisonment for six months, and to stand with both ears nailed to the pillory. Perjury itself is thereby punished with six months imprisonment, perpetual

Perjury  
Permutation.

infamy, and a fine of 20*l*. or to have both ears nailed to the pillory. But the prosecution is usually carried on for the offence at common law; especially as, to the penalties before inflicted, the statute 2 Geo. II. c. 25. superadds a power for the court to order the offender to be sent to the house of correction for a term not exceeding seven years, or to be transported for the same period; and makes it felony, without benefit of clergy, to return or escape within the time. It has sometimes been wished, that perjury, at least upon capital accusations, whereby another's life has been or might have been destroyed, was also rendered capital, upon a principle of retaliation; as it is universally by the laws of France. And certainly the odiousness of the crime pleads strongly in behalf of the French law. But it is to be considered, that there they admit witnesses to be heard only on the side of the prosecution, and use the rack to extort a confession from the accused. In such a constitution, therefore, it is necessary to throw the dread of capital punishment into the other scale, in order to keep in awe the witnesses for the crown; on whom alone the prisoner's fate depends: so naturally does one cruel law beget another. But corporal and pecuniary punishments, exile and perpetual infamy, are more suited to the genius of the English law; where the fact is openly discussed between witnesses on both sides, and the evidence for the crown may be contradicted and disproved by those of the prisoner. Where indeed the death of an innocent person has actually been the consequence of such wilful perjury, it falls within the guilt of deliberate murder, and deserves an equal punishment; which our ancient law in fact inflicted. But the mere attempt to destroy life by other means not being capital, there is no reason that an attempt by perjury should; much less that this crime should, in all judicial cases, be punished with death. For to multiply capital punishments lessens their effect, when applied to crimes of the deepest dye; and, detestable as perjury is, it is not by any means to be compared with some other offences, for which only death can be inflicted; and therefore it seems already (except perhaps in the instance of deliberate murder by perjury) very properly punished by our present law; which has adopted the opinion of Cicero, derived from the law of the twelve tables, *Perjuri pœna divina, exitium; humana, dedecus*.

**PERIPNEUMONY**, an inflammation of the lungs. See **MEDICINE**, n° 289, 290. and **FARRIERY**, § 5.

**PERIZONIUS** (James), a very learned and laborious writer, was born at Dam in 1651. He became professor of history and eloquence at the university of Franeker, when, by his merit and learning, he made that university flourish. However, in 1693, he went to Leyden, where he was made professor of history, eloquence, and the Greek tongue; in which employment he continued till his death, which happened in 1715. He wrote many Dissertations, and other learned and curious works, particularly *Origines Babylonica et Aegyptiaca*, 2 vols 8vo, &c.

**PERMEABLE**, a term applied to bodies of so loose a texture as to let something pass through them.

**PERMUTATION**, in commerce, the same with bartering. In the canon-law, permutation denotes

Permski  
|  
Perpignan.

the actual exchange of one benefic for another.

**PERMSKI**, or **PERMIA**, a town of the Russian empire, and capital of a province of the same name, seated on the river Kama between the Dwina and the Ob; E. Long. 55. 50. N. Lat. 70. 26. The province is bounded on the north by the Samoiedes, on the west by Zirania and Ulatka, and on the east by Siberia.

**PERNAMBUCO**, a province of Brasil in South America, bounded on the north by Tamara, on the east by the ocean; on the south by Seregipia, and on the west by Tapuyers. It is about 200 miles in length, and 150 in breadth. The Dutch became masters of it in 1630, but the Portuguese soon retook it from them. It produces a great quantity of sugar, and the best Brasil wood.

**PERNIO**, a kibe, or chilbain, is a little ulcer, occasioned by cold in the hands, feet, heels, nose, and lips. It will come on when warm parts are too suddenly exposed to cold, or when parts from being too cold are suddenly exposed to a considerable warmth; and has always a tendency to gangrene, in which it frequently terminates. It most commonly attacks children of a sanguine habit and delicate constitution; and may be prevented or removed by such remedies as invigorate the system, and are capable of removing any tendency to gangrene in the constitution. See *Medicine*, n° 281.

**PERONEUS**, in anatomy, is an epithet applied to some of the muscles of the perone or fibula. See *Anatomy*, *Table of the muscles*.

**PERORATION**, in rhetoric, the epilogue or last part of an oration, wherein what the orator had insisted on through his whole discourse is urged afresh with greater vehemence and passion. The peroration consists of two parts. 1. Recapitulation; wherein the substance of what was dissuaded throughout the whole speech is collected briefly and cursorily, and summed up with new force and weight. 2. The moving the passions; which is so peculiar to the peroration, that the masters of the art call this part *sedes affectuum*. The passions to be raised are various, according to the various kinds of oration. In a panegyric, love, admiration, emulation, joy, &c. In an invective, hatred, contempt, &c. In a deliberation, hope, confidence, or fear. The qualities required in the peroration are, that it be very vehement and passionate, and that it be short; because, as Cicero observes, tears soon dry up.

**PERONNE**, a strong town of France, in Picardy, capital of Santerre. It is said never to have been taken, though often besieged. It is seated on the river Somme, in E. Long. 3. 1. N. Lat. 44. 50.

**PERPENDICULAR**, in geometry, a line falling directly on another line, so as to make equal angles on each side. See *Geometry*.

**PERPETUAL**, something that endures always, or lasts for ever.

*PERPETUAL Motion*. See *MOVEMENT*.

**PERPIGNAN**, a considerable town of Roussillon in France, with a strong citadel, an university, and a bishop's see. It is seated on the river Tet; over which there is a handsome bridge, partly in a plain, and partly on a hill, E. Long. 0. 43. N. Lat. 45. 18.

**PERQUISITE**, in a general sense, something gained by a place over and above the settled wages.

**PERQUISITE**, in law, is any thing gotten by a man's own industry, or purchased with his money; in contradistinction to what descends to him from his father or other ancestor.

**PERRAULT** (Claude), the son of an advocate in parliament, was born at Paris in 1613; and was bred a physician, though he never practised but among his relations, friends, and the poor. He discovered early a particular taste for the sciences and fine arts; of which he acquired a consummate knowledge without the assistance of a master; he excelled in architecture, painting, sculpture, mathematics, physics, and all those arts that relate to designing and mechanics. The entrance into the Louvre, which was designed by him, is, according to the judgment of Voltaire, one of the most august monuments of architecture in the world. M. Colbert put him upon translating Vitruvius into French; which he performed, and published it in 1673, folio, with figures from his own drawings; which are said to have been more exactly finished than the plates themselves. When the academy of sciences was established, he was one of its first members, and was chiefly depended on for mechanics and natural philosophy. His works are, *Memoirs pour servir à l'Histoire naturelle des Animaux*, folio, 1676, with figures; *Essais de Physique*, 4 vols 12mo, 1688; *Recueil de plusieurs machines de nouvelle invention*, 4to, 1700, &c. He died in 1688.

**PERRAULT** (Charles), the brother of Claude, was born at Paris in 1626, with as great a genius for arts, and a greater for letters, than his brother. Colbert chose him first clerk of the buildings, of which he was superintendant, and afterward made him comptroller general of the finances under him. He was one of the first members of the academy of the belles lettres and inscriptions, and was received into the French academy in 1671. His poem, *La Peinture*, printed in 1668, was universally admired: that intitled *La siecle de Louis le Grand*, in which he exalted the modern authors above the ancient, was a prelude to a war with all the learned. After he had disengaged himself from this contest, he applied himself to draw up eulogies of several great men of the 17th century, with their portraits, of which he has collected 102. There are other esteemed works of Perrault.—Besides these there were two other brothers, *Peter* and *Nicholas*, who made themselves known in the literary world.

**PERRON** (James Davy Du), a cardinal distinguished by his abilities and learning, was born in the canton of Bern in 1556. He was educated by Julian Davy, his father, a very learned Calvinist, who taught him Latin and the mathematics; after which, he by himself became acquainted with the Greek and Hebrew, philosophy, and the poets. Philip Desportes, abbot of Tyron, made him known to Henry III. king of France, who conceived a great esteem for him. Some time after, Du Perron abjured Calvinism, and afterwards embraced the ecclesiastical function; and having given great proofs of his wit and learning, he was chosen to pronounce the funeral oration of Mary queen of Scots. After the murder of Henry III. he retired to the house of Cardinal de Bourbon, and took great pains

Perquisite.  
|  
Perron.

**Perrot** pains in bringing back the Protestants to the church of Rome. Among others, he gained over Henry Spontanus, afterwards bishop of Pamiers. He also chiefly contributed to engage Henry IV. to change his religion; and that prince sent him to negotiate his reconciliation to the holy see, in which he succeeded. Du Perron was consecrated bishop of Evreux while he resided at Rome. On his return to France, he wrote, preached, and disputed against the reformed; particularly against Du Pleffis Mornay, with whom he had a public conference in the presence of the king at Fontainebleau. He was made cardinal in 1604, by pope Clement VIII. at the solicitation of Henry IV. who afterwards nominated him to the archbishopric of Sens. The king at length sent him to Rome with Cardinal Joyeuse, in order to terminate the disputes which had arisen between Paul V. and the Venetians. It is said that this pope had such an high opinion of the address of the cardinal Du Perron, that he used to say, "Let us pray to God to inspire the cardinal Du Perron, for he will persuade us to do whatever he pleases." After the death of Henry IV. he retired into the country, where he put the last hand to his works; and, setting up a printing-house, corrected every sheet himself. He died at Paris in 1618. His works were collected after his death; and published at Paris in 3 vols folio.

**PERROT** (Nicholas), Sieur d'Abancourt, one of the first geniuses of his age, was born at Chalons in 1606. After studying philosophy about three years, he was sent to Paris to follow the law. At eighteen years of age he was admitted advocate of parliament, and frequented the bar; but he soon conceived a distaste for it, and therefore discontinued his practice. This displeased an uncle, but whose favour he recovered by quitting the Protestant religion. He could not, however, be prevailed upon to take orders in the Romish church; and some years after, he had a desire to return to the religion he had abjured. But, that he might not do any thing rashly, he resolved to study philosophy and divinity. For that purpose he chose for his master Mr Stuart a Scotsman and Lutheran, a man of great learning. Almost three years he spent in the most assiduous study; and then set out from Paris to Champagne, where he abjured the Roman Catholic, and once more embraced the Protestant religion. In 1637 he was admitted a member of the French academy; a little after which, he undertook a translation of Tacitus. Whilst he was engaged in that laborious task, he retired to his small estate of Abancourt, and lived there till his death, in 1664. He was a man of fine understanding, of great piety and integrity, and of universal learning. Moreri has given a catalogue of his works, the greatest part of which consist of translations, which seemed rather originals.

**PERRY**, a drink made from pears, in the same manner as cyder is from apples. See **CYDER**.

**PERSECUTION**, is any pain or affliction which a person designedly inflicts upon another; and, in a more restrained sense, the sufferings of Christians on account of their religion.

Historians usually reckon ten general persecutions, the first of which was under the emperor Nero, 31 years after our Lord's ascension; when that emperor

having set fire to the city of Rome, threw the odium of that execrable action on the Christians, who under that pretence were wrapped up in the skins of wild beasts, and worried and devoured by dogs; others were crucified, and others burnt alive. The second was under Domitian, in the year 95. In this persecution St John the apostle was sent to the isle of Patmos; in order to be employed in digging in the mines. The third began in the third year of Trajan, in the year 100, and was carried on with great violence for several years. The fourth was under Antoninus the philosopher, when the Christians were banished from their houses, forbidden to shew their heads, reproached, beaten, hurried from place to place, plundered, imprisoned, and flogged. The fifth began in the year 197, under the emperor Severus. The sixth began with the reign of the emperor Maximinus in 235. The seventh, which was the most dreadful persecution that had ever been known in the church, began in the year 250, in the reign of the emperor Decius, when the Christians were in all places driven from their habitations, stripped of their estates, tormented with racks, &c. The eighth began in the year 257, in the fourth year of the reign of the emperor Valerian. The ninth was under the emperor Aurelian, A. D. 274; but this was very inconsiderable: and the tenth began in the 19th year of Dioclesian, A. D. 303. In this dreadful persecution, which lasted ten years, houses filled with Christians were set on fire, and whole droves were tied together with ropes and thrown into the sea.

**PERSEPOLIS**, formerly the capital of Persia, situated in N. Lat. 30. 30. E. Long. 84°; now in ruins, but remarkable for the most magnificent remains of a palace or temple that are to be found throughout the world.—This city stood in one of the finest plains in Persia, being 18 or 19 leagues in length, and in some places two, in some four, and in others six leagues in breadth. It is watered by the great river Araxes, now Bendemir, and by a multitude of rivulets besides. Within the compass of this plain, there are between 1000 and 1500 villages, without reckoning those in the mountains, all adorned with pleasant gardens, and planted with shady trees. The entrance of this plain on the west side has received as much grandeur from nature, as the city it covers could do from industry or art. It consists of a range of mountains steep and high, four leagues in length, and about two miles broad, forming two flat banks, with a rising terrace in the middle, the summit of which is perfectly plain and even, all of native rock. In this there are such openings, and the terraces are so fine and so even, that one would be tempted to think the whole the work of art, if the great extent, and prodigious elevation thereof, did not convince one that it is a wonder too great for aught but nature to produce. Undoubtedly these banks were the very place where the advanced guards from Persepolis took post, and from which Alexander found it so difficult to dislodge them. One cannot from hence desery the ruins of the city, because the banks are too high to be overlooked; but one can perceive on every side the ruins of walls and of edifices, which heretofore adorned the range of mountains of which we are speaking. On the west and on the north, this city is defended in the

Perfe-  
rance  
Perſia.

like manner: ſo that, conſidering the height and evenneſs of theſe banks, one may ſafely ſay, with a late ingenious traveller, that there is not in the world a place ſo fortified by nature. The ancient palace of the kings of Perſia, called by the inhabitants *Chilminar*, i. e. forty columns, is ſituated at the foot of the mountain; the walls of this ſtately building are ſtill ſtanding on three ſides: but as a particular account of the noble remains of antiquity to be met with there would exceed our limits, we muſt refer the reader to Sir John Chardin's travels, or the fifth volume of the *Universal Hiſtory*, where a full deſcription of them is given.

**PERSEVERANCE**, in theology, a Chriſtian virtue, by which we are enabled to perſiſt in the way of ſalvation to the end.

The final perfeverance of the ſaints is a doctrine much controverted between the Arminians and Calviniſts; the latter of whom maintain that it is impoſſible for grace to be loſt, and conſequently make perfeverance to the end a neceſſary conſequence thereof; while the others imagine, that the moſt confirmed believers are never out of a poſſibility of falling.

**PERSEUS**, the moſt ancient of all the Greek heroes, founded the city of Mycenæ, of which he became afterwards king, and where he and his poſterity reigned for 100 years. He flouriſhed, according to moſt chronologiſts, 1348 B. C. but, according to Sir Iſaac Newton, only 1028.

**PERSEUS**, in aſtroonomy. See there, n<sup>o</sup> 206.

**PERSIA**, a moſt ancient and celebrated empire of Aſia, extending in length from the mouth of the river Araxes to that of the river Indus, about 1840 of our miles, and in breadth from the river Oxus to the Perſian gulph, about 1080 of the ſame miles. It is bounded on the north by the Caſpian Sea, the river Oxus, and mount Caucasus; on the eaſt, by the river Indus and the dominions of the Great Mogul; on the ſouth, by the Perſian gulph and the Indian ocean; and on the weſt, by the dominions of the Grand Signior.

The moſt ancient name of this country was that of *Elam*, or, as ſome write it, *Elam*, from Elam the ſon of Shem, from whom its firſt inhabitants are deſcended. Herodotus calls its inhabitants *Cephenes*; and in very ancient times the people are ſaid to have called themſelves *Artai*, and the country where they dwelt *Artæa*. In the books of Daniel, Eſdras, &c. it is called by the names of *Parſ*, *Pharas*, or *Fars*, whence the modern name of *Perſia*; but whence thoſe names have been derived, is now uncertain.

That Perſia was originally peopled by Elam the ſon of Shem is univerſally allowed; but before the time of Cyrus we know little or nothing of their hiſtory. This prince is celebrated both by ſacred and profane hiſtorians; but the latter are at no ſmall variance concerning his birth and acceſſion to the throne. According to Herodotus, Aſtyages, the laſt king of the Medes, being warned in a dream, that the ſon who was to be born of his daughter Mandane, ſhould one day be lord of Aſia, reſolved to marry her, not to a Mede, but to a Perſian. Accordingly, he choſe for her husband one Cambyſes, a man of a peaceable diſpoſition, and of no very high ſtation. However, about a year after they were married, Aſtyages was frightened by another

Perſia.

dream, which made him reſolve to diſpatch the infant as ſoon as it ſhould be born. Hereupon the king ſent for his daughter, and put her under confinement, where ſhe was ſoon after delivered of a ſon. The infant was committed to the care of one Harpagus, with ſtrict orders to deſtroy it in what manner he thought proper. But he, having acquainted his wife with the command he had received, by her advice gave it to a ſhepherd, deſiring him to let it perſiſh by expoſing it. But the ſhepherd, out of compaſſion, expoſed a ſtill-born child which his wife happened to be then delivered of, and brought up the ſon of Mandane as his own, giving him the name of *Cyrus*.

When the young prince had attained the age of ten years, as he was one day at play with other children of the ſame age, he was choſen king by his companions; and having, in virtue of that dignity, divided them into ſeveral orders and claſſes, the ſon of Artambares, a lord of eminent dignity among the Medes, reſuſed to obey his orders; whereupon Cyrus cauſed him to be ſeized, and whipped very ſeverely. The boy ran crying to his father; and he immediately haſtened to the king's palace, loudly complaining of the affront his ſon had received from the ſon of a ſlave, and intreating Aſtyages to revenge, by ſome exemplary puniſhment, the indignity offered to him and his family. Aſtyages, commanding both the herſman and his ſon to be brought before him, aſked the latter, how he, who was the ſon of ſo mean a man, had dared to abuſe the ſon of one of the chief lords of the kingdom? Cyrus replied, that he had done no more than he had a right to do; for the boys of the neighbourhood having choſen him king, becauſe they thought him moſt worthy of that dignity, and performed what he, veſted with that character, had commanded, the ſon of Artambares alone had ſlighted his orders, and for his diſobedience had ſuffered the puniſhment he deſerved. In the courſe of this converſation Aſtyages happening to recollect, that his grandſon, whom he had ordered to be deſtroyed, would have been about the ſame age with Cyrus, began to queſtion the ſhepherd concerning his ſuppoſed ſon, and at laſt obtained from him a confeſſion of the whole truth.

Aſtyages having now diſcovered Cyrus to be his grandſon, ſent for Harpagus, who alſo confeſſed that he had not ſeen Mandane's ſon deſtroyed, but had given him to the ſhepherd; at which Aſtyages was ſo much incenſed, that, having invited Harpagus to an entertainment, he cauſed him to be ſerved with the fleſh of his own ſon. When he had done, the king aſked him whether he liked his victuals; and Harpagus anſwering, that he had never taſted any thing more delicious, the officers appointed for that purpoſe brought in a baſket, containing the head, hands, and feet of his ſon, deſiring him to uncover the baſket, and take what he liked beſt. He did as they deſired, and beheld the mangled remains of his only child without betraying the leaſt concern, ſo great was the command which he had over his paſſions. The king then aſked him, whether he knew with what kind of meat he had been entertained. Harpagus replied, that he knew very well, and was always pleaſed with what his ſovereign thought fit to ordain; and having thus replied, with a ſurpriſing temper, he collected the mangled parts of his innocent ſon, and went home.

of Cyrus.

Persia.

Altyages having thus vented his rage on Harpagus, began next to consult what he should do with Cyrus. The magi, however, eased him of his fears with regard to him, by assuring him; that as the boy had been once chosen king by his companions, the dream had been already verified, and that Cyrus never would reign in any other sense. The king, being well pleased with this answer, called Cyrus, and, owning how much he had been wanting in the affection which he ought to have had towards him, desired him to prepare for a journey into Persia, where he would find his father and mother in circumstances very different from those of the poor shepherd and his wife with whom he had hitherto lived. Cyrus, on his arrival at his father's house, was received with the greatest joy. When he grew up, he soon became popular on account of his extraordinary parts; till at last his friendship was courted by Harpagus, who had never forgot the cruel treatment he received from Altyages. By his means a conspiracy was formed against Altyages; who being overthrown in two successive engagements, was taken prisoner and confined for life.

The account given by Xenophon of the rise of Cyrus is much more consonant to scripture; for he tells us, that Babylon was conquered by the united forces of the Medes and Persians. According to him, Cyrus was the son of Cambyzes king of the Medes, and Mandane the daughter of Altyages king of Persia. He was born a year after his uncle Cyaxares, the brother of Mandane. He lived till the age of twelve with his parents in Persia, being educated after the manner of the country, and inured to fatigues and military exercises. At this age he was taken to the court of Altyages, where he resided four years; when the revolt of the Medes and Persians from the Babylonians happened, and which ended in the destruction of the Babylonish empire, as related under the article *BABYLON*.

While Cyrus was employed in the Babylonish war, before he attacked the metropolis itself, he reduced all the nations of Asia Minor. The most formidable of these were the Lydians, whose king Croesus assembled a very numerous army, composed of all the other nations in that part of Asia, as well as of Egyptians, Greeks, and Thracians. Cyrus being informed of these vast preparations, augmented his forces to 196,000 men, and with them advanced against the enemy, who were assembled near the river Pactolus. After long marches, he came up with them at Thymbra, not far from Sardis the capital of Lydia. Besides the horse and foot, which amounted to 196,000, as already observed, Cyrus had 300 chariots armed with scythes, each chariot drawn by four horses abreast, covered with trappings that were proof against all sorts of missile weapons: he had likewise a great number of chariots of a larger size, upon each of which was placed a tower about 18 or 20 feet high, and in each tower were lodged 20 archers. These towers were drawn by 16 oxen yoked abreast. There was moreover a considerable number of camels, each mounted by two Arabian archers, the one looking towards the head, and the other towards the hinder part of the camel. The army of Croesus consisted of 420,000 men. The Egyptians, who alone were 120,000 in number, being the main strength of the army, were placed in the centre. Both armies were drawn up in an im-

mense plain, which gave room for the extending of the wings on either side; and the design of Croesus, upon which alone he founded his hopes of victory, was to surround and hem in the enemy's army.

When the two armies were in sight of each other, Croesus, observing how much his front exceeded that of Cyrus, made the centre halt, but commanded the two wings to advance, with a design to inclose the Persian army, and begin the attack on both sides at once. When the two detached bodies of the Lydian forces were sufficiently extended, Croesus gave the signal to the main body, which marched up to the front of the Persian army, while the two wings attacked them in flank; so that Cyrus's army was hemmed in on all sides, and, as Xenophon expresses it, was inclosed like a small square drawn within a great one. This motion, however, did not at all alarm the Persian commander; but, giving his troops the signal to face about, he attacked in flank those forces that were going to fall upon his rear, so vigorously, that he put them into great disorder. At the same time a squadron of camels was made to advance against the enemy's other wing, which consisted mostly of cavalry. The horses were so frightened at the approach of these animals, that most of them threw their riders and trod them under foot; which occasioned great confusion. Then Artagefes, an officer of great valour and experience, at the head of a small body of horse, charged them so briskly, that they could never afterwards rally; and at the same time the chariots, armed with scythes, being driven in among them, they were entirely routed. Both the enemy's wings being thus put to flight, Cyrus commanded his chief favourite Abradates to fall upon the centre with the large chariots above-mentioned. The first ranks, consisting mostly of Lydians, not being able to stand so violent a charge, immediately gave way; but the Egyptians, being covered with their bucklers, and marching so close that the chariots had not room to penetrate their ranks, a great slaughter of the Persians ensued. Abradates himself was killed, his chariot overturned, and the greatest part of his men were cut in pieces. Upon his death, the Egyptians, advancing boldly, obliged the Persian infantry to give way, and drove them back quite to their engines. There they met with a new shower of darts and javelins from their machines; and at the same time the Persian rear advancing sword in hand, obliged their spearmen and archers to return to the charge. In the mean time Cyrus, having put to flight both the horse and foot on the left of the Egyptians, pushed on to the centre, where he had the misfortune to find his Persians again giving ground; and judging that the only way to stop the Egyptians, who were pursuing them, would be to attack them in the rear, he did so; and at the same time the Persian cavalry coming up to his assistance, the fight was renewed with great slaughter on both sides. Cyrus himself was in great danger; for his horse being killed under him, he fell among the midst of his enemies: but the Persians, alarmed at the danger of their general, threw themselves headlong on their opponents, rescued him, and made a terrible slaughter; till at last Cyrus, admiring the valour of the Egyptians, offered them honourable conditions; letting them know at the same time, that all their allies had abandoned them. They accepted the terms offered them; and having

3  
His war  
with the  
Lydians.

Perſia. having agreed with Cyrus that they ſhould not be obliged to carry arms againſt Croſus, they engaged in the ſervice of the conqueror, and continued faithful to him ever after.

5 Sardis taken, and the Lydian empire overthrown. The next morning Cyrus advanced towards Sardis, and Croſus marched out to oppoſe him at the head of the Lydians only; for his allies had all abandoned him. Their ſtrength conſiſted moſtly in cavalry: which Cyrus being well apprized of, he ordered his camels to advance; by whom the horſes were ſo frightened, that they became quite ungovernable. However, the Lydians diſmounted, and for ſome time made a vigorous reſiſtance on foot; but were at laſt driven into the city, which was taken two days after: and thus the Lydian empire was totally deſtroyed.

6 Reduces Babylon. After the conqueſt of Sardis, Cyrus turned his arms againſt Babylon itſelf, which he reduced in the manner related under that article. Having ſettled the civil government of the conquered kingdoms, Cyrus took a review of all his forces, which he found to conſiſt of 600,000 foot, 120,000 horſe, and 2000 chariots armed with ſcythes. With theſe he extended his dominion all over the nations to the confines of Ethiopia, and to the Red ſea; after which he continued to reign peaceably over his vaſt empire till his death, which happened about 529 before Chriſt. According to Xenophon, he died a natural death; but others tell us, that, having engaged in a war with the Scythians, he was by them overthrown and cut in pieces with his whole army, amounting to 200,000 men. But this is very improbable, ſeeing all authors agree, that the tomb of Cyrus was extant at Paſargada in Perſia in the time of Alexander the Great; which it could not have been, if his body had remained in the poſſeſſion of the Scythians, as theſe authors aſſert.

7 His death. In the time of Cyrus, the Perſian empire extended from the river Indus to the Egean ſea. On the north it was bounded by the Euxine and Caſpian ſeas, and on the ſouth by Ethiopia and Arabia. That monarch kept his reſidence for the ſeven cold months at Babylon, by reaſon of the warmth of that climate; three months in the ſpring he ſpent at Suſa, and two at Ec-batan during the heat of ſummer. On his death-bed he appointed his ſon Cambyſes to ſucceed him in the empire; and to his other ſon, Smerdis, he gave ſeveral conſiderable governments. The new monarch immediately ſet about the conqueſt of Egypt; which he accompliſhed in the manner related in the hiſtory of that country.

8 Cambyſes conquers Egypt. Having reduced Egypt, Cambyſes next reſolved to turn his arms againſt the Carthaginians, Hammonians, and Ethiopians. But he was obliged to drop the firſt of theſe enterprizes, becauſe the Phœnicians reſuſed to ſupply him with ſhips againſt the Carthaginians, who were a Phœnician colony. However, he ſent ambaffadors into Ethiopia with a deſign to get intelligence of the ſtate and ſtrength of the country. But the Ethiopian monarch, being well apprized of the errand on which they came, treated them with great contempt. In return for the preſents ſent him by Cambyſes, he ſent his own bow; and adviſed the Perſians to make war upon the Ethiopians when they could bend ſuch a ſtrong bow as eaſily as he did, and to thank the gods that the Ethiopians had no ambition to extend their dominions beyond their own country.

Cambyſes was no ſooner informed of this anſwer by his ambaffadors, than he flew into a violent paſſion; and ordered his army immediately to begin their march, without conſidering that they were neither furniſhed with provisions nor any other neceſſary. When he arrived at Thebes in Upper Egypt, he detached 50,000 men, with orders to deſtroy the temple of Jupiter Ammon: but all theſe perished in the deſert; not a ſingle perſon arriving either at the oracle, or returning to Thebes. The reſt of the army, led by Cambyſes himſelf, experienced incredible hardſhips; for, not being provided with any neceſſaries, they had not marched a fifth part of the way when they were obliged to kill and eat their beaſts of burthen. When theſe failed, the ſoldiers fed on graſs and roots, as long as any could be found; and at laſt were reduced to the dreadful neceſſity of eating one another; every tenth man, on whom the lot fell, being condemned to ſerve as food for his companions. The king, however, obſtinately perſiſted in his deſign; till, being apprehenſive of the danger he himſelf was in, he retreated to Thebes, after having loſt the greateſt part of his army.

Cambyſes was a man of a very cruel and ſuſpicious temper, of which he gave many inſtances; and the following proved indirectly the cauſe of his death.—We have already obſerved that the king of Ethiopia ſent his bow in return for the preſents brought to him by the ambaffadors of Cambyſes. The only man in the Perſian army who could bend this bow was Smerdis the king's brother; and this inſtance of his perſonal ſtrength ſo alarmed the tyrant, that, without any crime alleged, he cauſed him to be murdered. This gave occaſion to one Smerdis, a magi, who greatly reſembled the other Smerdis in looks, to aſſume the name of the deſeased prince, and to raiſe a rebellion againſt Cambyſes who was generally hated for his cruelty; and this he could the more eaſily do, as the chief management of affairs had been committed to this Smerdis during the king's abſence. Cambyſes, on receiving the news of this revolt, immediately ordered his army to march, in order to ſuppreſs it; but as he was mounting his horſe, his ſword, ſlipping out of its ſcabbard, wounded him in the thigh. On this accident, he aſked the name of the city where he was; and being told that it was Ec-batan, he ſaid in the preſence of all his attendants, "Fate has decreed, that Cambyſes the ſon of Cyrus ſhall die in this place." For, having conſulted the oracle of Butus, which was very famous in that country, he was told that he ſhould die at Ec-batan. This he had always underſtood of Ec-batan in Media, and had therefore reſolved to avoid it. Being now, however, convinced that his end approached, he aſſembled the chief Perſian lords who ſerved in the army, and having told them that his brother was certainly dead, he exhorted them never to ſubmit to the impoſtor, or ſuffer the ſovereignty again to paſs from the Perſians to the Medes, to which nation Smerdis belonged, but to uſe their utmoſt endeavours to place one of their own blood on the throne.

As the king's wound mortified, he lived but a few days after this; but the aſſembly ſuppoſing that he had ſpoken only out of hatred to his brother, quietly ſubmitted to the impoſtor, who was thus for a time eſta-

Perſia. His unſucceſſful expedition againſt Ethiopia and monians.

10 He murders his brother.

11 His death.

Perſia. eſtabliſhed on the throne. Indeed, from his conduct during the ſhort time which he enjoyed the kingdom, he appears to have been not at all undeſerving of a crown. He began with granting to all his ſubjects an exemption from taxes and military ſervice for three years, and treated all of them in the moſt beneficent manner.

12  
Reign of  
Smerdis the  
magi.

To ſecure himſelf on the throne the more eſſentially, he married Atoſſa the daughter of Cyrus; thinking, that, in caſe of a diſcovery, he might hold the empire by her title. She had before been married to her brother Cambyſes, on a deciſion of the magi that a king of Perſia might do as he pleaſed; and by virtue of this deciſion Smerdis alſo married her as her brother.

13  
His impoſ-  
ture diſco-  
vered.

The extreme caution of Smerdis, however, promoted the diſcovery of his impoſture. He had married all his predecessor's wives, among whom was one Phedyma, the daughter of Otanes a Perſian nobleman of the firſt rank. Otanes, who ſuſpected that the king was not Smerdis the ſon of Cyrus, ſent a truſty meſſenger to his daughter, deſiring to know whether he was ſo or not; but Phedyma, having never ſeen this Smerdis, could not give any answer. Her father then deſired her to inquire at Atoſſa, who could not but know her own brother. However, he was again diſappointed; for Phedyma acquainted him that all the king's wives were lodged in diſtinct and ſeparate apartments, without being allowed to ſee each other. This greatly increaſed the ſuſpicions of Otanes; upon which he ſent his daughter a third meſſage, deſiring her, the next time ſhe ſhould be admitted to the king's bed, to take an opportunity of feeling whether he had ears or not: for Cyrus had formerly cauſed the ears of Smerdis the magi to be cut off for ſome crime of which he had been guilty; ſo that, if the king had ears, he might then be aſſured that he was Smerdis the ſon of Cyrus. The event ſhewed that the ſuſpicions of Otanes were juſt; and Phedyma having acquainted her father that the king had

14  
A conſpi-  
racy form-  
ed againſt  
him.

no ears, a conſpiracy was immediately formed againſt him. While the conſpirators were debating about the proper means of carrying their deſigns into execution, Darius the ſon of Hyſtaſpes happening to arrive at Suſa where his father was governor, they all agreed to make him privy to their deſign. He told them, at their firſt meeting, that he thought nobody in the empire but himſelf had known that Smerdis the ſon of Cyrus was dead, and the throne uſurped by a magi; that he had come with a deſign to kill the uſurper, without imparting his deſign to any one, that the glory of ſuch an action might be entirely his own. But ſince others were apprized of the impoſture, he inſiſted that the uſurper ſhould be diſpatched without delay. Otanes, on the other hand, was for putting off the enterpriſe till ſome better opportunity offered; but Darius proteſted, that if they did not make the attempt that very day, he would prevent any one from accuſing him, by diſcloſing the whole matter to the magi himſelf.

In the mean time, Smerdis and his brother had by great promiſes prevailed on Prenaspes (the executioner of the true Smerdis) to bind himſelf by an oath not to diſcover the fraud they had put on the Perſians, and even to make a public ſpeech, declaring that the preſent king of Perſia was really the ſon of Cyrus. At the time appointed, he began his diſcourſe with the genealogy of Cyrus, putting his hearers in mind of the

great favours the nation had received from that prince. After having extolled Cyrus and his family, to the great aſtoniſhment of all preſent, he confeſſed the whole tranſaction with regard to the death of Smerdis; telling the people, that the apprehenſions of the danger he muſt inevitably run by publiſhing the impoſture had conſtrained him to conceal it ſo long; but now, not being able any longer to act ſuch a diſhonourable part, he acknowledged that he had been compelled by Cambyſes to put his brother to death with his own hand, and that the perſon who poſſeſſed the throne was Smerdis the Magi. He then begged pardon of the gods and men for the crime he had committed; and fulminating many imprecations againſt the Perſians if they failed to recover the ſovereignty, he threw himſelf headlong from the top of the tower on which he ſtood, and died on the ſpot.

Perſia.

In the mean time the conſpirators, who were ad-<sup>15</sup> vancing towards the palace, were informed of what had happened; and Otanes was again for deſerring the execution of their enterpriſe: but Darius inſiſting upon the danger of delay, they proceeded boldly to the palace; and being admitted by the guards, who did not ſuſpect them, they killed both the uſurper and his brother; after which, they expoſed their heads to the people, and declared the whole impoſture. The Perſians at this were ſo enraged, that they fell on the whole ſect, and killed every one of the magi they could meet with; and had not the ſlaughter been ſtopped by night, not one of the order would have been left alive. The day on which this ſlaughter happened was afterwards celebrated by the Perſians with the greateſt ſolemnity, and called by the name of *Magophonia*, or the *ſlaughter of the Magi*. On that feſtival the magi durſt not appear abroad, but were obliged to ſhut themſelves up in their houſes. Smerdis the magi reigned only eight months.

When the tumult was a little ſubſided, the conſpirators, who were ſeven in number, met together in order to elect a new king, or to determine what form of government they ſhould next introduce. Otanes was for a republic: but being over-ruled by the reſt, he declared, that as he was determined not to be a king, neither would he be ruled by one; and therefore inſiſted that he and his family ſhould ever afterwards remain free from ſubjection to the royal power. This was not only granted, but it was further agreed by the other fix, that whoever was choſen ſhould every year preſent Otanes with a Median veſt, a mark of great diſtinction among the Perſians, becauſe he had been the chief author of the enterpriſe. They further agreed to meet at a certain place next morning at ſun-riſe on horſeback, and that he whoſe horſe firſt neigh-<sup>16</sup> ed ſhould be king. This being overheard by Oebores, Darius Hy- ſtaſpes choſen king.

Darius Hyſtaſpes was elected king of Perſia in the year 522 B. C. Immediately after his acceſſion, he promoted the other fix conſpirators to the firſt employments in the kingdom, married the two daughters of Cyrus, Atoſſa and Artyſtana, Parmys the daughter of the true Smerdis, and Phedyma the daughter of O-  
tanes,

Persia.

tanes, who had detected the magi. He then divided the whole empire into 20 satrapies or governments, and appointed a governor over each division, ordering them to pay him an annual tribute. The inhabitants of Colchis, with some others, were enjoined only to make annual presents, and the Arabians to furnish every year such a quantity of frankincense as equalled the weight of 1000 talents. Thus Darius received the yearly tribute of 14,560 Eubæic talents, upwards 260,000 pounds Sterling.

17  
Revolt of  
the Babylo-  
nians.

Under Darius, the building of the temple of Jerusalem, which had been obstructed by Cambyzes and Smerdis, went on successfully, and the Jewish state was entirely reformed. The most remarkable of Darius's other transactions were his expeditions against Babylon; against Scythia, India, and Greece. The expedition against Babylon took place in the 517 B. C. when that people, unable to bear the oppression of the Persians, and likewise discontented because the seat of government was removed from their city to Susa in Persia, took the opportunity of the troubles which happened in the reigns of Cambyzes and Smerdis, to store their city with all kinds of provisions sufficient to serve them for many years; after which they broke out into an open rebellion, and this quickly brought upon them Darius with all his forces. The Babylonians perceiving themselves shut up by so numerous an army, turned all their thoughts towards the supporting of a long siege, which they imagined would tire out the king's troops. To prevent the consumption of their provisions, they took the most barbarous and cruel resolution that ever was put in execution by any nation. They agreed among themselves to get rid of all unnecessary mouths; and therefore, gathering together all the old men, women, and children, they strangled them without distinction; every one being allowed only to keep the wife he liked best, and a maid-servant to do the work of the house. The siege continued for a year and eight months; nor was there any likelihood of its being ended, when Zopyrus, one of Darius's chief commanders, put him in possession of it by the following stratagem. He cut off his nose and ears, and having mangled his body with stripes in a most cruel manner, he fled to the Babylonians thus disfigured, pretending that he had been so treated by Darius, for advising him to raise the siege. Being intrusted with the command of some forces, he cut off several parties of the Persian army, whom Darius thus sacrificed in order to raise the character of Zopyrus the higher among the Babylonians. In this manner he so much established his credit, that at last he was made commander in chief of all the Babylonian forces, and the guard of the city committed entirely to his care; and no sooner was this done, than he delivered it up to Darius, who, to prevent their rebelling a second time, beat down the walls of that metropolis to the height of 50 cubits. Three thousand of the most active in the rebellion were impaled; the rest pardoned. As they had destroyed most of their women, the neighbouring nations were commanded to furnish them with wives, and 50,000 women were sent to that city, by which means it was prevented from being depopulated. Zopyrus was rewarded with the highest honours, and had the whole revenues of Babylon bestowed on him for life.

After the reduction of Babylon, Darius undertook a Scythian expedition, directed against those nations which lie between the Danube and the Tanais. His pretext for this war was, to revenge the calamities which these nations had brought upon Asia about 120 years before, when they invaded and subdued Media; keeping it in subjection for the space of 28 years, as we have related under that article. In this expedition he was attended with an army of 700,000 men. With these he marched to the Thracian Bosphorus; which having passed on a bridge of boats, he reduced all Thrace. From Thrace he advanced to the Danube, where he had appointed his fleet to meet him. This river he passed on another bridge of boats, and entered Scythia. His enemies, however, were too wise to oppose such a formidable power in the open field; and therefore retired before him, wasting the country as they went along, till at last the king, sensible of the danger he was in, resolved to give over the enterprise and return home. In order to do so with safety, he lighted a great number of fires in the night-time, and decamped; leaving behind him the old men and the sick, who fell into the hands of their enemies. The Scythians perceiving that Darius was gone, detached a considerable body to the bridge over the Danube; and as they were well acquainted with the roads, they got thither before the Persians. The Scythians had sent express before-hand to persuade the Ionians, whom Darius had left to guard the bridge, to break it down and retire to their own country; and this they pressed the more earnestly, that as the time prescribed by Darius was now expired, they were at liberty to return home, without breaking their word or being wanting in their duty. Miltiades, prince of the Chersonesus of Thrace, was for embracing so favourable an opportunity of cutting off Darius's retreat, and shaking off the Persian yoke at once: all the other commanders agreed with him, except Hystius prince of Miletus; who represented to the Ionian chiefs, that their power was connected with that of Darius, since it was under his protection that each of them was lord in his own city; and that the cities of Ionia would not fail to depose them and recover their liberty, if the Persian power should sink or decline. This speech made a deep impression on the rest, and it was at last determined that they should wait for Darius; and in order to deceive the Scythians, they began to break down the bridge, but advised them to return back and defeat Darius. They did so, but missed him; and he having thus safely escaped to great a danger, immediately repassed the Bosphorus, and took up his winter-quarters at Sardis, leaving Megabyzus, one of his chief generals, to complete the conquest of Thrace.

The king having sufficiently refreshed his troops, who had suffered extremely in the Scythian expedition, began to think of extending his dominions eastward; and, in order to facilitate his design, resolved in the first place to discover those countries. With this view, he caused a fleet to be built and equipped at Caspatyrus, a city on the river Indus. The command of this fleet he gave to one Scylax, a Grecian of Caryandia a city of Caria, who was well versed in maritime affairs. Him he ordered to sail down the current, and make the best discoveries he could of the countries lying on either side of the river, till he arrived at the southern

dia.

<sup>10</sup> **Perſia.** ſouthern ocean; from whence he was to ſteer his courſe weſtward, and that way return to Perſia. Scylax, having exactly obſerved his inſtructions, and failed down the river Indus, entered the Red Sea by the ſtraits of Babelmandel, and on the 30th month from his firſt ſetting out, landed at the ſame place from whence Necho king of Egypt formerly ſent out the Phœnicians who circumnavigated Africa. From hence Scylax returned to Suſa, where he gave a full account of his diſcoveries; upon which Darius, marching into India at the head of a powerful army, reduced that large country, and made it a province of the Perſian empire, drawing from thence an annual tribute of 360 talents of gold.

<sup>20</sup> **Revolt of the Ionians, &c.** Soon after the expedition of Darius againſt India, happened the revolt of the Ionians, which gave occaſion to his expedition into Greece; an account of which is given under the articles *ATTICA*, *GREECE*, *SPARTA*, &c. The ill ſucceſs which attended him here, however, was ſo far from making him drop the enterpriſe, that it only made him the more intent on reducing the Grecians; and he reſolved to head his army in perſon, having attributed his former bad ſucceſs to the inexperience of his generals. But while he was employed in making the neceſſary preparations for this purpoſe, he received intelligence that the Egyptians had revolted, ſo that he was obliged to make preparations for reducing them alſo; and before this could be done, the king died, after having reigned 36 years, leaving the throne to his ſon Xerxes.

<sup>21</sup> **Expeditions of Xerxes againſt Greece.** This prince aſcended the throne of Perſia in the year 485 B. C.; and his firſt enterpriſe was to reduce the Egyptians; which he effectually did, bringing them into a worſe ſtate of ſlavery than they ever had experienced before. After this he reſolved on an expedition into Greece, the unfortunate event of which is related under the article *ATTICA*. By his miſfortunes in the Grecian expedition, he became at laſt ſo diſpirited, that he thenceforth abandoned all thoughts of war and conqueſts; but growing tyrannical, and oppreſſing his ſubjects, he was murdered in his bed, in the year 464 B. C. the 21ſt of his reign; and was ſucceeded by his third ſon Artaxerxes, ſurnamed *Longimanus* on account of the great length of his arms.

<sup>22</sup> **Xerxes ſucceeded by Artaxerxes Longimanus.** This prince is named *Abafuerus* in ſcripture, and is the ſame who married Eſther, and during the whole of his reign ſhewed the greateſt kindneſs to the Jewiſh nation. In the beginning of his reign he was oppoſed by Hyſtaſpes the ſecond ſon of Xerxes, whom, however, he overcame, though not without conſiderable difficulty. After this he applied himſelf to the ſettlement of the affairs of government, and reforming many abuſes which had crept in; and then, being fully eſtabliſhed on the throne, he appointed feaſts and rejoicings to be made for 180 days in the city of Suſa; at one of which he reſolved to divorce his queen for diſobedience; and afterwards married Eſther, as we find it recorded in the ſacred writings.

In the fifth year of the reign of Artaxerxes the Egyptians revolted anew, and, being aſſiſted by the Athenians, held out for fix years; but were again obliged to ſubmit, and continued in ſubjection during the whole of his reign. Nothing elſe remarkable happened during the life of Artaxerxes Longimanus,

<sup>23</sup> **Perſia.** who died in the 41ſt year of his reign; and was ſucceeded by Xerxes II. the only ſon he had by his queen, though by his concubines he had 17. Xerxes II. having drunk immoderately at an entertainment immediately after his acceſſion, retired to a chamber, in order to reſreſh himſelf with ſleep; but here he was murdered by Sogdianus, the ſon of Artaxerxes by one of his concubines, after he had reigned 45 days.

<sup>24</sup> **Sogdianus.** Sogdianus was ſcarce ſeated on the throne when he put to death Bagoragus, the moſt faithful of all his father's eunuchs; by which, and the murder of his ſovereign, he became generally odious. Upon this, ſenſible of the dangerous ſituation in which he was, he ſent for one of his brothers named *Ochus*, whom he ſuſpected, with a deſign to murder him the moment he arrived. Ochus, however, underſtanding his deſign, put off, by ſeveral pretences, his coming, till he had drawn together a powerful army, with which he advanced to the confines of Perſia. Here he openly declared, that his deſign was to revenge his brother's death; which brought over to him many of the nobility and governors of provinces, by whom he was immediately proclaimed king. Sogdianus, ſeeing himſelf thus deſerted, contrary to the advice of all his friends, came to an accommodation with Ochus; who no ſooner had him in his power than he cauſed him to be ſuffocated among aſhes; a puniſhment invented on purpoſe for him.

<sup>25</sup> **Ochus.** Ochus being firmly ſettled on the throne by the death of Sogdianus, changed his name to Darius; and is by hiſtorians commonly called *Darius Notbuz*, or the *Baſtard*. But Arſites, another of the brothers, ſeeing in what manner Sogdianus had got the better of Xerxes, and been afterwards driven out by Ochus, began to entertain thoughts of treating him in the ſame manner. He was not, however, ſo ſucceſſful; for, being defeated in an engagement, he ſurrendered himſelf in hopes of mercy, but was immediately put to death by ſuffocation in aſhes. Several other perſons were executed: but theſe ſeverities did not procure him the repoſe which he expected; for his whole reign was diſturbed with violent commotions in various parts of the empire. One of the moſt dangerous was raiſed by Piſuthna governor of Lydia; but he being deſerted by his Greek mercenaries, was at laſt overcome, and put to death: however, his ſon Amorgas continued to infeſt the maritime provinces of Aſia Minor for two years; till he alſo was taken priſoner by Tiſſaphernes, the new governor of Lydia, who put him to death. Other inſurrections quickly followed this: but the greateſt miſfortune which beſet Darius during the whole courſe of his reign was the revolt of the Egyptians, who could not be reduced. Before his death, he inveſted Cyrus his youngſt ſon with the ſupreme government of all the provinces of Aſia Minor. This was done through the perſuaſions of his mother Paryſatis, who had an abſolute ſway over her husband; and he procured this command for him, that he might thereby be enabled to contend for the kingdom after his father's death. She even inſiſted that the king ſhould declare him heir to the crown before he died; but this he could not by any means be induced to do. He died in the year 405 B. C. and was ſucceeded by his ſon Artaxerxes, by the Greeks ſurnamed *Mnemon*, on account of his extraordinary memory.

<sup>26</sup> **Artaxerxes Mnemon.**

Persia.

The most remarkable transaction which happened during the reign of this prince was the revolt of his brother Cyrus. This young prince had been raised to go great power through the interest of his mother, on purpose that he might revolt, as we have already seen. He began with gaining over the cities under the government of Tissaphernes; which quickly produced a war with that governor. Cyrus then began to assemble troops, which he pretended were designed only against Tissaphernes. As he had given great assistance to the Lacedæmonians in their wars against the Athenians, he now in return demanded assistance from them: which request they very readily complied with, ordering their fleet immediately to join him, and to obey in every thing the commands of Tamos his admiral. At last Cyrus, having collected an army of 130,000 Greek mercenaries and 100,000 regular troops of other nations, set out from Sardis, directing his march towards Upper Asia; the army being entirely ignorant of the expedition on which they were going. When they arrived at Tarsus, the Greeks, suspecting that they were marching against the king, refused to proceed any further; but Cyrus having gained them over with presents and promises, they soon went on with satisfaction. Having arrived at Cunaxa in the province of Babylon, Cyrus found his brother with 900,000 men ready to engage him. Whereupon, leaping out of his chariot, he commanded his troops to stand to their arms and fall into their ranks; which was done with great expedition, no time being allowed the soldiers to refresh themselves.

28  
Battle of  
Cunaxa.

Clearchus, the commander of the Peloponnesian troops, advised Cyrus not to charge in person, but to remain in the rear of the Greek battalions; but this advice he rejected with indignation, saying, that he should thus render himself unworthy of the crown for which he was fighting. As the king's army drew near, the Greeks fell upon them with such fury, that they routed the wing opposite to them almost at the first onset; upon which Cyrus was with loud shouts proclaimed king by those who stood next to him. But he, in the mean time, perceiving that Artaxerxes was wheeling about to attack him in flank, advanced against him with 600 chosen horse, killed Artageses captain of the king's guards with his own hand, and put the whole body to flight. In this encounter, discovering his brother, he spurred on his horse, and, coming up to him, engaged him with great fury; which in some degree turned the battle into a single combat. Cyrus killed his brother's horse, and wounded himself on the ground; but he immediately mounted another horse, when Cyrus attacked him again, gave him a second wound, and had already lifted up his hand to give him a third, when the guards, perceiving the danger in which their king was, discharged their arrows at once against his antagonist, who at the same time throwing himself headlong upon his brother, was pierced through by his javelin. He fell dead upon the spot; and all the chief lords of his court, resolving not to survive him, were slain in the same place.

In the mean time, the Greeks having defeated the enemy's left wing commanded by Tissaphernes, and the king's right wing having put to flight Cyrus's left, both parties, being ignorant of what had passed else-

where, imagined that they had gained the victory. But Tissaphernes acquainting the king that his men had been put to flight by the Greeks, he immediately rallied his troops in order to attack them. The Greeks, under the command of Clearchus, easily repulsed them, and pursued them to the foot of the neighbouring hills. As night was drawing near, they halted at the foot of the hill, much surprised that neither Cyrus himself, nor any messenger from him, had appeared; for as yet they knew nothing of his death and the defeat of the rest of the army. They determined therefore to return to their camp, which they did accordingly; but found there that the greatest part of their baggage had been plundered, and all their provisions taken, which obliged them to pass the night in the camp without any sort of refreshment. The next morning, as they were still expecting to hear from Cyrus, they received the news of his death, and the defeat of that part of the army. Whereupon they sent deputies to Artaxerxes, who was commander in chief of all the other forces of Cyrus, offering him, as conquerors, the crown of Persia. Artaxerxes rejected the offer, and acquainting them that he intended to set out early in the morning on his return to Ionia, advised them to join him in the night. They followed his directions, and, under the conduct of Clearchus, began their march, arriving at his camp about midnight, whence they set out on their return to Greece. They were at a vast distance from their own country, in the very heart of the Persian empire, surrounded by a victorious and numerous army, and had no way to return again but by forcing their way through an immense track of the enemy's country. But their valour and resolution mattered all these difficulties; and, in spite of a powerful army, which pursued and harassed them all the way, they made good their retreat for 2325 miles through the provinces belonging to the enemy, and got safe to the Greek cities on the Euxine sea. This retreat, (the longest that ever was made through an enemy's country) was conducted at first by Clearchus; but he being cut off through the treachery of Tissaphernes, Xenophon was chosen in his room, who at last brought his men safe into Greece: but for a full account of that famous retreat, see the article XENOPHON.

Persia.

29  
Retreat of  
ten thousand  
Greeks

The war with Cyrus was scarce ended, when another broke out with the Lacedæmonians, on the following account. Tissaphernes being appointed to succeed Cyrus in all his power, to which was added all which he himself possessed formerly, began to oppress the Greek cities in Asia in a most cruel manner. On this they sent ambassadors to Sparta, desiring the assistance of that powerful republic. The Spartans having ended their long war with the Athenians, willingly laid hold of the present opportunity of breaking again with the Persians, and therefore sent against them an army under the command of Timbro, who, being strengthened by the forces which returned under Xenophon, took the field against Tissaphernes. But Timbro being soon recalled upon some complaints, Dercylidas, a brave officer and experienced engineer, was appointed to succeed him; and he carried on the war to much more advantage than his predecessor. On his arrival in Asia, finding that Tissaphernes was at variance with another governor named Pharnabazus, he concluded a truce

30  
War with the  
Lacedæmonians.

*Perſia.* truce with the former, and marching againſt Pharnabazus, drove him quite out of Æolia, and took ſeveral cities in other parts. The latter, however, immediately repaired to the Perſian court, where he made loud complaints againſt Tiſſaphernes, but gave the king a moſt ſalutary advice, which was to equip a powerful fleet, and give the command of it to Conon the Athenian, the beſt ſea-officer of his time, by which means he would obſtruct the paſſage of further recruits from Greece; and thus ſoon put an end to the power of the Lacedæmonians in Aſia. This advice being approved of, the king ordered 500 talents for the equipment of a fleet, with directions to give Conon the command of it.

In the mean time, Darcyllidas, with all his valour and ſkill, ſuffered himſelf to be drawn into ſuch a diſadvantageous ſituation, that he muſt inevitably have been deſtroyed with his whole army, had it not been through the cowardice of Tiſſaphernes, who, having experienced the Grecian valour at the battle of Cunaxa, could not by any means be induced to attack them. The Lacedæmonians, however, having heard that the Perſian monarch was fitting out a great fleet againſt them, reſolved to puſh on the war as vigorouſly as poſſible; and for this purpoſe ſent over Ageſilaus one of their kings, and a moſt experienced commander, into Aſia. This expedition was carried on with ſuch ſecrecy, that Ageſilaus arrived at Ephelus before the Perſians had the leaſt notice of his deſigns. Here he took the field with 10,000 foot and 4000 horſe, and falling upon the enemy while they were totally unprepared, carried every thing before him. Tiſſaphernes deceived him into a truce till he had leiſure to aſſemble his forces, but gained little by his treachery; for Ageſilaus deceived him in his turn, and, while Tiſſaphernes marched his troops into Caria, the Greeks invaded and plundered Phrygia.

Early in the ſpring, Ageſilaus gave out that his deſign was to invade Lydia; but Tiſſaphernes, who remembered the laſt year's ſtratagem, now taking it for granted that Ageſilaus would really invade Caria, made his troops again march to the defence of that province. But Ageſilaus now led his army into Lydia as he had given out, and approached Sardis; upon which Tiſſaphernes recalled his forces from their former rout, with a deſign to relieve the place. But Caria being a very mountainous country, and unfit for horſe, he had marched thither only with the foot, and left the horſe behind on the borders of that province. Whence, on their marching back to the relief of Sardis, the horſe being ſome days march before the foot, Ageſilaus took the advantage of ſo favourable an opportunity, and fell upon them before the foot could come to their aſſiſtance. The Perſians were routed at the very firſt onſet; after which Ageſilaus over-ran the whole country, enriching both himſelf and his army with the ſpoils of the conquered Perſians.

By this continued ill fortune Artaxerxes was ſo much provoked againſt Tiſſaphernes, that he ſoon after cauſed him to be put to death.

On the death of Tiſſaphernes, Tithrauſtes, who was appointed to ſucceed him, ſent large preſents to Ageſilaus, in hopes of perſuading him to abandon his conqueſts; but finding that commander was not by any means to be induced to relinquish the war, he ſent Ti-

mocrates of Rhodes into Greece, with large ſums of money to corrupt the leading men in the cities, and re-<sup>31</sup> kindle a war againſt the Lacedæmonians. This ſtra- Ageſilaus tegem produced the intended effect; for the cities of Perſia obliged to leave Aſia. Thebes, Argos, Corinth, and others, entering into a confederacy, obliged them to recall Ageſilaus to the defence of his own country.

After the departure of Ageſilaus, which happened in the year 354 B. C. the Lacedæmonian power received a ſevere blow at Cnidus, where their fleet was entirely defeated by that of Artaxerxes under Conon, 50 of their ſhips being taken in the engagement; after which, Conon and Pharnabazus being maſters of the Lacedæmo- ſea, ſailed round the iſlands and coaſts of Aſia, taking the cities there which had been reduced by the Lacedæmonians. Saſſos and Abydos only held out, and reſiſted the utmoſt efforts of the enemy, tho' they had been beſieged both by ſea and land.

Next year, Conon having aſſembled a powerful fleet, again took Pharnabazus on board, and reduced the iſland of Melos, from whence he made a deſcent on the coaſts of Lyconia, pillaging all the maritime provinces, and loading his fleet with an immenſe booty. After this, Conon obtained leave of him to repair to Athens with 80 ſhips and 50 talents, in order to re-build the walls of that city; having firſt convinced Pharnabazus, that nothing could more effectually contribute to the weakening of the power of Sparta than putting Athens again in a condition to rival its power. He no ſooner arrived at Piræus the port of Athens, but he began to work; which, as he had a great number of hands, and was ſeconded by the zeal of all thoſe that were well inclined to the Athenians, was ſoon completed, and the city not only reſtored to its former ſplendour, but rendered more formidable than ever. The Lacedæmonians were now reduced to the neceſſity of accepting ſuch terms of peace as they <sup>33</sup> could procure. The terms were, that all the Greek cities in Aſia ſhould be ſubject to the king of Perſia, as alſo the iſlands of Cyprus and Clazomena; that the iſlands of Scyros, Lemnos, and Imbros, ſhould be reſtored to the Athenians, and all the cities of Greece, whether ſmall or great, ſhould be declared free; and by the ſame treaty Artaxerxes engaged to join thoſe who accepted the terms he propoſed, and to aſſiſt them to the utmoſt of his power againſt ſuch as ſhould rejeſt them.

Artaxerxes, being now diſengaged from the Grecian war, turned his arms againſt Evagoras king of Cyprus. This man was deſcended from the ancient kings of Salamine, the capital city of the iſland of Cyprus. His anceſtors had held that city for many ages in quality of ſovereigns; but were at laſt driven out by the Perſians, who, making themſelves maſters of the whole iſland, reduced it to a Perſian province. Evagoras, however, being a man of an enterpriſing genius, ſoon became weary of living in ſubjection to a foreign power, drove out the Perſian governor, and recovered his paternal kingdom. Artaxerxes attempted to drive him out of it; but, being diverted by the Greek war, was obliged to put off the enterpriſe. However, Conon, by means of Cleſias chief phyſician to Artaxerxes, got all differences accommodated, and Artaxerxes promiſed not to moleſt him in the poſſiſſion of his ſmall kingdom. But Evagoras ſoon becoming

Persia.

discontented with such a narrow possession, gradually reduced under his subjection almost the whole of the island. Some, however, there were who held out against him, and these immediately applied to Artaxerxes for assistance; and he, as soon as the war with Greece was at an end, bent all his force against Evagoras, intending to drive him quite out of the island. The Athenians, however, notwithstanding the favours lately conferred upon them by the king of Persia, could not forbear assisting their old ally in such a dreadful emergency. Accordingly, they sent him ten men of war under the command of Philocrates; but the Lacedæmonian fleet, commanded by Talentias brother to Agestilaus, falling in with them near the isle of Rhodes, surrounded them so that not one ship could escape. The Athenians, determined to assist Evagoras at all events, sent Chabrias with another fleet and a considerable body of land-forces; and with the assistance of these he quickly reduced the whole island. But in a short time, the Athenians being obliged, in consequence of the treaty concluded with the Persians, to recall Chabrias, Artaxerxes attacked the island with an army of 300,000 men, and a fleet of 300 ships. Evagoras applied to the Egyptians, Libyans, Arabians, Tyrians, and other nations, from whom he received supplies both of men and money; fitting out a fleet with which he ventured an engagement with that of Artaxerxes. But being defeated, and obliged to shut himself up in Salamine, he was closely besieged by sea and land. Here at last he was obliged to capitulate, and abandon to the Persians the whole of the island except Salamine, which he held as a king tributary to Artaxerxes.

35  
Unsuccessful  
expeditions  
against the  
Cadusians  
and Egyptians.

The Cyprian war being ended, Artaxerxes turned his arms against the Cadusians, whose country lay between the Euxine and Caspian Seas. But these nations were too well accustomed to war to be overcome by the Persians; and therefore the king was obliged to abandon the project, after having lost a great number of his troops and all the horses which he took out with him. In his Egyptian expedition, which happened immediately after the Cadusian war, he was attended with little better success; which, however, was owing to the bad conduct of his general Pharnabazus. This commander being entrusted with the management of the Egyptian war, sent an ambassador to Athens, complaining that Chabrias had engaged in the service of an enemy of the king of Persia, with whom the state of Athens was in alliance, and threatening the republic with his master's resentment if proper satisfaction was not given: at the same time he demanded Iphicrates, another Athenian, and the best general of his time, to command the Greek mercenaries in the Persian service. This the Athenians complied with; and Iphicrates having mustered his troops, so exercised them in all the arts of war, that they became afterwards very famous among the Greeks under the name of *Iphicratean soldiers*. Indeed he had sufficient time to instruct them; for the Persians were so slow in their preparations, that two whole years elapsed before they were ready to take the field. At the same time Artaxerxes, that he might draw the more mercenaries out of Greece, sent ambassadors to the different states in it, declaring it to be his will and pleasure that they should live at peace with each other, on the terms of

Persia.

the treaty lately concluded: which declaration was received with pleasure by all the states except Thebes, who aspired at the sovereignty of Greece; and accordingly refused to conform to it. All things, however, at last being ready for the expedition, the troops were mustered at the city then called *Ace*, and since *Ptolemais*; where they were found to consist of 200,000 Persians under the command of Pharnabazus, and 20,000 Greeks led by Iphicrates. The fleet consisted of 300 galleys, besides a vast number of other vessels which followed with provisions. The fleet and army began to move at the same time; and that they might act in concert, they separated as little as possible. It was proposed, that the war should begin with the siege of Pelusium; but Nectanebis, the revolted king of Egypt, had provided so well for the defence of the place, that it was thought expedient to drop the enterprise, and make a descent at one of the mouths of the Nile. In this they succeeded; for the Egyptians not expecting them at that place, had not taken such care to fortify it as at Pelusium. The fortresses of consequence was easily taken, and all the Egyptians in it put to the sword. After this, Iphicrates was for embarking the troops without loss of time, and attacking Memphis the capital of Egypt. Had this opinion been followed before the Egyptians recovered from the consternation into which they were thrown, it is highly probable that the whole country might have been reduced at once; but Pharnabazus would undertake nothing before the rest of the forces were come up. Iphicrates then, in the utmost vexation at losing so favourable an opportunity, pressed Pharnabazus to allow him to attack the place with the Greek mercenaries only; but he refused this also, from a mean jealousy of the honour which Iphicrates might acquire; and in the mean time the Egyptians recovered sufficient courage to put themselves in such a posture of defence that they could not be attacked with any probability of success; and at the same time the Nile overflowing as usual, obliged them to return to Phœnicie. The expedition was again undertaken 12 years after, but without success.

The last years of the reign of Artaxerxes were greatly disturbed by dissensions in his family; which at last broke his heart, and he died in the 94th year of his age, and 46th of his reign. He was succeeded by one of his sons named *Ochus*, who behaved with such cruelty, that almost one half of his dominions revolted as soon as he came to the throne. But, by reason of the dissensions of the rebels among themselves, all of them were reduced, one after another; and among the rest, the Sidonians, finding themselves betrayed, burnt themselves to the number of 40,000, together with their wives and children.

Ochus, having quelled all the insurgents, immediately set himself about reducing Egypt, and for this purpose procured a reinforcement of other 10,000 mercenaries from Greece. On his march, he lost a great number of his men drowned in the lake Serbonis, which lies between Phœnicie and Egypt, extending about 30 miles in length. When the south wind blows, the whole surface of this lake is covered with sand, in such a manner that no one can distinguish it from the firm land. Several parties of Ochus's army were lost in it for want of proper guides; and it is said that

36  
Ochus suc-  
ceeds Artaxerxes.

37  
Reduces Egypt.

Persia.

that whole armies have sometimes perished in the same place. When he arrived in Egypt, he detached three bodies to invade the country in different parts; each being commanded by a Persian and a Greek general. The first was led by Lachares the Theban, and Rofaces governor of Lydia and Ionia; the second by Nicoftratus the Theban and Ariftrazanes; the third by Mentor the Rhodian and Bagoas an eunuch. The main body of the army he kept with himself, and encamped near Pelufium, with a design to watch the events of the war there. The event was fuccefful, as we have related under the article EGYPT; and Ochus having reduced the whole country, difmantled their ftrong-holds, plundered the temples, and returned to Babylon loaded with booty.

The king, having ended this war with fuch fuccefs, conferred very high rewards on his mercenaries and others who had diftinguifhed themfelves. To Mentor the Rhodian he gave 100 talents, and other prefents to a great value; appointing him alfo governor of all the coafts of Afia, and committing to his care the whole management of the war which he was ftill carrying on againft fome provinces that had revolted in the beginning of his reign; and all thefe either by ftratagems, or by force, he at laft reduced; reftoring the king's authority in all thefe places.—Ochus then, finding himfelf free from all troubles, gave his attention to nothing but his pleasures, leaving the adminiftration of affairs entirely to Bagoas the eunuch, and to Mentor. Thefe two agreed to fhare the power between them; in confequence of which the former had the provinces of Upper Afia, and the latter all the reft. Bagoas, being by birth an Egyptian, had a great zeal for the religion of his country, and endeavoured, on the conqueft of Egypt, to influence the king in favour of the Egyptian ceremonies; but, in fpite of all his endeavours, Ochus not only refufed to comply, but killed the facred bull, the emblem of the Egyptian god Apis, plundered the temples, and carried away their facred records. This Bagoas fuppofed to be the high-eft guilt which a human creature could commit; and therefore poifoned his mafter and benefactor in the 21ft year of his reign. Nor did his revenge ftop here; for he kept the king's body, caufing another to be buried in its ftead; and becaufe the king had caufed his attendants eat the flefh of Apis, Bagoas cut his body in pieces, and gave it fo mangled to be devoured by cats, making handles for fwords of his bones. He then placed Arfes the youngft of the deceased king's fons on the throne, that he might the more eafily prefeve the whole power to himfelf.

Arfes did not long enjoy even the fhadow of power which Bagoas allowed him, being murdered in the fecond year of his reign by that treacherous eunuch, who now conferred the crown on Darius Codomannus, a diftant relation of the royal family. Neither did he incline to let him enjoy the crown much longer than his predecessor; for, finding that he could not fuffer himfelf to be guided by him in all things, the treacherous Bagoas brought him a poifonous potion; but Darius got rid of him by his own artifice, caufing him to drink the poifon which he brought. This eftablifhed Darius in the throne as far as fecurity from internal enemies could do fo; but in a very little time his dominions were invaded, and, we may fay, the fame

moment conquered by Alexander the Great. The particulars of that heroic's conquefts are related under the article MACEDON; we fhall therefore here only take notice of the fate of Darius himfelf, with which the Persian empire concluded for many ages. After the battle of Arbela, which was decifive in favour of Alexander, the latter took and plundered Perfepolis, from whence he marched into Media, in order to purfue Darius, who had fled to Ecbatan the capital of that province. This unhappy prince had ftill an army of 30,000 foot, among whom were 4000 Greeks, who continued faithful to the laft. Befides, thefe he had 4000 flingers, and 3000 horfe, moft of them Baftrians, and commanded by Belfus governor of Baftria.—When Darius heard that Alexander was marched to Ecbatan, he retired into Baftria, with a defign to raife another army; but foon after, changing his mind, he determined to venture a battle with the forces he ftill had left. On this Belfus governor of Baftria, and Nabarzanes a Persian lord of great diftinction, formed a confpiracy againft him, propofing to feize his perfon, and, if Alexander purfued them, to gain his friendfhip and protection by betraying their mafter into his hands; but if they efaped, their defign was to murder him and ufurp the crown. The troops were eafily gained over, by reprefenting to them the defperate fituation of Darius's affairs; but Darius himfelf, though informed of their proceedings, and foliicited to truft his perfon among the Greeks, refufed to give credit to the report, or follow fuch a falutary counfel. The confequence of this was, that he was in a few days feized by the traitors; who, out of refpect to the royal dignity, bound him with golden chains, and fhutting him up in a covered cart, fled with him towards Baftria. The cart was covered with fkins, and ftrangers appointed to drive it, without knowing who the prifoner was. Belfus was proclaimed commander in chief in the room of Darius by the Baftrian horfe; but Artabazus and his fons, with the forces they commanded, and the Greeks, under the command of one *Patron*, retired from the body of the army under Belfus, and marched over the mountains towards Parthiene. In the mean time Alexander arriving at Ecbatan, was informed that Darius had left the place five days before. He then difpatched orders to Clitus, who had fallen fick at Sufa, to repair, as foon as he recovered, to Ecbatan, and from thence to follow him into Parthia with the cavalry and 6000 Macedonians who were left in Ecbatan. Alexander himfelf with the reft of the army purfued Darius; and the 11th day arrived at *Rhages*, having marched in that fpace of time 3300 furlongs. Moft of thofe who accompanied him died through the fatigue of fo long a march; infomuch that, on his arrival at Rhages, he could fcarce mufter 60 horfemen. Finding that he could not come up with Darius, who had already paffed the Cafpian ftraits, he ftaid five days at Rhages, in order to refrefh his army and fettle the affairs of Media. From thence he marched into Parthia, and encamped at a fmall diftance from the Cafpian ftraits, which he paffed the next day without oppofition. He had fcarce entered Parthia, when he was informed that Belfus and Nabarzanes had confpired againft Darius, and defigned to feize him. Hereupon, leaving the main body of the army behind with Craterus, he

Persia.

advanced with a small troop of horse lightly armed; and having marched day and night without ever halting, except for a few hours, he came on the third day to a village where Bessus with his Bactrians had encamped the day before. Here he understood that Darius had been seized by the traitors; that Bessus had caused him to be shut up in a close cart, which he had lent before, that he might be the more sure of his person; and that the whole army except Artabazus and the Greeks, who had taken another rout, obeyed Bessus. Alexander therefore taking with him a small body of light-armed horse, for the others could not possibly proceed further, at last came in sight of the barbarians, who were marching in great confusion. His unexpected appearance struck them, though far superior in number, with such terror, that they immediately betook themselves to flight; and because Darius refused to follow them, Bessus and those who were about him discharged their darts at the unfortunate prince, leaving him wallowing in his blood. After this they all fled different ways, and were pursued with great slaughter by the Macedonians. In the mean time the horses that drew the cart in which Darius was, stopping of their own accord, for the drivers had been killed by Bessus, near a village about four furlongs from the highway. Thither Polystratus a Macedonian, being pressed with thirst in the pursuit of the enemy, was directed by the inhabitants to a fountain to refresh himself, not far from the place where they stopped. As he was filling his helmet with water he heard the groans of a dying man; and looking round him, discovered a cart with a team of horses, unable to move by reason of the many wounds they had received. When he drew near he perceived Darius lying in the cart, and very near his end, having several darts sticking in his body. However, he had strength enough left to call for some water, which Polystratus readily brought him. Darius, after drinking, turned to the Macedonian, and with a faint voice told him, that, in the deplorable state to which he was reduced, it was no small comfort to him that his last words would not be lost: he then charged him to return his hearty thanks to Alexander for the kindness he had shewn to his wife and family, and to acquaint him, that, with his last breath, he besought the gods to prosper him in all his undertakings, and make him sole monarch of the universe. He added, that it did not so much concern him as Alexander to pursue and bring to condign punishment those traitors who had treated their lawful sovereign with such cruelty, that being the common cause of all crowned heads. Then, taking Polystratus by the hand, "Give Alexander your hand, says he, as I give you mine, and carry him, in my name, the only pledge I am able to give, in this condition, of my gratitude and affection." Having uttered these words, he expired in the arms of Polystratus. Alexander coming up a few minutes after, bewailed his death, and caused his body to be interred with the highest honours. The traitor Bessus being at last reduced to extreme difficulties, was delivered up by his own men naked and bound into the hands of the Macedonians; on which Alexander gave him up to Oxathres the brother of Darius, to suffer what punishment he should think proper. Plutarch tells us that he was executed in the following manner: Several

42  
And murdered.

43  
His murderers punished.

trees being by main force bent down to the ground, and one of the traitor's limbs tied to each of them, the trees, as they were suffered to return to their natural position, flew back with such violence, that each carried with it the limb that was tied to it.

Thus ended the empire of Persia, 209 years after it had been founded by Cyrus. After the death of Alexander the Persian dominions became subject to Seleucus Nicator, and continued subject to him for 62 years, when the Parthians revolted, and conquered the greatest part of them. To the Parthians they continued subject for 475 years; when the sovereignty was again restored to the Persians, as related under the article PARTHIA.

The restorer of the Persian monarchy was Artaxerxes, or Artaxares, who was not only a private person, but of spurious birth. However, he possessed great abilities, by which means he executed his ambitious projects. He was no sooner seated on the throne than he took the pompous title of *king of kings*, and formed a design of restoring the empire to its ancient glory. He therefore gave notice to the Roman governors of the provinces bordering on his dominions, that he had a just right, as the successor of Cyrus, to all the Lesser Asia; which he therefore commanded them immediately to quit, as well as the provinces on the frontiers of the ancient Parthian kingdom, which were already his. The consequence of this was a war with Alexander Severus the Roman emperor. Concerning the event of this war there are very different accounts. It is certain, however, that, on account of his exploits against Artaxares, Alexander took the titles of *Parthicus* and *Persicus*; though, it would seem, with no great reason, as the Persian monarch lost none of his dominions, and his successors were equally ready with himself to invade the Roman territories.

Artaxares dying after a reign of 12 or 15 years, was succeeded by his son Sapor; a prince of great abilities both of body and mind, but fierce, haughty, untractable, and cruel. He was no sooner seated on the throne than he began a new war with the Romans. In the beginning he was unsuccessful; being obliged, peror prisoner. by the young emperor Gordian, to withdraw from the Roman dominions, and was even invaded in his turn; but, in a short time, Gordian being murdered by Philip, the new emperor made peace with him upon terms very advantageous to the Persians. He was no sooner gone than Sapor renewed his incursions, and made such alarming progress, that the emperor Valerian, at the age of 70, marched against him in person with a numerous army. An engagement ensued, in which the Romans were defeated and Valerian taken prisoner. Sapor pursued his advantages with such insolence of cruelty, that the people of the provinces took arms, first under Callistus a Roman general, and then under Odenatus prince of Palmyrene. Thus they not only protected themselves from the insults of the Persians, but even gained many great victories over them, and drove Sapor with disgrace into his own dominions. In his march he is said to have made use of the bodies of his unfortunate prisoners to fill up the hollow roads, and to facilitate the passage of his carriages over such rivers as lay in his way. On his return to Persia, he was solicited by the kings of the Cadusians, Armenians, Bactrians, and other nations, to set Valerian at liberty; but

imprudently.

but to no purpose. On the contrary, he used him the worse; treated him daily with indignities, set his foot upon his neck when he mounted his horse, and, as is affirmed by some, flayed him alive after some years confinement; and caused his skin to be tanned, which he kept as a monument of his victory over the Romans. This extreme insolence and cruelty was followed by an uninterrupted course of misfortune. Odenatus defeated him in every engagement, and even seemed ready to overthrow his empire; and after him Aurelian took ample vengeance for the captivity of Valerian. Sapor died in the year of Christ 273, after having reigned 31 years; and was succeeded by his son Hormisdas, and he by Varanes I. Concerning both these princes we know nothing more than that the former reigned a year and ten days, and the latter three years; after which he left the crown to Varanes II. who seems to have been so much awed by the power of the Romans, that he durst undertake nothing. The rest of the Persian history, to the overthrow of the empire by the Saracens, affords nothing but an account of their continued invasions of the Roman empire, which more properly belongs to the history of Rome; and to which therefore we refer. The last of the Persian monarchs of the line of Artaxares, was Isdigerdes, or Jezdegerd, as he is called by the Arabian and Persian historians, who was cotemporary with Omar the second caliph after Mahomet. He was scarce seated on the throne, when he found himself attacked by a powerful army of Saracens under the command of one Sad, who invaded the country through Chaldaea. The Persian general took all imaginable pains to harass the Arabs on their march; and having an army superior to them in numbers, employed them continually in skirmishes; which were sometimes favourable to him, and sometimes otherwise. But Sad, perceiving that this lingering war would destroy his army, determined to hasten forward, and force the enemy to a general engagement. The Persians declined this for a long time; but at length, finding a convenient plain where all their forces might act, they drew up in order of battle, and resolved to wait for the Arabs. Sad having disposed his men in the best order he could, attacked the Persians with the utmost fury. The battle lasted three days and three nights; the Persians retiring continually from one post to another, till at last they were entirely defeated; and thus the capital city, and the greatest part of the dominions of Persia, fell into the hands of the Arabs. The conquerors seized the treasures of the kings; which were so vast, that, according to a Mahometan tradition, their prophet gave the Saracen army a miraculous view of those treasures before the engagement, in order to encourage them to fight.

After the loss of this battle, Jezdegerd retired into Chorassan, where he maintained himself as king, having under his subjection two other provinces, named *Kerman* and *Segestan*. But after he had reigned in this limited manner for 19 years, one of the governors of the few towns he had left betrayed it, and called in the Turks. This place was called *Merou*, seated on the river Gihon or Odus. Jezdegerd immediately marched against the rebels and their allies. The Persians were defeated; and the unfortunate monarch, having with much difficulty reached the river, found there a little boat, and a fisherman to whom it belong-

ed. The king offered him a bracelet of precious stones; but the fellow, equally brutal and stupid, told him that his fare was five farthings, and that he would neither take more nor less. While they disputed, a party of the rebel horse came up, and knowing Jezdegerd, killed him in the year 652.

Jezdegerd left behind him a son named *Fiروز*, and a daughter named *Dara*. The latter espoused Bostanay, whom the rabbinical writers have dignified with the title of the *head of the captivity*; and who, in fact, was the prince of the Jews settled in Chaldaea. As for Fiروز, he still preserved a little principality; and when he died, left a daughter named *Mah Afrid*, who married Walid the son of the caliph Abdalmalek, by whom he had a son named *Tesid*, who became caliph, and consequently sovereign of Persia; and so far was this prince from thinking himself above claiming the title derived from his mother, that he constantly styled himself the *son of Khosrau king of Persia, the descendant of the caliph Marwan, and among whose ancestors on the side of the mother were the Roman emperor and the khacan*.

Persia continued to be subject to the Arabs till the decline of the Saracen empire, when it was seized by various usurpers, till the time of Jenghiz Khan, who conquered it as well as almost all the rest of Asia. After his death, which happened in the year 1227, Persia, together with the neighbouring countries, were governed by officers appointed by his successors, who reigned at Kæarakorum, in the eastern parts of Tartary, till the year 1253, when it became once more the seat of a mighty empire under Hulaku the Mogul, who in 1256 abolished the caliphate, by taking the city of Bagdad, as related under that article. After the death of Hulaku, his son Abaka succeeded to his extensive dominions; and his first care was to shut up all the avenues of his empire against the other princes of the race of Jenghiz Khan, who reigned in different parts of Tartary. His precautions, however, were of little avail; for, in the very beginning of his reign, he was invaded by Barkan Khan, of the race of Jagatay the son of Jenghiz Khan, from Great Bukharia, with an army of 300,000 men. Abaka was but indifferently prepared to oppose such a formidable power; but, happily for him, his antagonist died before the armies came to an engagement, upon which the invaders dispersed and returned to Tartary. In the year 1264, Armenia and Anatolia were ravaged by the Mamluks from Egypt, but were obliged to fly from Abaka; who thus seemed to be established in the possession of an empire almost as extensive as that of the ancient Persian kings. His tranquillity, however, was of short duration; for, in 1268, his dominions were invaded by Borak Khan, a prince likewise of the race of Jagatay, with an army of 100,000 men. He quickly reduced the province of Chorassan, where he met with little opposition, and, in 1269, advanced as far as Aderbijan, where Abaka had the bulk of his forces. A bloody battle ensued; in which Abaka was victorious, and Borak obliged to fly into Tartary, with the loss of all his baggage and great part of his army. Abaka died in 1282, after a reign of 17 years, not without suspicion of being poisoned; and was succeeded by his brother Ahmed Khan. He was the first of the family of Jenghiz Khan who embraced Mahometanism; but neither he nor his successors appear to have been in the least versed in the

arts of government; for the Persian history, from this period, becomes only an account of insurrections, murders, rebellions, and poisonings, till the year 1335, when it split all to pieces, and was possessed by a great number of petty princes; all of whom were at perpetual war with each other till the time of Timur Beg, or Tamerlane, who once more reduced them all under one jurisdiction.

50  
Under Tamerlane and his successors.

After the death of Tamerlane, Persia continued to be governed by his son Shah Rukh, a wife and valiant prince; but, immediately after his death, fell into the same confusion as before; being held by a great number of petty tyrants, till the beginning of the 16th century, when it was conquered by Shah Ismael Safi, or Sefi; of whose family we have the following account. His father was Sheykh Hayder or Haydr, the son of Soltan Juncy, the son of Sheykh Ibrahim, the son of Sheykh Ali, the son of Sheykh Musa, the son of Sheykh Sefi, who was the 13th in a direct line from Ali the son-in-law of the prophet Mahomet. When Tamerlane returned from the defeat of Bajazet the Turkish sultan, he carried with him a great number of captives out of Karamania and Anatolia, all of whom he intended to put to death on some remarkable occasion; and with this resolution he entered Ardebil, or Ardevil, a city of Aderbijan, about 25 miles to the east of Taurus, where he continued for some days. At this time lived in that city the Sheykh Safi or Sefi abovementioned, reputed by the inhabitants to be a saint; and, as such, much revered by them. The fame of Safi's sanctity so much moved Tamerlane, that he paid him frequent visits; and, when he was about to depart, promised to grant whatever favour he should ask. Sheykh Safi, who had been informed of Tamerlane's design to put the captives to death, requested of the conqueror that he would spare the lives of those unfortunate men. Tamerlane, desirous of obliging him, not only granted this request, but delivered them up to him to be disposed of as he thought fit; upon which the Sheykh furnished them with cloaths and other necessaries as well as he could, and sent them home to their respective countries. This generous action proved very beneficial to the family; for the people were so much affected with such an extraordinary instance of virtue, that they repaired in great numbers to Safi, bringing with them considerable presents; and this so frequently, that few days passed in which he was not visited by many. Thus the descendants of the Sheykh made a conspicuous figure till the year 1486, when they were all destroyed by the Turkmen except Ismael, who fled to Ghilan, where he lived under the protection of the king of that country; after which he became conspicuous on the following occasion.

There was at that time, among the Mahometans, a vast number of people dispersed over Asia; and among these a particular party who followed that of Haydr the father of Ismael, which Sheykh Safi, one of his ancestors, had brought into great reputation. Ismael, who had assumed the surname of *Sofi*, or *Sage*, finding that Persia was all in confusion, and hearing that there was a great number of the Hayderian sect in Karamania, removed thither. There he collected 7000 of his party, all devoted to the interest of his family; and while he was yet only 14 years of age, conquered Shirwan. After this he pursued his con-

quests; and as his antagonists never united to oppose him, had conquered the greatest part of Persia, and reduced the city of Bagdad by the year 1510. However, his conquests on the west side were soon stopped by the Turks; for, in 1511, he received a great defeat from Salem I. who took Tauris; and would probably have crushed the empire of Ismael in its infancy, had he not thought the conquest of Egypt more important than that of Persia. After his defeat by Selim, Ismael never undertook any thing of consequence. He died in 1523, leaving the crown to his eldest son Tahmasp I.

The new Shah was a man of very limited abilities, and was therefore invaded by the Turks almost instantly on his accession to the throne. However, they were obliged to retreat by an inundation, which overflowed their camp, and which frightened them with its red colour, probably arising from the nature of the soil over which it passed. Tahmasp, however, reduced Georgia to a province of the Persian empire; that country being in his time divided among a number of petty princes, who, by reason of their divisions, were able to make little opposition.

The reigns of the succeeding princes afford nothing remarkable till the time of Shah Abbas I. surnamed the *Great*. He ascended the throne in the year 1584; and his first care was to recover from the Turks and Tartars the large provinces they had seized which formerly belonged to the Persian empire. He began with declaring war against the latter, who had seized the finest part of Choraslan. Accordingly, having raised a powerful army, he entered that province, where he was met by Abdallah Khan the chief of the Usbeck Tartars. The two armies lay in sight of each other for six months; but at length Abbas attacked and defeated his enemies, forcing them, for that time, to abandon Choraslan. Here he continued for three years; and on his leaving that place, fixed the seat of government at Ispahan, where it has continued ever since. His next expedition was against the Turks. Understanding that the garrison of Tauris were in no expectation of an enemy, he formed a design of surprising the place; and, having privately assembled a few forces, he marched with such celerity, that he reached a pass called *Shibli*, very near Tauris, in six days, tho' it is usually 18 or 20 days journey for the caravans. Here the Turks had posted a few soldiers, rather for the purpose of collecting the customs on such commodities as were brought that way, than of defending the pass against an enemy. Before they came in sight of this pass, Abbas and some of his officers left the rest of the army, and rode briskly up to the turnpike. Here the secretary of the custom-house, taking them for merchants, demanded the usual duties. Abbas replied, that the person who had the pass was behind, but at the same time ordered some money to be given him. But while the secretary was counting it, he was suddenly stabbed by the Shah's order; and the officers who were with him suddenly falling upon the few soldiers who were there, obliged them to submit; after which he entered the pass with his army. The governor of Tauris marched out with all the troops he could collect on so short a warning; but being inferior to the Persians, he was utterly defeated, and himself taken prisoner; after which the city was obliged to submit,

Persia.

52  
Reign of Shah Abbas the Great.

51  
Conquered by Ismael Sofi.

submit, as also a number of places in the neighbourhood. One city only, called *Orumi*, being very strongly situated, resisted all the efforts of Abbas; but was at last taken by the assistance of the Kurds, whom he gained over by promising to share the plunder of the place with them. But instead of this, he formed a design to cut them all off at once; fearing that they might at another time do the Turks a service of the same nature that they had done to him just now. For this reason he invited their chiefs to dine with him; and having brought them to a tent, the entrance to which had several turnings; and on the inside were stationed two executioners, who cut off the heads of the guests as soon as they entered.

After this Shah Abbas considerably enlarged his dominions, and repelled two dangerous invasions of the Turks. He attempted also to promote commerce, and civilise his subjects; but stained all his great actions by his abominable cruelties, which he practised on every one who gave him the least cause of offence; nay, frequently without any cause at all. He took the Isle of Ormus from the Portuguese, who had kept it since 1507, by the assistance of some English ships in 1622; and died six years after, aged 70.

The princes who succeeded Shah Abbas the Great, were remarkable only for their cruelties and debaucheries, which occasioned a revolution in 1716, when the Shah Huseyn was dethroned by the Afghans, a people inhabiting the country between Persia and India; who being oppressed by the ministers, revolted under the conduct of one Mereweis. The princes of the Afghan race continued to enjoy the sovereignty for no more than 16 years, when Ashraf the reigning Shah was dethroned by one of his officers. On this Tahmasp, otherwise called *Prince Thamas*, the only survivor of the family of Abbas, assembling an army, invited into his service Nadir Khan, who had obtained great reputation for his valour and conduct. He was the son of a Persian nobleman, on the frontiers of Usbeck Tartary; and his uncle, who was his guardian, keeping him out of possession of the castle and estate, which was his inheritance, he took to robbing the caravans; and, having increased his followers to upwards of 500 men, became the terror of that part of the country, and especially of his uncle, who had seized his estate. His uncle therefore resolved to make his peace with him, and with that view invited him to the castle, where he entertained him in a splendid manner; but Nadir Khan ordered his throat to be cut next night, and all his people to be turned out of the castle. No sooner had Nadir Khan got the command of the Persian army, than he attacked and defeated the usurper Efriss, put him to death, and recovered all the places the Turks and Russians had made themselves masters of during the rebellion; and then prince Thamas seemed to be established on the throne: but Nadir Khan, to whom Thamas had given the name of *Thamas Kouli Khan*, that is, *the Slave of Thamas*, thinking his services not sufficiently rewarded, and pretending that the king had a design against his life, or at least to set him aside, conspired against his sovereign, and put him to death, as is supposed: after which, he usurped the throne, styling himself *Shah Nadir*, or *King Nadir*.

He afterwards laid siege to Candahor, of which a

son of Mereweis had possessed himself. While he lay at this siege, the court of the Great Mogul being distracted with factions, one of the parties invited Shah Nadir to come to their assistance, and betrayed the Mogul into his hands. He thereupon marched to Delhi, the capital of India, and summoned all the viceroys and governors of provinces to attend him, and bring with them all the treasures they could raise, and those that did not bring as much as he expected, he tortured and put to death. Having thus amassed the greatest treasure that ever prince was master of, he returned to Persia, giving the Mogul his liberty, on condition of his resigning the provinces on the west side of the Indus to the crown of Persia. He afterwards made a conquest of Usbeck Tartary, and plundered Bochara the capital city. Then he marched against the Dagistan Tartars; but lost great part of his army in their mountains, without fighting. He defeated the Turks in several engagements; but laying siege to Bagdad, was twice compelled to raise the siege. He proceeded to change the religion of Persia to that of Omar, hanged up the chief priests, put his own son to death, and was guilty of such cruelty, that he was at length assassinated by his own relations, anno 1747. A contest upon this ensued between these relations for the crown; which continued for several years, and made Persia a dreadful scene of confusion, bloodshed, and devastation: but at last fortune declared in favour of Kerim Khan, who was crowned in the month of October 1763, at Tauris.

As to the air and climate of this country, considering the great extent thereof, it cannot but be very different, according to the situation of its several parts; some being frozen with cold, whilst others are burnt with heat at the same time of the year. The air, wherever it is cold, is dry; but, where it is extremely hot, it is sometimes moist. All along the coast of the Persian Gulph, from west to east, to the very mouth of the river Indus, the heat for four months is so excessive, that even those who are born in the country, unable to bear it, are forced to quit their houses, and retire to the mountains; so that such as travel in these parts, at that season, find none in the villages but wretched poor creatures, left there to watch the effects of the rich, at the expence of their own health. The extreme heat of the air, as it is insupportable, so it makes it prodigiously unwholesome; strangers frequently falling sick there, and seldom escaping. The eastern provinces of Persia, from the river Indus to the borders of Tartary, are subject to great heats, though not quite so unwholesome as on the coasts of the Indian Ocean and the Persian Gulph; but in the northern provinces, on the coast of the Caspian Sea, the heat is full as great, and, though attended with moisture, as unwholesome as on the coast before mentioned. From October to May, there is no country in the world more pleasant than this; but the people carry indelible marks of the malign influence of their summers, looking all of them of a faint yellow, and having neither strength nor spirits; though, about the end of April, they abandon their houses, and retire to the mountains, which are 25 or 30 leagues from the sea. But this moistness in the air is only in these parts: the rest of Persia enjoys a dry air, the sky being perfectly serene, and hardly so much as a cloud seen to fly there-

Persia.

54  
Air and  
climate of  
Persia.

Perfia. in. Though it seldom rains, it does not follow that the heat admits of no mitigation; for in the night, notwithstanding there is not a cloud to be seen, and the sky is so clear, that the stars alone afford a light sufficient to travel by, a brisk wind springs up, which lasts until within an hour of the morning, and gives such a coolness to the air, that a man can dispense with a tolerable warm garment. The seasons in general, and particularly in the middle of this kingdom, happen thus: the winter, beginning in November, and lasting until March, is very sharp and rude, attended with frost and snow; which last descends in great flakes on the mountains, but never in the plains. There are mountains, three days journey to the west of Spaulhawn, or Isphahan, on which the snow lies for eight months in the year. From the month of March to that of May there are brisk winds; from May to September the air is serene and dry, refreshed by pleasant gales, which blow in the night, at evening and morning; and in September and November the wind blows as in the spring. The great drifels of the air exempts Persia from thunder and earthquakes. In the spring, indeed, there sometimes falls hail; and, as the harvest is then pretty far advanced, it does a great deal of mischief. The rainbow is seldom seen in this country, because there rise not vapours sufficient to form it; but in the night there are seen rays of light shooting thro' the firmament, and followed as it were by a train of smoke. The winds, however brisk, seldom swell into storms or tempests; but, on the other hand, they are sometimes poisonous and infectious on the shore of the Gulph, as all travellers agree. Mr Tavernier says, that at Gombroon people often find themselves struck by a south wind, in such a manner that they cry, "I burn;" and immediately fall down dead. M. le Brun tells us, that he was assured while he was there, that the weather was sometimes so excessively sultry as to melt the seals of letters. At this time the people go in their shirts, and are continually sprinkled with cold water; and some even lie several hours naked in the water. Among the inconveniences consequent from this malign disposition of the air, one of the most terrible is the engendering, in the arms and legs, a kind of long small worms, which cannot be extracted without great danger of breaking them; upon which a mortification ensues.

55  
Soil.

The soil of Persia is in general stony, sandy, barren, and every where so dry, that, if it be not watered, it produces nothing, not even grass; but, where they can turn the water into their plains and valleys, it is not unfruitful. There is a great difference in point of fertility, in the different provinces of the empire; and that of Media, Iberia, Hyrcania, and Bactria, are now, in a great measure, what they were formerly, and surpass most of the others in their productions. All along the Persian Gulph, the soil is still more barren, cattle less plenty, and every thing in a worse condition than any where else.

56  
Produce,  
&c.

Though there is scarce a province in Persia which does not produce wine, yet the wine of some provinces is much more esteemed than that of others; but Schiras wine is universally allowed to be the very best in Persia: inasmuch, that it is a common proverb there, That to live happily one must eat the bread of Yezd, and drink the wine of Schiras.

Perfia.

The grain most common in Persia is wheat; which is wonderfully fair and clean. As for barley, rice, and millet, they only make bread of them in some places, as in Courdestan, when their wheat-bread is exhausted before the return of harvest. They do not cultivate in this country either oats or rye; except where the Armenians are settled, who make great use of the latter in Lent. Rice is the universal aliment of all sorts of people in Persia; for this reason they are extremely careful in its cultivation; for, after they have sown it in the same manner as other grain, they in three months time transplant it, root by root, into fields, which are well watered, otherwise it would never attain that perfection in which we find it there; since it is softer, sooner boiled, and more delicious, than the same grain in any other part of the world. Perhaps its taste is, in some measure, heightened by a practice they make use of to give it a glossy whiteness, viz. by cleansing it, after it is beaten out of the husks, with a mixture of flour and salt. Corn ripens exceedingly in this country; so that in some parts they have a threefold crop in the year. The Persian bread is generally very thin, white, and good; and commonly cheap enough.

Metals of all sorts have been found in Persia. Since the reign of Shah Abbas the Great, iron, copper, and lead, have been very common; but there are no gold or silver mines open at present; though, as Persia is a very mountainous country, such might very probably be found, if pains were taken to search them out. There are silver mines in Kirman and Mazanderan, and one not far from Spaulhawn; but they cannot be worked for want of wood. Minerals are also found in Persia in abundance; especially sulphur, saltpetre, salt, and alum. Nothing is more common in this country than to meet with plains, sometimes 10 leagues in length, covered entirely with salt, and others with sulphur or alum. In some places salt is dug out of mines, and even used in building houses. Marble, free-stone, and slate, are found in great plenty about Hamadan. The marble is of four colours, viz. white, black, red and black, and white and black. Persia yields two sorts of petroleum, or napthe; namely, black and white. In the neighbourhood of Tauris they find azure; but it is not so good as that brought from Tartary. Among the most valuable productions of Persia, are the precious stones called *turquoises*, of which there are several rocks or mines.

The horses of Persia are the most beautiful of the East, though they are not so much esteemed as those of Arabia; so great, however, is the demand for them, that the finest ones will fetch from 90l. to 450l. sterling. They are higher than the English saddle-horses; straight before, with a small head, legs wonderfully slender, and finely proportioned; they are mighty gentle, good travellers, very light and sprightly, and do good service till they are 18 or 20 years old. The great numbers of them sold into Turkey and the Indies, though none can be carried out of the kingdom without special licence from the king, is what makes them so dear. Next to horses, we may reckon mules, which are much esteemed here, and are very fine; and next to these we may justly place asses, of which they have in this country two sorts; the first bred in Persia, heavy and doltish, as asses in other countries are; the other originally of an Arabian breed, the most docile and

useful

useful creature of its kind in the world. They are used wholly for the saddle; being remarkable for their easy manner of going, and are very sure-footed, carrying their heads lofty, and moving gracefully. Some of them are valued at 20*l*. sterling. The mules here are also very fine; they pace well, never fall, and are seldom tired. The highest price of a mule is about 45*l*. sterling. Camels are also numerous in Persia, and very servicable: they call them *kechty-krouch kotion*, i. e. the "ships of the land;" because the inland trade is carried on by them, as the foreign is by ships. Of these camels there are two sorts, the northern and southern: the latter, which is much the smaller, but swifter, will carry a load of about 700 weight, and trot as fast as a horse will gallop; the other will travel with a load of 1200 or 1300 weight: both are profitable to their masters, as costing little or nothing to keep. They travel without halter or reins; grazing on the road from time to time, notwithstanding their load. They are managed entirely by the voice; those who direct them making use of a kind of song, and the camel moving brisker, or at its ordinary pace, as they keep a quicker or slower time. The camels shed their hair so clean in the spring, that they look like scaled swine; but then they are pitched over, to keep the flies from stinging them. The camels hair is the most profitable fleece of all the tame beasts: fine fluffs are made of it, and in Europe, hats, with a mixture of a little beaver.

As beef is little eaten in Persia, their oxen are generally employed in ploughing, and other sorts of labour. Hogs are nowhere bred in Persia, if we except a province or two on the borders of the Caspian Sea. Sheep and deer are very common throughout all Persia.

Of wild beasts, the number is not great in that country, because there are few forests; but where there are any, as in Hyrcania, now called *Tabristan*, abundance of lions, bears, tigers, leopards, porcupines, wild boars, and wolves, are to be found; but the last are not so numerous as any of the other species.

There are but few insects in this country; which may be ascribed to the driness of the climate. In some provinces, however, there is an infinite number of locusts or grasshoppers, which fly about in such clouds as to darken the air. In certain parts of the Persian dominions they have large black scorpions, so venomous, that such as are stung by them die in a few hours. In others, they have lizards, frightfully ugly, which are an ell long, and as thick as a large toad, their skins being as hard and tough as that of the sea-dog: they are said to attack and kill men sometimes; but that may be doubted. The southern provinces are infested with gnats; some with long legs, like those we call *midge*; and some white, and as small as fleas, which make no buzzing, but sting suddenly, and so smartly, that the sting is like the prick of a needle. Among the reptiles is a long square worm, called by the inhabitants *hazar-foy*, i. e. "thousand-feet," because its whole body is covered with feet: it runs prodigiously fast; and its bite is dangerous, and even mortal, if it gets into the ear.

There are in Persia all the several sorts of fowls which we have in Europe, but not in such great plenty; excepting, however, wild and tame pigeons, of which vast numbers are kept all over the kingdom, chiefly on

account of their dung; which is the best manure for melons. It is a great diversion among the lower sort of people in town and country to catch pigeons, tho' it be forbidden: for this purpose they have pigeons so taught, that flying in one flock, they surround such wild ones as they find in the field, and bring them back with them to their masters. The partridges of this country are the largest and finest in the world, being generally of the size of our fowls. Geese, ducks, cranes, herons, and many other sorts of water fowl, are common here; as are likewise nightingales, which are heard all the year, but chiefly in the spring; martlets, which learn whatever words are taught them; and a bird called *noura*, which chatters incessantly, and repeats whatever it hears. Of birds of a larger size, the most remarkable is the pelican, by the Persians called *tacab*, i. e. "water-carrier;" and also *mifc*, i. e. "sheep;" because it is as large as one of those animals\*. There are in Persia various birds of prey. Some of their fowls are the largest and finest in the world: the people take great pains to teach them to fly at game; the Persian lords being great lovers of falconry, and the king having generally 800 of these sort of birds, each of which has a person to attend it.

There is perhaps no country in the world which, generally speaking, is more mountainous than Persia; rivers, and but many of them yield neither springs nor metals, and but few of them are shaded with trees. It is true, some of the chief of them are situated on the frontiers, and serve as a kind of natural ramparts, or bulwarks, to this vast empire. Among the latter are the mountains of Caucasus and Ararat, sometimes called the *mountains of Daghestan*; which fill all the space between the Euxine and Caspian Seas: those called *Taurus*, and the several branches thereof, run through Persia from Natosia to India, and fill all the middle of the country.

As to rivers, except the Araxes, which rises in the mountains of Armenia, and falls into the Kur or Cyrus before it reaches the Caspian Sea, there is not one navigable stream in this country. The Oxus divides Persia on the north-east, from Usbeck Tartary. The Indus also may now be reckoned among the rivers of Persia, as the provinces lying to the west of that river are now in possession of that crown: this river is said to run a course of more than 1000 miles, and overflows all the low grounds in April, May, and June.

The seas on the south of Persia are, the Gulph of Persia or Baffora, the Gulph of Ormus, and the Indian Ocean. The only sea on the north is the Caspian, or Hyrcanian sea; which is more properly a lake, having no communication with any other sea. These seas, together with the lakes and rivers, supply Persia with plenty of fish. The Caspian sea contains very fine fish on one side; and the Persian Gulph on the other, is believed to have more fish than any other sea in the world. On the coasts of this gulph is taken a sort of fish, for which they have no particular name: its flesh is of a red colour, very delicious, and some of them weigh 200 or 300 pounds. The river-fish are chiefly barbels; but far from being good. Those of the lakes are carps and shads. In the river at Spauhawn are a great number of crabs, which crawl up the trees, and live night and day under the leaves, whence they are taken; and are esteemed very delicious food.

Perſia.  
58  
Trade.

The English, and other nations, trade with the Perſians ſeveral ways, particularly by the Gulph of Ormus at Gombroon, and by the way of Turkey. A trade alſo was not many years ſince opened by the English with Perſia through Ruſſia and the Caſpian Sea; but that is now diſcontinued, having been prohibited by the court of Ruſſia, who were apprehenſive that the English would teach the Perſians to build ſhips, and diſpute the navigation of the Caſpian Sea with them. The principal commodities and manufactures of Perſia are, raw and wrought ſilks, mohair, camblets, carpets, leather; for which, and ſome others, the European merchants exchange chiefly woollen manufactures; but the trade is carried on altogether in European ſhipping, the Perſians having ſcarce any ſhips of their own, and the Ruſſians the ſole navigation of the Caſpian Sea. There is not a richer or more profitable trade in the world, than that which is carried on between Gombroon and Surat in the Eaſt Indies; and the English Eaſt India company frequently let out their ſhips to tranſport the merchandize of the Banians and Armenians from Perſia to India. The civil wars which deſolated this country, and put a ſtop to all trade, after the death of Shah Nadir, ſeem to have been over ſeveral years, Kerim Khan, one of the competitors, having gained ſuch a ſuperiority in the year 1763 over his rivals, that he was crowned king; ſince which time peace and tranquillity ſeem to have taken place of anarchy and conſuſion. The Shah, or ſovereign of Perſia, is the chief merchant; and he uſually employs his Armenian ſubjects to traffic for him in every part of the world. The king's agents muſt have the reſuſal of all merchandize, before his ſubjects are permitted to trade. It is computed that Perſia produces yearly upwards of 22,000 bales of ſilk, chiefly in the provinces of Ghilan and Mazanderan, each bale weighing 263 pounds. Vaſt quantities of Perſian ſilk uſed to be imported into Europe, eſpecially by the Dutch, English, and Ruſſians, before the civil wars began. The goods exported from Perſia to India are, tobacco, all ſorts of fruits, pickled and preſerved, eſpecially dates, marmalade, wines, diſtilled waters, horſes, Perſian feathers, and Turkey leather of all ſorts and colours, a great quantity whereof is alſo exported to Muſcovy and other European countries. The exports to Turkey are, tobacco, galls, thread, goats hair, Ruſſia, mats, box-work, and many other things. As there are no poſts in the eaſt, and trading by commiſſion, with the uſe of bills of exchange, is little known, traffic muſt proceed in a very aukward heavy manner, in compariſon of that of Europe.

59  
Money.

The moſt current money of Perſia are the abaſſees, worth about 1 s. 4 d. Sterling, they are of the fineſt ſilver. An abaſſee is worth two mahmoudes; a mahmoude, two ſhahees; and a ſhahee, ten ſingle or five double caſbeghes: theſe laſt pieces are of braſs, the others of ſilver; for gold is not current in trade. The ſhahees are not very common; but mahmoudes and caſbeghes are current every where. Horſes, camels, houſes, &c. are generally ſold by the toman, which is an imaginary coin, worth 200 ſhahees, or 50 abaſſees; and they uſually reckon their eſtates that way. Such a one, they ſay, is worth 50 toman, as we ſay pounds in England.

Perſia is an abſolute monarchy, the lives and eſtates

of the people being entirely at the diſpoſal of their prince. The king has no council eſtabliſhed, but is adviſed by ſuch miniſters as are moſt in favour; and the reſolutions taken among the women of the haram frequently defeat the beſt laid deſigns. The crown is hereditary, excluding only the females. The ſons of a daughter are allowed to inherit. The laws of Perſia exclude the blind from the throne; which is the reaſon that the reigning prince uſually orders the eyes of all the males of the royal family, of whom he has any jealouſy, to be put out. The king has generally a great many wives, which it would be death for any one, beſides the eunuchs, who have the ſuperintendance of them, to look at, or even ſee by accident; wherefore, when he travels, notice is given to all men to quit the road, nay their very houſes, and to retire to a great diſtance.

The prime miniſter is called *attemaet doulet*, which ſignifies the director of the empire, and alſo *vizir azeem*, or the great ſupporter of the empire; as he alone almoſt ſuſtains the whole weight of the adminiſtration. This miniſter's chief ſtudy is to pleaſe his maſter, to ſecure to himſelf an aſcendant over his mind, and to avoid whatever may give him any uneaſineſs or umbrage. With this view, he never fails to flatter him, to extol him above all the princes upon earth, and to throw a thick veil over every thing that might help to open his eyes, or diſcover to him the weakneſs of the ſtate. He even takes particular care to keep the king in utter ignorance, to hide from him, or at leaſt to ſoften, all unwelcome news; and, above all, to exalt immoderately every the leaſt advantage he obtains over his enemies. As he takes theſe methods, which indeed are and muſt be taken, more or leſs, by the miniſters of every deſpotic prince, to ſecure the favour and confidence of his maſter; ſo the inferior officers and governors of provinces are obliged to employ all the means in their power to ſecure the prime miniſters, they depending no leſs upon him than he does upon the king. There is a gradation of deſpotiſm and flattery, down from the prime miniſter to the loweſt retainer to the court, or dependent on the government. Children are ſometimes, in Perſia, required by the king to cut off the ears and noſe, and even to cut the throats, of their parents; and theſe orders cannot be objected to, without endangering their own lives. Indeed, their baſeneſs and mercenarineſs are ſuch, that they will perpetrate ſuch atrocious deeds without the leaſt ſcruple or difficulty, when they have a promiſe or expectation of poſſeſſing their poſts. The prime miniſters, notwithstanding the precarious footing on which they ſtand, in effect of their abilities or good fortune, ſometimes continue in their employments during life, or, if removed, are only baniſhed to ſome city, where they are allowed to ſpend the remainder of their days in a private ſtation.

Next to the prime miniſter are the na-dir, or grand-maſter of the houſehold; the mehter, or groom of the chambers, who is always a white eunuch; the mir-akbor-baſhe, or maſter of the horſe; the mir-shikar-baſhe, or great huntſman and falconer; the divan-beggi, or chief juſtice, to whom there lies an appeal from the deroga, or the lieutenant of police, in every town; the vacka-noviez, or recorder of events, or firſt ſecretary of ſtate; the muſlau-the-elmenaleck, or ma-  
ſter

Perſia.

ster of the accounts and finances of the kingdom; the numes-humbashes, or the king's chief physicians; the shickada-shabashes, or inspector of the palace, and regulator of rank at court; and the khans, or governors of provinces, under whom are other governors, called *jeltans*, appointed also by the king.

The chief ministers, in spirituals, are the zedder, or grand-pontiff, answering to the mufti among the Turks; under him are the sheik-el, selom, and cadi, who decide in all matters of religion, and make all contracts, testaments, and other public deeds, being appointed by the king in all the principal towns; and next to these are the pichnamas, or directors of the prayers; and the moullahs, or doctors of the law.

There is no nobility in Persia, or any respect shewn to a man on account of his family, except to those who are of the blood of their great prophet or patriarchs; but every man is esteemed according to the post he possesses; and when he is dismissed he loses his honour, and he is no longer distinguished from the vulgar.

With respect to the forces of Persia, their two bodies, called the *Kortshier* and *Goulans*, that serve on horseback, are well kept and paid, and may amount, the former to about 22,000, and the latter to about 18,000. The *kortshies* are descended from an ancient but foreign race; and the *goulans* are either Georgian renegades or slaves, or the children of slaves of all nations. The infantry, called *Tangtchieh*, are picked out from among the most robust and vigorous of the peasants, and compose a body of 40,000 or 50,000. The Persians have few fortified towns, and had no ships of war till Kouli Khan built a royal navy, and among them had a man of war of 80 guns; but since the death of that usurper, we hear no more of their fleet.

The arms of the king of Persia are a lion couchant, looking at the sun as he rises over his back. His usual title is *Shah* or *Patschaw*, the "disposer of kingdoms." They add also to the king's titles those of *sultan*, and *chan* or *cham*, which is the title of the Tartar sovereigns. To acts of state the Persian monarch does not subscribe his name; but the grant runs in this manner, *viz. This act, or edict, is given by him whom the universe obeys.*

As to the manners of the ancient Persians, we know little of them; excepting that they were exceedingly voluptuous and effeminate. After the conquest of the empire by Alexander, the Greek discipline and martial spirit being in part communicated to them, they became much more formidable; and hence the Parthians were found to be a match, not only for the Syro-Macedonian princes, but even for the Romans. Of their manners we know little or nothing, but that to their valour and military skill they joined in a surprising degree all the luxury and dissipation of the ancient Persians.

The modern Persians, like the Turks, plundering all the adjacent nations for beauties to breed by, are men of a good stature, shape, and complexion; but the Gaures, or ancient Persians, are homely, ill-shaped, and clumsy, with a rough skin, and olive complexions. In some provinces, not only the complexions but the constitutions of the inhabitants, suffer greatly by the extreme heat and unwholesomeness of the air. The

Persian women, too, are generally handsome and well-shaped, but much inferior to those of Georgia and Circassia. The men wear large turbans on their heads, some of them very rich, interwoven with gold and silver; a vest, girt with a sash; and over it a loose garment, something shorter; with sandals, or slippers, on their feet. When they ride, which they do every day, if it be but to a house in the same town, they wear pliant boots of yellow leather; the furniture of their horses is extremely rich, and the stirrups generally of silver: whether on horseback or on foot, they wear a broad sword and a dagger in their sash. The dresses of the women does not differ much from that of the men; only their vests are longer, and they wear stiffened caps on their heads, and their hair down.

Their usual drink is water and sherbet, as in other Mahometan countries, wine being prohibited; but the officers and soldiers frequently break through these restraints, and drink wine, which is made by the Armenians and Gaures in Schiras and other Persian provinces; and none of them make any scruple of intoxicating themselves with opium, of which any of them will eat as much as would poison half a dozen Christians.

The Persians excel more in poetry than any other sort of literature; and astrologers are now in as great reputation in Persia as the magi were formerly. Their books are all manuscripts, the art of printing having not yet been introduced among them: they excel indeed in writing, and have eight different hands. They write from the right hand to the left, as the Arabs do. In their short-hand, they use the letters of the alphabet; and the same letters, differently pointed, will have 20 different significations. In short, the Persians are born with as good natural parts as any people in the East, but make a bad use of them; being great dissemblers, cheats, liars, and flatterers, and having a strong propensity to voluptuousness, luxury, idleness, and indolence; vices, indeed, to which the Asiatics in general are much addicted.

PERSIAN WHEEL. See HYDROSTATICS.

PERSICA, the PEACH, is by Linnaeus referred to the same class and genus with amygdalus; however, as they are so commonly reckoned to be different genera, we have thought proper to distinguish them. There are a great variety of peach-trees planted in the gardens, some of which are preserved only for the beauty of their flowers, but most of them for the sake of the fruit. Of those remarkable for the beauty of their flowers the principal are, 1. The vulgaris, or common peach-tree, with double flowers, which is a very great ornament in gardens, producing very large double flowers of a beautiful red or purple colour, and grows to a considerable size. 2. The humilis, or dwarf-almond. 3. The africana, or double-flowering dwarf-almond. These two reach not above the height of three or four feet, though their flowers are of equal beauty with the former.

Of the peach-trees cultivated for the sake of their fruit there are a great number, to describe which particularly would exceed the proper bounds of this article. They are raised from the stones of the fruit, which should be planted in autumn on a bed of light dry earth, about three inches deep and four inches asunder. In the winter the beds should be covered with

## P E R S P E C T I V E.

with mulch to protect them from the frost. In this bed they should remain for a year; when they are to be taken up and planted in a nursery, where they are to remain one or two years; after which they must be removed to the places where they are to continue.

PERSICANA, in botany. See POLYGONUM.

PERSIUS (Flaccus Aulus), a Latin poet in the reign of Nero, celebrated for his satires. He was born, according to some, at Volterra in Tuscany; and according to others, at Tigulia, in the gulf Della Specia, in the year 34. He was educated till 12 years old at Valerrio; and afterwards continued his studies at Rome under Palæmon the grammarian, Virginius the rhetorician, and Cornutus the Stoic philosopher, who contracted a friendship for him. Persius consulted that illustrious friend in the composition of his verses. Lucian also studied with him under Cornutus; and appeared so charmed with his verses, that he was incessantly breaking out into acclamations at the beautiful passages in his satires: an example rarely seen in poets of equal rank. He was a steady friend, a good son, an affectionate brother and parent. He was chaste, meek, and modest: which shews how wrong it is to judge of a man's morals by his writings; for the satires of Persius are not only licentious, but sharp and full of bitterness. He wrote but seldom; and it was some time before he applied himself regularly to it.

Persius was of a weak constitution, and troubled with a bad stomach; of which he died in the 30th year of his age. Six of his satires remain; in their judgments of which the critics have been much divided, excepting as to their obscurity, Persius being indeed the most obscure of all the Latin poets. As a poet, he is certainly inferior to Horace and Juvenal; and all the labours of Isaac Casaubon, who has written a most learned and elaborate commentary upon him, cannot make him equal to either of them as a satirist, though in virtue and learning he exceeded them both. He was a professed imitator of Horace; yet had little of Horace's wit, ease, and talent at ridicule. His style is grand, figurative, poetical, and suitable to the dignity of the Stoic philosophy: and hence he shines most in recommending virtue and integrity: here it is that satire becomes him. He was too grave to court the muses with success: but he had a great soul, susceptible of noble sentiments, which give a grace but to indifferent poetry. His contemporaries thought highly of him. Quintilian allows, that Persius, although he wrote but one book of satires, acquired a great deal of true glory, *Multum et*

*vere gloria quævis uno libro Persius meruit; and Martial says much the same thing, Sæpius in libro memoratur Persius uno, &c.*

PERSON, an individual substance of a rational intelligent nature. Thus we say, an ambassador represents the person of his prince; and that, in law, the father and son are reputed the same person.

PERSON, in grammar, a term applied to such nouns or pronouns as, being either prefixed or understood, are the nominatives in all inflections of a verb; or it is the agent or patient in all finite or personal verbs. See GRAMMAR.

PERSONAL, any thing that concerns, or is restrained to, the person: thus it is a maxim in ethics, that all faults are personal.

PERSONAL Action, in law, is an action levied directly and solely against the person; in opposition to a real or mixed action. See ACTION.

PERSONAL Goods, or Chattels, in law, signifies any moveable thing belonging to a person, whether alive or dead. See CHATELS.

PERSONAL Verb, in grammar, a verb conjugated in all the three persons: thus called in opposition to an impersonal verb, or that which has the third person only.

PERSONALITY, in the schools, that which constitutes an individual a distinct person.

PESONATE, the name of the 40th order in Linnæus's Fragments of a Natural Method, consisting of a number of plants whose flowers are furnished with an irregular gaping or grinning petal, which, in figure, somewhat resembles the snout of an animal. The bulk of the genera of this natural order arrange themselves under the class and order didynamia angiospermia of the Sexual Method.

The rest, although they cannot enter into the artificial class just mentioned, for want of the classic character, the inequality of the stamina; yet, in a natural method, which admits of greater latitude, may be arranged with those plants, which they resemble in their habit and general appearance, and particularly in the circumstance expressed in that title.

PERSONIFYING, or PERSONALIZING, the giving an inanimate being the figure, sentiments, and language of a person.

Personifying is essential to poetry, especially to the epopeia: the poets have therefore personified all the passions, and even represented them as deities; as, the goddess Persuasion, the god Sleep; the Furies, Envy, Discord; and Fame, Fortune, Victory, Sin, Death, &c.

## P E R S P E C T I V E.

PERSPECTIVE teaches how to represent objects on a plane superficies, such as they would appear at a certain distance and height, upon a transparent plane perpendicular to the horizon, placed between the objects and the eye.

It was in the 16th century that *Perspective* was revived, or rather re-invented. It owes its birth to painting, and particularly to that branch of it which was employed in the decorations of the theatre, where landscapes were properly introduced, and which would

have looked unnatural and horrid if the size of the objects had not been pretty nearly proportioned to their distance from the eye. We learn from Vitruvius, that Agatharchus, instructed by Æschylus, was the first who wrote upon this subject; and that afterwards the principles of this art were more distinctly taught by Democritus and Anaxagoras, the disciples of Agatharchus. Of the theory of this art, as described by them, we know nothing; since none of their writings have escaped the general wreck that

Person  
Personify-  
ing.

Fig. 10.

Perspective, was made of ancient literature in the dark ages of Europe. However, the revival of painting in Italy was accompanied with a revival of this art.

The first person who attempted to lay down the rules of perspective was Pietro del Borgo, an Italian. He supposed objects to be placed beyond a transparent tablet, and endeavoured to trace the images which rays of light, emitted from them, would make upon it. But we do not know what success he had in this attempt, because the book which he wrote upon this subject is not now extant. It is, however, very much commended by the famous Egnazio Dante; and, upon the principles of Borgo, Albert Durer constructed a machine, by which he could trace the perspective appearance of objects.

Balthazar Peruzzi studied the writings of Borgo, and endeavoured to make them more intelligible. To him we owe the discovery of points of distance, to which all lines that make an angle of 45 degrees with the ground-line are drawn. A little time after, Guido Ubaldo, another Italian, found that all the lines that are parallel to one another, if they be inclined to the ground-line, converge to some point in the horizontal line; and that through this point also, a line drawn from the eye, parallel to them, will pass. These principles put together enabled him to make out a pretty complete theory of perspective.

Great improvements were made in the rules of perspective by subsequent geometers; particularly by professor Gravende, and still more by Dr Brook Taylor, whose principles are, in a great measure new, and far more general than any before him.

Plate CCXXXV. In order to understand this subject, a general knowledge of the principles of Optics is absolutely necessary. The foundation of perspective may be understood, by supposing the pentagon ABDEF (fig. 1.) were to be represented by the rules of perspective on the transparent plane VP, placed perpendicularly on the horizontal plane HR; dotted lines are imagined to pass from the eye C to each point of the pentagon, as CA, CB, CD, &c. which are supposed, in their passage through the plane, PV to leave their traces or vestigia in the points *a, b, d*, &c. on the plane, and thereby to delineate the pentagon *abdef*; which, as it strikes the eye by the same rays that the original pentagon ABDEF does, will be a true perspective representation of it.

The business of perspective, therefore, is to lay down geometrical rules for finding the points *a, b, d, e, f*, upon the plane; and hence also we have a mechanical method of delineating any object very accurately.

Perspective is either employed in representing the ichnographies or ground-plots of objects: or the scenographies, or representations of the objects themselves.

But before we give any examples of either, it will be proper to explain some technical terms in regard to perspective in general: and first, the horizontal line is that supposed to be drawn parallel to the horizon through the eye of the spectator; or rather it is a line which separates the heaven from the earth, and which limits the sight. Thus, A, B, (*ibid.* fig. 2.) are two pillars below the horizontal line CD, by reason the line is elevated above them; in fig. 3. they are said to be equal with it, and in fig. 4. raised above it. Thus,

according to the different points in view, the objects will be either higher or lower than the horizontal line. The point of sight A (*ibid.* fig. 5.) is that which makes the central ray on the horizontal line *ab*: or, it is the point where all the other visual rays, DD, unite. The points of distance C, C, are points set off in the horizontal line at equal distances on each side of the point of sight A; and in the same figure BB represents the base line, or fundamental line: EE is the abridgment of the square; of which D, D, are the sides; F, F, the diagonal lines, which go to the points of distance C, C. Accidental points are those where the objects end: these may be cast negligently; because neither drawn to the point or sight, nor to those of distance, but meeting each other in the horizontal line. For example, two pieces of square timber G and H (*ibid.* fig. 6.) make the points I, J, I, J, on the horizontal line: but go not to the point of sight K, nor to the points of distance C, C; these accidental points serve likewise for cafements, doors, windows, tables, chairs, &c. The point of direct view, or of the front, is when we have the object directly before us; in which case it shews only the fore-side; and, if below the horizon, a little of the top; but nothing of the sides, unless the object be polygonous.

Thus the plane ABCD, (*ibid.* fig. 7.) is all in front; and if it were raised we should not see any thing of the sides AB or CD, but only the front AD: the reason is, that the point of view E being directly opposite thereto, causes a diminution on each side; which, however, is only to be understood where an elevation is the object; for if it be a plan, it shews the whole, as ABCD.

The point of oblique view, is when we see an object aside of us, and as it were afant, or with the corner of the eye: the eye, however, being all the while opposite to the point of sight; in which case, we see the object laterally, and it presents to us two sides or faces.

For instance, if the point of sight be in F, (*ibid.* fig. 8.) the object GHK will appear athwart, and shew two faces GK and GH; in which case it will be a side point.

We shall now give some examples, by which it will appear, that the whole practice of perspective is built upon the foundation already laid down. Thus, to find the perspective appearance of a triangle ABC (*ibid.* fig. 9.) between the eye and the triangle draw the line DE, which is called the *fundamental line*; from 2 draw 2 V, representing the perpendicular distance of the eye above the fundamental line, be it what it will; and through V draw, at right angles to 2 V, HK parallel to DE: then will the plane DHKE represent the transparent plane on which the perspective representation is to be made. Next, to find the perspective points of the angles of the triangle, let fall perpendiculars A 1, C 2, B 3. from the angles to the fundamental DE: set off these perpendiculars upon the fundamental opposite to the point of distance K, to B, A, C; from 1, 2, 3, draw lines to the principal point V; and from the points A, B, and C, on the fundamental line, draw the right lines AK, BK, CK, to the point of distance K; which is so called, because the spectator ought to be so far removed

from

*Perspective.* from the figure or painting, as it is distant from the principal point V. The points *a*, *b*, and *c*, where the visual lines V 1, V 2, V 3, intersect the lines of distance AK, BK, CK, will be the angular points of the angle *a b c*, the true representation of ABC.

To draw a Square Pavement in Perspective.

Plate CXXXVI.  
fig. 10. SUPPOSE your piece of pavement to consist of 64 pieces of marble, each a foot square. Your first business is, to draw an ichnographical plan or ground-plot of it, which is thus performed. Having made an exact square of the size you intend your plan, divide the base and horizon into eight equal parts; and from every division in the base to its opposite point in the horizon, rule perpendicular lines: then divide the sides into the same number, ruling parallel lines across from point to point: so will your pavement be divided into 64 square feet; because the eight feet in length, multiplied by the same in breadth, give the number of square feet or pieces of marble contained in the whole; then rule diagonals from corner to corner; and thus will your ground-plot appear as in fig. 10.

Fig. 11. Now, to lay this in perspective, draw another square to your intended size, and divide the base line AB into eight equal parts, as before; then fix your point of sight C in the middle of the horizon DE, and from the same point rule lines to every division in the base AB; after which, rule diagonal lines from D to B, and from E to A, answerable to those in the ground-plot, and your square will be reduced to the triangle ABC; then from the point F, where the diagonal DB intersects the line AC, to the opposite intersection G, where the diagonal EA crosses the line CB, rule a parallel line, which is the abridgment of the square. Then, through the points where the diagonals cross the rest of the lines which go from the base to the point of sight, rule parallel lines, and your square pavement will be laid in perspective, as in fig. 11.

Fig. 12. To diminish a Square viewed by the Angle D, fig. 12.

HAVING described the plane ABCD, draw a line to touch or raise the angle B, and falling perpendicularly on BD.

This being continued as a base line, lay your ruler on the side of the square AD and DC, and where the ruler cuts the terrestrial line make the points H, I.

Then from H and B draw lines to the point of distance P, and from I draw a line to the other point of distance G; and in the intersection of those lines, make points, which will give you the square KLMB.

To do without the plan: set off the diameter each way from the middle point B, as to H and I. But in either case no line is to be drawn to the point of sight O.

To diminish a Circle. See fig. 13.

DRAW a square ABCD about it, and from the angles AD and CB draw diagonals, dividing the circle into eight parts, and through the points where they cut it OO, draw lines from the base line perpendicular to DEF.

Then draw two diagonals QR, SP, intersecting each other at right angles in the centre G.

Having thus disposed the plan, draw lines from all

the perpendiculars to the point of sight H; and where *Perspective* they are intersected by the diagonals AK and BI, make points; the two last of which, M, N, give the square, which is to be divided into four by diagonals, intersecting each other in the point P.

In the last place, from the extremes of this cross, draw curve lines through the said points, which will give the form of the circle in perspective.

Of the Measures upon the Case in Perspective.

By the base line alone any depth may be given, and in any place at pleasure, without the use of squares; which is a very expeditious way.

As, for example, suppose the base line BS (fig. 1.) Plate CXXXVII. the point of view A, and the points of distance DE; if now you would make a plan of a cube BC, draw two occult or dotted lines from the extremes BC to the point of sight: then, to give the breadth, take the same measure BC, and set it off on the terrestrial line CF, and from F draw a line to the point of distance D; and where this line intersects the first ray C in the point G, will be the diminution of the plan of the cube BHGC.

If you would have an object farther towards the middle, take the breadth and the distance of the base line, as IK; and to have the depth, set it as you would have it on the same base as LM, and its width both on LM. Then from L and M draw occult lines to the point of distance D, and from the points NO, where those lines intersect the ray K, draw parallels to the terrestrial line, and you will have the square QPON.

After the same manner you may set off the other side of the square which should be on the base, as BHGC is here transferred to V. The points M and T, which are only two feet from the point S, afford a very narrow figure in X, as being very near.

Of the Base Line, and a single Point of Distance.

SINCE the depths and widths may be had by the means of this base line, there is no need of any further trouble in making of squares; as shall be shewn in this example.

Suppose a row of trees or columns is to be made on each side; on the base line lay down the place, and the distance between them, with their breadth or diameters, as ABCDEFG: then laying a ruler from Fig. 2, point of distance O to each of the points ABCDEFG, the intersections it makes on the visual ray AH will be the bounds of the objects desired.

To set them off on the other side upon the ray GH, set one foot of the compasses upon the point of the eye H, and with the other strike an arch; the point wherein this cuts the ray GH, will be the corresponding bound.

Thus M will be the same with N, and so of the rest; through which drawing parallels, you will have the breadths.

And as for the length, you may make it at pleasure: setting it off from A, as for instance to P, and then from P drawing a line to H; and where this cuts the other parallels, will be formed the plan required; which you may make either round or square.

*To find the Height and Proportion of any Objects, as they appear above the Horizon on a suppos'd Plane.*

Plate  
c c k x x v i i .  
fig. 3.

FIRST rule your horizontal line NO, and fix your point of sight, as at M; then mark the place of your nearest pillar, by making a dot for the base or bottom, as at A; and another for the summit or top, as at B: rule a line from A to the point of sight M, and another from B to M, and these two lines will give the height of any number of pillars. As for example: Suppose you would have a pillar at C, fix your dot for the base, and rule from thence a parallel line to meet the diagonal AM at D: then rule the perpendicular DE to the diagonal BM: which perpendicular is the height of your figure required at C. Or, if you would place pillars at F and I, observe the same method, ruling the parallels FG and IK, and the perpendiculars GH and KL will give their heights at the distances required.

To find the diameter or thickness of pillars at any particular distances, you are also to be guided by that nearest the base. For instance: Suppose your nearest pillar AB to be ten feet high, and one foot in diameter: divide it from top to bottom into ten equal parts, and set off one of them upon the base of the pillar; then rule a line from the point of sight M to the diameter P, and you will have the thickness of all your pillars on their respective parallels or bases.

*The same Rule exemplified in Objects below the Horizon.*

Fig. 4.

IF you would know the heights of a number of figures below the horizon, rule your horizontal line QR, and fix your point of sight, as at P: then place your nearest figure, or mark the dots for the head and feet, by the points A and B, which answers the same purpose; and rule from these dots to the point of sight the lines AP and BP: and if you would find the height of a figure to be drawn at *c*, rule from thence the parallel *cd* to the diagonal BP, and the perpendicular *de* will give the height required. The same directions will shew the height of a figure at any distance you have a mind to place it, as at *f*, *i*, and *m*, by ruling the parallels *fg*, *ih*, and *mn*; and from each of these their respective perpendiculars *gh*, *kl*, and *no*; which perpendiculars will shew the heights of the figures at *f*, *i*, and *m*.

*To draw a Direct View.*

Fig. 5.

TO illustrate this example, suppose you were to draw the inside of a church, as represented in this figure: First take your station at the point A, in the centre of the base line BC: from which you have a front view of the whole body of the church, with all the pillars, &c. on each side: then fix your horizon on any height you think proper, as at DE: bisect it by the perpendicular EA: and where these two lines intersect, is the point of sight F. This perpendicular will pass through the centres of all the arches in the dome or cupola: which centres may be found by any three given points. Next divide your base line into any given number of feet; and the visual lines, ruled from these divisions to the point of sight, will reduce all your objects to their just proportion, by setting off their height upon a perpendicular raised at their respective distances. The base, in the example here

given, is divided into twelve equal parts of five feet each; from which (supposing your front column to be 35 feet high) take seven divisions from the base line of your drawing, and set them off upon the perpendicular GH; then (supposing this column to be five feet thick at the base) set off one of these divisions upon the parallel IK, which is the breadth required. So that, by proportioning this scale to any distance by the foregoing directions, you may not only find the dimensions of all your columns, but also of every distinct part of them, as well as of all the doors, windows, and other objects that occur. For instance: Having found the height and breadth of your first or nearest column G, draw from the top and bottom of the said column to the point of sight the lines HF and KF; after which, rule the line IF from the base of the column to the point of sight, and you have the height and breadth of all the rest of the columns, as has been already shewn in fig. 3.

By ruling lines from the points *a*, *b*, *c*, *d*, &c. to the point of sight, you will see that all the summits and bases of your columns, doors, windows, &c. must tend immediately to that point; and by lines drawn from the points 1, 2, 3, 4, &c. on each side, to the correspondent points on the opposite side, may be seen all the parts of your building lying upon the same parallel.

*To draw an Oblique View.*

FIRST draw your horizontal line AB; then, if your Fig. 6.  
favourite object be on the right hand, as at C, place yourself on the left hand upon the base line, as at D; then from that station erect a perpendicular DE, which will pass thro' the horizon at the point of sight F: to which rule the diagonals GF and HF, which will shew the roof and base of your principal building C, and will also, as before directed, serve as a standard for all the rest.

Observe also, either in direct or oblique views, whether the prospect before you make a curve; for if it does, you must be careful to make the same curve in your drawing.

*To draw a Perspective View, wherein are accidental Points.*

RULE your horizontal line *ab*, and on one part of it Fig. 7.  
fix your point of sight, as at *c*; from which rule the diagonals *cd* and *ce* on the one side, and *cf* and *cg* on the other; which will shew the roofs and bases of all the houses in the street directly facing you, (supposing yourself placed at A in the centre of the base line): Then fix your accidental points *g* and *h* upon the horizontal line, and rule from them to the angles *ik* and *lm*, (where streets on each side take a different direction, towards the accidental points *g* and *h*), and the lines *gi* and *hk* give the roofs and bases of all the buildings on one side, as *lh* and *mh* do on the other.

Accidental points seldom intervene where the distance is small, as in noblemen's seats, groves, canals, &c. which may be drawn by the strict rules of perspective; but where the prospect is extensive and varied, including mountains, bridges, castles, rivers, precipices, woods, cities, &c. it will require such an infinite number of accidental points, that it will be better to do them as nature shall dictate, and your ripened judgment approve.

To find the Centre for the Roof of a Houfe, in an Oblique View.

Plate  
C XXXVII.  
fig. 8.

SUPPOSE from the point of fight A, the vifual lines AB and AC be drawn, BC being one perpendicular given, and DE the other, rule the diagonals from D to C, and from E to E, and the perpendicular FG, raifed through the point of their interfection, will fhew the true centre of the roof, as will appear by ruling the lines GE and GC.

For want of being acquainted with this neceffary rule, many who have been well verfed in other parts of perspective, have fpoiled the look of their picture, by drawing the roofs of their houfes out of their true perpendicular.

We fhall conclude by giving a few practical rules.

1. Let every line, which in the object, or geometrical figure, is ftraight, perpendicular, or parallel to its bafe, be fo alfo in its fcenographic delineation.
2. Let the lines, which in the object return at right angles from the fore-right fide, be drawn fcenographically from the vifual point.
3. Let all ftraight lines, which in the object return from the fore-right fide, run in a fcenographic figure into the horizontal line.
4. Let the object you intend to delineate, ftanding on your right-hand, be placed alfo on the right-hand of the vifual point; and that on the left-hand, on the left-hand of the fame point; and that which is juft before, in the middle of it.
5. Let thofe lines which are (in the object) equidiftant to the returning line be drawn in the fcenographic figure, from that point found in the horizon.
6. In fetting off the altitude of columns, pedeftals, and the like, meafure the height from the bafe line upwards, in the front or fore-right fide; and a vifual ray down that point in the front fhall limit the altitude of the column or pillar, all the way behind the fore-right fide, or orthographic appearance, even to the vifual point. This rule you muft obferve in all figures, as well where there is a front or fore-right fide, as where there is none.
7. In delineating ovals, circles, arches, croffes, fpirals, and crofs-arches, or any other figure in the roof of any room, firft draw ichnographically, and fo with perpendiculars from the moft eminent points thereof, carry it up into the ceiling; from which feveral points, carry on the figure.
8. The centre in any fcenographic regular figure is found by drawing lines from oppofite angles; for the point where the diagonals crofs is the centre.
9. A ground plane of fquares is alike, both above and below the horizontal line; only the more it is diftant above or beneath the horizon, the fquares will be fo much the larger or wider.
10. In drawing a perspective figure, where many lines come together, you may, for the directing of your eye, draw the diagonals in red; the vifual lines in black; the perpendiculars in green, or other different colour, from that which you intend the figure fhall be of.
11. Having confidered the height, diftance, and pofition of the figure, and drawn it accordingly, with the fide or angle againft the bafe; raife perpendiculars from the feveral angles, or defigned points, from the figure of the bafe, and transfer the length of each perpendicular, from the place where it touches the bafe, to the bafe on the fide oppofite to the point of diftance; fo will the diametrals drawn to the perpendiculars in

the bafe, by interfection with the diagonals, drawn to the feveral transferred diftances, give the angles of the figures, and fo lines drawn from point to point will circumscribe the fcenographic figure.

12. If in a landscape there be any ftanding waters, as rivers, ponds, and the like, place the horizontal line level with the fartheft fight or appearance of it.
13. If there be any houfe, or the like, in the picture, confider their pofition, that you may find from what point in the horizontal lines to draw the front and fides thereof.
14. In defcribing things at a great diftance, obferve the proportion, both in magnitude and diftance, in draught, which appears from the object to the eye.
15. In colouring and shadowing of every thing, you muft do the fame in your picture, which you obferve with your eye, efpecially in objects lying near; but, according as the diftance grows greater and greater, fo the colours muft be fainter and fainter, till at laft they lofe themfelves in a darkifh fly-colour.
16. The catoptrics are beft feen in a common looking-glass, or other polished matter; where, if the glass be exactly flat, the object is exactly like its original; but, if the glass be not flat, the refemblance alters from the original; and that more or lefs, according as the glass differs from an exact plane.
17. In drawing catoptric figures, the furface of the glass is to be confidered, upon which you mean to have the reflection; for which you muft make a particular ichnographical draught, or projection; which on the glass muft appear to be a plane full of fquares, on which projection transfer what fhall be drawn on a plane, divided into the fame number of like fquares; where though the draught may appear very confufed, yet the reflection of it on the glass will be very regular, proportional, and regularly compofed.
18. The dioptric, or broken beam, may be feen in a tube through a crystal or glass, which hath its furface cut into many others, whereby the rays of the object are broken. For to the flat of the crystal, or water, the rays run ftraight; but then they break and make an angle, which alfo by the refracted beams is made and continued on the other fide of the fame flat.
19. When thefe faces on a crystal are returned towards a plane placed directly before it, they feparate themfelves at a good diftance on the plane; becaufe they are all directed to various far diftant places of the fame. See OPTICS.

#### *Of the Anamorphosis, or Reformation of Distorted Images.*

By this means pictures that are fo mifhapen, as to exhibit no regular appearance of any thing to the naked eye, fhall, when viewed by reflection, prefent a regular and beautiful image. The inventor of this ingenious device is not known. Simon Stevinus, who was the firft that wrote upon it, does not inform us from whom he learned it. The principles of it are laid down by S. Vauzelard in his *Perspective Conique et Cyllindrique*; and Galpar Schott profeffes to copy Marius Bettinus in his defcription of this piece of artificial magic.

It will be fufficient for our purpofe to copy one of the fimpleft figures of this writer, as by this means the myftery of this art will be fufficiently unfolded. Upon the cylinder of paper, or palteboard, ABCD, Plate  
draw whatever is intended to be exhibited, as the let- C XXXVIII.  
ters fig. 1.

ters IHS. Then with a needle make perforations along the whole out-line; and placing a candle, C, behind this cylinder, mark upon the ground-plane the shadow of them, which will be distorted more or less, according to the position of the candle or the plane, &c. This being done, let the picture be an exact copy of this distorted image, let a metallic speculum be substituted in the place of the cylinder, and let the eye of the spectator have the same position before the cylinder that the candle had behind it. Then looking upon the speculum, he will see the distorted image restored to its proper shape. The reformation of the image, he says, will not easily be made exact in this method, but it will be sufficiently so to answer the purpose.

Other methods, more exact and geometrical than this, were found out afterwards: so that these pictures could be drawn by certain rules, without the use of a candle. Schott quotes one of these methods from Bettinus, another from Herigonius, and another from Kircher, which may be seen in his *Magia*, vol. i. p. 162, &c. He also gives an account of the methods of reforming pictures by speculums of conical, and other figures.

Instead of copying any of these methods from Schott or Bettinus, we shall present our readers with that which Dr Smith hath given us in his *Optics*, vol. i. p. 250, as, no doubt, the best, and from which any person may easily make a drawing of this kind. The same description answers to two mirrors, one of which, fig. 34, is convex, and the other, fig. 35, is concave.

In order to paint upon a plane a deformed copy ABCDEKIHGF of an original picture, which shall appear regular, when seen from a given point O, elevated above the plane, by rays reflected from a polished cylinder, placed upon the circle *lnp*, equal to its given base; from the point R, which must be supposed to lie perpendicularly under O, the place of the eye, draw two lines *RaRe*; which shall either touch the base of the cylinder, or else cut off two small equal segments from the sides of it, according as the copy is intended to be more or less deformed. Then, taking the eye, raised above R, to the given height RO, somewhat greater than that of the cylinder, for a luminous point, describe the shadow *ackf* (of a square *acxz*, fig. 36, or parallelogram standing upright up-

on its base *ae*, and containing the picture required) any where behind the arch *lnp*. Let the lines drawn from R to the extremities and divisions of the base *a, b, c, d, e*, cut the remotest part of the shadow in the points *f, g, h, i, k*, and the arch of the base in *l, m, n, o, p*; from which points draw the lines *lAF, mBG, nCH, oDI, pEK*, as if they were rays of light that came from a focus R, and were reflected from the base *lnp*; so that each couple, as *lA, lR*, produced, may cut off equal segments from the circle. Lastly, transfer the lines *laf, mbg*, &c. and all their parts, in the same order, upon the respective lines *lAF, mBG*, &c. and having drawn regular curves, by estimation, through the points *A, B, C, D, E*, through *F, G, H, I, K*, and through every intermediate order of points; the figure ACEKHF, so divided, will be the deformed copy of the square, drawn and divided upon the original picture, and will appear similar to it, when seen in the polished cylinder, placed upon the base *lnp*, by the eye in its given place O.

The practical methods of drawing these images seem to have been carried to the greatest perfection by J. Leopold, who, in the *Acta Lipsienfis*, for the year 1712, has described two machines, one for the images to be viewed with a cylindrical, and the other with a conical, mirror. The person possessed of this instrument has nothing to do but to take any print he pleases, and while he goes over the out-lines of it with one pen, another traces the anamorphosis.

By methods of this kind, groves of trees may be cut, so as to represent the appearance of men, horses, and other objects from some one point of view, which are not at all discernible in any other. This might easily be effected by one person placing himself in any particular situation, and giving directions to other persons what trees to lop, and in what manner. In the same method it has been contrived, that buildings, of circular and other forms, and also whole groupes of buildings, consisting of walls at different distances, and with different positions to one another, should be painted so as to exhibit the exact representation of particular objects, which could only be perceived in one situation. Bettinus has illustrated this method by drawings in his *Apiaria*.

Perspiration PERSPECTIVE *Glass*, or *Graphical Perspectives*, in optics. See there, p. 5584.

Perth.

PERSPIRATION, in medicine, the evacuation of the juices of the body through the pores of the skin. Perspiration is distinguished into sensible and insensible; and here sensible perspiration is the same with sweating, and insensible perspiration that which escapes the notice of the senses; and this last is the idea affixed to the word *perspiration* when used alone.

PERSPICUITY, properly signifies the property which any thing has of being easily seen through; hence is generally applied to such writings or discourses as are easily understood.

PERSPICUITY, in composition. See ORATORY, n° 42.

PERTH, a county of Scotland, including Menteith, Braidalbin, Athol, Strathene, part of Gowrie,

and Perth Proper; is bounded by Badenoch and Lochaber on the north and north-west; by Marr on the north-east; by Argyle and Lennox on the west and south-west; having Clackmannanshire, part of Stirlingshire, and the Forth to the south; the shires of Kinross and Fife to the south-east, and Angus to the east. It extends above 70 miles in length, and near 60 at its greatest breadth, exhibiting a variety of Highlands and Lowlands; mountains, hills, dales, and straths, diversified with pasture-grounds, corn-fields, and meadows; rivers, lakes, forests, woods, plantations, inclosures, towns, villages, and a great number of elegant seats, beautifully situated, belonging to noblemen and gentlemen. The chief rivers of Perthshire are the Tay, the Keith, and the Lerne, besides a great number of subordinate streams. The Tay, which is the largest river in Scotland, derives its source from

Perth.

Perth.

the mountains of Braidalbin, and spreads itself into a lake, called *Loch Tay*, 15 miles in length and six in breadth; then, after a winding course of 40 miles, during which it is swelled by many brooks and rivulets, it ends in the Frith of Tay, a broad navigable inlet, which opens to the sea, not far from the bay of St Andrews. The river Keith is famous for its salmon-fishery, and its steep cataract, near the Blair of Drummond, the noise of which is so loud as to deafen those who approach it. The river Erne raises from Loch-erne, a lake seven miles long, in the mountainous country of Stratherne: this river, after a course of 34 miles from east to west, during which it receives many streams and rivulets, falls into the Tay, at Abernethy.

Free-stone, lead, iron, and copper ores, with some lapis calaminaris, are found in different places of Perthshire. The soil, being generally rich and well manured, produces excellent wheat, and all kinds of grain. The hilly country abounds with pasture for the black cattle, horses, sheep, goats, and deer. The heaths, woods, and forests, are stored with variety of game; the rivers teem with salmon and trout; the gardens and orchards are stored with all kinds of herbs, roots, apples, pears, cherries, plums, and almost every species of fruit found in South Britain. The houses and attire, even of the commonalty, are neat and decent; and every peasant can produce a good quantity of linen, and great store of blankets, made in his own family. Indeed, this is the case through all the Lowlands of Scotland. Flax is reared by every husbandman; and being dressed at home, is spun by the females of his family into thread for linen; this is woven by country weavers, of whom there is a great number through all the Low Country, and afterwards bleached or whitened by the good-wife and her servants; so that the whole is made fit for use at a very small expence. They likewise wash, card, spin, and weave their wool into tartan for plaids, kerseys, and coarse rustlet-cloth, for common wearing, besides great part of it which is knit into caps, stockings, and mitts. Plaids, made of the finest worsted, are worn either plain or variegated, as veils, by women of the lower, and even of the middle rank; nay, some years ago, ladies of fashion wore filken plaids with an undress: this is a loose piece of drapery, gathered about the head, shoulders, and waist, on which it is crossed, so as to leave the hands at liberty, and produces a very good effect to the eye of the spectator. The Lowlanders of Perthshire are civilized, hospitable, and industrious: the commerce of the country consists chiefly in corn, linen, and black cattle: there are, moreover, some merchants who trade to foreign countries.—For an account of the different divisions of this county above mentioned, see the articles as they occur in the order of the alphabet.

PERTH Proper, stretching 20 miles in length, and, at some places, 15 in breadth, is bounded on the north-east, by the Carse of Gowrie; on the east, by Angus; on the west, by Stratherne; on the north, by Athol; and on the south, by the Frith of Tay. This is likewise a fruitful country, populous, and well cultivated, abounding with gentlemen who possess opulent estates; with farmers who understand agriculture; and with manufacturers who turn their industry to great

account. North-eastward from Perth to Brechin, lies the vale of Strathmore, one of the most fertile districts in Scotland, which gives the title of *Earl* to the noble family of Lyon.

PERTH, the capital of the county of that name, is an agreeable, populous town, situated 20 miles within land, on the south bank of the river Tay. It was otherwise called *St Johnston's*, from a church dedicated to St John, as the patron of the place. It is a royal borough, second in dignity to the metropolis, the seat of a large presbytery, and gave the title of *Earl* to the family of Drummond, which is now forfeited. Perth, in the reign of Edward I. of England, was possessed by the English, who secured it with fortifications: but, after an obstinate resistance, they were expelled by Robert Bruce. In the year 1715, the rebels made it a place of arms, and retired to it, after the battle of Dumbline; but they were in a little time dislodged by the duke of Argyle, and retreated northwards with the pretender. The town is populous and handsome; the streets are well paved, and tolerably clean at all times; and the houses, tho' not stately, make a very decent appearance. Here is a large church, an old palace that belonged to the earls of Gowrie, but now devolved to the crown; a stately town-house, several other public edifices, and houses belonging to gentlemen. A monastery of Carthusians was here established by king James I. of Scotland, who lost his life on the very spot, by the treachery of Athol and his accomplices. The town was anciently provided with a stone-bridge over the river, which an inundation swept away; but a new and very fine one has lately been built.

This town has but one parish, which has two churches, besides meetings for separatists, who are very numerous. One church, which belonged to a monastery, is very ancient: not a vestige of the last is now to be seen; for the disciples of Knox made a general desolation of every edifice that had given shelter to the worshippers of the church of Rome: it being one of his maxims, to pull down the nests, and then the rooks would fly away.

The flourishing state of Perth is owing to two accidents: the first, that of numbers of Cromwell's wounded officers and soldiers choosing to reside here, after he left the kingdom, who introduced a spirit of industry among the people: the other cause was the long continuance of the earl of Mar's army here in 1715, which occasioned vast sums of money being spent in the place. But this town, as well as all Scotland, dates its prosperity from the year 1745; the government of this part of Great Britain having never been settled till a little after that time.

The trade of Perth is considerable. It exports annually 150,000 l. worth of linen, from 24,000 to 30,000 bolls of wheat and barley to London and Edinburgh, and about the same in cured salmon. That fish is taken there in vast abundance; 3000 have been caught in one morning, weighing, one with another, 16 pounds; the whole capture, 48,000 pounds. The fishery begins at St Andrew's day, and ends August 26th, old style. The rents of the fisheries amount to 3000 l. per annum. Smelts come up this river in May and June.

There has been in these parts a very great fishery of

Perth.

Pertinax

Peru.

of pearl, got out of the fresh-water-mufcles. From the year 1761 to 1764, 10,000l. worth were sent to London, and fold for 10s. to 1l. 16s. per ounce. Mr Pennant was told that a pearl has been taken there that weighed 33 grains. But this fishery is at present exhausted, from the avarice of the undertakers: it once extended as far as Loch-Tay.

**PERTINAX**, an illustrious Roman, raised himself by his valour and merit to the consular dignity; and upon the death of Commodus, was elected emperor by the pretorian band in 193. Though he owed his elevation to these soldiers, his first care was to repress their insolence, and to oblige them to observe strict discipline; upon which they revolted, and in the tumult one of the private men assassinated this renowned hero, who was the father of his people, after a reign of 87 days.

**PERTINENT** OF LANDS, in Scots law. See **LAW**, N° cxlviii. 6.

**PERU**, a country of South America, bounded on the north by Popayan, on the west by the South Sea, and on the east by the vast ridge of mountains called the *Andes*; and extending 1500 miles in length from north to south, though only 125 in breadth from east to west, between the *Andes* and the sea; though in other places it is much broader, and, according to some, not less than 300 miles.

How discovered by the Spaniards.

This country was discovered by the Spaniards; and the first intelligence they had of it was on the following occasion. Nunez de Balboa having been raised to the government of the small colony at Santa Maria in Darien by the suffrages of his companions, was very desirous of having that authority confirmed by the court of Spain. For this purpose he endeavoured to recommend himself to the Spanish ministry by some important service; that is, by extorting from the Indians as much gold and silver as he could. He therefore made frequent inroads into the adjacent country, subdued several of the caciques or petty princes, and collected a considerable quantity of gold. In one of these expeditions, the Spaniards contended so violently about the division of some gold which they had taken, that they were on the point of coming to blows with one another. A young cacique who was present, astonished at such contention about a thing of which he knew not the use, tumbled the gold out of the balance with indignation, and turning to the Spaniards, told them, that since they valued gold so very highly, he would conduct them to a country where the most common utensils were made of that metal. The Spaniards eagerly caught at this hint; and upon further questioning the cacique, were informed, that at the distance of six days journey, towards the south, from the place where they were at that time, they should discover another ocean, near which this desirable country was situated; but if they intended to attack that powerful state, they must assemble a much greater number of forces than had hitherto appeared on the continent.

Balboa was transported at the news. He immediately concluded, that the ocean mentioned by the cacique was that which Columbus had so long sought for in vain, and that the rich territory described to him must be part of the East Indies. He was therefore impatient till he should arrive at that happy coun-

Peru.

try, in comparison with the discovery of which all former exploits almost vanished into nothing. In order therefore to procure a force sufficient to ensure success in his enterprise, he first secured the friendship of the neighbouring caciques, and then dispatched some of his officers to Hispaniola, with a large quantity of gold as a proof of his past success, and an earnest of what he expected. By this means he secured the friendship of the governor, and procured a considerable reinforcement. But though he now imagined himself sufficiently strong to attempt the discovery, there were still prodigious difficulties to be surmounted. The isthmus of Darien, though not above 60 miles in breadth, has a chain of lofty mountains running through its whole extent. Being situated between two vast oceans, the Atlantic and Pacific, the climate is excessively moist, inasmuch that it rains for two-thirds of the year. In consequence of this the valleys are marshy, and so frequently overflowed, that the inhabitants find it necessary in some places to build their houses upon trees, in order to be elevated at some distance from the damp soil, and the odious reptiles engendered in the waters. There are also many large rivers very difficult to be crossed; and as the country at that time was only inhabited by a few wandering savages, the enterprise of Balboa is looked upon as the most difficult that had been undertaken by any Spanish adventurer.

On this arduous task Balboa set out on the 1st day of September 1513, about the time that the periodical rains begin to abate. He had only 190 Spaniards along with him; but all of them were hardy veterans, inured to the climate of America, and very much attached to their leader. A thousand Indians attended in order to carry their provisions and other necessaries; and they had along with them some of those fierce dogs so terrible to the natives of America.

Balboa proceeded by sea, and without difficulty, to the territories of a cacique whose friendship he had gained; but as soon as he began to advance into the interior parts of the country, he met with all the difficulties above mentioned. Some of the caciques also, at his approach, fled with all their people to the mountains, carrying off or destroying whatever could afford subsistence to an army. Others collected their force in order to oppose him; however Balboa continued unmoved in spite of all difficulties; and at last, after a most painful journey of 25 days, he arrived at the South Sea; when, with the most extravagant transports of joy, he went into it up to the middle, and took possession of the ocean in his master's name, vowing to defend it against all the enemies of Spain.

<sup>3</sup> Balboa first gets a sight of the South Sea.

That part of the South Sea which Balboa now discovered, he called the *Gulf of St Michael*; which name it still retains, and is situated to the east of Panama. From some of the neighbouring caciques he extorted provisions and gold by force; others sent him presents voluntarily; and he had the satisfaction to hear, that the adjacent coasts abounded with pearl-oysters. The inhabitants were also unanimous in declaring, that there was to the southward a very rich and populous country, where the people had tame animals, which they endeavoured to describe to him, meaning the Peruvian sheep. But however impatient he might be to visit this empire, he considered it as highly

Peru.

Peru.

4  
He is deprived of his command;

highly improper to venture thither with a handful of men exhausted by labour and disease. He therefore led back his followers to Santa Maria, in order to refresh them after their fatigues; and from thence he sent an account to the court of Spain of the important discovery he had made, demanding a reinforcement of 1000 men, in order to conquer the country he had newly discovered. But here his hopes were all blasted at once. The king indeed determined to prosecute the discovery, but refused to continue Balboa in his government, appointing Pedrarias Davila to supersede him, and giving him the command of 15 stout vessels, with 1200 soldiers, to ensure his success.

Balboa, though much mortified by his disgrace, submitted to the king's pleasure without repining. It was not long, however, before he met with an additional misfortune; the new governor tried him for some pretended irregularities committed before his arrival, and fined him of almost all he was worth. In the mean time the Spaniards, paying no regard to the treaties concluded by Balboa with the Indians, plundered and destroyed all indiscriminately, inasmuch that the whole country, from the gulph of Darien to the lake Nicaragua, was desolated. The new comers had also arrived at the most unlucky time of the year, namely, about the middle of the wet season, when the excessive rains produced the most violent and fatal diseases. To this was joined an extreme scarcity of provisions; so that in the space of a month above 600 Spaniards perished in the utmost misery.

Balboa failed not to send violent remonstrances to Spain against the conduct of the new governor; and he, on the other hand, accused his antagonist of having deceived the king by false accounts of the country, and magnifying his own exploits beyond measure. At last the king, sensible of his error in superseding Balboa, appointed him adelantado, or lieutenant-governor of the countries on the South Sea, with very extensive privileges and authority; enjoining Pedrarias to support him in all his enterprises, and to consult with him in every thing which he himself undertook. It was impossible, however, to extinguish the envy of Pedrarias; and therefore, though a reconciliation took place in appearance, even so far, that Pedrarias agreed to give his daughter in marriage to Balboa, yet he soon after had him condemned and executed on pretence of disloyalty, and an intention to revolt from the king.

On the death of Balboa, the thoughts of conquering Peru were for a time laid aside; however it still remained an object of desire to all the Spanish adventurers in America. Accordingly several armaments were fitted out with a design to explore and take possession of the countries to the east of Panama; but, either through the difficulties which attended the undertaking itself, or the bad conduct of the adventurers, all of them proved unsuccessful, until at last it became a general opinion, that Balboa's scheme had been entirely visionary.

6  
A new expedition set on foot.

Still, however, there were three persons settled at Panama, on whom the common opinion made so little impression, that they determined to go in quest of this country, looked upon to be chimerical by the generality of their neighbours. Their names were *Francisco Pizarro*, *Diego de Almagro*, and *Hernando Luque*. Pi-

zarro and Almagro were soldiers of fortune, and Luque was an ecclesiastic, who acted both as priest and school-master at Panama. Their confederacy was authorized by Pedrarias governor of Panama; and each engaged to employ his whole fortune in the adventure. Pizarro, being the least wealthy of the three, engaged to take upon himself the greatest share of the fatigue and danger, and to command in person the armament which was to go first upon the discovery. Almagro offered to conduct the supplies of provisions and reinforcements of troops which might be necessary; and Luque was to remain at Panama, in order to negotiate with the governor, and to superintend whatever was carrying on for the general interest.

7  
Meets with bad success at first.

In 1524, Pizarro set sail from Panama with a single vessel of small burthen, and 112 men; and so little was he or his countrymen at that time acquainted with the climate of America, that the most improper season of the whole year was chosen for his departure; the periodical winds, which were then set in, being directly opposite to the course which he proposed to steer. The consequence of this was, that after beating about for 70 days, with much danger and fatigue, he had advanced scarce as far to the south-east as a skilful navigator will now make in three days. He touched at several places of Terra Firma; but finding that country exceedingly inhospitable and unhealthy, he was obliged to retire to Chuchama, opposite to the Pearl Islands, where he hoped to receive some reinforcements from Panama. Here he was found by Almagro, who had set out in quest of him with a reinforcement of 70 men, and had suffered distresses very much resembling those of Pizarro himself. In particular, he had lost an eye in a combat with the Indians. However, he had advanced as far as the river of St Juan in the province of Popayan, where the country shewing a better aspect, and the inhabitants more friendly, our projectors again began to indulge themselves in hopes, and determined by no means to abandon their scheme.

Almagro returned to Panama, in hopes of recruiting their shattered troops. But the bad accounts of the service gave his countrymen such an unfavourable idea of it, that Almagro could levy no more than 80 men, and these with great difficulty. Slender as this reinforcement was, however, the adventurers did not hesitate at renewing their enterprise. The disasters and disappointments they met with in this new attempt, were scarce inferior to those they had already experienced, when part of the armament at last reached the bay of St Matthew on the coast of Quito, and landed at Tacamez, to the south of the River of Emeralds, where they met with a more fertile and champaign country than any they had yet seen; the natives also were more civilized, and clothed in garments of cotton or woolen stuff, adorned with trinkets of gold and silver. But notwithstanding these favourable appearances, Pizarro did not think fit to attack such a powerful empire with a handful of soldiers already exhausted; and therefore retired to a small island called *Gallo*, with part of the troops; from whence he dispatched Almagro to Panama, in hopes of obtaining a reinforcement.

The reception which Almagro met with was by no means agreeable. Some of the adventurers had informed their friends of the many dangers and losses which

Pern.

which they had sustained; which not only disheartened people from engaging in the service, but weighed so much with Pedro de los Rios, the successor of Pedrarias, that he prohibited the raising of new recruits, and even dispatched a vessel to bring home Pizarro and his companions from the island of Gallo. Almagro and Luque, though much mortified with this disappointment, privately advised Pizarro not to relinquish an enterprise on which they had built all their hopes. He therefore positively refused to obey the orders of the governor, and employed all his address in persuading his men not to abandon him. But the calamities to which they had been exposed had such an effect upon them, that when he drew a line upon the sand with his sword, telling such as wished to return that they might pass over it, only 13 had resolution to remain with him.

Pizarro with his little troop now fixed their residence on the island of Gorgona, which they considered as a safer retreat than Gallo, as being farther removed from the coast and uninhabited, so that they might with the greater security wait for supplies. Here, they continued five months in the most unwholesome climate imaginable, and at last had come to a resolution of committing themselves to sea on a float, when a vessel arrived from Panama to their relief. This was the effect of the continued solicitations of Almagro and Luque; who, though they could not prevail upon the governor to favour the undertaking, had succeeded so far as to induce him to send a small vessel to the relief of Pizarro and his unfortunate associates. However, the more effectually to shew his disapprobation of Pizarro's scheme, the governor refused to allow one land man to go on board of the ship which he sent.—The hopes of the adventurers, however, were now again revived, and Pizarro easily induced them to resume their scheme. Instead of returning to Panama, therefore, they failed to the south-east, and in 20 days after the discovery of Gorgona they discovered the coast of Peru. Having touched at some places of less note, they at length arrived at Tumbez, remarkable for its stately temple, and a palace of the Incas, or sovereigns of the country. Here, they found that what had been told them concerning the riches of the country was true; not only ornaments and sacred vessels being made of gold and silver, but even such as were for common use. Yet to attempt the conquest of this opulent empire with their slender force, would have been madness; they contented themselves therefore with viewing it, procuring two of the beads of burthen called *Llamas*, to which they gave the name of sheep, some vessels of gold and silver, and two young men, whom they proposed to instruct in the Castilian language. With these Pizarro arrived at Panama in the year 1527, near three years after he had set out from that place in his expedition.

The empire of Peru thus discovered, is said to have been originally possessed by independent tribes, justly reckoned among the most savage even in America; living more like wild beasts than men. For several ages they lived in this manner, when suddenly there appeared on the banks of a lake called *Tiaca*, a man and woman of majestic form, and clothed in decent garments. They declared themselves to be the children of the sun, sent by their beneficent parent to instruct and reclaim

mankind.

The names of these two extraordinary personages were *Manco Capac* and *Mama Ocello*. At their persuasion, several of the dispersed savages united, and, receiving their commands as heavenly injunctions, followed them to Cuzco, where they settled, and began to lay the foundations of a city. Manco Capac instructed the men in agriculture, and other useful arts; while Mama Ocello taught the women to spin and weave; after which Manco turned his attention towards the introducing of proper laws, and regulations into his new state.

Thus, according to the Indian tradition, was founded the empire of the Incas, or lords of Peru. At first its extent was small, the territory of Manco Capac reaching not above eight leagues from Cuzco his capital. Within these narrow limits, however, he exercised the most perfect despotism, and the same was maintained by his successors, all of whom were not only obeyed as monarchs, but revered as deities. Their blood was held to be sacred, and, by prohibiting intermarriages with the people, was never contaminated by mixing with that of any other race. The family, thus separated from the rest of the nation, was distinguished by peculiarities in dress and ornaments, which it was unlawful for others to assume. Among the Peruvians, however, it is said, that this high degree of veneration was made use of by the monarchs only to promote the good of their subjects. If we may believe the accounts given by their countrymen, the Peruvian monarchs extended their empire not with a view to increase their own power and wealth, but from a desire of diffusing the blessings of civilization, and the knowledge of the arts which they possessed, among the barbarous people whom they reduced, and, during a succession of 12 monarchs, not one deviated from this character.

When the Spaniards first visited this country, they found it agitated by a civil war. Huana Capac, the 12th monarch from the founder of the state, was seated on the throne; who is represented as a prince no less conspicuous for his abilities in war, than for his pacific virtues. By him the kingdom of Quito was subdued, which almost doubled the extent of the dominions and power of the Peruvian empire. Notwithstanding the ancient and fundamental law against polluting the blood of the Inca with any foreign alliance, Huana married the daughter of the conquered monarch, by whom he had a son named *Atabalipa*, commonly written *Atabalipa*, to whom, at his death in 1529, he left the kingdom of Quito, bestowing the rest of his dominions upon Huascar his eldest son by a mother of the royal race. This produced a civil war, in which Atabalipa proved victorious, and afterwards attempted to secure himself on the throne by putting to death all the descendants of Mingo Capac, styled the children of the Sun, whom he could seize either by force or stratagem; however, from a political motive, he spared the life of his rival Huascar, who had the misfortune to be taken prisoner in an engagement, that, by issuing out orders in his name, he might more easily establish his own authority, and cover the illegality of his birth.

This contest had so much engaged the attention of the Peruvians, that they never once attempted to check

History of the Incas of Peru.

11  
Progress of the Spaniards facilitated by a civil war among the natives.

check the progress of the Spaniards. It was some time, however, before Pizarro was informed of this contest, so much in his favour. The first intelligence which he received of it was a message from Huascar, asking his assistance against Atabalipa, whom he represented as a rebel and an usurper. Pizarro perceived the importance of the intelligence, and therefore determined to push forward, while intestine discord put it out of the power of the Peruvians to attack him with their whole force. Being obliged to divide his troops, in order to leave a garrison in St Michael, which might serve for a place of retreat in case of a disaster, he began his march with only 62 horsemen and 102 foot-soldiers, 20 of whom were armed with cross-bows, and only three with muskets. He directed his course towards Caxamalca, a small town at the distance of 12 days march from St Michael, where Atabalipa was encamped with a considerable body of troops. Before he had proceeded far, an officer dispatched by the Inca met him with a valuable present from that prince, accompanied with a proof of his alliance, and his assurances of a friendly reception at Caxamalca. Pizarro, according to the usual artifice of his countrymen in America, pretended to come as the ambassador of a very powerful monarch, and declared that he was now advancing with intention to disperse Atabalipa's aid against those enemies who disputed his title to the throne.

As the object of the Spaniards in entering their country was altogether incomprehensible to the Peruvians, they had formed various conjectures concerning it, without being able to decide whether they should consider their new guests as beings of a superior nature, who had visited them from some beneficent motive, or as formidable avengers of their crimes, and enemies to their repose and liberty. The continual professions of the Spaniards, that they came to enlighten them with the knowledge of truth, and lead them in the way of happiness, favoured the former opinion; the outrages which they committed, their rapaciousness and cruelty, were awful confirmations of the latter. While in this state of uncertainty, Pizarro's declaration of his pacific intentions so far removed all the Inca's fears, that he determined to give him a friendly reception. In consequence of this resolution, the Spaniards were allowed to march in tranquillity across the sandy desert between St Michael and Motupé, where the most feeble effort of an enemy, added to the unavoidable distresses which they suffered in passing through that comfortable region, must have proved fatal to them. From Motupé they advanced towards the mountains which encompass the low country of Peru, and passed through a defile so narrow and inaccessible, that a few men might have defended it against a numerous army. But here likewise, from the same inconsiderate credulity of the Inca, the Spaniards met with no opposition, and took quiet possession of a fort erected for the security of that important station. As they now approached near to Caxamalca, Atabalipa renewed his professions of friendship; and, as an evidence of his sincerity, sent them presents of greater value than the former.

On entering Caxamalca, Pizarro took possession of a large court, on one side of which was a house which the Spanish historians call a palace of the Inca, and on

the other a temple of the sun, the whole surrounded with a strong rampart or wall of earth. When he had posted his troops in this advantageous station, he dispatched Hernando Soto, and his brother Ferdinand, to the camp of Atabalipa, which was about a league distant from the town. He intrusted them to confirm the declaration which he had formerly made of his pacific disposition, and to desire an interview with the Inca, that he might explain more fully the intention of the Spaniards in visiting his country. They were treated with all the respectful hospitality usual among the Peruvians in the reception of their most cordial friends, and Atabalipa promised to visit the Spanish commander next day in his quarters. The decent deportment of the Peruvian monarch, the order of his court, and the reverence with which his subjects approached his person and obeyed his commands, astonished those Spaniards, who had never met in America with any thing more dignified than the petty cacique of a barbarous tribe. But their eyes were still more powerfully attracted by the vast profusion of wealth which they observed in the Inca's camp. The rich ornaments worn by him and his attendants, the vessels of gold and silver in which the repast offered to them was served up, the multitude of utensils of every kind formed of those precious metals, opened prospects far exceeding any idea of opulence that a European of the 16th century could form.

On their return to Caxamalca, while their minds were yet warm with admiration and desire of the wealth which they had beheld, they gave such a description of it to their countrymen, as confirmed Pizarro in a resolution which he had already taken. From his own observation of American manners during his long service in the New World, as well as from the advantages which Cortes had derived from seizing Montezuma, he knew of what consequence it was to have the Inca in his power. For this purpose, he formed a plan as daring as it was perfidious. Notwithstanding the character he had assumed of an ambassador from a powerful monarch, who courted an alliance with the Inca, and in violation of the repeated offers which he had made to him of his own friendship and assistance, he determined to avail himself of the unsuspecting simplicity with which Atabalipa relied on his professions, and to seize his person during the interview to which he had invited him. He prepared for the execution of his scheme with the same deliberate arrangement, and with as little compunction, as if it had reflected no disgrace on himself or his country. He divided his cavalry into three small squadrons, under the command of his brother Ferdinand, Soto, and Benalcázar; his infantry was formed into one body, except 20 of most tried courage, whom he kept near his own person to support him in the dangerous service which he reserved for himself; the artillery, consisting of two field-pieces, and the cross-bow men, were placed opposite to the avenue by which Atabalipa was to approach. All were commanded to keep within the square, and not to move until the signal for action was given.

Early in the morning the Peruvian camp was all in motion. But as Atabalipa was solicitous to appear with the greatest splendour and magnificence in his first interview with the strangers, the preparations for this

seize the  
Inca.

Peru.

this were so tedious, that the day was far advanced before he began his march. Even then, left the order of the procession should be deranged, he moved so slowly, that the Spaniards became impatient and apprehensive that some suspicion of their intention might be the cause of this delay. In order to remove this, Pizarro dispatched one of his officers with fresh assurances of his friendly disposition. At length the Inca approached. First of all appeared 400 men in an uniform dress, as harbingers to clear the way before him. He himself, sitting on a throne or couch, adorned with plumes of various colours, and almost covered with plates of gold and silver enriched with precious stones, was carried on the shoulders of his principal attendants. Behind him came some chief officers of his court, carried in the same manner. Several bands of fingers and dancers accompanied this cavalcade; and the whole plain was covered with troops, amounting to more than 30,000 men.

As the Inca drew near the Spanish quarters, father Vincent Valverde, chaplain to the expedition, advanced with a crucifix in one hand, and a breviary in the other, and in a long discourse explained to him the doctrine of the creation, the fall of Adam, the incarnation, the sufferings and resurrection of Jesus Christ, the appointment of St Peter as God's viceroy on earth, the transmission of his apostolical power by succession to the popes, the donation made to the king of Castile by pope Alexander of all the regions in the New World. In consequence of all this, he required Atabalipa to embrace the Christian faith, to acknowledge the supreme jurisdiction of the pope, and to submit to the king of Castile as his lawful sovereign; promising, if he complied instantly with this requisition, that the Castilian monarch would protect his dominions, and permit him to continue in the exercise of his royal authority; but if he should impiously refuse to obey this summons, he denounced war against him in his master's name, and threatened him with the most dreadful effects of his vengeance.

This strange harangue, unfolding deep mysteries, and alluding to unknown facts, of which no power of eloquence could have conveyed at once a distinct idea to an American, was so lamely translated by an unskilful interpreter, little acquainted with the idiom of the Spanish tongue, and incapable of expressing himself with propriety in the language of the Inca, that its general tenor was altogether incomprehensible to Atabalipa. Some parts in it of more obvious meaning, filled him with astonishment and indignation. His reply, however, was temperate. He began with observing, that he was lord of the dominions over which he reigned by hereditary succession; and added, that he could not conceive how a foreign priest should pretend to dispose of territories which did not belong to him; that if such a preposterous grant had been made, he, who was the rightful possessor, refused to confirm it; that he had no inclination to renounce the religious institutions established by his ancestors; nor would he forsake the service of the sun, the immortal divinity whom he and his people revered, in order to worship the God of the Spaniards, who was subject to death; that with respect to other matters contained in his discourse, as he had never heard of them before, and did not now understand their meaning, he desired to know

where he had learned things so extraordinary. "In this book," answered Valverde, reaching out to him his breviary. The Inca opened it eagerly; and turning over the leaves, lifted it to his ear: "This," says he, "is silent; it tells me nothing;" and threw it with disdain to the ground. The enraged monk, running towards his countrymen, cried out, "To arms, Christians, to arms; the word of God is insulted; avenge this profanation on those impious dogs."

Pizarro, who, during this long conference, had with difficulty restrained his soldiers, eager to seize the rich spoils of which they had now so near a view, immediately gave the signal of assault. At once the martial music struck up, the cannon and muskets began to fire, the horse sallied out fiercely to the charge, the infantry rushed on sword in hand. The Peruvians, astonished at the suddenness of an attack which they did not expect, and dismayed with the destructive effects of the fire-arms, and the irresistible impression of the cavalry, fled with universal consternation on every side, without attempting either to annoy the enemy, or to defend themselves. Pizarro, at the head of his chosen band, advanced directly towards the Inca; and though his nobles crowded around him with officious zeal, and fell in numbers at his feet, while they vied one with another in sacrificing their own lives, they might cover the sacred person of their sovereign, the Spaniards soon penetrated to the royal seat; and Pizarro seizing the Inca by the arm, dragged him to the ground, and carried him as a prisoner to his quarters. The fate of the monarch increased the precipitate flight of his followers. The Spaniards pursued them towards every quarter, and, with deliberate and unrelenting barbarity, continued to slaughter wretched fugitives, who never once offered at resistance. The carnage did not cease until the close of day. Above 4000 Peruvians were killed. Not a single Spaniard fell, nor was one wounded but Pizarro himself, whose hand was slightly hurt by one of his own soldiers, while struggling eagerly to lay hold on the Inca.

The plunder taken on this occasion was immense, but the Spaniards were still unsatisfied; which being observed by the Inca, he endeavoured to apply himself to their ruling passion, avarice, in order to obtain his liberty; and therefore offered such a ransom as astonished them, even after all they knew concerning the opulence of the country. The apartment in which he was confined was 22 feet in length and 16 in breadth; and all this space he engaged to fill with vessels of gold as high as he could reach. This proposal was eagerly caught by Pizarro, and a line was drawn upon the walls to mark the stipulated height.

Atabalipa, charmed with the thoughts of liberty, immediately set about performing his part of the agreement, and dispatched messengers into all parts of the empire, in order to collect the immense quantity of gold which he had promised; and though the unfortunate monarch was now in the hands of his enemies, such was the veneration which his subjects had for him, that his orders were obeyed with as great alacrity as though he had been at full liberty; while he, in the mean time, flattering himself with the hopes of being soon released, made no preparations for expelling the invaders from his dominions.

In a short time, Pizarro received intelligence that

liberty.

Peru.

Almagro was arrived at St Michael with a reinforcement equal to the force he had with him. This was a matter of great joy to the Spaniards, and no small vexation to Atabalipa, who now considered his kingdom as in danger of being totally over-run by these strangers, whose force he neither knew, nor the means they had of transporting themselves. For this reason he determined to put his brother Huascar to death, lest he should join the strangers against him. To this he was the rather inclined, as he had got information that the captive prince had been making applications to them, and had offered them a much larger sum than what was stipulated for the Inca's ransom; and in consequence of this determination the unfortunate prince lost his life.

In the mean time, the Indians daily arrived at Caxamalea with vast quantities of treasure; the sight of which so much inflamed the Spaniards, that they insisted upon an immediate division: and this being complied with, there fell to the share of each horseman 8000 pesos, at that time not inferior to the value of as many pounds sterling in the present century, and half as much to each foot-soldier, Pizarro and his officers receiving shares proportionable to their dignity. A fifth part was reserved for the emperor, together with some vessels of curious workmanship as a present. In consequence of this immense acquisition of wealth, many of the Spaniards became clamorous for their discharge; which was readily granted by their general, as well knowing that the display of their riches would not fail to allure adventurers more hardy, though less opulent, to his standard.

15  
Pizarro resolves to put the Inca to death.

After this division of the spoil, Atabalipa was very importunate with Pizarro in order to recover his liberty; but the Spaniard, with unparalleled treachery and cruelty, had now determined to put him to death. To this he was urged by Almagro's soldiers, who, though they had received an equal share with the rest, were still unsatisfied. The Inca's ransom had not been completed; and they were apprehensive, that whatever sums might afterwards be brought in, the troops of Pizarro would appropriate them to themselves as part of that ransom. They insisted with Pizarro, therefore, to put him to death, that all the adventurers might for the future be on an equal footing. Accounts were likewise received that troops were assembling in the remote provinces of the empire, which Pizarro suspected to be done by the Inca's orders. These accounts were heightened by one Philipillo an Indian interpreter, who had conceived a passion for one of the unhappy monarch's wives; and for that reason wished to have him put to death. Atabalipa himself, too, had the misfortune to hasten his own ruin by his conceiving a contemptuous notion of Pizarro, which he had not the precaution to conceal. He had long admired the European arts of reading and writing, and wished much to know whether he should regard it as a natural or acquired talent. In order to determine this, he desired one of the soldiers who guarded him to write the name of God upon the nail of his thumb. This he shewed to several Spaniards successively, asking its meaning; and, to his surprise, they all returned the same answer. At length Pizarro entered; and, on presenting it to him, he blushed, and was obliged to own his ignorance;

which inspired the Inca with the contemptuous notion of him abovementioned.

In order, however, to give some shew of justice to such a detestable action, and that he might be exempted from standing singly as the perpetrator, Pizarro resolved to accuse the Inca of some capital crime, <sup>16</sup> and institute a court of judicature for the purpose of trying him. For this purpose, he appointed himself and Almagro, with two assistants, as judges, with full powers to acquit or condemn: an attorney-general was named to carry on the prosecution in the king's name; counsellors were chosen to assist the prisoner in his defence; and clerks were ordained to record the proceedings of court. Before this strange tribunal, a charge was exhibited still more amazing. It consisted of various articles: that Atabalipa, though a bastard, had dispossessed the lawful owner of the throne, and usurped the regal power; that he had put his brother and lawful sovereign to death; that he was an idolater, and had not only permitted, but commanded the offering up of human sacrifices; that he had a great number of concubines; that since his imprisonment, he had wasted and embezzled the royal treasures, which now belonged of right to the conquerors; and that he had excited his subjects to take up arms against the Spaniards. On these heads of accusation they proceeded to try the sovereign of a great empire, over whom they had no jurisdiction. To all these charges the Inca pleaded not guilty. With respect to the death of his brother, he alleged, that the Spaniards could take no cognizance of the fact. With regard to the taxes which he had levied, and the wars he had carried on, they were nothing to the Spaniards; and as to the conspiracy against the Spaniards, he utterly denied it. He called heaven and earth to witness the integrity of his conduct, and how faithfully he had performed his engagements, and the perfidy of his accusers. He desired to be sent over to Spain to take his trial before the emperor; but no regard was paid to his intreaties; he was condemned to be burnt alive; which cruel sentence was mitigated, <sup>17</sup> as a great favour, to strangling; and the unhappy monarch was executed without mercy.

The death of the Inca was followed by a revolution in the Spanish affairs, who now became generally odious. Hateful cries were set up by his women as the funeral procession passed by their apartment: many offered to bury themselves alive with him; and on being hindered, strangled themselves out of grief and vexation. The whole town of Caxamalea was filled with lamentation, which quickly extended itself over revolt of the whole kingdom. Friends and enemies accused the Spaniards of inhumanity and treachery. Loads of gold that were coming to Caxamalea by order of the deceased Inca were now stopped; and the loss of the treasure was the first unfortunate consequence which the Spaniards felt from their late iniquitous conduct. The two factions of Indians united against Pizarro; and many of the Spaniards not only exclaimed against the cruelty of the invaders, but would even have mutinied, had not a sense of the impending danger kept them quiet. At Cuzco the friends of the emperor Huascar proclaimed Mango Capac the legitimate brother of the late Inca, determining to support him to the last against all the machinations of his enemies.

18  
A general  
of the Peruvians.

**Peru.** Pizarro, in the mean time, set up Taparapa, the son of Atabalipa, causing him to be treated with all the honours due to an emperor. Immediately he set out for Cuzco, the gaining of which was absolutely necessary for his design. An army of Indians occupied the passes, and resolved to dispute his progress. The contest, however, was soon decided; the Spanish cavalry bore down every thing before them, and great numbers of Indians were slain. The conquerors gained a considerable booty; and Pizarro dispatched Almagro to reduce Cuzco, while he himself founded a new colony in the fruitful valley of Xauxa; which, however, was not permanent, being afterwards removed to the place where Lima now stands.

While Pizarro was thus employed, another commander, named *Ferdinando Soto*, was detached with 60 horse to make the belt of his way to Cuzco, and clear the road for the march of the remainder of the army. He was opposed by a formidable collection of Indians, who had fortified themselves in order to defend a pass against him: for which reason, fearing lest his strength might be unequal, he sent a message to Pizarro, desiring that the Inca might join him, thinking that his presence would awe the Peruvians, and prevent the further effusion of blood; but his expectations were frustrated by the death of the Inca, which happened about this time; so that there was now a necessity for having recourse to arms; for as the Spaniards set up no person in his room, the title of *Mango Capac* was universally acknowledged.

In the mean time, a new supply of soldiers arriving from Spain, Benalcázar, governor of St Michael, undertook an expedition against Quito, where, according to the report of the natives, Atabalipa had left the greatest part of his treasure. He accomplished his purpose with very great difficulty, having a country covered with rocks and mountains to pass, and being opposed by large bodies of the natives. But when he got possession of the city, to his extreme mortification, he found that the inhabitants had carried off all their gold and silver; for they being now acquainted with the ruling passion of the Spaniards, had taken care to disappoint it, by removing the treasures which they knew very well had been the cause of the expedition.

About the same time, Alvarado, governor of Guatimala, invaded the province of Chili. In this expedition his troops endured such hardships, and suffered so much from the cold among the Andes, that a fifth part of the men and all the horses died, and at the same time the rest were so much dispirited and emaciated, that they became quite unfit for service. What was worst of all, when they had arrived at the end of their journey, they met with a body of Spaniards drawn up in hostile array to oppose them. These had been sent against him by Pizarro, who claimed Chili as part of his jurisdiction, and were now joined by Benalcázar, with the troops under his command. Alvarado, however, advanced boldly to the attack; but, on the interposition of some moderate men in each party, the difference was accommodated; Alvarado engaged to return to his government, upon his being paid 100,000 pesos to defray the expence of his armament; however, most of his followers remained in the country, and enlisted in the service of Pizarro.

In the mean time Ferdinand Pizarro, the brother of the general, had landed in Spain, where he produced such immense quantities of gold and silver as astonished the court, even after all they had seen of the wealth of their new-discovered territories. The general's authority was confirmed to him with new powers and privileges, and the addition of 70 leagues extending along the coast, to the southward of the territory granted in his former patent. Almagro had the title of *adelantado* or *governor* conferred upon him, with jurisdiction over 200 leagues of a country lying southward from the province allotted to Pizarro; he himself was made a knight of the order of St Jago.

Of these transactions some accounts were received at Peru before the arrival of Ferdinand Pizarro himself; and no sooner did Almagro hear that he had obtained the royal grant of an independent government, than, pretending that Cuzco, the capital of all Peru, lay within his jurisdiction, he attempted to seize it. Pizarro was no less ready to oppose him; and a very dangerous civil war was about to take place, when the quarrel was made up, on condition that Almagro should attempt the conquest of Chili; and if he did not find there an establishment equivalent to his expectations, Pizarro should yield up to him part of Peru.

By this reconciliation Pizarro was left at liberty to settle the internal policy of his province, which, though little qualified for a legislator, he attempted, by dividing the country into various districts, appointing magistrates to preside in each, and establishing such regulations concerning the administration of justice, the royal revenue, &c. as occurred to him. The seat of government he removed from Cuzco to Lima, which he named *Ciudad del Rey*, and which name it still retains among the Spaniards in all legal and formal deeds. Its other name, *Lima*, is a corruption of *Rimac*, the name of the valley in which the city stands.

In the mean time Almagro had set out on his expedition to Chili; the event of which has been related under the article *CHILI*; and while he was thus employed, Pizarro encouraged some of his most distinguished officers to invade those provinces of the empire which had not yet been visited by the Spaniards. This he did with a view to keep them employed, and prevent tumults; but it was attended with very terrible consequences. No sooner did *Mango Capac* the Inca perceive the security of the Spaniards in thus dividing their forces, than he seized the opportunity of making one vigorous effort to redress the wrongs of himself and his countrymen, and expel the invaders, who had tyrannized in such a cruel manner. Though strictly guarded by the Spaniards, he found means to communicate his intentions to the chief men of his nation, whom he joined in the year 1536, under pretence of celebrating a festival which he had obtained liberty from Pizarro to attend. Upon this the standard of a

A dreadful  
insurrection  
of the Peruvians,

Peru.

was made against Cuzco, which was defended by Pizarro and his two brothers, with only 170 men. The siege lasted nine months; many of the Spaniards were killed; among whom was Juan Pizarro, the general's brother, and the best beloved of them all. The rest were reduced to the most desperate situation, when Almagro appeared suddenly in the neighbourhood of Cuzco. He had received such accounts of the insurrection in Peru, as would at any rate have determined him to return to the assistance of Pizarro; but besides this, he had now received the royal patent, creating him governor of Chili, and deemed it certain beyond all contradiction, that Cuzco lay within his jurisdiction; for which reason he hastened to prevent it from falling into the hands of the Peruvians. On his arrival his assistance was solicited by both parties. The Inca made many advantageous proposals; but at length despairing of obtaining any cordial union with a Spaniard, he attacked him in the night by surprise with a great body of chosen troops. But the Spanish valour and discipline prevailed against all the numbers of their enemies; and the Peruvians were repulsed with such slaughter, that a great part of the remainder dispersed, and Almagro advanced to the gates of Cuzco without opposition. Pizarro's brothers took measures to oppose his entrance; but prudence for the present restrained both parties from entering into a civil war while they were surrounded with enemies; and therefore each leader endeavoured to corrupt the followers of his antagonist. In this Almagro had the advantage; and so many of Pizarro's troops deserted in the night, that Almagro was encouraged to advance towards the city, where he surprised the sentinels; and investing the house where the two brothers were lodged, he compelled them, after an obstinate defence, to surrender at discretion; and Almagro's authority over Cuzco was immediately recognized as authentic.

<sup>23</sup>

<sup>24</sup>  
Civil war  
between  
Pizarro and  
Almagro.

In this fray only two or three persons were killed; but matters soon began to wear a more serious aspect. Francis Pizarro, having dispersed the Peruvians who invested Lima, and received considerable reinforcements from other provinces, ordered 500 men under the command of Alonso de Alvarado to march to Cuzco, in hopes of relieving his brothers, if they were not already cut off. They advanced to a small distance from the capital, before they knew that they had a more formidable enemy than the Indians to encounter. When they saw their countrymen drawn up on the banks of a river to oppose them, they were greatly surprised; however, Almagro, who wished rather to gain them than to fight, began with attempting to seduce their leader. Alvarado could not by any means be gained over; but being inferior in military skill, Almagro attacked him by surprise, entirely defeated and dispersed his army, taking himself and some of his principal officers prisoners.

This victory seemed decisive; and Almagro was advised to make it so by putting to death Gonzalo and Ferdinand Pizarros, Alvarado, and some others whom he could not hope to gain. This advice, however, he declined from motives of humanity, and a desire of making his adversary appear the aggressor. For these reasons, instead of marching directly against Pizarro, he retired quietly to Cuzco; which gave his adversary time to recollect himself from the disorder into which

the news of so many disasters had thrown him. He began again to practise upon Almagro those arts which had before proved successful; and Almagro again suffered himself to be deceived by pretended offers of pacification. The negotiations for this purpose were protracted for several months; and while Almagro was employed in detecting and eluding the fraudulent intentions of the governor, Gonzalo Pizarro and Alvarado found means to corrupt the soldiers who guarded them, and not only made their own escape, but persuaded 60 of Almagro's men to accompany them. There now remained only Ferdinand Pizarro in the hands of Almagro; and he was delivered by another act of treachery. The general proposed that all points of controversy should be submitted to the decision of their sovereign; and that Ferdinand Pizarro should be instantly set at liberty, and return to Spain, together with some other officers whom the general proposed to send over to shew the justice of his claims. Though the intention of Pizarro by making this proposal was evident, Almagro was deceived by it, and released those whom Pizarro wanted; which he had no sooner done, than the latter threw off all disguise, and openly declared, that arms alone must now decide the matter between them. He therefore immediately set out for Cuzco with an army of 700 men, to which Almagro had only 500 to oppose. From the weakness of his forces, probably, Almagro did not attempt to guard some strong passes, through which Pizarro had to march, but waited patiently for his adversary in a plain open country.

In the mean time, Pizarro advanced without any obstruction from his enemy; and an engagement soon happened, in which Almagro was defeated and taken prisoner. The conquerors behaved with great cruelty, massacring a great number of officers, and treating Almagro himself with great severity. The Indians had assembled in great numbers to see the battle, with an intention to join the vanquished party; but were so much overawed by the Spaniards, that they retired quietly after the battle was over, and thus lost the only opportunity they ever had of expelling their tyrants.—Almagro, after having for some months languished in prison, was at length formally tried, and condemned to die by Pizarro. Notwithstanding his consummate bravery for which he was remarkable, this hardy veteran could not bear the deliberate approach of death, but descended to use intreaties to save his life. The Pizarros, however, continued inflexible; and he was first strangled in prison, and then publicly beheaded. He left one son by an Indian woman, whom he appointed his successor, by virtue of a power granted him by the emperor.

<sup>25</sup>

defeated  
and taken  
prisoner.

As during these dissensions all intercourse with Spain ceased, it was some time before the accounts of the civil war were received at court. The first intelligence was given by some of Almagro's soldiers, who had left America on the ruin of their cause; and they did not fail to represent the injustice and violence of Pizarro in the strongest colours, which strongly prejudiced the emperor against him. In a short time, however, Ferdinand Pizarro arrived, and endeavoured to give matters a new turn. The emperor was uncertain which of them he ought to believe; and therefore thought it necessary to send over some person with ample powers

<sup>26</sup>

to inquire into the merits of the cause, and to determine certainly who was in the wrong. If he found the governor still alive, he was to assume only the title of judge, in order to have the appearance of acting in concert with him; but if he was dead, the viceroy might then produce his commission appointing him Pizarro's successor in the government. This compliance to Pizarro, however, proceeded more from a dread of his power than from any other thing; for in the mean time, his brother Ferdinand was arrested at Madrid, and confined to a prison, where he remained above 20 years. The person nominated to this important trust was Christoval Vaco de Castro.

27  
Peru divided by Pizarro among his associates.

While this gentleman was preparing for his voyage, Pizarro, considering himself as the unrivalled master of Peru, proceeded to parcel out its territories among the conquerors; and had this division been made with any degree of impartiality, the extent of country which he had to bestow was sufficient to have gratified his friends, and to have gained his enemies. But Pizarro conducted this transaction, not with the equity and candour of a judge attentive to discover and to reward merit, but with the illiberal spirit of a party-leader. Large districts, in parts of the country most cultivated and populous, were set apart as his own property, or granted to his brothers, his adherents, and favourites. To others, lots less valuable and inviting were assigned. The followers of Almagro, amongst whom were many of the original adventurers, to whose valour and perseverance Pizarro was indebted for his success, were totally excluded from any portion in those lands, towards the acquisition of which they had contributed so largely. As the vanity of every individual sets an immoderate value upon his own services, and the idea of each, concerning the recompence due to them, rose gradually to a more exorbitant height in proportion as their conquests extended, all who were disappointed in their expectations exclaimed loudly against the rapaciousness and partiality of the governor. The partisans of Almagro murmured in secret, and meditated revenge.

Rapid as the progress of the Spaniards in South America had been since Pizarro landed in Peru, their avidity of dominion was not yet satisfied. The officers to whom Ferdinand Pizarro gave the command of different detachments, penetrated into several new provinces; and though some of them were exposed to great hardships in the cold and barren regions of the Andes, and others suffered distress not inferior amidst the woods and marshes of the plains, they made discoveries and conquests which extended their knowledge of the country, as well as added to their power. Pedro de Valdivia re-assumed Almagro's scheme of invading Chili; and, notwithstanding the fortitude of the natives in defending their possessions, made such progress in the conquest of the country, that he founded the city of St Jago, and gave a beginning to the establishment of the Spanish dominion there. But of all the enterprises undertaken about this period, that of

28  
Expedition of Gonzales Pizarro.

Gonzales Pizarro was the most remarkable. The governor, who seems to have resolved that no person in Peru should possess any station of distinguished eminence or authority but those of his own family, had deprived Benalcazar, the conqueror of Quito, of his command in that kingdom, and appointed his brother

Gonzalo to take the government of it. He instructed him to attempt the discovery and conquest of the country to the east of the Andes; which, according to the information of the Indians, abounded with cinnamon and other valuable spices. Gonzales, not inferior to any of his brothers in courage, and no less ambitious of acquiring distinction, eagerly engaged in this difficult service. He set out from Quito at the head of 340 soldiers, near one half of whom were horsemen, with 4000 Indians to carry their provisions. In forcing their way through the deserts, or over the ridges of the Andes, excels of cold and fatigue, to neither of which they were accustomed, proved fatal to the greater part of the wretched attendants. The Spaniards, tho' more robust, and inured to a variety of climates, suffered considerably, and lost some men; but when they descended into the low country, their distress increased. During two months it rained incessantly, without any interval of fair weather long enough to dry their cloaths. The vast plains upon which they were now entering, either altogether without inhabitants, or occupied by the rudest and least industrious tribes in the New World, yielded little subsistence. They could not advance a step but as they cut a road through woods, or made it through marshes. Such incessant toil, and continual scarcity of food, seem more than sufficient to have exhausted and dispirited any troops. But the fortitude and perseverance of the Spaniards in the 16th century were insuperable. Allured by frequent but false accounts of rich countries before them, they persisted in struggling on, until they reached the banks of the Coca or Napo, one of the large rivers whose waters pour into the Maragnon, and contribute to its grandeur. There, with infinite labour, they built a bark, which they expected would prove of great utility, both in conveying them over rivers, in procuring provisions, and in exploring the country. This was manned with 50 soldiers, under the command of Francis Orellana, the officer next in rank to Pizarro. The stream carried them down with such rapidity, that they were soon far ahead of their countrymen, who followed slowly and with difficulty by land.

At this distance from his commander, Orellana, a young man of an aspiring mind, began to fancy himself independent; and, transported with the predominant passion of the age, he formed the scheme of distinguishing himself as a discoverer, by following the course of the Maragnon until it joined the ocean, and by surveying the vast regions through which it flows. This scheme of Orellana's was as bold as it was treacherous. For, if he be chargeable with the guilt of having violated his duty to his commander, and with having abandoned his fellow-soldiers in a pathless desert, where they had hardly any hopes of success, or even of safety, but what were founded on the service which they expected from the bark, his crime is, in some measure, balanced by the glory of having ventured upon a navigation of near 2000 leagues, through unknown nations, in a vessel hastily constructed with green timber, and by very unskilful hands, without provisions, without a compass, or a pilot. But his courage and alacrity supplied every defect. Committing himself fearlessly to the guidance of the stream, the Napo bore him along to the south, until he reached the great channel of the Maragnon. Turning with it towards the

Pern.

the coast, he held on his course in that direction. He made frequent descents on both sides the river, sometimes seizing by force of arms the provisions of the fierce savages seated on its banks, and sometimes procuring a supply of food by a friendly intercourse with more gentle tribes. After a long series of dangers, and of which he encountered with amazing fortitude, and of distresses which he supported with no less magnanimity, he reached the ocean, where new perils awaited him. These he likewise surmounted, and got safe to the Spanish settlement in the island Cubagua; from thence he failed to Spain. The vanity natural to travellers who visit regions unknown to the rest of mankind, and the art of an adventurer, solicitous to magnify his own merit, concurred in prompting him to mingle an extraordinary proportion of the marvellous in the narrative of his voyage. He pretended to have discovered nations so rich, that the roofs of their temples were covered with plates of gold; and described a republic of women so warlike and powerful, as to have extended their dominion over a considerable tract of the fertile plains which he had visited. Extravagant as those tales were, they gave rise to an opinion, that a region abounding with gold, distinguished by the name of *El Dorado*, and a community of Amazons, were to be found in this part of the New World; and such is the propensity of mankind to believe what is wonderful, that it has been slowly, and with difficulty, that reason and observation have exploded those fables. The voyage, however, even when stripped of every romantic embellishment, deserves to be recorded, not only as one of the most memorable occurrences in that adventurous age, but as the first event that led to any certain knowledge of those immense regions that stretch eastward from the Andes to the ocean.

No words can describe the consternation of Pizarro, when he did not find the bark at the confluence of the Napo and Maragnon, where he had ordered Orellana to wait for him. He would not allow himself to suspect that a man, whom he had entrusted with such an important command, could be so base and so unfeeling as to desert him at such a juncture. But imputing his absence from the place of rendezvous to some unknown accident, he advanced about 50 leagues along the banks of the Maragnon, expecting every moment to see the bark appear with a supply of provisions. At length he came up with an officer whom Orellana had left to perish in the desert, because he had the courage to remonstrate against his perfidy. From him he learned the extent of Orellana's crime; and his followers perceived at once their own desperate situation, when deprived of their only resource. The spirit of the stoutest hearted veteran sunk within him; and all demanded to be led back instantly. Pizarro, though he assumed an appearance of tranquillity, did not oppose their inclination. But he was now 1200 miles from Quito; and in that long march the Spaniards encountered hardships greater than those they had endured in their progress outward, without the alluring hopes which then soothed and animated them under their sufferings. Hunger compelled them to feed on roots and berries, to eat all their dogs and horses, to devour the most loathsome reptiles, and even to gnaw the leather of their saddles and sword-belts. Four thousand Indians, and 210 Spaniards, perished in this wild and

disastrous expedition, which continued near two years; and as 50 men were aboard the bark with Orellana, only 80 got back to Quito. These were naked like savages, and so emaciated with famine, or worn out with fatigue, that they had more the appearance of spectres than of men.

But, instead of returning to enjoy the repose which his condition required, Pizarro, on entering Quito, received accounts of a fatal event that threatened calamities more dreadful to him than those through which he had passed. From the time that his brother made that partial division of his conquests which has been mentioned, the adherents of Almagro, considering themselves as proscribed by the party in power, no longer entertained any hope of bettering their condition. Great numbers in despair resorted to Lima, where the house of young Almagro was always open to them; and the slender portion of his father's fortune, which the governor allowed him to enjoy, was spent in affording them subsistence. The warm attachment with which every person who served under the elder Almagro devoted himself to his interests, was quickly transferred to his son, who was now grown up to the age of manhood, and possessed all the qualities which captivate the affections of soldiers. Of a graceful appearance, dextrous at all martial exercises, bold, open, generous, he seemed to be formed for command; and as his father, conscious of his own inferiority from the total want of education, had been extremely attentive to have him instructed in every science becoming a gentleman; the accomplishments which he had acquired heightened the respect of his followers, as they gave him distinction and eminence among illiterate adventurers. In this young man the Almagrians found a point of union which they wanted; and looking up to him as their head, were ready to undertake any thing for his advancement. Nor was affection for Almagro their only incitement; they were urged on by their own distresses. Many of them, destitute of common necessities, and weary of loitering away life, a burden to their chief, or to such of their associates as had saved some remnant of their fortune from pillage and confiscation, longed impatiently for an occasion to exert their activity and courage, and began to deliberate how they might be avenged on the author of all their misery. Their frequent cabals did not pass unobserved; and the governor was warned to be on his guard against men who meditated some desperate deed, and had resolution to execute it. But, either from the native intrepidity of his mind, or from contempt of persons whose poverty rendered their machinations of little consequence, he disregarded the admonitions of his friends. "Be in no pain (said he carelessly) about my life; it is perfectly safe, as long as every man in Peru knows that I can in a moment put him to death who dares to harbour a thought against it." This security gave the Almagrians full leisure to digest and ripen every part of their scheme; and Juan de Herada, an officer of great abilities, who had the charge of Almagro's education, took the lead in their consultations, with all the zeal which that connection inspired, and with all the authority which the ascendant that he was known to have over the mind of his pupil gave him.

On Sunday, the 26th of June, at mid-day, the sea-

murdered.

son of tranquillity and repose in all sultry climates, Herrada, at the head of 18 of the most determined conspirators, sallied out of Almagro's house in complete armour; and drawing their swords, as they advanced hastily towards the governor's palace, cried out, "Long live the king, but let the tyrant die." Their associates, warned of their motions by a signal, were in arms at different stations ready to support them. Though Pizarro was usually surrounded by such a numerous train of attendants as suited the magnificence of the most opulent subject of the age in which he lived, yet as he was just risen from table, and most of his own domestics had retired to their own apartments, the conspirators passed through the two outer courts of the palace unobserved. They were at the bottom of the stair-case, before a page in waiting could give the alarm to his master, who was conversing with a few friends in a large hall. The governor, whose steady mind no form of danger could appal, starting up, called for arms, and commanded Francisco de Chaves to make fast the door. But that officer, who did not retain so much presence of mind as to obey this prudent order, running to the top of the stair-case, wildly asked the conspirators what they meant, and whether they were going? Instead of answering, they stabbed him to the heart, and burst into the hall. Some of the persons who were there threw themselves from the windows; others attempted to fly; and a few drawing their swords, followed their leader into an inner apartment. The conspirators, animated with having the object of their vengeance now in view, rushed forward after them. Pizarro, with no other arms than his sword and buckler, defended the entry, and, supported by his half-brother Alcantara and his little knot of friends, maintained the unequal contest with intrepidity worthy of his past exploits, and with the vigour of a youthful combatant. "Courage," cried he, "companions, we are yet now to make those traitors repent of their audacity." But the armour of the conspirators protected them, while every thrust they made took effect. Alcantara fell dead at his brother's feet; his other defendants were mortally wounded. The governor, so weary that he could hardly wield his sword, and no longer able to parry the many weapons furiously aimed at him, received a deadly thrust full in his throat, sunk to the ground, and expired.

As soon as he was slain, the assassins ran out into the streets, and waving their bloody swords, proclaimed the death of the tyrant. Above 200 of their associates having joined them, they conducted young Almagro in solemn procession through the city; and assembling the magistrates and principal citizens, compelled them to acknowledge him as lawful successor to his father in his government. The palace of Pizarro, together with the houses of several of his adherents, were pillaged by the soldiers; who had the satisfaction at once of being avenged on their enemies, and of enriching themselves by the spoils of those through whose hands all the wealth of Peru had passed.

The new governor marched into the heart of the empire, in order to reduce such places as refused to acknowledge his authority. A multitude of ruffians joined him on his march. His army breathed nothing but vengeance and plunder: every thing gave way before it. If the military talents of the general had

equalled the ardour of his troops, the war had ended here. Unhappily for Almagro, he had lost his conductor John de Herrada. His inexperience made him fall into the snares that were laid for him by Pedro Alvares, who had put himself at the head of the opposite party. He lost, in attempting to unravel his plots, that time that he ought to have employed in fighting. In these circumstances, an event, which no one could have foreseen, happened to change the face of affairs.

The licentiate Vaca di Castro, who had been sent from Europe to try the murderers of old Almagro, arrived at Peru. As he was appointed to assume the government in case Pizarro was no more, all who had not fold themselves to the tyrant hastened to acknowledge him. Uncertainty and jealousy, which had for too long a time kept them dispersed, were no longer an obstacle to their re-union. Castro, who was as resolute as if he had grown old in the service, did not suffer their impatience to languish, but instantly led them against the enemy. The two armies engaged at Chapas on the 16th of September 1542, and fought with inexpressible obstinacy. Victory, after having wavered a long time, at the close of the day decided in favour of that party whose cause was the most just. Those among the rebels who were most guilty, dreading to languish under disgraceful tortures, provoked the conquerors to murder them, crying out, like men in despair, *It was I who killed Pizarro*. Their chief was taken prisoner, and died on the scaffold.

While these scenes of horror were transacting in America, the Spaniards in Europe were employed in finding out expedients to terminate them; though no measures had been taken to prevent them. Peru had only been made subject to the audience of Panama, which was too remote to superintend the maintenance of good order, and had too little influence to make its decrees respected. A supreme tribunal was then established at Lima for the dispensation of justice, which was to be invested with authority sufficient to enforce and to reward a due obedience to the laws. Blasco Nunez Vela, who presided in it as viceroy, arrived in 1544, attended by his subordinates in office, and found every thing in the most dreadful disorder.

To put an end to these tumults which now subsisted, would have required a profound genius, and many other qualities which are seldom united. Nunez had none of these advantages. Nature had only given him probity, firmness, and ardour; and he had taken no pains to improve these gifts. With these virtues, which were almost defects in his situation, he began to fulfil his commission, without regard to places, persons, or circumstances.

Contrary to the opinion of all intelligent persons, <sup>35</sup> had con- who wished that he should wait for fresh instructions <sup>dict of the</sup> from Europe, he published ordinances, which declared viceroy Nu- that the lands the conquerors had seized should not <sup>bez Vela</sup> pass to their descendants, and which dispossessed those who had taken part in the civil commotions. All the Peruvians who had been enslaved by monks, bishops, and persons belonging to the government, were declared free. Those who belonged to other masters were to be freed from their shackles at the death of their oppressors. They could no longer be compelled to bury themselves in the mines, nor could any kind of labour

Peru. labour be exacted from them without payment. Their tribute was fixed. The Spaniards who travelled on foot were deprived of the right of taking three Indians to carry their baggage; and those who travelled on horseback, of the right of taking five. The caciques were discharged from the obligation of furnishing the traveller and his retinue with provisions gratis. Other tyrannical establishments also would soon have been proscribed; and the conquered people were on the eve of being sheltered under the protection of laws, which would at least have tempered the rigours of the right of conquest, if even they had not entirely repaired the injustice of them; but it should seem that the Spanish government was only to be unfortunate in the good it attempted to effect.

A change to unexpected filled those with consternation who saw their fortunes wrested from them, or who lost the flattering hope of transmitting theirs to their posterity. Even those who were not affected by these interested views, being accustomed to look upon the Indians as the instruments and victims of their avarice, had no conception that any other ideas could prevail concerning them. From astonishment they proceeded to indignation, murmuring, and sedition. The viceroy was degraded, put in irons, and banished to a desert island, till he could be conveyed to Spain.

Gonzales Pizarro was then returned from his hazardous expedition, which had employed him long enough to prevent him from taking a part in those revolutions which had so rapidly succeeded each other. The anarchy he found prevailing at his return, inspired him with the idea of seizing the supreme authority. His fame and his forces made it impossible that this should be refused him; but his usurpation was marked with so many enormities, that Nunez was regretted. He was recalled from exile, and soon collected a sufficient number of forces to enable him to take the field. Civil commotions were then renewed with extreme fury by both parties. No quarter was asked or given on either side. The Indians took part in this as they had done in the preceding wars; some ranged themselves under the standard of the viceroy, others under the banners of Gonzales. From 15,000 to 20,000 of these unhappy wretches, who were scattered about in each army, dragged up the artillery, levelled the roads, carried the baggage, and destroyed one another. Their conquerors had taught them to be sanguinary. After a variety of advantages for a long time alternately obtained, fortune at length favoured the rebellion under the walls of Quito in the month of January, in the year 1545; and Nunez with the greatest part of his men were massacred.

Pizarro took the road of Lima, where they were deliberating on the ceremonies with which they should receive him. Some officers wished that a canopy should be carried for him to march under, after the manner of kings. Others, with adulation still more extravagant, pretended that part of the walls of the town, and even some houses, must be pulled down; as was the custom at Rome, when a general obtained the honours of a triumph. Gonzales contented himself with making his entrance on horseback, preceded by his lieutenant, who marched on foot. Four bishops accompanied him, and he was followed by the magi-

strates. The streets were strewn with flowers, and the air resounded with the noise of bells and various musical instruments. This homage totally turned the head of a man naturally haughty, and of confined ideas. He spoke and acted in the most despotic manner.

Had Gonzales possessed judgment and the appearance of moderation, it would have been possible for him to render himself independent. The principal persons of his party wished it. The majority would have beheld this event with indifference, and the rest would have been obliged to consent to it. Blind cruelties, insatiable avarice, and unbounded pride, altered these dispositions. Even those, whose interests were connected with those of the tyrant, wished for a deliverer.

Such a deliverer arrived from Europe in the person of the licentiate Pedro di la Gasca. The squadron and the provinces of the mountains immediately declared for a person who was invested with a lawful authority to govern them. Those who lived concealed in deserts, caverns, and forests, quitted their retreats to join him. Gonzales, who saw no resource left to support him but in some great achievement, took the road of Cuzco, with a resolution to give battle. At some leagues distance from this place he met the royal army, and attacked it on the 9th of June 1548. One of his lieutenants, seeing him abandoned at the first charge by his best soldiers, advised him to throw himself into the enemy's battalions, and perish like a Roman: but this weak man chose rather to surrender, and end his life on a scaffold. Carvajal, a more able warrior, and more ferocious than himself, was quartered. This man, when he was expiring, boasted that he had massacred with his own hand 1400 Spaniards and 20,000 Indians.

Such was the last scene of a tragedy, of which every act has been marked with blood. The government was moderate enough not to continue the prosecutions; and the remembrance of the horrid calamities they had suffered kept the Spaniards in the bounds of subjection. What still remained of that commotion that had been raised in their minds, insensibly sunk into a calm; and the country hath remained in quiet ever since.

With regard to the Peruvians, the most cruel measures were taken to render it impossible for them to rebel. Tupac Amaru, the heir of their last king, had taken refuge in some remote mountains, where he lived in peace. There he was so closely surrounded by the troops which had been sent out against him, that he was forced to surrender. The viceroy Francis de Toledo caused him to be accused of several crimes that he had not committed, and for which he was beheaded in 1571. All the other descendants of the Incas shared the same fate, under pretence that they had conspired against their conquerors. The horror of these enormities excited so universal an indignation both in the Old and the New World, that Philip II. thought himself obliged to disavow them; but the infamous policy of this prince was so notorious, that no credit was given to this appearance of his justice and humanity.

The empire of Peru, at the time it was subdued, extended along the South Sea, from the River of Emperal to Chili, and on the land side to Popayan, according

cording to some geographers. It contained within its extent that famous chain of mountains which rises in the Terra Magellanica, and is gradually lost in Mexico, in order to unite, as it should seem, the southern parts of America with the northern. Its territory, which is very irregular, may be divided into three classes.

40  
Description  
of the  
mountains  
called Cor-  
deleras.

The principal Cordeleras form the first. The summits of these, says M. de la Condamine, are lost in the clouds, and almost all of them are covered with enormous masses of snow as old as the world. From several of these summits, which have in part tumbled down, and from these immense heaps of snow, torrents of smoke and flame issue. Such are the summits of Colopaxi, Tongourargua, and Sangai. The greatest part of the rest have formerly been volcanoes, or will probably one day become such. History has only preserved to us the era of their eruptions since the discovery of America; but the pumice-stones, the calcined earths with which they are strewn, and the evident vestiges that the flame hath left, are authentic testimonies of the reality of former eruptions: their height is prodigious.

Cayambour, which is situated directly under the equator, and Antifona, which is only five leagues distant from it to the south, are more than 3000 toises high, reckoning from the level of the sea; and Chimborazo, which is near 3220 toises high, surpasses by one third the altitude of the Peak of Teneriffe, the highest mountain of the old hemisphere. Pitchincha and Caracazo, where the French Academicians made most of their observations with regard to the figure of the earth, have only 2430 and 2470 toises of absolute height; and this is the highest mountain that was ever ascended. Eternal snows have hitherto rendered summits of greater altitude inaccessible.

From this boundary, which is where the snow never melts, not even in the torrid zone, one hardly sees, in descending 100 or 150 toises down, any thing except naked rocks or dry sands: a little lower, one may perceive some moss that covers the rocks; various kinds of heath, which, though green and damp, make a clear fire; round hillocks of spongy earth, on which grow small radiated and starry plants, whose petals are like the leaves of yew. Throughout the whole of this space, the snow is only temporary; but it continues sometimes whole weeks and months. Lower still, the ground is commonly covered with a sort of loose grass, which rises a foot and a half high, or two feet. This species of hay is the proper characteristic that distinguishes the mountains which the Spaniards call *Paramos*. They only give this name to heath, or such uncultivated ground as is too high for wood to grow on it, or where the rain seldom falls otherwise than in the form of snow, tho' it immediately melts. And, lastly, in descending still lower, to the height of about 2000 toises above the level of the sea, one sees it sometimes snow and sometimes rain.

When we come down from these mountains, we find others that are less considerable, which occupy the middle of Peru. The summit of these is commonly cold, barren, and full of mines. The valleys between them are covered with numerous flocks, and seem to offer to agriculture the most copious harvests. There are seldom above two months of winter here; and in the

greatest heat we need only pass out of the sun into the shade, to enjoy the temperate zone. This rapid alternative of sensation is not, however, invariable in a climate, which, by the disposition alone of the ground, often changes in the course of a league. But let it be as it will, it is always found healthy. There is no malady peculiar to these countries, and those of our climate seldom prevail there. An European vessel, however, in 1719, brought thither an epidemic disorder, which carried off a great number of Spaniards and Mestices, and above 200,000 Indians. A more fatal present still, which these people have received in exchange for their gold, is the small-pox. It shewed itself here for the first time in 1588, and has not failed since to make at intervals inexpreffible ravages.

The people are not less exposed to this fatal distemper on the coasts known by the name of *valleys*. Their temperature is not the same as is elsewhere found in the same latitude. It is very agreeable; and, though the four seasons of the year are sensibly felt here, there is none that can with propriety be deemed inconvenient. The winter is the most strongly marked. This has been accounted for by the winds of the south pole, which bring along with them the impression of those snows and that ice from which they first came: but this they preferre only in part, because they blow while a thick fog lies upon the earth. In reality, these gross vapours never regularly rise till towards noon: but it is seldom that they disperse. The sky commonly continues so much covered with them, that the rays of the sun, which sometimes appear, can only in a very slight manner mitigate the cold.

Whatever may be the cause of so regular a winter under the torrid zone, it is certain that these valleys, which are covered with heaps of sand, are absolutely barren for a space of more than 100 leagues, from Truxillo to Lima. The rest of the coast is less sandy, but it is still too much so to be fruitful. No fields are there found that can be styled *fertile*, except in such lands as are watered by the streams which descend from the mountains.

Rain might contribute to impart to the soil the fertility of which it is destitute; but it is never known to rain in Lower Peru. Natural philosophy has exerted its efforts in vain to discover the cause of a phenomenon so extraordinary. To this it is owing, that the houses, though only built of crude brick, or of earth mixed with a little grass, are of very long duration. Their covering is only a simple matting, placed horizontally, with a layer of ashes an inch deep above, to absorb the moisture of the fog.

The same reasons that prevent its raining in the valleys, undoubtedly also hinder storms. Those of their inhabitants who never travelled in the mountains, are perfect strangers to thunder and lightning. Their terror is equal to their astonishment, when, out of their country, they first behold so uncommon a spectacle.

But they have a phenomenon much more dangerous and dreadful, and which, in its consequences, leaves much deeper impressions in the human imagination than thunder and the ravages that accompany it. Earthquakes, which in other countries are so rare, that whole generations pass without beholding one, are so common in the valleys of Peru, that they have there contracted an habit of reckoning them as a se-

Peru.

41

Peru.

ries of dates; and they are so much the more memorable, as their frequent return does not diminish their violence. There are few places on this extensive coast which do not present most dreadful monuments of these horrible convulsions of the earth.

42  
How the  
country was  
originally  
settled by  
the Spaniards.

At the time when the first conquests were made, when emigrations were most frequent, the country of the Incas had a much greater reputation for riches than New Spain; and, in reality, for a long time much more considerable treasures were brought away from it. The desire of partaking of them must necessarily draw thither, as was really the case, a greater number of Castilians. Though they all almost went over there with the hope of returning to their country to enjoy the fortune they might acquire, yet the majority of them settled in the colony. They were induced to this by the softness of the climate, the salubrity of the air, and the goodness of the provisions. Mexico presented not the same advantages, and did not give them reason to expect so much independence as a land infinitely more remote from the mother-country.

Cusco attracted the conquerors in multitudes. They found this capital built on a ground that was very irregular, and divided into as many quarters as there were provinces in the empire. Each of the inhabitants must follow the usages of his native country; but every body was obliged to conform to the worship established by the founder of the monarchy. There was no edifice that had any grandeur, elegance, or convenience; because the people were ignorant of the first elements of architecture. The magnificence of what they called the *palace of the sovereign, of the princes of the blood, and of the great men of his empire*, consisted in the profusion of the metals that were lavished in decorating them. The temple of the Sun was distinguished above all other edifices; its walls were inlaid or sheathed with gold and silver, ornamented with divers figures, and loaded with the idols of all the nations whom the Incas had enlivened and subdued.

As it was not a solicitude for their own preservation which occupied the Spaniards at first, they had no sooner pillaged the immense riches which had been amassed at Cusco for four centuries, than they went in great numbers in 1534, under the order of Sebastian de Benalcazar, to undertake the destruction of Quito. The other towns and boroughs of the empire were over-run with the same spirit of rapine; and the citizens and the temples were plundered in all parts.

Those of the conquerors, who did not take up their residence in the settlements which they found already formed, built towns on the sea-coasts, where before there were none: for the sterility of the soil had not permitted the Peruvians to multiply much there; and they had not been induced to remove thither from the extremity of their country, because they failed very little. Paiza, Truxillo, Callao, Pisco, and Arica, were the roads which the Spaniards deemed most convenient for the communication they intended to establish among themselves and with the mother-country. The different positions of these new cities determined the degree of their prosperity.

Those which were afterwards built in the inland parts of the country were not erected in regions which presented a fertile soil, copious harvests, excellent pa-

tures, a mild and salubrious climate, and all the conveniences of life. These places, which had hitherto been so well cultivated by a numerous and flourishing people, were now totally disregarded. Very soon they exhibited only a deplorable picture of a horrid desert; and this wildness must have been more melancholy and hideous than the dreary aspect of the earth before the origin of societies. The traveller, who was led by accident or curiosity into these desolate plains, could not forbear abhorring the barbarous and bloody authors of these devastations, while he reflected that it was not owing even to the cruel illusions of glory and to the fanaticism of conquest, but to the stupid and abject desire of gold, that they had sacrificed so much more real treasure, and so numerous a population.

This insatiable thirst of gold, which neither tended to subsistence, safety, nor policy, was the only motive for establishing new settlements, some of which have been kept up, while several have decayed, and others have been formed in their stead. The fate of them all has corresponded with the discovery, progress, or declension, of the mines to which they were subordinate.

Fewer errors have been committed in the means of procuring provisions. The natives had hitherto lived hardly on any thing else but maize, fruits, and pulse, for which they had used no other seasoning except salt and pimento. Their liquors, which were made from different roots, were more diversified: of these the chicha was the most usual; which is made from maze soaked in water, and taken out of the vessel when it begins to sprout. It is dried in the sun, then parched a little, and at last ground. The flour, after it has been well kneaded, is put with water into large pitchers. The fermentation may be expected in two or three days, and must not continue longer. The great inconvenience of this drink, which, when used immoderately, infallibly intoxicates, is, that it will not keep more than eight days without turning sour. Its taste is nearly that of the most indifferent kind of cyder. It is a refreshing, nourishing, and aperitive liquor. The Indians, who are never troubled with suppressions of urine, are said to owe that advantage to the use of this drink.

The conquerors were not satisfied either with the liquors or with the food of the people they had subdued. They imported vines from the Old World, which soon multiplied sufficiently in the sands of the coasts at Ica, Pisco, Nasca, Moquequa, and Truxillo, to furnish the colony with the wine and brandy it wanted. Olives succeeded still better; and yielded a great abundance of oil, which was much superior to that of the mother-country. Other fruits were transplanted with the same success. Sugar succeeds so well, that none of any other growth can be compared to that which is cultivated in these parts, where it never rains. In the inland country wheat and barley were sown; and at length all the European quadrupeds were soon found grazing at the foot of the mountains.

This was a considerable step; but there still remained much more to be done. After they had provided for a better and a greater choice of subsistence, the next care of the Spaniards was to have a dress more commodious and more agreeable than that of the Peruvians. These were, however, better clothed than any other  
Amc-

Peru.

43  
Manner of  
living of the  
natives.

Peru.

Peru.

American nation. They owed this superiority to the advantage which they alone possessed, of having the LAMA and PACOS, domestic animals which served them for this use. See CAMELUS.

After the conquest, all the Indians were obliged to wear cloths. As the oppression under which they groaned did not allow them to exercise their former industry, they contented themselves with the coarser cloths of Europe, for which they were made to pay an exorbitant price. When the gold and silver which had escaped the rapacity of the conquerors were exhausted, they thought of re-establishing their national manufactures. These were some time after prohibited, on account of the deficiency which they occasioned in the exports of the mother-country. The impossibility which the Peruvians found of purchasing foreign stuffs and paying their taxes, occasioned permission to be given at the end of ten years for their re-establishment. They have not been discontinued since that time, and have been brought to as great a degree of perfection as it was possible they could be under a continual tyranny.

44  
Manufac-  
tures, &c.

With the wool of the vicuna, a species of wild paco, they make, at Cuzco and in its territory, stockings, handkerchiefs, and scarfs. These manufactures would have been multiplied, if the spirit of destruction had not fallen on animals as well as on men. The same wool, mixed with that of the sheep imported thither from Europe, which hath exceedingly degenerated, serves for carpets, and makes also tolerably fine cloth. Fleeces of inferior quality are employed in serges, drugges, and in all kinds of coarse stuffs.

The manufactures subservient to luxury are established at Arequipa, Cuzco, and Lima. In these three towns is made a prodigious number of gold toys and plate, for the use of private persons, and also for the churches. All these manufactures are but coarsely wrought, and mixed with a great deal of copper. We seldom discover more taste in their gold and silver laces and embroideries which their manufactures also produce. This is not altogether the case in regard to their lace, which, when mixed with that of Europe, looks very beautiful. This last manufacture is commonly in the hands of the nuns, who employ in it the Peruvian girls, and the young Mestees of the towns, who for the most part before marriage pass some years in the convent.

Other hands are employed in painting and gilding leather for rooms, in making with wood and ivory pieces of inlaid work and sculpture, and in drawing figures on the marble that is found at Cucuca, or on linen imported from Europe. These different works, which are almost all manufactured at Cuzco, serve for ornaments for houses, palaces, and temples: the drawing of them is not bad, but the colours are neither exact nor permanent. If the Indians, who invent nothing, but are excellent imitators, had able masters and excellent models, they would at least make good copyists. At the close of the last century, some works of a Peruvian painter, named *Michael de St Jacques*, were brought to Rome; and the connoisseurs discovered marks of genius in them.

45  
Of the  
mines of  
gold and sil-  
ver.

Though the Peruvians were unacquainted with coin, they knew the use of gold and silver; for they employed them in different kinds of ornaments. Indepen-

dent of what the torrents and accident procured them of these metals, some mines had been opened of little depth. The Spaniards have not transmitted to us the manner in which these rich productions were drawn from the bosom of the earth. Their pride, which has deprived us of so much useful knowledge, undoubtedly made them think, that, in the inventions of a people whom they called *barbarous*, there was nothing that was worthy to be recorded.

The difference as to the manner in which the Peruvians worked their mines, did not extend to the mines themselves. The conquerors opened them on all sides. At first the gold mines tempted the avarice of the greater number. Fatal experience discouraged those whom passion had not blinded. They clearly saw, that, for some enormous fortunes raised in this manner, great numbers, who had only moderate fortunes, were totally ruined. These mines sunk into such discredit, that, in order to prevent them from being abandoned, the government was obliged to take the 20th part of their produce, instead of the fifth which it at first received.

The mines of silver were more common, more equal, and richer. They even produced silver of a singular species, rarely found elsewhere. Towards the sea-coast, great lumps of this metal are found in the sands.

There are a great number of other mines which are infinitely more important, and are found in the rocks and on the mountains. Several of them gave false hopes. Such, in particular, was that of Ucutayna, discovered in 1713. This was only an incrustation of almost massive silver, which at first yielded several millions, but was soon exhausted.

Others which were deeper, have been alike deserted. Their produce, though equal to what it was originally, was not sufficient to support the expence of working them, which augmented every day. The mines of Quito, Cuzco, and Arequipa, have experienced that revolution which awaits many of the rest.

There are greater numbers of very rich mines which the waters have invaded. The disposition of the ground, which from the summit of the Cordeleras goes continually shelving to the South Sea, must necessarily render these events more common at Peru than in other places. This inconvenience, which with greater care and skill might often have been prevented or diminished, has been in some instances remedied.

Joseph Salcedo, about the year 1660, had discovered, not far from the town of Puna, the mine of Layacota. It was so rich, that they often cut the silver with a chisel. Prosperity had so elevated the mind of the proprietor, that he permitted all the Spaniards who came to seek their fortune in this part of the New World, to work some days on their own account, without weighing or taking any account of the presents he made them. This generosity drew around him an infinite number of people, whose avidity made them quarrel with each other, and the love of money made them take up arms and fall upon one another; and their benefactor, who had neglected no expedient to prevent and extinguish their sanguinary contentions, was hanged as being the author of them. Whilst he was in prison, the water got possession of his mine. Superstition soon made it imagined that this was a punishment for the horrid act they had perpetrated against him. This

idea of divine vengeance was revered for a long time; but at last, in 1740, Diego de Bacna associated with other opulent people, to avert the springs which had deluged so much treasure. The labours which this difficult undertaking required, were not finished till 1754. The mine yields as much now as it did at first. But mines still richer than this have been discovered. Such, for example, is that of Potosí, which was found in the same country where the Incas worked that of Porco.

An Indian, named *Hualpa*, in 1545, pursuing some deer, in order to climb certain steep rocks laid hold of a bush, the roots of which loosened from the earth, and brought to view an ingot of silver. The Indian had recourse to it for his own use; and never failed to return to his treasure every time that his wants or his desires solicited him to it. The change that had happened in his fortune was remarked by one of his countrymen, and he discovered to him the secret. The two friends could not keep their counsel and enjoy their good fortune. They quarrelled; on which the indifereent confidant discovered the whole to his master, Villaroell, a Spaniard who was settled in the neighbourhood. Upon this the mine became known, and was worked; and a great number of them were found in its vicinity; the principal of which are in the northern part of the mountain, and their direction is from north to south. The most intelligent people of Peru have observed, that this is in general the direction of the richest mines.

The fame of what was passing at Potosí soon spread abroad; and there was quickly built at the foot of the mountain, a town consisting of 60,000 Indians, and 10,000 Spaniards. The sterility of the soil did not prevent its being immediately peopled. Corn, fruit, flocks, American stuffs, European luxuries, arrived there from every quarter. Industry, which every where follows the current of money, could not search for it with so much success as at its source. It evidently appeared that in 1738 these mines produced annually near 978,000*l.* without reckoning the silver which was not registered, and what had been carried off by fraud. From that time the produce has been so much diminished, that no more than one-eighth part of the coin which was formerly struck is now made.

The mines of Potosí, and all the mines of South America, in purifying their gold and silver, use mercury, with which they are supplied from Guanaca Velica. The common opinion is, that this mine was discovered in 1564. The trade of mercury was then still free; it became an exclusive trade in 1571. At this period all the mines of mercury were shut; and that of Guanaca Velica alone was worked, the property of which the king reserved to himself. It is not found to diminish. This mine is dug in a prodigiously large mountain, 60 leagues from Lima. In its profound abysses are seen freets, squares, and a chapel, where the mysteries of religion on all festivals are celebrated. Millions of flambeaux are continually kept to enlighten it.

Private people at their own expence work the mine of Guanaca Velica. They are obliged to deliver to government, at a stipulated price, all the mercury they extract from it. As soon as they have procured the quantity which the demands of one year require, the work is suspended. Part of the mercury is sold on

the spot, and the rest is sent to the royal magazines throughout all Peru; from whence it is delivered out at the same price it is sold for in Mexico. This arrangement, which has occasioned many of the mines to drop, and prevented others from being opened, is inexcusable in the Spanish system. The court of Madrid, in this respect, merits the same reproaches as a ministry in other countries would incur, that would be blind enough to lay a duty on the implements of agriculture.

The mine of Guanaca Velica generally affects those who work in it with convulsions: this and the other mines, which are not less unhealthy, are all worked by the Peruvians. These unfortunate victims of an insatiable avarice are crowded all together and plunged naked into these abysses, the greatest part of which are deep, and all excessively cold. Tyranny has invented this refinement in cruelty, to render it impossible for any thing to escape its relentless vigilance. If there are any wretches who long survive such barbarity, it is the use of cocoa that preserves them.

PERUGIA, a town of Italy, in the pope's territories, and capital of Perugia. It is an ancient, handsome, populous, and large city, with a strong citadel, an university, and a bishop's see. The churches, and many other buildings as well public as private, are very handsome. It is seated on a hill, in E. Long. 12. 26. N. Lat. 43. 6.

PERUGINO, a province of Italy, in the territory of the church, bounded on the west by Tuscany, on the south by Orvieto, on the west by the duchies of Spoleto and Urbino, and on the north by the county of Citra Castellana. It is one of the smallest provinces in the territory of the Church. The air is very pure, and the soil fertile in corn and good wine; besides, the lake Perugia supplies them with plenty of fish. The capital town is Perugia. The lake is eight miles from the city, and is almost round, being about five miles in diameter; in it there are three islands. This province is about 25 miles in length, and near as much in breadth.

PERUVIAN BARK. See CINCHONA.

PESARO, a town of Italy, in the territory of the pope, and duchy of Urbino, with a bishop's see. It is a large place, whose streets are paved with bricks. The castle is very well fortified; the harbour excellent, and the cathedral church magnificent. The environs are remarkable for producing good figs, of which they send large quantities to Venice. It is seated on an eminence at the mouth of the river Foglia, on the gulph of Venice. E. Long. 13. 0. N. Lat. 43. 56.

PESCARA, a very strong town in the kingdom of Naples, and in the Hither Abruzzo; seated at the mouth of a river of the same name, which falls into the Gulph of Venice. E. Long. 14. 20. N. Lat. 42. 22.

PESSIERA, a small but strong town of Italy, in the Veronese, with a castle, and a strong fort; seated on the river Mincio, or Menzo, which proceeds from the lake Garda. E. Long. 10. 37. N. Lat. 45. 23.

PESSARY, in medicine, a solid substance composed of wool, lint, or linen, mixed with powder, oil, wax, &c. made round and long like a finger, in order to be introduced into the exterior neck of the matrix.

Pestilence trix, for the cure of several uterine disorders.

PESTILENCE, in medicine, the same with the PLAGUE.

PETAL, in botany, one of the coloured leaves which compose the flower.

PETALISM, in antiquity, a kind of banishment at Syracuse, by writing the person's name on a leaf; whence the name.

PETARD, in the art of war. See GUNNERY, n° 57. and Plate cxti.

PETAU (Denis), or *Dionysus* PETAUVIUS, a French Jesuit of great erudition, born at Orleans in 1583. He entered into the society of Jesuits in 1605; and did no little honour to it by his learning, which he employed in defending the Catholic church, by criticiſing and abuſing its adverſaries. Joſeph Scaliger was the perſon againſt whom he was the moſt inveterate; nor did he ſpare his friend Caſaubon when he came in his way. Petavius excelled particularly in the dark ſcience of chronology, the learned world in general being obliged to him for ſome exact and nice diſquiſitions on this ſubject. His chief work, which is in great repute to this day, he intitled, *Rationarum temporum*. It is an abridgement of univerſal hiſtory, from the earlieſt times to 1632, in chronological order, with references to proper authorities. It was improved, and ſeveral additions made to it, by Perizonius, and others after his death. He died in 1652.

PETECHIE, in medicine, a name given to thoſe ſpots, whether red or of any other colour, which appear in malignant fevers.

PETCHELI, a province of Aſia, in China, and the chief in the whole empire; bounded on the eaſt by the ſea, on the north by the great wall, on the weſt by Chanſi, and on the ſouth by Chantong and Honan. It contains Peking, which is the principal city in the whole empire, and on which 140 towns depend, beſides a vaſt number of villages. The air is temperate, unleſs when the wind blows from the north; and there is a rainy ſeaſon in the latter end of July and the beginning of Auguſt, but it ſeldom rains any other time. The ſoil is fertile, and produces all ſorts of corn; and there are plenty of cattle, pulſe, and fruits. They have alſo mines of pit-coal, which is their only fuel. All the riches of China are brought into this province, particularly to Peking, where the emperor reſides.

PETER, or *Epistles of St PETER*, two canonical books of the New Teſtament written by the apoſtle St Peter, and addreſſed to thoſe Jewiſh converts who were ſcattered throughout Pontus and Galatia, not only upon the perſecution raiſed at Jeruſalem, but upon former diſperſions of the Jews into thoſe places. The firſt of theſe epiſtles is principally deſigned to comfort and confirm them under thoſe fiery trials they were then ſubject to, and to direct them how to behave in the ſeveral ſtates and relations both in the civil and Chriſtian life. In the ſecond epiſtle, the apoſtle proſecutes the ſame ſubject, to prevent their apoſtaſy from the faith, and guard them againſt the corrupt principles of the Gnoſtics, and thoſe who ſcoffed at the promiſe of Chriſt's coming.

PETER (St), one of the apoſtles, was born at Bethſaida in Galilee, and was named *Simon*; but Chriſt having called him to be an apoſtle, changed his name

into that of *Cephas*, which is the ſame with Peter: for as he was fiſhing on the lake of Genazereth with Andrew his brother, the Son of God ordered them to leave their nets and to follow him; and from that time they continued his diſciples. He was a witneſs to our Lord's tranſfiguration on the mount. He was preſent at the laſt ſupper; and was in the garden when the ſoldiers came to ſeize Jeſus, where, being tranſported with zeal, he drew his ſword and cut off the high-prieſt's ſervant's ear. But he ſoon after denied his knowing his Lord; and perſiſted in it three times, till the cock-crowing reminded him of Jeſus's having foretold this inſtance of his weakneſs; on which he ſhewed his repentance by his tears. St Peter was likewiſe a witneſs of Chriſt's reſurrection and aſcenſion, and of the deſcent of the Holy Ghoſt. He afterwards preached the goſpel with great zeal, converted 3000 perſons at his firſt ſermon, and performed many ſurpriſing miracles in proof of his divine miſſion. Some time after, Herod Agrippa cauſed him to be put in priſon at Jeruſalem, whence he was delivered by an angel. Dr Pearſon has proved, that this apoſtle was at Rome, where he met with Philo the Jew, with whom he contracted an intimate acquaintance. When Claudius baniſhed the Jews, he returned to Jeruſalem; and, ſome ſay, travelled thence into Africa, or, according to others, preached in Britain: that toward the latter end of Nero he returned to Rome, where he was crucified, and buried in the Vatican. Conſtantine the Great rebuilt and enlarged the Vatican in honour of St Peter, which at this day is one of the wonders of the world. He wrote two epiſtles, addreſſed to the converted Jews diſperſed throughout Aſia; but the other works attributed to St Peter are ſpurious.

PETER of Blois, a learned man of the 12th century, was born about the year 1120, at the city of Blois in France, from whence he derived his name. His parents being opulent, gave him a learned education. In his youth, when he ſtudied in the univerſity of Paris, he was exceſſively fond of poetry; and when he was a little further advanced in life, he became no leſs fond of rhetoric, to the ſtudy of which he applied with the greateſt ardour. From Paris he removed to Bononia in Italy, to acquire the civil and canon law; in the knowledge of both which he very much excelled. He appears from his writings to have cultivated medicine, and ſeveral branches of the mathematics, with no little care and ſucceſs. The ſtudy of theology was the chief delight and buſineſs of his life, in which he ſpent the greateſt part of his time, and made the greateſt progreſs. But unfortunately it was that ſcholastic theology, which conſiſted in vain attempts to prove and explain the many abſurd opinions which then prevailed in the church, by the ſubtleties of Ariſtotelian logic. In attempting to explain in this manner the moſt abſurd of all opinions that ever exiſted among mankind, he was the very firſt perſon who employed the famous word *transubſtantiation*, which was ſoon after adopted by the church of Rome, and hath ever ſince made too great a noiſe. Being appointed preceptor to William II. king of Sicily in 1167, he obtained the cuſtody of the privy ſeal; and, next to the archbiſhop of Palermo, the prime miniſter, had the greateſt influence in all affairs. But his power was not of long duration: for the archbiſhop being baniſhed in 1168,

Peter.

our author soon after left the court of Sicily, and returned into France. He was not long, however, without a royal patron, being invited into England by Henry II. who employed him as his private secretary, made him archdeacon of Bath, and gave him some other benefices. When he had spent a few years at court, he conceived a disgust at that way of life, (of which he hath drawn a very unpleasing picture in one of his letters), and retired into the family of Richard archbishop of Canterbury, who had made him his chancellor about the year 1176. In this station he continued to the death of the archbishop in 1183, enjoying the highest degree of favour with that prelate, though he used much freedom in reproving him for his remissness in the government of the church. Our author remained in the same station in the family of archbishop Baldwin, who succeeded Richard, acting both as his secretary and chancellor. He was also sent by that prelate on an embassy to Rome in 1187, to plead his cause before Pope Urban III. in the famous controversy between him and the monks of Canterbury about the church of Hackington. After the departure of his friend and patron Baldwin for the Holy Land in 1190, our author was involved in various troubles in his old age, the causes of which are not distinctly known; and died about the end of the 12th century. He appears from his works, which may be justly reckoned among the most valuable monuments of the age in which he flourished, to have been a man of great integrity and sincere piety, as well as of a lively inventive genius and uncommon erudition. His printed works consist of 134 letters, which he collected together at the desire of Henry II.; of 65 sermons, delivered on various occasions; and of 17 tracts on different subjects.

PETER the Hermit. See CRUSADE.

PETER I. justly styled *Peter the Great*, czar, and afterwards emperor, of Russia, founder of the Russian empire; for though the country was well known, and of great antiquity, yet it had no extent of power, of political influence, or of general commerce in Europe, till his time. He was born in 1672; and was proclaimed czar when but ten years of age; in exclusion of John his elder brother, who, being of a sickly constitution, was at the same time very weak in his understanding. The princess Sophia, his half-sister, made an insurrection in favour of John; and to put an end to the civil war, it was at last agreed that the two brothers should jointly share the imperial dignity. Peter had been very ill brought up, not only through the general defects of the Russian education, but likewise through the arts of the princess Sophia, who surrounded him with every thing that might stifle his natural desire of knowledge, deprave his mind, and enervate it with pleasures. Notwithstanding this, his inclination for military exercises discovered itself in his tenderest years. He formed a company of 50 men, commanded by foreign officers, clothed and exercised after the German manner. He entered himself into the lowest post, that of a drummer; and never rose otherwise than as a soldier of fortune. Herein his design was to teach his nobility, that merit, not birth, was the only title to military employments. He reinforced his company with several others, till at last he had got together a considerable body of soldiers. As

he then had no war on his hands, he exercised them in all sorts of mock-engagements, and by this means secured to himself a body of well-disciplined troops. The sight of a Dutch vessel, which he had met with on a lake belonging to one of his pleasure-houses, made such an impression on his mind, that he conceived the almost impracticable design of forming a navy. His first care was to get some Hollanders to build some small vessels at Moscow; and he passed two successive summers on board English or Dutch ships, which set out from Archangel, that he might instruct himself in every branch of naval affairs. In 1696 czar John died, and Peter was now sole master of the empire. In 1698, he sent an embassy to Holland; and went *incognito* in the retinue, and visited England as well as Holland, in order to inform himself fully in the art of ship-building. At Amsterdam he worked in the yard as a private ship carpenter, under the name of *Peter Michaeloff*; but he has been often heard to say, that if he had never gone to England, he had still remained ignorant of that art. In 1700 he had got together a body of standing forces, consisting of 30,000 foot, and now the vast project he had formed displayed itself in all its parts. He opened his dominions, which till then had been shut up, having first sent the chief nobility of his empire into foreign countries to improve themselves in knowledge and learning. He invited into Russia all the foreigners he could meet with, who were capable of instructing his subjects in any manner, and offered them great encouragement to settle in his dominions. This raised many discontents; and the despotic authority he exerted on that occasion was scarcely powerful enough to suppress them. In 1700, being strengthened by the alliance of Augustus king of Poland, he made war on Charles XII. king of Sweden. His first ill success did not deter him: for he used to say, I know that my armies must be overcome for a great while; but even this will at last teach them to conquer. He afterwards gained considerable advantages, and founded Peterburg in 1703. In 1709 he gained a complete victory over the Swedes at Poltava. In 1712, he was inclosed by the Turks on the banks of the Pruth; and seemed inevitably lost, had not the Czarina Catherine bribed the grand vizier, and the czar's prudence completed his deliverance. In 1716, he made a tour through Germany and Holland, and visited the royal academy of sciences at Paris. It would be endless to enumerate all the various establishments for which the Russians are obliged to him: He formed an army according to the manner of the poliest and most experienced nations: he fitted out fleets in all the four seas which border upon Russia: he caused many strong fortresses to be raised after the best plans; and made convenient harbours: he introduced arts and sciences into his dominions, and freed religion from many superstitious abuses: he made laws, built cities, cut canals, &c.; was generous in rewarding, impartial in punishing; faithful, laborious, and humble; yet was not free from a certain roughness of temper natural to his nation. He had indeed cured himself of excess in drinking; but he has been branded with several other vices, particularly cruelty. He published the unfortunate history of his son prince Alexei; towards whom some blame his severity, while others think it no more than was necessary. He perfectly

Peter.

knew

*Peterburg.* knew the honour due to persons of merit; and not only heaped honours upon them during their life, but gave them marks of esteem even after their death. He died of the itragrany in 1725, and left the world with the magnanimity of a hero and the piety of a Christian.

*PETER-PENCE*, and ancient tax of a penny on each house paid to the pope.—It was called *Peter-pence*, because it was collected on the day of St Peter ad vincula, and sent to Rome; whence it was also called *Rome-foot* and *Rome-penny*.

**PETERBOROUGH**, a city of Northamptonshire, with a bishop's see, a market on Saturdays, and two fairs, on July 10. and October 2. for all sort of stock-wrought timber and cheefe. It is seated on the river Nen, over which there is a bridge that leads into Huntingdonshire, in marshy ground. It is not a large place, for it has but one parish-church besides the cathedral; but the market-place is spacious, and the streets are regular. It sends two members to parliament. The cathedral was formerly a monastery; and is a majestic structure, full of curious work, and has a large choir. W. Lon. 0. 15. N. lat. 52. 33.

**PETERSBURG**, a city of the province of Ingria in Russia, and capital of the whole empire, situated in E. Long. 30. 23. N. Lat. 54. 56. It was founded in the year 1703 by Czar Peter the Great, whose ambition it was to have a fleet on the Baltic; for which reason he determined to found a city which might become the centre of trade throughout all his dominions. The spot he pitched upon was a low, fenny, uncultivated island, formed by the branches of the river Nieva, before they fall into the gulph of Finland. In the summer this island was covered with mud; and in winter became a frozen pool, rendered almost inaccessible by dreary forests and deep morasses, the haunts of bears, wolves, and other savage animals. Having taken the fort of Nattenbourg, and the town of Neischanz, in the year 1703, this mighty conqueror assembled in Ingria above 300,000 men, Russians, Tartars, Cossacks, Livonians, and others, even from the most distant parts of his empire, and laid the foundation of the citadel and fortifications, which were finished in four months, almost in despite of nature. He was obliged to open ways through forests, drain bogs, raise dykes, and lay causeways, before he could pretend to found the new city. The workmen were ill provided with necessary tools and implements, such as spades, pick-axes, shovels, planks, and wheel-barrows: they were even obliged to fetch the earth from a great distance in the skirts of their garments, or in little bags made of old mats and rags sewed together. The had neither huts nor houses to shelter them from the severity of the weather: the country, which had been desolated by war, could not accommodate such a multitude with provisions; and the supplies by the lake Ladoga were often retarded by contrary winds. In consequence of these hardships, above 100,000 men are said to have perished: nevertheless the work proceeded with incredible vigour and expedition; while Peter, for the fecurity of his workmen, formed a great camp, in such a manner, that his infantry continued in Finland, and his cavalry were quartered in Ingria. Some Swedish cruisers being desiered in the neighbourhood, the Czar posted a body of troops in the isle

of Rutzark, by whom the Swedes were repulsed, and *Petersburg.* the work met with no farther interruption. The buildings of the city kept pace with the fortrefs, which is the centre of the town, surrounded on all sides by the Nieva; and, in little more than a year, above 30,000 houses were erected. At present there may be about double that number in Petersburg, tho' many of them are paultry and inconsiderable. In order to people this city, Peter invited hither merchants, artificers, mechanics, and seamen, from all the different countries of Europe: he demolished the town of Nieuſchants, and brought hither not only the materials of the houses, but the inhabitants themselves. A thousand families were drawn from Moscow; he obliged his nobility to quit their palaces and their villas in and about Moscow, and take up their residence at Petersburg, in a much more cold and comfortable climate. Finally, resolving to remove hither the trade of Archangel, he issued an ordonnance, importing, That all such merchandise as had been conveyed to Archangel, in order to be sold to foreigners, should now be sent to Petersburg, where they should pay no more than the usual duties. These endeavours and regulations have rendered this one of the greatest and most flourishing cities in Europe. The Russian boyars and nobility have built magnificent palaces, and are now reconciled to their situation. At first many houses were built of timber; but these being subject to sudden conflagrations in spite of all the precautions that could be taken, the Czar, in the year 1714, issued an order, that all new houses should be walled with brick and covered with tiles. The fort is an irregular hexagon, with opposite bastions. This, together with all the rest of the fortifications, was in the beginning formed of earth only; but in the sequel they were faced with strong walls, and provided with casemates, which are bomb-proof. In the curtain of the fort, on the right-hand side, is a noble dispensary, well supplied with excellent medicines, and enriched with a great number of porcelain vases from China and Japan. From one of gates of the fort a draw-bridge is thrown over an arm of the river, in which the Czar's galleys and other small vessels are sheltered in the winter. The most remarkable building within the fort is the cathedral, built by the direction of an Italian architect. Petersburg is partly built on little islands, some of which are connected by draw-bridges; and partly on the continent. In the highest part, on the bank of the Nieva, the Czar fixed his habitation, or ordinary residence, built of free-stone, and situated so as to command a prospect of the greater part of the city. Here likewise is a royal foundery; together with the superb houses of many noblemen. The marshy ground on which the city is built, being found extremely slippery, dirty, and incommodious, the Czar ordered every inhabitant to pave a certain space before his own door. In the year 1716, Peter, taking a fancy to the island Wasil-Otkerno, which he had given as a present to prince Menzikoff, refused the grant, and ordered the city to be extended into this quarter. He even obliged the boyars, or nobles, to build stone houses on this spot, though they were already in possession of others on the side of Ingria: accordingly this is now the most magnificent part of the city. On the other side of a branch of the Nieva

stands

Petersburg. stands the Czar's country or summer palace, provided with a fine garden and orangery. On the bank of the same river is the slaboda, or suburbs, in which the Germans generally choose their habitation. Petersburg is very much subject to dangerous inundations. In the year 1715, all the bastions and draw-bridges were either overwhelmed, or carried away. The breadth, depth, and rapidity of the Nieva, have rendered it extremely difficult, if not impracticable, to join the islands and the continent by bridges. Besides, Peter was averse to this expedient for another reason: resolved to accustom his subjects to navigation, he not only rejected the project of a bridge; but also ordered, that no boat should pass between the islands and continent, except by the help of sails only. In consequence of this strange regulation, many lives were lost: but at length he gained his point; and by habituating his sluggish Muscovites to the dangers of the sea, in a little time produced a breed of hardy sailors. The adjacent country is so barren, that the town must be supplied with provisions from a great distance; consequently they are extremely dear. Here are woods in plenty, consisting of pine, fir, alder, birch, poplar, and elm; but the oak and the beech are generally brought from Casan. In winter the weather is extremely cold, and hot in the summer. In June the length of the night does not exceed three hours, during which the natives enjoy a continued twilight: but in December the sun is not visible more than three hours above the horizon.

The Czar Peter, who was indefatigable in his endeavours to improve and civilize his subjects, neglected nothing which he thought could contribute to these purposes. He condescended even to institute and regulate assemblies at Petersburg: these were opened at five in the afternoon, and the house was shut at ten: between these hours the fashionable people of both sexes met without ceremony, danced, conversed, or played either at cards or at chefs, this last being a favourite diversion among the Russians. There was likewise an apartment set apart for drinking brandy and smoking tobacco. Plays and operas were likewise introduced for the same purposes; but as Peter had little relish, and less taste, for those entertainments, they were performed in a very awkward manner in his life-time: however, since his death, these performances have been brought to a greater degree of art and decorum.

This great northern legislator established, in the neighbourhood of Petersburg, manufactures of linen, paper, saltpetre, sulphur, gun-powder, and bricks, together with water-mills for sawing timber. He instituted a marine academy, and obliged every considerable family in Russia to send at least one son or kinsman, between the ages of ten and eighteen, to this seminary, where he was instructed in navigation, learned the languages, was taught to perform his exercises, and to live under the severest discipline. To crown his other plans of reformation, he granted letters-patent for founding an academy, upon a very liberal endowment; and though he did not live to execute this scheme, his empress, who survived him, brought it to perfection. It was modelled on the plans of the royal society in London, and the academy of France. Mr Bullinger opened it in the year 1726,

with an eloquent speech on the design and utility of an academy of sciences; and the professors, who have always distinguished themselves by their merit and erudition, published an annual collection of their transactions: a task the more easy, as they have the benefit of printing presses, well managed, at Petersburg.

PETERSFIELD, a handsome town of Hampshire in England, sending two members to parliament. It is seated in W. Long. 1. 5. N. Lat. 51. 5.

PETERWARADIN, a fortified town in Sclavonia, and one of the strongest frontier places the house of Austria has against the Turks, seated on the Danube between the Drave and the Save. E. Long. 20. 0. N. Lat. 45. 20.

PETIOLE, in botany, the slender stalks that support the leaves of a plant.

PETIT, or PETITE, a French word signifying little or small.

PETITE Guerre, denotes the operations of detached parties, and the war of posts. See WAR, Part III.

PETIT Sergeanty. See SERGEANTY.

PETIT Treason. See TREASON.

PETIT (John Lewis), an eminent surgeon, born at Paris in 1674. He had so early an inclination to surgery, that Mr Littre, a celebrated anatomist, being in his father's house, he regularly attended that gentleman's lectures, from his being seven years of age. He was received master in surgery in the year 1700; and acquired such reputation in the practice of that art, that in 1726 the king of Poland sent for him to his court, and in 1734 the king of Spain prevailed on him to go into that kingdom. He restored the health of those princes; and they endeavoured to detain him by offering him great advantages, but he chose rather to return to France. He was received into the academy of sciences in 1715; became director of the royal academy of surgery; made several important discoveries; and invented new instruments for the improvement of surgery. He died at Paris in 1750. He wrote an excellent Treatise on the Diseases of the Bones, the best edition of which is that of 1723; and many learned Dissertations in the Memoirs of the Academy of Sciences, and in the first volume of the Memoirs of Surgery.

PETITIO PRINCIPII, in logic, the taking a thing for true, and drawing conclusions from it as such, when it is really false, or at least wants to be proved before any inferences can be drawn from it.

PETITION, a supplication made by an inferior to a superior, and especially to one having jurisdiction. It is used for that remedy which the subject hath to help a wrong done by the king, who hath a prerogative not to be sued by writ: In which sense it is either general, That the king do him right; whereupon follows a general indorsement upon the same, *Let right be done the party*: Or it is special, when the conclusion and indorsement are special, for this or that to be done, &c.

By statute, the soliciting, labouring, or procuring the putting the hands or consent of above twenty persons to any petition to the king or either house of parliament, for alterations in church or state, unless by assent of three or more justices of peace of the county, or a majority of the grand jury at the assizes or sessions, &c. and repairing to the king or parliament

Petersfield  
Petition.

Petitory,  
Petitot.

ment to deliver such petition with above the number of ten persons, is subject to a fine of 100 l. and three months imprisonment, being proved by two witnesses, within six months, in the court of B. R. or at the assizes, &c. And if what is required by this statute be observed, care must be taken that petitions to the king contain nothing which may be interpreted to reflect on the administration; for if they do, it may come under the denomination of a libel: and it is remarkable, that the petition of the city of London for the fitting of a parliament was deemed libellous, because it suggested that the king's dissolving a late parliament was an obstruction of justice; also the petition of the seven bishops, sent to the Tower by James II. was called a libel, &c. To subscribe a petition to the king, to frighten him into a change of his measures, intimating, that if it be denied many thousands of his subjects will be discontented, &c. is included among the contempts against the king's person and government; tending to weaken the same, and is punishable by fine and imprisonment.

PETITORY ACTION, in Scots law. See LAW, N° clxxxiii. 18. 20.

PETITOT (John), a curious painter in enamel, born at Geneva in 1607. He studied the art with such application, that he arrived to a degree of perfection that may almost be accounted inimitable. He was wonderfully patient in finishing his works, though he had the address to conceal his labour: however, he only painted the heads and hands of the figures; the hair, grounds, and drapery, being executed by Bordier his brother-in-law. These two artists had the credit of associating and labouring together for fifty years, without the least misunderstanding happening between them. It is asserted by an ingenious French writer, that Petitot and Bordier derived the knowledge of the most curious and durable colours proper for enamelling, from Sir Theodore Mayerne at London, who recommended Petitot to Charles I. He had the honour to paint the portraits of that monarch and the whole royal family, and continued in England until Charles's unhappy end: he then went to Paris, where he was highly favoured by Lewis XIV. and acquired an ample fortune. Being a Protestant, the revocation of the edict of Nantz obliged him to retire to Geneva; but settling soon after at Veray in the canton of Bern, he passed the remainder of his life in ease and affluence. He died in 1691; and had 17 children: of whom one took to painting, and settled at London, where he gained good reputation; but was much inferior to his father.

Petitot may be called the inventor of painting portraits in enamel. Though his friend Bordier made several attempts before him, and Sir Theodore Mayerne had facilitated the means of employing the most beautiful colours; yet Petitot completed the works, which under his hand acquired a softness and liveliness of colouring that will never change, and will ever render his works valuable. He made use of gold and silver plates, and seldom enamelled on copper. When he first came in vogue, his price was 20 louis's a head, which he soon raised to 40. It was his custom to take a painter with him, who painted the picture in oil; after which Petitot sketched out his work, which he always finished after the life. When he painted

the king of France, he took those pictures for his copies that most resembled him; and the king afterwards gave him a sitting or two to finish his work.

PETRA, (Cæsar, Lucian), a town of Greece on the coast of Illyricum, near Dyrrhachium, and not far from the mouth of the river Panyassus.—Another PETRA, (Livy); a town of Mædica, a district of Thrace, lying towards Macedonia; but in what part of Macedonia, he does not say.

PETRA, (Ptolemy), *Petræa* (Silius Italicus), *Petrina* (Italicus), in both which last *urbs* is understood; an inland town of Sicily, to the south-west of Engyum. Now *Petraglia*, (Cluverius).

PETRA *Jektael*, (2 Kings xiv.), a town of the Amalekites; near the Adscensus Scorpionis (Judg. i.) and the Valley of Salt in the south of Judea: afterwards in the possession of the Edomites, after destroying the Amalekites.

PETRA *Rekem*, or *Rekem*, so called from Rekem king of the Midianites, slain by the Israelites, (Num. xxxi.) Formerly called *Arce*, now *Petra*; the capital of Arabia *Petræa*, (Josephus). Ptolemy places it in Long. 66. 45. from the Fortunate Islands, and Lat. 30. 20. It declines therefore 80 miles to the south of the parallel of Jerusalem, and 36 miles, more or less, from its meridian to the east. Josephus says, that the mountain on which Aaron died stood near Petra; which Sirabo calls the capital of the Nabatæi; at the distance of three or four days journey from Jericho. This Petra seems to be the Sela of Isaiah xvi. 1. and xlii. 11. the Hebrew name of Petra "a rock." Though some imagine Petra to be no older than the time of the Macedonians.

PETRARCH (Francis), a celebrated Italian poet, was born at Arezzo in 1304, and was the son of Petracco di Parenzo. He studied grammar, rhetoric, and philosophy, for four years at Carpentras; from whence he went to Montpellier, where he studied the law under John Andreas and Cino di Pistoia, and probably from the latter received a taste for Italian poetry. As Petrarch only studied the law out of complaisance to his father, who on his visiting him at Bologna had thrown into the fire all the Latin poets and orators except Virgil and Cicero, he, at 22 years of age, hearing that his father and mother were dead of the plague at Avignon, returned to that city to settle his domestic affairs, and purchased a country-house in a very solitary but agreeable situation, called *Vaucluse*; where he first knew the beautiful Laura, with whom he fell in love, and whom he has immortalised in his poems. He at length travelled into France, the Netherlands, and Germany; and at his return to Avignon entered into the service of Pope John XXII. who employed him in several important affairs. Petrarch was in hopes of being raised to some considerable posts: but being disappointed, he applied himself entirely to poetry; in which he met with such applause, that in one and the same day he received letters from Rome and the chancellor of the university of Paris, by which they invited him to receive the poetic crown. By the advice of his friends, he preferred Rome to Paris, and received that crown from the senate and people on the 8th of April 1341. His love of solitude at length induced him to return to Vaucluse; but, after the death of the beau-

Petra,  
Petrarch.

Petre  
Petrification

tiful Laura, Provence became insupportable to him, and he returned to Italy in 1352; when, being at Milan, Galeas Viceconti made him counsellor of state. Petrarch spent almost all the rest of his life in travelling to and from the different cities in Italy. He was archdeacon of Parma, and canon of Padua; but never received the order of priesthood. All the princes and great men of his time gave him public marks of their esteem; and while he lived at Arcqua, three miles from Padua, the Florentines deputed Boccaccio to go to him with letters, by which they invited him to Florence, and informed him, that they restored to him all the estate of which his father and mother had been deprived during the dissensions between the Guelphs and Ghibelins. He died a few years after at Arcqua, in 1374. He wrote many works that have rendered his memory immortal; these have been printed in four volumes folio. His life has been written by several authors.

PETRE, or SALT-PETRE, in chemistry. See NITRE.

PETREA, in botany, a genus of the angiospermia order belonging to the didynamia class of plants. There is only one species, a native of New Spain. It rises to the height of 15 or 16 feet, with a woody stalk covered with grey bark, sending out several long branches. These have a whiter bark than the stem, and are garnished with leaves at each joint, which, on the lower part of the branches, are placed by threes round them; but, higher up, they are rough, and have a rough surface. The flowers are produced at the ends of the branches, in loose bunches nine or ten inches long, each flower standing on a slender flower-stalk about an inch long: the empalement of the flower is composed of five narrow obtuse leaves about an inch long, which are of a fine blue colour, and much more conspicuous than the petals, which are white, and not more than half the length of the empalement. The plant is propagated by seeds procured from the places where they are natives, and of which very few are good; for though Dr Houlston, the discoverer of the plant, sent parcels of seeds to several persons in England, only two plants were produced from the whole. The seeds must be sown in a good hot-bed; and when the plants come up, they should all be planted in a separate small pot filled with light loamy earth, and plunged into a hot-bed of tanners bark, where they should afterwards constantly remain.

PETREL, in ornithology. See PROCELLARIA.

PETRIDIA, in natural history, a genus of scrupi, of a plain, uniform texture; of no great variety of colours, and emulating the external form of pebbles.

PETRIFICATION, in physiology, denotes the conversion of wood, bones, and other substances, into stone.

The fossil bodies found petrified are principally either of vegetable or animal origin; and are more or less altered from their original state, according to the different substances they have lain buried among in the earth; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone or lumps of the matter of the common pyrites; but they are generally of the external dimensions, and retain more or less of

the internal figure, of the bodies into the pores of which this matter has made its way.

The animal-substances thus found petrified are shells; the teeth, bony palates, and bones, of fish; the bones of land-animals, &c. These are found variously altered, by the insinuation of stony and mineral matter into their pores; and the substance of some of them is now wholly gone, there being only stony, sparry, or other mineral matter remaining in the shape and form.

As to the manner in which petrification is accomplished, we know very little. It has been thought by many philosophers, that this was one of the rare processes of nature; and accordingly such places as afforded a view of it, have been looked upon as great curiosities. However, it is now discovered, that petrification is exceedingly common; and that every kind of water carries in it some earthy particles, which being precipitated from it, become stone of a greater or lesser degree of hardness; and this quality is most remarkable in those waters which are much impregnated with selenitic matter. Of late, it has also been found by some observations on a petrification in East Lothian in Scotland, that iron contributes greatly to the process: and this it may do by its precipitation of any aluminous earth which happens to be dissolved in the water by means of an acid; for iron has the property of precipitating this earth, though it cannot precipitate the calcareous kind. The calcareous kinds of earth, however, by being soluble in water without any acid, must contribute very much to the process of petrification, as they are capable of a great degree of hardness by means only of being joined with fixed air, on which depends the solidity of our common cement or mortar used in building houses. See the articles CEMENT and MORTAR. See also SAND, SELENITES, ROCK, STONE, and WATER.

PETROBRUSSIANS, in church-history, a religious sect which arose in France and the Netherlands about the year 1126, so called from their leader Peter Bruys. They denied, that children, before the use of reason, can be justified by baptism. They also condemned all places of public worship, crosses, &c. and are said to have rejected the sacrament of the eucharist, and prayers for the dead.

PETROLEUM, or ROCK-OIL, is an extremely subtle and penetrating fluid, and is much the thinnest of all the native bitumens. It is very light and very pellucid; but though equally bright and clear under all circumstances, it is liable to a very great variety in its colour. It is naturally almost colourless, and in its appearance greatly resembles the most pure oil of turpentine: this is called *white petroleum*, though it has no more colour than water. It is sometimes tinged of a brownish, reddish, yellowish, or faint greenish colour; but its most frequent colour is a mixture of the reddish and blackish, in such a degree that it looks black when viewed behind the light, but purple when placed between the eye and a candle or window. It is of a pungent and acrid taste; and of a very strong and penetrating smell, which very much approaches to that of the distilled oil of amber. The white is most esteemed. It is so very inflammable, that while it floats on the surface of the water, as it does in many parts of Italy, it takes fire at the approach of a candle.

Petroleum is found in rivers, in wells, and trickling down

Petrobrus-  
sians,  
Petroleum.

Vide Phil.  
Trans. v. 69.  
part. i. p. 35.

**Petroleum.** down the sides of hills along with little streams of water. It short, it is the most frequent of all the liquid bitumens, and is perhaps the most valuable of them all in medicine. It is to be chosen the purest, lightest, and most pellucid that can be had, such as is of the most penetrating smell and is most inflammable.

It is principally used externally, in paralytic cases, and in pains of the limbs.

Mr Bouldoc made several experiments with the white petroleum of Modena, an account of which he gave to the Paris academy.

It easily took fire on being brought near a candle, and that without immediately touching the flame; and when heated in any vessel, it will attract the flame of a candle, though placed at a great height above the vessel, and the vapour it sends up taking fire, the flame will be communicated to the vessel of heated liquor, and the whole will be consumed. It burns in the water; and when mixed with any liquor swims on the surface of it, even of the highest rectified spirit of wine, which is  $\frac{1}{2}$  heavier than pure petroleum. It readily mixes with all the essential oils of vegetables, as oil of lavender, turpentine, and the rest, and seems very much of their nature: nor is this very strange, since the alliance between these bodies is probably nearer than is imagined, as the essential oils of vegetables may have been originally mineral ones, and drawn up out of the earth into the vessels of the plants.

Petroleum, when shaken, yields a few bubbles; but they sooner subside than in almost any other liquor, and the liquor resumes its clear state again almost immediately. This seems owing to the air in this fluid being very equally distributed to all its parts, and the liquor being composed of particles very evenly and nicely arranged.

This extensibility of the oil is also amazing. A drop of it will spread over several feet of water, and in this condition it gives a great variety of colours; that is, the several parts of which this thin film is composed, act as so many prisms. The most severe frost never congeals petroleum into ice; and paper wetted with it becomes transparent, as when wetted with oil; but it does not continue so, the paper becoming opaque again in a few minutes, as the oil dries away.

Spirit of wine, which is the great dissolvent of sulphur, has no effect upon petroleum, not even with ever so long a digestion. It will not take fire with the dephlegmated acid spirits; as oil of cloves, and other of the vegetable essential oils do: and in distillation, either by balneum mariæ, or in sand, it will neither yield phlegm nor acid spirit; but the oil itself rises in its own form, leaving in the retort only a little matter, thick as honey, and of a brownish colour.

Alonso Barba, in his book of metals, gives a very melancholy instance of the power of petroleum of taking fire at a distance: he tells us, that a certain well, yielding petroleum on the surface of its water, being to be repaired, the workman took down into the well with him a lantern and a candle in it; there were some holes in the lantern, through which the petroleum at a considerable distance sucked out the flame of the candle, and, taking fire, burst up with the noise of a cannon, and tore the man to pieces.

The people of mount Ciario, in Italy, have some years since found out a much easier way of finding petro-

leum than that which they formerly had been used to. This mountain abounds with a sort of greyish salt, which lies in large horizontal beds, mingled with strata of clay, and large quantities of a spar of that kind called by the Germans *selenites*; which is the common sort, that ferments with acids, and readily dissolves in them, and calcines in a small fire. They pierce these slates in a perpendicular direction till they find water; and the petroleum which had been dispersed among the cracks of those slates, is then washed out by the water, and brought from all the neighbouring places to the hole or well which they have dug, on the surface of the water of which it swims after eight or ten days. When there is enough of it got together, they lade it from the top of the water with bras basons, and it is then easily separated from what little water is taken up with it. These wells or holes continue to furnish the oil in different quantities for a considerable time; and when they will yield no more, they pierce the slates in some other place.

Petroleum is never used among us; but the French give it internally in hysterical complaints, and to their children for worms: some also give it from 10 to 15 drops in wine, for suppressions of the menses. This, however, is rather the practice of the common people than of the faculty.

**PETROMYZON**, the **LAMPREY**, a genus of fishes belonging to the class of amphibia nantes. It has seven spiracula at the side of the neck, no gills, a fistula on the top of the head, and no breast or belly fins. There are three species, distinguished by peculiarities in their back-fins. There are three species.

1. The marinus, or sea-lamprey, is sometimes found so large as to weigh four or five pounds. The mouth is round, and placed rather obliquely below the end of the nose: the edges are jagged, which enables them to adhere the more strongly to the stones, as their custom is, and which they do so firmly as not to be drawn off without some difficulty. Mr Pennant mentions one weighing three pounds, which was taken out of the Esk, adhering to a stone of 12 pounds weight, suspended at its mouth, from which it was forced with no small pains. There are in the mouth 20 rows of small teeth, disposed in circular orders, and placed far within. The colour is dusky, irregularly marked with dirty yellow, which gives the fish a disagreeable look.

Lampreys are found at certain seasons of the year in several of our rivers, but the Severn is the most noted for them. They are sea-fish; but, like salmon, quit the salt waters, and ascend the latter end of the winter, or beginning of spring, and after a stay of a few months return again to the ocean, a very few excepted. The best season for them is in the months of March, April, and May; for they are more firm when just arrived out of the salt water than they are afterwards, being observed to be much wasted, and very flabby at the approach of hot weather. They are taken in nets along with salmon and shad, and sometimes in weels laid in the bottom of the river. It has been an old custom for the city of Gloucester, annually, to present his majesty with a lamprey pike, covered with a large railed crust. As the gift is made at Christmas, it is with great difficulty the corporation can procure any fresh lampreys at that time, though they give a guinea a-piece for them, so early

**Petromy-** in the season. They are reckoned a great delicacy, either when potted or stewed; but are a surfeiting food, as one of our monarchs fatally experienced, Henry I.'s death being occasioned by a too plentiful meal of these fish. It appears, that, notwithstanding this accident, they continued in high esteem; for Henry IV. granted protections to such ships as brought over lampreys for the table of his royal consort.

Mr Pennant is of opinion, that the ancients were unacquainted with this fish; at least, he says, it is certain, that which Dr Arbuthnot and other learned men render the word *lamprey*, is a species unknown in our seas, being the *muræna* of Ovid, Pliny, and others, for which we want an English name. This fish, the *lupus* (our bass), and the *myxo* (a species of mullet), formed that pride of Roman banquets, the *tripatinum*, so called, according to Arbuthnot, from their being served up in a machine with three bottoms. The words *lampetra* and *petromyzon* are but of modern date, invented from the nature of the fish; the first à *lambendo petras*, the other from *πτερος* and *μυσα*, because they are supposed to lick or suck the rocks.

2. The fluviatilis, or lesser lamprey, sometimes grows to the length of 10 inches. The mouth is formed like that of the preceding. On the upper part is a large bifurcated tooth: on each side are three rows of very minute ones: on the lower part are seven teeth, the exterior of which on one side is the largest. The irides are yellow. As in all the other species, between the eyes, on the top of the head, is a small orifice of great use to clear its mouth of the water that remains on adhering to the stones, for through that orifice it ejects the water in the same manner as cetaceous fish. On the lower part of the back is a narrow fin, beneath that rises another, which at the beginning is high and angular, then grows narrow, surrounds the tail, and ends near the anus. The colour of the back is brown or dusky, and sometimes mixed with blue; the whole under-side silvery. These are found in the Thames, Severn, and Dee, are potted with the larger kind, and are by some preferred to it, as being milder tasted. Vast quantities are taken about Mortlake, and sold to the Dutch for bait for their cod-fishery. Above 430,000 have been sold in a season at 40s. per 1000. Of late, about 100,000 have been sent to Harwich for the same purpose. It is said that the Dutch have the secret of preserving them till the turbot fishery.

3. The bronchialis, or lampren, is sometimes found of the length of eight inches, and about the thickness of a swan's quill; but they are generally much smaller. The body is marked with numbers of transverse lines, that pass cross the sides from the back to the bottom of the belly, which is divided from the mouth to the anus by a frail line. The back fin is not angular like that of the former, but of an equal breadth. The tail is lanceolated, and short at the end. They are frequent in the rivers near Oxford, particularly the Isis; but not peculiar to that county, being found in others of the English rivers, where, instead of concealing themselves under the stones, they lodge themselves in the mud, and never are observed to adhere to any thing like other lampreys.

**PETRONIUS ARBITER** (Titus), a great critic and polite writer of antiquity, the favourite of Nero, sup-

posed to be the same mentioned by Tacitus in the 16th book of his Annals. He was proconsul of Bithynia, and afterwards consul, and appeared capable of the greatest employments. He was, nevertheless, extremely voluptuous; for he spent the greatest part of the day in sleep, and the night in pleasure and buffets. He was one of Nero's principal confidants, and in a manner the superintendent of his pleasures; for that prince thought nothing agreeable or delightful but what was approved by Petronius. The great favour shewn him drew upon him the envy of Tigellinus, another of Nero's favourites, who accused him of being concerned in a conspiracy against the emperor; on which Petronius was seized, and being sentenced to die, he from time to time caused his veins to be opened and closed again, entertaining himself the while in discoursing on poetry with his friends. He afterwards sent to Nero a book sealed up with his own hand, in which he described the debaucheries of that prince under borrowed names, and died in the year 65 or 66. There are still extant a satire, and some other of his pieces, well written in Latin, but filled with indecencies; which occasioned Petronius's being called *Autor purissima impuritatis*. There was found in the last century a fragment of his works at Traou, in Dalmatia. It is a folio manuscript two fingers thick, in which is contained Trimalcio's supper; it made much noise among the learned, and occasioned many disputes for and against its authenticity.

**PETROSA** ossa, in anatomy, a name given to the fourth and fifth bones of the cranium, called also *ossa temporum*, and *ossa squamosa*; the substance whereof, as their first and last names express, is squamous and very hard.

**PETTY** (Sir William), son of Anthony Petty a clothier, was born at Rumsey, a little haven-town in Hampshire, in 1623; and while a boy took great delight in spending his time among the artificers there, whose trades he could work at when but twelve years of age. Then he went to the grammar-school there: at 15, he was master of the Latin, Greek, and French tongues, and of arithmetic and those parts of practical geometry and astronomy useful to navigation. Soon after, he went to Caen in Normandy, and Paris, where he studied anatomy, and read Vesalius with Mr Hobbes. Upon his return to England, he was preferred in the king's navy. In 1643, when the war between the king and parliament grew hot, he went into the Netherlands and France for three years; and having vigorously prosecuted his studies, especially in physic, at Utrecht, Leyden, Amsterdam, and Paris, he returned home to Rumsey. In 1647, he obtained a patent to teach the art of double-writing for seven years. In 1648, he published at London "Advice to Mr Samuel Hartlib, for the advancement of some particular parts of learning." At this time he adhered to the prevailing party of the kingdom; and went to Oxford, where he taught anatomy and chemistry, and was created a doctor of physic. In 1650, he was made professor of anatomy there; and soon after, a member of the college of physicians in London. The same year he became physician to the army in Ireland; where he continued till 1659, and acquired a great fortune. After the Restoration he was introduced to king Charles II. who knighted him in 1661.

In.

**Petrosa,**  
**Petty.**

Petty  
Pearson.

In 1662, he published "A treatise of taxes and contributions." Next year he was greatly applauded in Ireland for his invention of a double-bottomed ship. He died at London of a gangrene in the foot, occasioned by the swelling of the gout, in 1687. Besides the works above-mentioned, he wrote a vast many others.

PETTY, any thing little or diminutive, when compared with another.

PETTY-Bag, an office in chancery; the three clerks of which record the return of all inquisitions out of every county, and make all patents of comptrollers, gaugers, customers, &c.

PETTY-Fogger, a little tricking solicitor or attorney, without either skill or conscience.

PETTY, or *Petit*, Larceny. See LARCENY.

PETTY-Pateer, among confectioners, a sort of small pies, made of a rich crust filled with sweet-meats.

PETTY-Singles, among falconers, are the toes of a hawk.

PETTY-Tally, in the sea-language, a competent allowance of victuals, according to the number of the ship's company.

PETTY, or *Petit*, Treason. See TREASON.

PETUNSE, in natural history, one of the two substances whereof porcelain or china-ware is made. The petunse is a coarse kind of flint or pebble, the surface of which is not so smooth when broken as that of our common flint. See PORCELAIN.

PEUCEDANUM, or SULPHUR-WORT; a genus of the digynia order, belonging to the pentandria class of plants. There are three species; none of which have any remarkable properties excepting the officinale, or common hogs-fennel, growing naturally in the English salt-marshes. This rises to the height of two feet, with channelled stalks, which divide into two or three branches, each crowned with an umbel of yellow flowers, composed of several small circular umbels. The roots, when bruised, have a strong fetid scent like sulphur, and an acrid, bitterish, unctuous taste. Wounded in the spring, they yield a considerable quantity of yellow juice, which dries into a gummy resin, and retains the strong smell of the root. This should seem to be possessed of some medicinal virtues, but they have never been ascertained with any precision. The expressed juice was used by the ancients in lethargic disorders.

PEWIT, SEA-CROW, or *Mire-crow*, in ornithology. See LARUS.

PEWTER, a facitious metal used in making domestic utensils, as plates, dishes, &c.—The basis of the metal is tin; which is converted into pewter, by mixing at the rate of an hundred weight of tin with 15 pounds of lead and six pounds of brass.—Besides this composition, which makes the common pewter, there are other kinds, compounded of tin, regulus of antimony, bismuth, and copper, in several proportions.

PEZRON (Paul), a very learned and ingenious Frenchman, born at Hennebion in Britany in 1639, and admitted into the order of Cîteaux in 1660. He was a great antiquary, and was indefatigable in tracing the origin of the language of the Goths; the result of which was, that he was led to espouse a system of the world's being much more antient than modern chronologers have supposed. This he communicated

to the public in a treatise printed at Paris in 1687, 4to. intitled *The antiquity of Time, restored and defended against the Jews and modern chronologers*. This book of Pezron's was extremely admired for the ingenuity and learning in it; yet caused no small alarm among the religious, against whom he nevertheless defended his opinions. He went through several promotions, the last of which was the abbey of Charmoye, to which he was nominated by the king; and died in 1706.

PHÆACIA, one of the names of the island Corcyra, (Homer, Stephanus). *Phæaces* the people, (Ovid), noted for their indolence and luxury: hence Horace uses *Phæax* for a person indolent and sleek; and hence arose their indolence and pride, (Aristotle). The island was famous for producing large quantities of the finest flavoured apples, (Ovid, Juvenal, Propertius).

PHÆDRUS, an ancient Latin writer, who composed five books of fables, in Iambic verse. He was a Thracian; and was born, as there is reason to conclude, some years before Julius Cæsar made himself master of the Roman empire. How he came into the service of Augustus is not known; but his being called *Augustus's freedman* in the title of the book, shows that he had been that emperor's slave. The fables of Phædrus are valued for their wit and good sense, expressed in very pure and elegant language; and it is remarkable that they remained buried in libraries altogether unknown to the public, until they were discovered and published by Peter Pithou, or Pitheus, a learned French gentleman, toward the close of the 16th century.

PHÆNOMENON, in philosophy, denotes any remarkable appearance, whether in the heavens or earth, and whether discovered by observation or experiment.

PHAETON, in fabulous history, was the son of Apollo and of the nymph Clymene. He had a dispute with Epaphus, the son of Jupiter and Io; when the latter, upbraiding him, said, that he was not the son of Phœbus, but that his mother artfully made use of that pretence to cover her infamy. Phaeton, fired at this reproach, flew to his mother, and by her advice carried his complaint to Apollo, who received him with great tenderness, and swore by Styx to grant whatever he requested, as a proof of his acknowledging him for his son. The youth boldly asked the direction of the chariot of the sun for one day. His father, grieved and surprized at this demand, used all his arguments to dissuade him from the rash attempt; but all was in vain, and, being by his oath reduced to submit to his obstinacy, entrusted him with the reins, after he had directed him how to use them. The young adventurer was however soon sensible of his madness. He was unable to guide the fiery steeds; and loosing the reins, Jupiter, to prevent his consuming the heavens and earth, struck him with a thunder-bolt, and hurled him from his seat into the river Eridanus or Po. His sisters Phaethusa, Lamætia, and Phæbe, lamenting his loss upon its banks, were changed by the gods into black poplar trees; and Cycnus, king of Liguria, also grieving at his fate, was transformed into a swan.

PHAGEDÆNA, in medicine, denotes a corroding ulcer.

PHAGEDENIC MEDICINES, those used to eat off proud

Phæacia  
Phagedenic.

*Phalæna* proud or fungous flesh; such as are all the caustics.  
*Phalaris*.

**PHALÆNA**, the Μοῖνη, in zoology, a genus of insects belonging to the order of lepidoptera. The feelers are fetaceous, and taper gradually towards the points; the wings are often bent backwards; and there are no less than 460 species.

All the creatures of this class are quiet by day, remaining fixed to the stalks or leaves of plants, except only some of the males, which are now and then found fluttering about in the woods in search of the females; but as soon as night approaches, they all fly about. This disposition is very remarkably implanted in their nature: for when kept shut up in boxes, they always remain quiet without changing place all day; but as soon as the sun is about setting, they always begin to flutter about and fly as much as their prison will permit them.

**PHALANGIUM**, in zoology, a genus of insects belonging to the order of aptera. They have eight feet, two eyes on the top of the head placed very near each other, and other two on the sides of the head: the feelers resemble legs, and the belly is round. There are nine species.

**PHALANX**, in Grecian antiquity, a square battalion, consisting of 8000 men, with their shields joined and pikes crossing each other; so that it was next to impossible to break it.

**PHALARIS**, a remarkable tyrant, born at Crete, where his ambitious designs occasioned his banishment: he took refuge in Agrigentum, a free city of Sicily, and there obtained the supreme power by stratagem. Two circumstances have contributed to preserve his name in history. His cruelty, in one act of which he gave an example of strict justice. It is thus related: Perillus, a brafs founder at Athens, knowing the cruel disposition of Phalaris, contrived a new species of punishment for him to inflict on his subjects. He cast a brazen bull, bigger than the life, with an opening in the side, to admit the victims; who being shut up in the body, a fire was kindled under it to roast them to death; and the throat was so contrived, that their dying groans resembled the roaring of a bull. The artist brought it to the tyrant, expecting a great reward. Phalaris admired the invention and workmanship, but ordered the inventor to be put into it to make the first trial. At last the tyrant was put to death by his own subjects. Some epistles are attributed to him, concerning the genuineness of which there was a dispute in the last century between Mr Boyle and Dr Bentley.

**PHALARIS**, or *Canary-grass*; a genus of the digynia order, belonging to the triandria class of plants. There are ten species, of which the most remarkable are the canariensis, or manured Canary-grass; and the arundinacea, or reed Canary-grass. These are both natives of Britain. The first grows by the road-sides; and is frequently cultivated for the sake of the seeds, which are found to be the best food for the Canary and other small birds. The second grows on the banks of rivers. It is used for thatching ricks or cottages, and endures much longer than straw. In Scandinavia they mow it twice a-year, and their cattle eat it. There is a variety of this cultivated in our gardens with beautifully striped leaves. The stripes are generally green and white; but sometimes they have a purplish

cast. This is commonly called painted *lady-grass*, or *ladies-tresses*.

**PHALEREUS** (Nepos), a village and port of Athens: this last neither large nor commodious, for which reason Themistocles put the Athenians on building the Piræus; both joined to Athens by long walls. The Phalerus lay nearer the city, (Pausanias). Demetrius Phalereus, the celebrated scholar of Theophrastus, was of this place; to whom the Athenians erected above 300 statues; which were afterwards destroyed by his enemies, on his flight to Ptolemy king of Egypt, (Strabo). Here Demosthenes was wont to declaim, to accustom his voice to surmount the noise and roaring of the sea, a just and lively emblem of popular assemblies.

**PHALEUCIAN** VERSE, in ancient poetry, a kind of verse consisting of five feet, the first of which is a spondee, the second a dactyl, and the three last trochees.

**PHALLUS**, the MOREL; a genus of the order of fungi, belonging to the cryptogamia class of plants. There are two species.

1. The esculentus, or esculent morel, is a native of Britain, growing in woods, groves, meadows, pastures, &c. The substance, when recent, is wax-like and friable; the colour a whitish yellow, turning brownish in decay; the height of the whole fungus, about four or five inches. The stalk is thick and clumsy, somewhat tuberous at the base, and hollow in the middle. The pileus is either round or conical; at a medium about the size of an egg, often much larger; hollow within its base united to the stalk; and its surface cellular, or latticed with irregular sinuses. The magnified seeds are oval. It is much esteemed at table both recent and dried, being commonly used as an ingredient to lighten the flavour of ragouts. We are informed by Gleditsch, that morels are observed to grow in the woods of Germany in the greatest plenty in those places where charcoal has been made. Hence the good women who collect them to sell, receiving a hint how to encourage their growth, have been accustomed to make fires in certain places of the woods, with heath, broom, vaccinium, and other materials, in order to obtain a more plentiful crop. This strange method of cultivating morels being however sometimes attended with dreadful consequences, large woods having been set on fire and destroyed by it, the magistrates thought fit to interpose his authority, and the practice is now interdicted.

2. The impudicus, stinking morel, or stinkhorns, is also a native of Britain, and found in woods and on banks. It arises from the earth under a veil or volva, shaped exactly like a hen's egg, and of the same colour, having a long fibrous radicle at its base. This egg-like valva is composed of two coats or membranes, the space between which is full of a thick, viscid, transparent matter, which, when dry, glues the coats together, and shines like varnish. In the next stage of growth, the volva suddenly bursts into several lacinated permanent segments, from the centre of which arises an erect, white, cellular, hollow stalk, about five or six inches high and one thick, of a wax-like friable substance, and most fœtid cadaverous smell, conical at each end, the base inserted in a white, concave, membranaceous turbinate cup, and the summit capped with a hollow, conical pileus, an inch long, having

Phanatic  
Phantasy.

having a reticulated cellular surface, its base detached from the stalk, and its summit umbilicated, the umbilicus sometimes perforated and sometimes closed. The under side of this pileus is covered with a clear, viscid, gelatinous matter, similar to that found between the membranes of the volva; and under this viscid matter, concealed in reticulated receptacles, are found the seeds, which when magnified appear spherical. As soon as the volva bursts, the plant begins to diffuse its intolerable odours, which are so powerful and widely expanded, that the fungus may be readily discovered by the scent only, before it appears to the sight. At this time, the viscid matter between the coats of the volva grows turbid and fuscous; and when the plant attains its full maturity, the clear viscid substance in the pileus becomes gradually discoloured, putrid, and extremely fetid, and soon afterwards turns blackish, and, together with the seeds and internal part of the pileus itself, melts away. The fetid smell then begins to remit, the fungus fades, and continues for a short time sapless and coriaceous, and at last becomes the food of worms. The cadaverous scent of this fungus greatly allures the flies; which, lighting upon the pileus, are entrapped in the viscid matter, and perish. We are informed by Gleditsch, that the vulgar people in Thuringia call the unopened volva by the ridiculous name of *ghosts and demon eggs*; and that they collect and dry them either in the smoke or open air, and, when reduced to powder, use them in a glass of spirits as an aphrodisiac.

PHANATIC, or FANATIC, a visionary; one who fancies he sees spectres, spirits, apparitions, or other imaginary objects, even when awake; and takes them to be real. See PHANTASY and FANATIC.

Such are phrenetics, necromancers, hypochondriac persons, lycanthropi, &c. See PHRENETIC, HYPOCHONDRIAC, LYCANTHROPY.

Hence the word is also applied to enthusiasts, pretenders to revelation, new lights, prophecies, &c. See ENTHUSIAST, and SECOND-SIGHT.

PHANTASM, a term sometimes used in a synonymous sense with idea, or notion retained in the mind of an external object.

PHANTASY, or FANCY, the *Imagination*; the second of the powers or faculties of the sensitive or

rational soul, by which the species of objects received by the common sense are retained, recalled, further examined, and either compounded or divided. See IMAGINATION.

Others define the *phantasy* to be that internal sense or power, whereby the ideas of absent things are formed, and represented to the mind as if they were present. In melancholics and madmen this faculty is very strong, representing many extravagant and monstrous things, and framing its images as lively as those of sensation: whence the visions and deceptions those persons are liable to.

PHARISEES, a famous sect of the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the same fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore both of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men: and therefore separated themselves from those whom they thought sinners or profane, so as not to eat or drink with them; and hence, from the Hebrew word *pharis*, which signifies to separate, they had the name of *Pharisees* or *Separatists*.

Their pretences to extraordinary piety drew after them the common people, who held them in the highest esteem and veneration. They held a resurrection from the dead, and the existence of angels and spirits; but, according to Josephus, this was no more than a Pythagorean resurrection, that is, of the soul only, by its transmigration into another body, and being born anew with it. From this resurrection they excluded all who were notoriously wicked, being of opinion that the souls of such persons were transmitted into a state of everlasting punishment; but as to lesser crimes, they imagined that they were punished in the bodies which the souls of those who had committed them were sent into. According to this notion it was, that Christ's disciples asked him concerning the blind man, "Who did sin, the man or his parents, that he was born blind?" With the Essenes, they held absolute predestination; and with the Sadducees, free-will: but how they reconciled these doctrines, we are nowhere informed.

## P H A R M A C Y

IS the art of compounding natural and artificial substances for the purposes of medicine, in such a manner as is most suitable to the respective properties of each, and may best answer the indications of cure.

This art, which in some way or other must have been coeval with medicine itself, has for a long time been divided into the chemical and galenical. No rational principles of distinction, however, were preferred; and those which were ranked among the chemical medicines in one dispensatory, have been ranked among the galenical ones in another. Hence the London college rejected the division altogether; and Dr Lewis reckons pharmacy, in its full extent, to be no other than a branch of chemistry; and the most simple pharmaceutical preparation is chemical, in as far as

it has any dependance on the properties of its materials.

The theory of pharmacy therefore is the same with that of chemistry; as are also the operations, which remain to be discussed here only in as far as they are made subservient to the medicinal art, distinct from that which is purely chemical. The objects of pharmacy, however, are much more limited than those of chemistry: the latter comprehending, in the utmost latitude of the word, almost every substance in nature; while pharmacy regards only such bodies in the vegetable, animal, and mineral kingdoms, as, by their effects on the human frame, tend to preserve health, or to restore it when lost.

## PART I. ELEMENTS OF PHARMACY.

## CHAP. I.

A general view of the Properties of medicinal substances, and their relations to one another.

SECT. I. *Of Vegetables.*

1. The medicinal virtues of vegetables differ very considerably according to the different circumstances of the plant, such as its age, the season of the year, and the soil in which it grows.

2. This is exemplified in herbs, some of which contain most odoriferous matter when young, while others have little or none till they have attained a considerable age:—In fruits, some of which contain an austere acid, afterwards changed into a sweet by maturation; others, such as the orange, at first contain a strong aromatic, and then an acid:—In roots; some of which, during the summer, contain a thin watery juice; but, if wounded early in the spring, yield rich balsamic juices, concreting into solid gummy resins, some of which, from our indigenous plants, are superior to those brought from foreign countries:—In aromatic and in fetid plants; the former of which grow stronger and more fragrant in open exposures, dry soils, and fair warm seasons; while the latter lose their smell in such circumstances. Regard must therefore be had to these and other similar circumstances in the collecting of plants for medical purposes.

3. The different parts of the same plant are very often different in quality from one another. Thus, the leaves and flowers of wormwood are intensely bitter, while the root is aromatic. The capsule inclosing the seeds of poppy has a narcotic virtue, but the seeds themselves have none.

4. The active parts of vegetables are generally capable of being extracted, without any alteration of their qualities, by some operations of a very simple nature; but by others, of a nature seemingly as simple, their nature may be entirely changed. The operations of fermentation, and of fire, are of this nature; for by means of them, the products of vegetables may be converted into substances having quite different properties from what they have naturally. Of the changes produced by these operations we shall therefore now take notice.

Art. 1. *Of the Changes produced in Vegetables, or their Juices, by Fermentation.*

5. All juices, or infusions, which are either simply sweet, or have a sweetness mixed with acidity, throw off by fermentation a great quantity of gross feculent matter; and are converted into a *vinous liquor*, affording by distillation an inflammable spirit.

6. The effects of the products just now mentioned on the human body are directly opposite to those of the juices from which they were produced. The latter attenuate the animal fluids, and relax the solids, in such a manner as in some cases to prove useful aperient medicines, and, if taken to too great excess, to produce dangerous fluxes; but the former always thicken the fluids, and constringe the solids.

7. In consequence of the different qualities of the juices or infusions, there are differences among the vinous liquors produced from them; but the spirit, when pure, is always found to be the same, from whatever substance it is produced.

8. Besides the gross matter thrown off during the fermentation, there is separated from several wines an acid saline substance named *tartar*; of a reddish or white colour, according to the wine which produces it. The red colour is not essential to the salt; for red tartar may be purified by solution in water, and then the tartar of all wines is found to be the same.

9. In fermentation there is also separated from the fermenting substance a great quantity of incoercible vapour, formerly known by the name of *gas*, but now discovered to be one of the component parts of our atmosphere, and the same with that which is called *fixed air*; concerning which see the articles *AIR*, *FIXED AIR*, *GAS*, &c.

10. Many substances, not susceptible of fermentation by themselves, may yet be brought into that state by an admixture of artificial ferments, or even of those which admit of a spontaneous fermentation, together with a proper quantity of water. This method is sometimes followed with vegetable matters intended for distillation, on a supposition that a slight fermentation will unlock their texture, and give out their principles more freely than otherwise; but it is much to be doubted whether this is really the case. The operation of fermentation is the same from first to last; and if its last effects are to convert the whole, or a great part, of the essential oil and saline parts of the vegetable into ardent spirit, it may reasonably be thought that its first effects must be to convert a part of these substances into the same spirit. At any rate, it is universally agreed, that when fermentation is employed with the abovementioned view, it must be continued only for a very short time.

11. The juices of fruits, though very susceptible of fermentation in their natural state, yet, when boiled till they become thick, are found to be indispensed to ferment; and this not only in their thick state, but when diluted again with water; though there appears to be scarcely any other alterations produced in them by the boiling. Hence liquids, prone to fermentation, may thus be preserved. How far this diminution of their fermentability may affect their medical virtues, is not as yet clear.

12. The degree of the species of fermentation, by which wines and inflammable spirits are produced, is called *vinous fermentation*. If the process is further protracted, more gross matter is thrown off, and new changes succeed, but in a slower and less tumultuary manner than before. The heating inebriating wine becomes by degrees a cooling acid vinegar, which seems to counteract the effects of the other: the more the wine abounded with inflammable spirit, the more does the vinegar abound with unflammable acid.

There are, however, certain qualities of vegetables, which are not completely subdued even by this second stage of fermentation; some vinegars being apparent-ly

ly more coloured, and containing more of an oily and viscid matter than others. By adding to the fermentable liquor subjects of other kinds, the qualities both of wines and vinegars may be still further diversified, so as to adapt them to particular medicinal uses.

13. It is observable, that though the acetous fermentation will always succeed the vinous, unless industriously prevented, yet it is not always preceded thereby; for many, perhaps all, fermentable liquors may be made to pass to the acetous state, without any intermediate period of true vinosity.

14. If the process is still further continued, further changes takes place. The matter putrefies: and at length what little liquor remains unevaporated, is found to be mere water, and the solid substance at the bottom appears to be the same with common mould.

15. This is reckoned by the chemists one of the stages of fermentation, and distinguished by the name of the *putrefactive stage*: it is far more general in its object than the other two; every vegetable matter being susceptible of putrefaction, but some particular kinds only being adapted to vinous or acetous fermentation.

16. Putrefaction discovers one difference in vegetables, which seems worthy of being remarked. The generality of vegetables rot and turn to mould, without yielding any very offensive smell from the beginning to the end of the resolution: but there are some which emit, throughout the whole process, a strong fetor, very nearly of the same kind with that which accompanies the putrefaction of animal substances. See the articles FERMENTATION and PUTREFACTION.

#### Art. 2. Productions from Vegetables by Fire.

17. FIRE, the other grand agent in the resolution of bodies, produces in vegetables decompositions of a different kind. Its general effects are the following.

18. Vegetable substances, burnt in the open air, are reduced partly into ashes, and partly into flame and smoke; which last, condensed in long canals, forms a nauseous black foot. In the burning of moist vegetables, an acid vapour accompanies the smoke; but the foot is never found to partake of it.

19. Vegetables urged with a red heat in close vessels (the vessel containing the subject being made to communicate with another placed beyond the action of the fire for receiving the matters forced out by the heat) give over a watery liquor called *phlegm*; an acid liquor called *spirit*; an elastic incoercible vapour, which appears to be partly fixed and partly inflammable air, and to which an exit must be occasionally allowed lest it burst the vessels or blow off the receiver; a thin oil, at length a very thick dark coloured oil, both which are of an acrimonious taste, and a burnt fetid smell, whence they are called *emphyreumatic oils*. There remains behind a black coal, not dissoluble in any kind of liquors, nor susceptible of putrefaction, not alterable by the most vehement degree of fire so long as the air is excluded, but which, on admitting air to it, burns without flaming, and with little or no smoke, and leaves a very small quantity of white ashes.

20. The white ashes of vegetables, infused or boiled in water, impart to it a pungent saline substance, called *fixt alkaline salt*, which may be separated in a solid form by evaporating the water. The remaining part of the ashes, which is by far the largest in quantity, is a pure earth differing from that which is the result of putrefaction, in being readily dissoluble by every acid liquor, while the other is not acted upon by any acid.

21. Such is the general analysis of vegetables by fire. But there are some vegetables, which, as they seem to shew, during putrefaction, some analogy in their matter with that which constitutes animal-bodies, discover also a like analogy in the present resolution; yielding little or no acid; and, instead of a fixt alkaline salt which remains in the ashes, affording a volatile alkaline salt, which arises along with the aqueous and oily principles.

22. Alkaline salts, and acid or four substances, are looked upon as being opposite in their nature to one another. Most of the bodies which are dissoluble in alkaline liquors, are precipitated or thrown out from the solution on the addition of an acid; and most of those which are dissoluble in acids, are in like manner precipitated by alkalis. If an acid and an alkali be directly mixed together, there generally ensues an effervescence or tumultuary discharge of air-bubbles, owing to the fixed air they contain; but if they are previously deprived of their fixed air, no effervescence takes place.

23. In all cases, the alkali and acid uniting together, compose a new body, called a *neutral salt*, which has neither the sourness of the one ingredient, nor the peculiar pungency of the other, and which will not dissolve those substances which either the acid or the alkali, separately, would dissolve.

24. To these characters it may be added, that alkaline salts change the colour of blue flowers or their infusions, as of violets, to a green, and acids to a red; while the neutral compound, formed by the coalition of the two, makes no alteration in the colour.

25. It must be observed, however, that to change blue flowers to a green, is not universally a mark of alkalies, for some solutions of earthy bodies in acids have the same effect: these last may be distinguished from alkalies, by adding to them a known alkali, which will immediately precipitate the earth, and form a neutral compound with the acid.

26. Fixed alkaline salts, perfectly purified, appear to be one and the same, whatever kind of vegetable they were produced from; those of some marine plants excepted. In volatile alkalies, and in the pure earthy part of the ashes, there appears to be, respectively, the like identity.

27. Emphyreumatic oils differ somewhat in the degree of acrimony and fetidness, and the acid spirits differ in degree of strength, or in the quantity of water they are diluted with; how far they may differ in any other respects is little known, these preparations having been rarely used or examined.

28. It may be observed, that the alkaline salts, both of the fixed and of the volatile kind, are entirely creatures of the fire, being seldom if ever found to exist naturally in any vegetable: the oil, doubtless, pre-existed in the subject, but owes its acrimony and fetidness

Elements.

to the fire; for the most mild and insipid oils receive the same qualities on being urged with the same degree of heat: the acid, which is likewise naturally contained in vegetable subjects, proves always tainted in the present process with the ill smell and taste of the oil that accompanies it; but whether the acid itself suffers any change in its nature, is unknown.

29. When chemistry began first to be formed into a rational science, and to examine the component parts and internal constitution of bodies, it was imagined, that this resolution of vegetables by fire, discovering to us all their active principles, unclogged and unmixed with one another, would afford the surest means of judging of their medicinal powers. But, on prosecuting these experiments, it was soon found, that they were insufficient for that end; that the analyses of poisonous and esculent plants agreed often as nearly with one another as two analyses of one plant: that by the action of a burning heat, the principles of vegetables are not barely separated, but altered, transposed, and combined into new forms; inasmuch that it was impossible to know what form they existed in, and what qualities they were endowed with, before these changes and transpositions happened.

Art. 3. *Substances naturally contained in Vegetables, and separable by Art without Alteration of their native Qualities.*

I. *Gross oils* abound chiefly in the kernels of fruits, and in certain seeds; from which they are commonly extracted by expression, and hence are distinguished by the name of *expressed oils*. They are contained also in all the parts of all vegetables that have been examined, and may be forced out by vehemence of fire; but here their qualities are greatly altered in the process by which they are extracted or discovered.

31. These oils, in their common state, are not dissoluble either in vinous spirits or in water, though, by means of certain intermedia, they may be united both with one and the other. Thus a skilful interposition of sugar renders them miscible with water into what are called *lobochs* and *oily draughts*; by the intervention of gum or mucilage, they unite with water into a milky fluid; by alkaline salts they are changed into a soap, which is miscible both with watery and spiritous liquors, and is perfectly dissolved by the latter into a uniform transparent fluid. The addition of any acid to the soapy solution absorbs the alkaline salt; and the oil, which of course separates, is found to have undergone this remarkable change, that it now dissolves, without any intermedium, in pure spirit of wine.

32. Expressed oils, exposed to the cold, lose greatly of their fluidity; some of them, in a small degree of cold, congeal into a consistent mass. Kept for some time in a warm air, they become thin and highly rancid; their soft, lubricating, and relaxing quality, is changed into a sharp acrimonious one: and in this state, instead of allaying, they occasion irritation; instead of obviating corrosive humours, they corrode and inflame. These oils are liable to the same noxious alteration while contained in the original subject; hence the rancidity which the oily seeds and kernels, as almonds, and those called the *cold seeds*, are so liable to contract in keeping. Nevertheless, on triturating these seeds and kernels with water, the oil, by the inter-

Elements.

vention of the other matter of the subject, unites with the water into an emulsion or milky liquor, which, instead of growing rancid, turns sour on standing. The rancidity also to which the oils are subject, appears to be owing to the impurities contained in them; for pure oil is found to be quite incorruptible.

33. In the heat of boiling water, and even in a degree of heat as much exceeding this as the heat of boiling water does that of the human body, these oils suffer little dissipation of their parts. In a greater heat, they emit a pungent vapour, seemingly of the acid kind; and when suffered to grow cold again, they are found to have acquired a greater degree of consistency than they had before, together with an acrid taste. In a heat approaching to ignition, in close vessels, greatest part of the oil arises in an empyreumatic state, a black coal remaining behind.

34. II. *Gross sebaceous matter*. From the kernels of some fruits, as that of the chocolate-nut, we obtain, instead of a fluid oil, a substance of a butyrous consistency; and from others, as the nutmeg, a solid matter as firm as tallow. These concretes are most commodiously extracted by boiling the subject in water; the sebaceous matter, liquefied by the heat, separates and rises to the surface, and resumes its proper consistency as the liquor cools.

35. The substances of this class have the same general properties with expressed oils, but are less disposed to become rancid in keeping than most of the common fluid oils.

36. III. *Essential oils* are obtained only from those vegetables, or parts of vegetables, that are considerably odorous. They are the direct principle, in which the odour, and oftentimes the warmth, pungency, and other active powers of the subject, reside; whence their name of *essence* or *essential oils*.

37. Essential oils unite with rectified spirit of wine, and compose with it one homogeneous transparent fluid; though some of them require for this purpose a much larger proportion of the spirit than others. Water also, though it does not dissolve their whole substance, may be made to imbibe some portion of their more subtle matter, so as to become considerably impregnated with their flavour: by their admixture with sugar, gum, the yolk of an egg, or alkaline salts, they are made totally dissoluble in water. Digested with volatile alkalies, they undergo various changes of colour, and some of the less odorous acquire considerable degrees of fragrance; whilst fixed alkalies universally impair their odour.

38. In the heat of boiling water, these oils totally exhale: and on this principle they are commonly extracted from subjects that contain them; for no other fluid that naturally exists in vegetables is exhalable by that degree of heat, except the aqueous moisture, from which greatest part of the oil is easily separated. Some of these oils arise with a much less heat, a heat little greater than that in which water begins visibly to evaporate. In their resolution by a burning heat, they differ little from expressed oils.

39. Essential oils, exposed for some time to a warm air, suffer an alteration very different from that which the expressed undergo. Instead of growing thin, rancid, and acrimonious, they gradually become thick, and at length harden into a solid, brittle concrete, with

**Elements.** a remarkable diminution of their volatility, fragrant, pungency, and warm stimulating quality. In this state they are found to consist of two kinds of matter; a fluid oil, volatile in the heat of boiling water, and nearly of the same quality with the original oil; and of a grosser substance which remains behind, not exhalable without a burning heat, or such a one as changes its nature, and resolves it into an acid, an empyreumatic oil, and a black coal.

40. The admixture of a concentrated acid instantly produces in essential oils a change nearly similar to that which time effects. In making these kinds of mixtures, the operator ought to be on his guard; for when a strong acid, particularly that of nitre, is poured hastily into an essential oil, a great heat and ebullition ensue, and often an explosion happens, or the mixture bursts into a flame. The union of expressed oils with acids is accompanied with much less conflict.

41. IV. *Concrete essential oil.* Some vegetables, as roses and elecampane roots, instead of a fluid essential oil, yield a substance possessing the same general properties, but of a thick or fæbaceous consistence. This substance appears to be of as great volatility and subtlety of parts as the fluid oils: it equally exhales in the heat of boiling water, and concretes upon the surface of the collected vapour. The total exhalation of this matter, and its concreting again into its original consistent state, without any separation of it into a fluid and a solid part, distinguishes it from essential oils that have been thickened or indurated by age or by acids.

42. V. *Camphor.* This is volatile like essential oils, and soluble both in oils and inflammable spirits: it unites freely with water by the intervention of gum, but very sparingly and imperfectly by the other intermedia that render oils miscible with watery liquors. It differs from the fæbaceous as well as fluid essential oils, in suffering no sensible alteration from long keeping; in being totally exhalable, not only by the heat of boiling water, but in a warm air, without any change or separation of its parts, the last particle that remains unexhaled appearing to be of the same nature with the original camphor; in its receiving no empyreumatic impression, and suffering no resolution, from any degree of fire to which it can be exposed in close vessels, though readily combustible in the open air; in being dissolved by concentrated acids into a liquid form; and in several other properties which it is needless to specify in this place.

43. VI. *Resin.* Essential oils, indurated by age or acids, are called *resins*. When the indurated mass has been exposed to the heat of boiling water, till its more subtle part, or the pure essential oil, that remained in it, has exhaled, the gross matter left behind is likewise called *resin*. We find in many vegetables resins analogous both to one and the other of these concretes; some containing a subtle oil, separable by a heat of boiling water; others containing nothing that is capable of exhaling in that heat.

44. Resins in general dissolve in rectified spirit of wine, though some of them much more difficultly than others: it is chiefly by means of this solvent that they are extracted from the subjects in which they are contained. They dissolve also in oils, both expressed and essential; and may be united with watery liquors

by means of the same intermedia which render the fluid oils miscible with water. In a heat less than that of boiling water, they melt into an oily fluid; and in this state they may be incorporated one with another. In their resolution by fire, in close vessels, they yield a manifest acid, and a large quantity of empyreumatic oil.

45. VII. *Gum* differs from the foregoing circumstances in being uninflamable: for though it may be burnt to a coal, and thence to ashes, it never yields any flame. It differs remarkably also in the proportion of the principles into which it is resolved by fire; the quantity of empyreumatic oil being far less, and that of acid far greater. In the heat of boiling water, it suffers no dissipation; nor does it liquefy like resins; but continues unchanged, till the heat is so far increased as to scorch or turn it to a coal.

46. By a little quantity of water it is softened into a viscous adhesive mass, called *mucilage*: by a larger quantity it is dissolved into a fluid, which proves more or less glutinous according to the proportion of gum. It does not dissolve in vinous spirits, or in any kind of oil; nevertheless, when softened with water into a mucilage, it is easily miscible both with the fluid oils and with resins, which by this means become soluble in watery liquors along with the gum, and are thus excellently fitted for medicinal purposes.

47. As oily and resinous substances are thus united to water by the means of gum, so gums may in like manner be united to spirit of wine by the intervention of resins and essential oils; though the spirit does not take up near so much of the gum as water does of the oil or resin.

48. Acid liquors, though they thicken pure oils, or render them consistent, do not impede the dissolution of gum, or of oils blended with gum. Alkaline salts, on the contrary, both fixed and volatile, though they render pure oils dissoluble in water, prevent the solution of gum, and of mixtures of gum and oil. If any pure gum be dissolved in water, the addition of any alkali will occasion the gum to separate, and fall to the bottom in a consistent form: if any oily or resinous body was previously blended with the gum, this also separates, and either sinks to the bottom, or rises to the top, according to its gravity.

49. VIII. *Gum-resin.* By gum-resin is understood a mixture of gum and resin. Many vegetables contain mixtures of this kind, in which the component parts are so intimately united, with the interposition perhaps of some other matter, that the compound, in a pharmaceutical view, may be considered as a distinct kind of principle; the whole mass dissolving almost equally in aqueous and in spirituous liquors; and the solutions being not turbid or milky, like those of the grosser mixtures of gum and resin, but perfectly transparent. Such is the altringent matter of bilwort root, and the bitter matter of gentian.

50. IX. *Saline matter.* Of the saline juices of vegetables there are different kinds; the sweet and the acid ones are the most plentiful, and those which are the most known.

51. These juices, exposed to a heat equal to that of boiling water, suffer generally no other change than the evaporation of their watery moisture; the saline matter remaining behind, along with such of the other

not volatile parts as were blended with it in the juice; from many, after the exhalation of great part of the water, the saline matter gradually separates in keeping, and concretes into little solid masses, leaving the other substances dissolved, or in a moist state; from others, no means have yet been found of obtaining a pure concrete salt.

52. These salts dissolve not only in water like other saline bodies, but many of them, particularly the sweet, in rectified spirit also. The gross oily and gummy matter with which they are almost always accompanied in the subject, dissolves freely along with them in water, but is by spirit in great measure left behind. Such heterogeneous matters as the spirit takes up are almost completely retained by it, while the salt concretes; but of those which water takes up, a considerable part always adheres to the salt. Hence essential salts, as they are called, prepared in the common manner from the watery juices of vegetables, are always found to partake largely of the other soluble principles of the subject; whilst those extracted by spirit of wine prove far more pure. By means of rectified spirit, some productions of this kind may be excellently freed from their impurities; and perfect saccharine concretions be obtained from many of our indigenous sweets.

53. There is another kind of saline matter, obtained from some resinous bodies, particularly from benzoin, of a different nature from the foregoing, and supposed by some of the chemists to be a part of the essential oil of the resin, coagulated by an acid, with the acid more predominant or more disengaged than in the other kinds of coagulated or indurated oils. These concretions dissolve both in water and in vinous spirits, though difficultly and sparingly in both: they show some marks of acidity, have a considerable share of smell like that of the resin they are obtained from, exhale in a heat equal to that of boiling water, or a little greater, and prove inflammable in the fire.

*General observations on the foregoing principles.*

54. 1st, Essential oils, as already observed, are obtainable only from a few vegetables, and camphor from a much smaller number: but gross oil, resin, gum, and saline matter, appear to be common, in greater or less proportion, to all; some abounding more with one, and others with another.

55. 2dly, The several principles are in many cases intimately combined, so as to be extracted together from the subject by those solvents, in which some of them, separately, could not be dissolved. Hence watery infusions, and spirituous tinctures of a plant, contain, respectively, more than water or spirit is the proper dissolvent of.

56. 3dly, After a plant has been sufficiently infused in water, all that spirit extracts from the residuum may be looked upon as consisting wholly of such matter as directly belongs to the action of spirit. And contrariwise, when spirit is applied first, all that water extracts afterwards may be looked upon as consisting only of that matter of which water is the direct dissolvent.

57. 4thly, If a vegetable substance, containing all the principles we have been speaking of, be boiled in water, the essential oil, whether fluid or concrete, and

the camphor and volatile essential salt, will gradually exhale with the steam of the water, and may be collected by receiving the steam in proper vessels placed beyond the action of the heat. The other principles not being volatile in this degree of heat, remain behind; the gross oil and sebaceous matter float on the top; the gummy and saline substance, and a part of the resin, are dissolved by the water, and may be obtained in a solid form by straining the liquor, and exposing it to a gentle heat till the water has exhaled. The rest of the resin still retained by the subject may be extracted by spirit of wine, and separated in its proper form by exhaling the spirit. On these foundations most of the substances contained in vegetables may be extracted, and obtained in a pure state, however they may be compounded together in the subject. By this operation, however, some very considerable change is undoubtedly produced by the fire; since, by pouring back the liquor which has arisen in distillation upon that which remains in the still, we shall never be able to recompose a liquor like that before it was distilled.

58. 5thly, Sometimes one or more of the principles is found naturally disengaged from the others, lying in distinct receptacles within the subject, or extravasated and accumulated on the surface. Thus, in the dried roots of angelica, cut longitudinally, the microscope discovers veins of resin. In the flower-cups of hypericum, and the leaves of the orange-tree, transparent points are distinguished by the naked eye, which, on the first view, seem to be holes; but, on a closer examination, are found to be little vesicles filled with essential oil. In the bark of the fir, pine, larch, and some other trees, the oily receptacles are extremely numerous, and so copiously supplied with the oily and resinous fluid, that they frequently burst, especially in the warm climates, and discharge their contents in great quantities. The acacia tree in Egypt, and the plum and cherry among ourselves, yield almost pure gummy exudations. From a species of ash is secreted the saline sweet substance manna; and the only kind of sugar which the ancients were acquainted with, appears to have been a natural exudation from the cane.

59. 6thly, The foregoing principles are, so far as is known, all that naturally exist in vegetables; and all that art can extract from them, without such operations as change their nature, and destroy their original qualities. In one or more of these principles, the colour, smell, taste, and medicinal virtues of the subject, are almost always found concentrated.

60. 7thly, In some vegetables, the whole medicinal activity resides in one principle. Thus, in sweet almonds, the only medicinal principle is a gross oil; in horse-radish root, an essential oil; in jalap-root, a resin, in marshmallow-root, a gum; in the leaves of fennel, a saline acid substance.

61. 8thly, Others have one kind of virtue residing in one principle, and another in another. Thus Peruvian bark has an astringent resin and a bitter gum; wormwood, a strong-flavoured essential oil, and a bitter gum-resin.

62. 9thly, The gross insipid oils and sebaceous matters, the simple insipid gums, and the sweet and acid saline substances, seem nearly to agree in their medicinal

**Elements.** cinal qualities, as well as in their pharmaceutic properties.

63. 10thly, But essential oils, resins, and gum-resins, differ greatly in different subjects. As essential oils are universally the principle of odour in vegetables, it is obvious that they must differ in this respect as much as the subjects from which they are obtained. Resins frequently partake of the oil, and consequently of the differences depending thereon; with this further diversity, that the gross resinous part often contains other powers than those which reside in oils. Thus from wormwood a resin may be prepared, containing not only the strong smell and flavour, but likewise the whole bitterness of the herb; from which last quality the oil is entirely free. The bitter, astringent, purgative, and emetic virtues of vegetables, reside generally in different sorts of resinous matter, either pure, or blended with gummy and saline parts; of which kind of combinations there are many so intimate, that the component parts can scarcely be separated from one another, the whole compound dissolving almost equally in aqueous and spirituous menstrua.

64. 11thly, There are some substances also which, from their being totally dissoluble in water, and not at all in spirit, may be judged to be mere gums; but which, nevertheless, possess virtues never to be found in the simple gums. Such are the astringent gum called *acacia*, and the purgative gum extracted from aloes.

65. 12thly, It is supposed that vegetables contain certain subtle principles or presiding spirits, different in different plants, of too great tenuity to be collected in their pure state, and of which oils, gums, and resins, are only the matrices or vehicles. This inquiry is foreign to the purposes of pharmacy, which is concerned only about grosser and more sensible objects. When we obtain from an odoriferous plant an essential oil, containing in a small compass the whole fragrance of a large quantity of the subject, our intentions are equally answered, whether the substance of the oil be the direct odorous matter, or whether it has diffused through it a fragrant principle more subtle than itself. And when this oil, in long keeping, loses its odour, and becomes a resin, it is equal, in regard to the present considerations, whether the effect happens from the avolation of a subtle principle, or from a change produced in the substance of the oil itself.

## SECT. II. *Animals.*

66. In animal-bodies we find certain substances which have a great resemblance, in their general properties, to those of the vegetable kingdom.

67. Animal oils and fats, like the gross oils of vegetables, are not of themselves dissoluble either in water or vinous spirits: but they may be united with water by the intervention of gum or mucilage; and most of them may be changed into soap, and thus rendered miscible with spirit, as well as water, by fixt alkaline salts.

68. The odorous matter of some odoriferous animal-substances, as musk, civet, castor, is, like essential oils, soluble in spirit of wine, and volatile in the heat of boiling water. Cartheuser relates, that from castor an actual essential oil has been obtained, in very

small quantity, but of an exceedingly strong diffusive smell.

69. The vesicating matter of cantharides, and those parts of sundry animal-substances in which their peculiar tastes reside, are dissolved by rectified spirit, and seem to have some analogy with resins and gummy resins.

70. The gelatinous principle of animals, like the gum of vegetables, dissolves in water, but not in spirit or in oils; like gums also, it renders oils and fats miscible with water into a milky liquor.

71. Some insects, particularly the ant, are found to contain an acid juice which approaches nearly to the nature of vegetable acids.

72. There are, however, sundry animal-juices, which differ greatly, even in these general kinds of properties, from the corresponding ones of vegetables. Thus animal-serum, which appears analogous to vegetable gummy juices, has this remarkable difference, that though it mingles uniformly with cold or warm water, yet, on considerably heating the mixture, the animal-matter separates from the watery fluid, and concretes into a solid mass. Some have been apprehensive, that the heat of the body, in some circumstances, might rise to such a degree as to produce this dangerous or mortal concretion of the ferrous humours: but the heat requisite for this effect is greater than the human body appears capable of sustaining, being nearly about the middle point between the greatest human heat commonly observed and that of boiling water.

73. The soft and fluid parts of animals are strongly disposed to run into putrefaction; they putrefy much sooner than vegetable matters, and when corrupted prove more offensive.

74. This process takes place, in some degree, in the bodies of living animals, as often as the juices stagnate long, or are prevented, by an obstruction of the natural emunctories, from throwing off their more volatile and corruptible parts.

75. During putrefaction, a quantity of air is generated, all the humours become gradually thinner, and the fibrous parts more lax and tender. Hence the tympany which succeeds the corruption of any of the viscera, or the imprudent suppression of dysenteries by astringents; and the weakness and laxity of the vessels observable in scurvy, &c.

76. The crassamentum of human blood changes by putrefaction into a dark livid-coloured liquor; a few drops of which tinge the serum of a tawny hue; like that of the ichor of sores and dysenteric fluxes, and of the white of the eye, the saliva, the serum of blood drawn from a vein, and that which oozes from a blister in deep scurvy, and in the advanced state of malignant fevers.

77. The putrid crassamentum changes a large quantity of recent urine to a flame-coloured water so common in fevers and in the scurvy. This mixture, after standing an hour or two, gathers a cloud resembling what is seen in the crude water of acute distempers, with some oily matter on the surface, like the scum which floats on scorbutic urine.

78. The serum of blood deposits, in putrefaction, a sediment resembling well-digested pus, and changes to a faint olive green. A serum, so far putrefied as

Elements.

Elements.

to become green, is perhaps never to be seen in the vessels of living animals; but in dead bodies this serum is to be distinguished by the green colour which the flesh acquires in corrupting. In salted meats, this is commonly ascribed to the brine, but erroneously; for that has no power of giving this colour, but only of qualifying the taste, and in some degree the ill effects, of corrupted aliments. In foul ulcers, and other sores, where the serum is left to stagnate long, the matter is likewise found of this colour, and is then always acriminous.

79. The putrefaction of animal-substances is prevented or retarded by all saline matters, even by the fixt and volatile alkaline salts, which have generally been supposed to produce a contrary effect. Of all the salts that have been made trial of, sea-salt seems to resist putrefaction the least: in small quantities, it even accelerates the process. The vegetable bitters, as chamomile-flowers, are much stronger antiseptics, not only preserving flesh long uncorrupted, but likewise somewhat correcting it when putrid: the mineral acids have this last effect in a more remarkable degree. Vinous spirits, aromatic and warm substances, most of the diaphoretic drugs, and the acrid plants falsely called *alkalescent*, as scurvy-grass and horse-radish, are also found to resist putrefaction; and some of the absorbent earths, as chalk, to promote it.

80. It is observable, that notwithstanding the strong tendency of animal-matters to putrefaction, yet broths made from them with the admixture of vegetables, instead of putrefying, turn sour. Dr Pringle finds, that when animal-flesh in substance is beaten up with bread or other farinaceous vegetables, and a proper quantity of water, into the consistence of a pap, this mixture likewise, kept in a heat equal to that of the human body, grows in a little time sour; whilst the vegetable matters, without the flesh, suffer no such change. See the *Appendix to his Observations on the Diseases of the Army*.

81. Animal-substances, burnt in the open air, are resolved, like vegetables, into soot and ashes; but with this difference, that no fixt alkaline salt can be obtained from the ashes, and that no acid vapour accompanies the smoke. They emit, during the burning, a fetid smell of a peculiar kind, by which animal-substances may be distinguished at once from all those of the vegetable kingdom. In close vessels, they give over, after the watery moisture, a volatile alkaline salt, which either concretes into a solid form, or dissolves in the water, and thus composes what is called *spirit*; together with an empyreumatic oil, of a more fetid kind than the oils of vegetables, without the least footstep of acid throughout the whole process. A black coal remains, which, in the open air, burns into white ashes void of saline matter.

82. It was observed in the preceding section, that some few vegetables, in this resolution of them by fire, discover some agreement in their matter with bodies of the animal kingdom, yielding a volatile alkaline salt in considerable quantity, with little or nothing of the acid or fixed alkali which the generality of vegetables afford. In animal-substances also there are some exceptions to the general analysis: from animal-fats, instead of a volatile alkali, an acid liquor is obtained, and their empyreumatic oil wants the peculiar offensiveness of the other animal-oils.

### SECT. III. Minerals.

#### Art. 1. Oils and Bitumens.

83. In the mineral kingdom is found a fluid oil, called *naphtha* or *petroleum*, floating on the surface of waters, or issuing from clefts of rocks, particularly in the eastern countries, of a strong smell, very different from that of vegetable or animal oils, limpid almost as water, highly inflammable, not soluble in spirit of wine, and more averse to union with water than any other oils.

84. There are different sorts of these mineral oils, more or less tinged, of a more or less agreeable, and a stronger or weaker smell. By the admixture of concentrated acids, which raise no great heat or conflict with them, they become thick, and at length consistent; and in these states are called *bitumens*.

85. These thickened or concreted oils, like the corresponding products of the vegetable kingdom, are generally soluble in spirit of wine, but much more difficultly, more sparingly, and for the most part only partially: they liquefy by heat, but require the heat to be considerably stronger. In a proper degree of heat they give out a fluid oil, greatly resembling the native petrolea, a small quantity of a black coaly matter remaining behind. Their smells are various; but all of them, either in their natural state, or when melted or set on fire, yield a peculiar kind of strong scent, called, from them, *bituminous*.

#### Art. 2. Earths.

86. In treating of vegetables and animals, we forbore to speak of their earthy matters, that the distinguishing characters of the several classes of earthy bodies might be the easier apprehended, by having them placed here in one synoptical view: the little impropriety, of joining the vegetable and animal earths to the mineral, must be overlooked for the sake of that advantage. Under the mineral earths are included stones, these being no other than earths in an indurated state. The different kinds of these bodies hitherto taken notice of, are the following.

1. *Earths soluble in the nitrous, marine, and vegetable acids, but not at all, or exceeding sparingly, in the vitriolic acid. When previously dissolved in other acids, they are precipitated by the addition of this last, which thus unites with them into insipid, or nearly insipid concretes, not dissoluble in any liquor. Of this kind are,*

87. [1.] The mineral calcareous earth: distinguished by its being convertible, in a strong fire without addition, into an acriminous calx called quicklime. This earth occurs in a variety of forms in the mineral kingdom. The fine soft chalk, the coarser limestones, the hard marbles, the transparent spars, the earthy matter contained in waters, and which, separating from them, incrustates the sides of caverns or hangs in icicles from the tops, receiving from its different appearances different appellations; how strongly soever some of these bodies have been recommended for particular medicinal purposes, are at bottom no other than different forms of this calcareous earth; simple pulverization depriving them of the superficial characters by which they are distinguished in the mass. Most of them contain generally a greater or less admixture of some of the

the indissoluble kinds of earth; which, however, affects their medicinal qualities no otherwise than by the addition which it makes to their bulk. Chalk appears to be one of the purest, and is therefore in general preferred. They all burn into a strong quicklime: in this state, a part of them dissolves in water, which thus becomes impregnated with the astringent and lithontriptic powers that have been erroneously ascribed to some of the earths in their natural state.

88. [2.] The animal calcareous earth: *burning into quicklime, like the mineral*. Of this kind are oyster-shells, and all the marine shells that have been examined; though with some variation in the strength of the quicklime produced from them.

89. [3.] The earth of bones and horns: *not at all burning into quicklime*. This kind of earth is more difficult of solution in acids than either of the preceding. It is accompanied in the subject with a quantity of gelatinous matter, which may be separated by long boiling in water, and more perfectly by burning in the open air: the earth may be extracted also from the bone or horn, though difficultly, by means of acids; whereas vegetables, and the soft parts of animals, yield their pure earth by burning only.

II. *Earths soluble with ease in the vitriolic as well as other acids; and yielding, in all their combinations therewith, saline concretes soluble in water.*

90. [1.] Magnesia alba: *composing with the vitriolic acid a bitter purgative liquor*.

91. [2.] Aluminous earth: *composing with the vitriolic acid a very astringent liquor*.

III. *Earths, which by digestion in acids, either in the cold or in a moderate warmth, are not at all dissolved.*

92. [1.] Argillaceous earth: *becoming hard, or acquiring an additional hardness, in the fire*. Of this kind of earth there are several varieties, differing in some particular properties: as the purer clays, which when moistened with water form a very viscous mass, difficultly diffusible through a large quantity of the fluid, and slowly subsiding from it; *boles*, less viscous, more readily miscible with water, and more readily subsiding; and *ochres*, which have nothing of the viscosity of the two foregoing, and are commonly impregnated with a yellow or red ferrugineous calx.

93. [2.] Crystalline earth: *naturally hard, so as to strike sparks with steel; becoming friable in a strong fire*. Of this kind are flints, crystals, &c. which appear to consist of one and the same earth, differing in the purity, hardness, and transparency of the mass.

94. [3.] Gypseous earth: *reducible by a gentle heat into a soft powder, which unites with water into a mass, somewhat viscous and tenacious while moist, but quickly drying and becoming hard*. A greater heat deprives the powder of this property, without occasioning any other alteration. Such are the transparent *selenites*; the fibrous stony masses improperly called *English talc*; and the granulated gypsa, or plaster of Paris stones.

95. [4.] Talky earth: *scarcely alterable by a vehement fire*. The masses of this earth are generally of a fibrous or leafy texture; more or less pellucid, bright, or glittering; smooth and unctuous to the touch; too flexible and elastic to be easily pulverized; soft, so as to be cut with a knife. In these respects some of the gypseous earths greatly resemble them: but the difference is readily discovered by fire; a weak heat redu-

cing the gypseous to powder, while the strongest makes no other alteration in the talky, than somewhat diminishing their flexibility, brittleness, and unctuousity.

#### Art. 3. Metals.

96. Of metals, the next division of mineral bodies, the most obvious characters are, their peculiar bright aspect, perfect opacity, and great weight: the lightest of them is fix, and the heaviest upwards of 19 times heavier than an equal bulk of water.

97. They all melt in the fire, except platina; a metallic body which has not been applied to any medicinal use, and which is therefore excluded from this general view of medicinal subjects.

98. Gold and silver, how long soever they are continued in fusion, remain unchanged and undiminished. The others, if air is admitted to them, are gradually converted, with different degrees of facility, into a powdery or friable substance called *calx*, destitute of the metallic aspect, and much lighter in proportion to its bulk than the metal itself. This change in their obvious properties is generally accompanied with a notable alteration in their medicinal virtues: thus quicksilver, which, taken into the body in its crude state and undivided, seems inactive; when calcined by fire, proves, even in small doses, a strong emetic and cathartic, and in smaller ones a powerful alterative in chronic disorders; while regulus of antimony, on the contrary, is changed, by the same treatment, from a high degree of virulence to a state of inactivity.

99. Calces of mercury and arsenic exhale in a heat below ignition: those of lead and bismuth, in a red or low white heat, run into a transparent glass: the others are not at all vitrescible, or not without extreme vehemence of fire. Both the calces and glasses recover their metallic form and qualities again, by the skilful addition of any kind of inflammable substance that does not contain a mineral acid.

100. All metallic bodies dissolve in acids; some only in particular acids, as silver and lead in the nitrous; some only in compositions of acids, as gold in a mixture of the nitrous and marine; and others, as iron and zinc, in all acids. Some likewise dissolve in all alkaline liquors, as copper; and others, as lead, in expressed oils. Fused with a composition of sulphur and fixed alkaline salt, they are all, except zinc, made soluble in water.

101. All metallic substances dissolved in saline liquors have powerful effects in the human body, tho' many of them appear in their pure state to be inactive. Their activity is generally in proportion to the quantity of acid combined with them: thus lead, which in its crude form has no sensible effect, when united with a small portion of vegetable acid into ceruss, discovers a low degree of the styptic and malignant quality which it so strongly exerts when blended with a larger quantity of the same acid, into what is called *saccharum saturni*: and thus mercury, with a certain quantity of the marine acid, forms the violent corrosive sublimate, which, by diminishing the proportion of acid, becomes the mild medicine called *mercurius dulcis*.

#### Art. 4. Acids.

102. THE mineral acids are distinguished by the names of the concretes from which they have been principally

Elements.

Elements.

cipally extracted; the *vitriolic* from vitriol, the *nitrous* from nitre or saltpetre, and the *marine* from common sea-salt. They are all highly corrosive, inasmuch as not to be safely touched, unless largely diluted with water, or united with such substances as obtund or suppress their acidity. Mixed hastily with vinous spirits, they raise a violent ebullition and heat, accompanied with a copious discharge of noxious fumes: a part of the acid unites intimately with the vinous spirit into a new compound void of acidity, called *dulcified spirit*. It is observable, that the marine acid is much less disposed to this union with spirit of wine than either of the other two: nevertheless, many of the compound salts resulting from the combination of earthy and metallic bodies with this acid, are soluble in that spirit, while those with the other acids are not. All these acids effervesce strongly with alkaline salts, both fixed and volatile; and form with them neutral salts, that is, such as discover no marks either of an acid or alkaline quality.

103. We have already taken notice of two kinds of alkaline salt; the volatile alkali of animals, and the fixed alkali of vegetables. In the mineral kingdom, another species of fixed alkali, different in several respects from the vegetable, is found sometimes in a detached state, but more plentifully in combination with the marine acid, with which it composes sea-salt. From the coalition of the different acids with these three alkalies, and with the several soluble earths and metallic bodies, result a variety of saline compounds, the principal of which will be particularized in the sequel of this treatise.

104. The vitriolic acid, in its concentrated liquid state, is much more ponderous than the other two, emits no visible vapours in the heat of the atmosphere, but imbibes moisture there from, and increases in its weight: the nitrous and marine emit copious corrosive fumes, the nitrous yellowish red, and the marine white ones. If bottles containing the three acids are stopp'd with cork, the cork is found in a little time tinged black by the vitriolic, corroded into a yellow substance by the nitrous, and into a whitish one by the marine.

105. It is above laid down as a character of one of the classes of earths, that the vitriolic acid precipitates them when they are previously dissolved in any other acid: it is obvious, that on the same principle this particular acid may be distinguished from all others. This character serves not only for the acid in its pure state, but likewise for all its combinations that are soluble in water: if a solution of any compound salt whose acid is the vitriolic, be added to a solution of chalk in any other acid, the vitriolic acid will part from the substance it was before combined with, and join itself to the chalk, forming therewith a compound, which, being no longer dissoluble in the liquor, renders the whole milky for a time, and then gradually subsides.

106. This acid may be distinguished also in compound salts, by another criterion not less strongly marked: if any salt containing it be mixed with powdered charcoal, and the mixture exposed, in a close vessel, to a moderately strong fire, the acid will unite with the directly inflammable part of the charcoal, and compose therewith a genuine sulphur. Common brimstone is no other than a combination of the

vitriolic acid with a small proportion of inflammable matter. With any kind of inflammable matter that is not volatile in close vessels, as the coal of vegetables, of animals, or of bitumens, this acid composes always the same identical sulphur.

107. The nitrous acid also, whatever kind of body it be combined with, is both distinguished and extricated therefrom, by means of any inflammable substance brought to a state of ignition: if the subject be mixed with a little powdered charcoal, and made red-hot, a deflagration or fulmination ensues, that is, a bright flame with a hissing noise; and the inflammable matter and the acid being thus consumed or dissipated together, there remains only the substance that was before combined with the acid, and the small quantity of ashes afforded by the coal.

108. This property of the nitrous acid, deflagrating with inflammable substances, and that of the vitriolic of forming sulphur with them, serve not only as criteria of the respective acids in their various forms and disguises, but likewise for discovering inflammable matter in bodies, when its quantity is too small to be sensible on other trials.

109. If a fixed alkaline salt be united with a vegetable acid, as that of vinegar, into a neutral salt; on adding to this compound some marine acid, the acetous acid will be disengaged, so as to exhale totally in a moderate heat, leaving the marine in possession of the alkali; the addition of the nitrous will in like manner dispossess the marine, which now arises in its proper white fumes, though without such an addition it could not be extricated from the alkali by any degree of heat: on the addition of the vitriolic acid, the nitrous gives way in its turn, exhaling in red fumes, and leaving only the vitriolic acid and the alkali united together.

110. Again, if any metallic body be dissolved in an acid, the addition of any earthy body that is dissoluble in that acid will precipitate the metal: a volatile alkaline salt will in like manner precipitate the earth, and a fixed alkali will dislodge the volatile; which last being readily exhaled by heat, the remaining salt will be the same as if the acid and fixed alkali had been joined together at first, without the intervention of any of the other bodies.

111. The power in bodies, on which these various transpositions and combinations depend, is called by the chemists *affinity*; a term, like the Newtonian *attraction*, designed to express, not the cause, but the effect. When an acid spontaneously quits a metal to unite with an alkali, they say it has a greater affinity to the alkali than the metal; and when, conversely, they say it has a greater affinity to fixed alkalies than to those of the volatile kind, they mean only that it will unite with the fixed in preference to the volatile, and that, if previously united with a volatile alkali, it will forsake this for a fixed one.

112. The doctrine of the affinities of bodies is of a very extensive use in the chemical pharmacy: many of the officinal processes, as we shall see hereafter, are founded on it: several of the preparations turn out very different from what would be expected by a person unacquainted with these properties of bodies; and several of them, if, from an error in the process, or other causes, they prove unfit for the use intended, may be

Elements. be rendered applicable to other purposes, by such transpositions of their component parts as are pointed out by the knowledge of their affinities. See CHEMISTRY, n° 64.

## C H A P. II.

## Of the Pharmaceutical APPARATUS.

117. *Furnaces.* ONE of the principal parts of the pharmaceutical apparatus consists in contrivances for containing and applying fire, and for directing and regulating its power. Of these contrivances, called *furnaces*, there are different kinds, according to the convenience of the place, and the particular purposes they are intended to answer. See the article FURNACE; and CHEMISTRY, n° 98, 99, 101, 102.

118. The most simple pharmaceutical furnace is the common stove, otherwise called the *furnace for open fire*. This is usually made of an iron hoop, five or six inches deep; with a grate or some iron-bars across the bottom, for supporting the fuel. It either stands upon feet, so as to be moveable from place to place, or is fixed in brick-work. In this last case, a cavity is left under the grate for receiving the ashes that drop thro' it; and an aperture or door, in the fore-part of this ash-pit, serves both for allowing the ashes to be occasionally raked out, and for admitting air to pass up through the fuel. This furnace is designed for such operations as require only a moderate heat; as infusion, decoction, and the evaporation of liquids. The vessel containing the subject-matter is supported over the fire by a retort.

119. A deeper hoop or body, cylindrical, parallelipedal, widening upwards, elliptical, or of other figures; formed of, or lined with, such materials as are capable of sustaining a strong fire, with a grate and ash-pit beneath, as in the preceding, and communicating at the top with a perpendicular pipe, or chimney, makes a wind-furnace.

120. The greater the perpendicular height of the chimney, the greater will be the draught of air thro' the furnace, and the more intensely will the fire burn; provided the width of the chimney is sufficient to allow a free passage to all the air that the furnace can receive thro' the grate: for which purpose, the area of the aperture of the chimney should be nearly equal to the area of the interstices of the grate.

121. Hence, where the chimney consists of moveable pipes, made to fit upon one another at the ends, so that the length can be occasionally increased or diminished, the vehemence of the fire will be increased or diminished in the same proportion.

122. In furnaces whose chimney is fixed, the same advantage may be procured on another principle. As the intensity of the fire depends wholly upon the quantity of air successively passing through and animating the burning fuel, it is obvious, that the most vehement fire may be suppressed or restrained at pleasure, by more or less closing either the ash-pit door by which the air is admitted, or the chimney by which it passes off; and that the fire may be more or less raised again, by more or less opening those passages. A moveable plate or register, in any convenient part of the chimney, affords commodious means of varying the width of the passage, and consequently of regulating the heat.

VOL. VIII.

I

123. There are two general kinds of these wind-furnaces; one, with the chimney on the top, over the middle of the furnace; the other with the chimney on one side, and the mouth clear.

124. In the first, either the upper part of the furnace is contracted to such an aperture, that the chimney may fit upon it; or it is covered with an arched dome, or with a flat plate, having a like aperture in the middle. As in this disposition of the chimney, the inside of the furnace cannot be come at from above; a door is made in the side, a little above the grate, for supplying fuel, inspecting the matter in the fire, &c.

125. For performing fusions in this furnace, the crucible, or melting vessel, is placed immediately above the fuel; with a slip of brick, or some other like support, between it and the grate, to keep the cold air, which enters underneath, from striking on its bottom.

126. When designed as a reverberatory, that is, for distillation in long necks or coated glass-retorts, two iron bars are placed across, above the fire, for supporting the vessel, whose neck comes out at an aperture made for that purpose in the side. This aperture should be made in the side opposite to that in which the door above-mentioned, or at least so remote from it, that the receiver, fitted on the neck of the distilling vessel without the furnace, may not lie in the operator's way when he wants to stir the fire or throw in fresh fuel.

127. The other kind of wind-furnace communicates, by an aperture in its back-part near the top, either with an upright pipe of its own, or with the chimney of the room; in which last case, all other passages into the chimney must be closed up. Here the mouth of the furnace serves for a door, which may be occasionally covered with a plate or tile. Of this kind is the furnace most commonly used for fusion in a crucible.

151. *Vessels.* Of these and other pharmaceutical instruments the principal will be mentioned in the following chapter, in speaking of the several operations to which they are respectively subservient.

152. *Weights.* Two different kinds of weights are made use of in this country; one in the merchandize of gold and silver; the other for almost all goods besides. The first we call *Troy*, the latter *Averdupois weight*.

153. The goldsmiths divide the Troy pound into 12 ounces; the ounce into 20 penny-weights; and the penny-weight into 24 grains. The Averdupois pound is divided into 16 ounces; and the ounce into 16 parts, called *drams*.

The pound of the London and Edinburgh dispensaries (which is the only one made use of in this article) is that of the goldsmiths, divided in the following manner:

The Pound	} contains	twelve Ounces.
The Ounce		eight Drams.
The Dram		three Scruples.
The Scruple		twenty Grains.

The grain is equal to the goldsmiths grain.

154. The medical or Troy pound is less than the averdupois, but the ounce and the dram greater. The Troy pound contains 5760 grains; the averdupois 7000 grains. The Troy ounce contains 480 grains; the averdupois only 437½. The Troy dram 60; the averdupois dram somewhat more than 27. Eleven drams averdupois are equal to five drams Troy; 12 ounces

33 Y

avardupois

Elements.

averdupois to nearly 11 ounces Troy; and 19 pounds averdupois to somewhat more than 23 pounds Troy.

155. These differences in our weights have occasioned great confusion in the practice of Pharmacy. As the druggists and grocers sell by the averdupois weight, the apothecaries have not in general kept any weights adjusted to the Troy pound greater than two drams, using for all above averdupoise. By this means it is apparent, that in all compositions, where the ingredients are prescribed, some by pounds and others by ounces, they are taken in a wrong proportion to each other; and the same happens when any are directed in lesser denominations than the ounce, as these subdivisions used by the apothecaries are made to a different ounce. The mercurial plaster of the late Pharmacopœia, and the mercurial cerate of the present, if compounded by the averdupoise weight, contain about one sixth less quicksilver than if made, as they ought to be, by the Troy. This error prevailed so far as to be received in some former editions of the London Pharmacopœia itself; but is now happily removed.

156. *Measures.* The measures employed with us in pharmacy are the common wine-measures.

A Gallon } contains { eight Pints (*libra*).  
The Pint } { sixteen Ounces.  
The Ounce } { eight Drams.

157. By a spoonful, in the London dispensatory, is understood, the measure of half an ounce; in the Edinburgh, half an ounce weight in syrups, and three drams in distilled waters.

158. Though the pint is called by Latin writers *libra* or "pound," there is not any known liquor of which a pint-measure answers to that weight. A pint of the highest rectified spirit of wine exceeds a pound by above half an ounce; a pint of water exceeds it by upwards of three ounces; and a pint of oil of vitriol weighs more than two pounds and a quarter.

159. A table of the weights of certain measures of different fluids may on many occasions be useful, both for assisting the operator in regulating their proportions in certain cases, and for shewing the comparative gravities of the fluids themselves. Dr Lewis has drawn up such a table for a pint, an ounce, and a dram measure of those liquids, whose gravity has been determined by experiments that can be relied on. The wine-gallon contains 231 cubic inches; whence the pint contains  $28\frac{1}{2}$ ; the ounce  $1\frac{17}{32}$ ; and the dram  $\frac{53}{128}$  of a cubic inch.

**QUICKSILVER.****C H A P. III.****Of the Pharmaceutical OPERATIONS.****SECT. I. Solution.**

160. **SOLUTION** is an intimate commixture of solid bodies with fluids into one seemingly homogeneous liquor. The dissolving fluid is called a *Menstruum* or *Solvent*.

161. The principal menstrua made use of in pharmacy, are water, vinous spirits, oils, acid and alkaline liquors.

162. Water is the menstruum of all salts, of vegetable gums, and of animal-gellies. Of salts it dissolves only a determinate quantity, though of one kind of salt more than another; and being thus saturated, leaves any additional quantity of the same salt undissolved.

163. Experiments have been made for determining the

**Elements.** the quantities of water which different salts require for their dissolution: Mr Eller has given a large set in the Memoirs of the royal academy of sciences of Berlin for the year 1750, from which the following table is extracted.

Eight ounces by weight of distilled water dissolved

	oz.	dr.	grs.
Of refined sugar	24	0	0
Green vitriol	9	4	0
Blue vitriol	9	0	0
White vitriol	4	4	0
Epsom salt	4	0	0
Purified nitre	4	0	0
Soluble tartar	4	0	0
Common salt	3	4	0
Sal gemmæ	3	4	0
Sal catharticus Glauberi	3	4	0
Seignette's salt	3	0	0
Alum	3	4	0
Sal ammoniac	3	4	0
Vitriolated tartar	1	4	0
Salt of hartshorn	1	4	0
Sugar of lead	1	3	0
Cream of tartar	1	0	0
Borax	0	4	20

164. Though great care appears to have been taken in making these experiments, it is not to be expected, that the proportions of the several salts, soluble in a certain quantity of water, will always be found exactly the same with those above set down. Salts differ in their solubility according to the degree of their purity, perfection, and driness: the vitriols, and the artificial compound salts in general, differ remarkably in this respect, according as they are more or less impregnated with the acid ingredient. Thus vitriolated tartar, perfectly neutralized, is extremely difficult of solution: the matter which remains in making Glauber's spirit of nitre, is no other than a vitriolated tartar; and it dissolves so difficultly, that the operator is obliged to break the retort in order to get it out; but on adding more of the vitriolic acid, it dissolves with ease. Hence many have been tempted to use an over-proportion of acid in this preparation; and we frequently find in the shops, under the name of *vitriolated tartar*, this acid soluble salt. The degree of heat occasions also a notable difference in the quantity of salt taken up: in very cold weather, eight ounces of water will dissolve only about one ounce of nitre; whereas, in warm weather, the same quantity will take up three ounces or more. To these circumstances are probably owing, in great part, the remarkable differences in the proportional solubilities of salt, as determined by different authors: it is observable, that common salt is less affected in its solubility, by a variation of heat, than any other, water in a temperate state dissolving nearly as much of it as very hot water; and accordingly this is the salt in which the different experiments agree the best. In the experiments of Hoffmann, Neumann, and Petit, the proportion of this salt, on a reduction of the numbers, comes out exactly the same, viz. three ounces of the salt to eight of water: Dr Brownrigg makes the quantity of salt a little more; Dr Grew, a dram and a scruple more;

and Eller, as appears in the above table, four drams more: so that in the trial of six different persons, made probably in different circumstances, the greatest difference is only one-sixth of the whole quantity of salt; whereas in some other salts there are differences of twice or thrice the quantity of the salt. In the experiments from which the table is drawn, the water was of the temperature of between 40 and 42 degrees of Fahrenheit's thermometer, or above freezing by about one-seventh of the interval between freezing and the human heat.

165. Some salts omitted by Eller are here subjoined: the first is taken from Dr Grew, and the other four from Neumann.

Eight ounces of water dissolved

	oz.	dr.	grs.
Of fixed alkaline salt	8	0	0
Sal diuretics	8	0	0
Sugar-candy, both brown and white	9	0	0
Sugar of milk	0	2	40
Essential salt of sorrel	1	2	0

166. Though water takes up only a certain quantity of one kind of salt, yet when saturated with one, it will still dissolve some portion of another; and when it can bear no more of either of these, it will still take up a third, without letting go any of the former. The principal experiments of this kind that have been made relative to pharmaceutic subjects, are exhibited in the following table, of which the two first articles are from Grew, and the others from Eller.

Water, 32 parts by weight			
fully saturated with	dissolved afterwards		
Nitre	Sal ammoniac	10	
Common salt	Nitre	10	Sal amm. 2
Nitre	Fixed alkali	7	Com. salt 2
Common salt	Nitre, near 2		Fixt alk. 2½
Volatile alkali	Nitre	4	Sugar 2
Sal ammoniac	Common salt	2½	
Soluble tartar	Nitre	2	
Vitriolated tartar	Fixed alkali	2	
Glauber's salt	Nitre	1	Sugar 1
Epsom salt	Sugar	6	
Borax	Fixed alkali	2	

167. In regard to the other class of bodies which water is a menstruum for, viz. those of the gummy and gelatinous kind, there is no determinate point of saturation: the water unites readily with any proportions of them, forming with different quantities liquors of different consistencies. This fluid takes up likewise, when assisted by trituration, the vegetable gummy resins, as ammoniacum and myrrh; the solutions of which, though imperfect, that is, not transparent, but turbid and of a milky hue, are nevertheless applicable to valuable purposes in medicine. It mingles with vinous spirits, with acid and alkaline liquors, not with oils; but imbibes some of the more subtle parts of essential oils, so as to become impregnated with their smell and taste.

168. Rectified spirit of wine is the menstruum of the essential oils, resins and camphor of vegetables; of the pure distilled oils, and several of the colouring and medicinal parts of animals; of some mineral bi-

tuminous substances, as of ambergris: and of soaps, though it does not act upon the expressed oil and fixed alkaline salt of which soap is compounded; whence, if soap contains any superfluous quantity of either the oil or salt, it may, by means of this menstruum, be excellently purified therefrom. It dissolves, by the assistance of heat, volatile alkaline salts; and, more readily, the neutral ones, composed either of fixed alkali and the acetic acid, as the sal diureticus, or of volatile alkali and the nitrous acid, as also the salt of amber, &c. It mingles with water and with acids; not with alkaline lixivia.

169. Oils dissolve vegetable resins and balsams, wax, animal-fat, mineral bitumens, sulphur, and certain metallic substances, particularly lead. The expressed oils are, for most of these bodies, more powerful menstrua than those obtained by distillation; as the former are more capable of sustaining, without injury, a strong heat, which is, in most cases, necessary to enable them to act. It is said, that one ounce of sulphur will dissolve in three ounces of expressed oil, particularly that of linseed; but requires six ounces of essential oil, as that of turpentine.

170. All acids dissolve alkaline salts, alkaline earths, and metallic substances. The different acids differ greatly in the action upon these last; one dissolving only some particular metals; and another, others.

171. The vegetable acids dissolve a considerable quantity of zinc, iron, copper, lead, and tin; and extract so much from the metallic part of antimony, as to become powerfully emetic: they dissolve lead more readily, if the metal is previously calcined by fire, than in its metallic state.

172. The marine acid dissolves zinc, iron, and copper; and though it scarce acts on any other metallic substance in the common way of making solutions, it may nevertheless be artfully combined with them all except gold: the corrosive sublimate, and antimonial caustic of the shops, are combinations of it with mercury and the metallic part of antimony, effected by applying the acid, in the form of fume, to the subjects, at the same time also strongly heated.

173. The nitrous acid is the common menstruum of all metallic substances, except gold and the metallic part of antimony; of which two, the proper solvent is a mixture of the nitrous and marine acids called *aqua regia*.

174. The vitriolic acid, diluted with water, easily dissolves zinc and iron: in its concentrated state, and assisted by a boiling heat, it may be made to corrode, or imperfectly dissolve, most of the other metals.

175. Alkaline lixivia dissolve oils, resinous substances, and sulphur. Their power is greatly promoted by the addition of quicklime; instances of which occur in the preparation of soap, and in the common caustic. Thus acuated, they reduce the flesh, bones, and other solid parts of animals, into a gelatinous matter.

176. Solutions made in water, and in spirit of wine, possess the virtues of the body dissolved; whilst oils generally sheathe its activity, and acids and alkalies vary its quality. Hence watery and spirituous liquors are the proper menstrua of the native virtues of vegetable and animal matters.

177. Most of the foregoing solutions are easily effected, by pouring the menstruum on the body to be dissolved, and suffering them to stand together, for

some time, exposed to a suitable warmth. A strong heat is generally requisite to enable oils and alkaline liquors to perform their office: nor will acids act on some metallic bodies without its assistance. The action of watery and spirituous menstrua is likewise expedited by a moderate heat; though the quantity which they afterwards keep dissolved is not, as some suppose, by this means increased: all that heat occasions these to take up more than they would do in a longer time in the cold, will, when the heat ceases, subside again: this at least is most commonly the case, though there may be some instances of the contrary.

178. The action of acids on the bodies which they dissolve, is generally accompanied with heat, effervescence, and a copious discharge of fumes. The fumes which arise during the dissolution of some metals in the vitriolic acid, prove inflammable: hence in the preparation of the artificial vitriols of iron and zinc, the operator ought to be careful, especially where the solution is made in a narrow-mouthed vessel; lest, by the imprudent approach of a candle, the exhaling vapour be set on fire.

179. There is another species of solution, in which the moisture of the air is the menstruum. Fixed alkaline salts, and those of the neutral kind, composed of alkaline salts and the vegetable acids, or of soluble earths and any acid except the vitriolic, and some metallic salts, on being exposed for some time to a moist air, gradually attract its humidity, and at length become liquid. Some substances, not dissolvable by the application of water in its grosser form, as the butter of antimony, are easily liquefied by this slow action of the aerial moisture. This process is termed *Deli- quation*.

## SECT. II. *Extraction.*

180. The liquors which dissolve certain substances in their pure state, serve likewise to extract them from admixtures of other matter. Thus rectified spirit of wine, the menstruum of essential oils and resins, takes up the virtues of the resinous and oily vegetables; as water does those of the mucilaginous and saline; the inactive earthy parts remaining untouched by both. Water extracts likewise from many plants substances which by themselves it has little effect upon; even essential oils being, as we have formerly observed, rendered soluble in that fluid, by the admixture of gummy and saline matter, of which all vegetables participate in a greater or less degree. Thus many of the aromatic plants, and most of the bitters and astringents, yield their virtues to this menstruum.

181. Extraction is performed by *macerating* or steeping the subject in its appropriated menstruum in the cold, or *digesting* or *circulating* them in a moderate warmth; or *infusing* the plant in the boiling liquor, and suffering them to stand in a covered vessel till grown cold; or actually *boiling* them together for some time.

182. The term *digestion* is sometimes used for maceration; and in this case the process is directed to be performed without heat: where this circumstance is not expressed, digestion always implies the use of heat. Circulation differs from digestion only in this, that the steam, into which a part of the liquor is resolved by the heat, is, by means of a proper disposition of the vessels,

vessels, condensed and conveyed back again upon the subject. Digestion is usually performed in a *matrasi*, (or *bolthead*), Florence flask, or the like; either of which may be converted into a circulatory vessel, by inverting another into the mouth, and securing the juncture with a piece of wet bladder. A single matrasi, if its neck is very long and narrow, will answer the purpose as effectually, the vapour cooling and condensing before it can rise to the top. In a vessel of this kind, even spirit of wine, one of the most volatile liquors we know of, may be boiled without any considerable loss. The use of this instrument is likewise free from an inconvenience which may, in some cases, attend the other, of the uppermost vessel being burnt or thrown off. As the long-necked matrasis here recommended are difficultly filled or emptied, and likewise very dear, a long glass-pipe may be occasionally luted to the shorter ones.

183. Heat greatly expedites extraction; but by this means proves as injurious to some substances, by occasioning the menstruum to take up their grosser and more ungrateful parts, as it is necessary for enabling it to extract the virtues of others. Thus guaiacum or logwood impart little to aqueous liquors without a boiling heat, whilst even a small degree of warmth proves greatly prejudicial to the fine bitter of *carduus benedictus*. This plant, which, infused in boiling, or digested in sensibly hot water, gives out a nauseous taste, so offensive to the stomach as to promote vomiting, yields to the cold element a grateful balsamic bitter, the most elegant stomachic of the shops.

184. As heat promotes the dissolving power of liquids; so cold, on the other hand, diminishes it. Hence tinctures, or extractions made by a considerable heat, deposit in cold weather a part of their contents, and thus become proportionably weaker; a circumstance which deserves particular regard.

#### SECT. III. *Depuration.*

185. There are different methods of depurating or purifying liquors from their feculences, according as the liquor itself is more or less tenacious, or the feculent matter of greater or less gravity.

186. Thin fluids readily deposit their more ponderous impurities upon standing at rest for some time in a cool place: and may then be *decanted*, or poured off clear, by inclining the vessel.

187. Glutinous, unctuous, or thick substances, are to be liquefied by a suitable heat; when the grosser feculencies will fall to the bottom, the lighter arising to the surface, to be *despumated* or scummed off.

188, 189. Where the impurities are neither so ponderous as to subside freely to the bottom, nor so light as to arise readily to the surface, they may be separated in great measure by *colature* through strainers of linen, woollen, or other cloth, and more perfectly by *filtration* through a soft bibulous kind of paper made for this use.

190. Glutinous and unctuous liquors, which do not easily pass through the pores of a filter or strainer, are *clarified* by beating them up with whites of eggs; which concreting or growing hard when heated, and entangling the impure matter, arise with it to the surface. The mixture is to be gently boiled till the scum begins to break, when the vessel is to be removed from

the fire, the crust taken off, and the liquor passed through a flannel-bag.

191. Decantation, colature, and filtration, are applicable to most of the medicated liquors that stand in need of purification. Despumation and clarification very rarely have place; since these, along with the impurities of the liquor, frequently separate its medicinal parts. Thus, if the decoction of poppy-heads for making diacodium be solicitously scummed or clarified, (as some have been accustomed to do), the medicine will lose almost all that the poppies communicated; and instead of a mild opiate, turn out little other than a plain syrup of sugar.

192. It may be proper to observe, that the common sorts of filtering-paper are apt to communicate a disagreeable flavour: and hence, in filtering fine bitters, or other liquors whose gratefulness is of primary consequence, the part which passes through first ought to be kept apart for inferior purposes.

#### SECT. IV. *Crystallization.*

193,—197. Water, assisted by heat, dissolves a larger proportion of saline substances than it can retain when grown cold. Hence, on the abatement of the heat, a part of the salt separates from the menstruum, and concretes at the sides and bottom of the vessel. These concretions, unless too hastily formed by the sudden cooling of the liquor, or disturbed in their coalescence by agitation or other like causes, prove transparent, and of regular figures, resembling in appearance the natural spg.-crystals.

198. Different salts require different quantities of water to keep them dissolved: and hence if a mixture of two or more be dissolved in this fluid, they will begin to separate and crystallize at different periods of the evaporation. Upon this foundation salts are freed not only from such impurities as water is not capable of dissolving and carrying through the pores of a filter, but likewise from admixtures of one another; that which requires most water to dissolve in shooting first into crystals.

#### SECT. V. *Precipitation.*

199. By this operation, bodies are recovered from their solutions by means of the addition of some other substance, with which either the menstruum, or the body dissolved, have a greater affinity than they have with one another.

200, 201. Precipitation, therefore, is of two kinds; one where the substance superadded unites with the menstruum, and occasions that before dissolved to be thrown down; the other, in which it unites with the dissolved body, and falls along with it to the bottom. Of the first we have an example in the precipitation of sulphur from alkaline lixivia by the means of the acid; of the second, in the precipitation of mercury from aquafortis by sea-salt or its acid.

189. Where metals are employed as precipitants, as in the purification of martial vitriol from copper, by the addition of fresh iron, they ought to be perfectly clean and free from any rusty or greasy matter: otherwise they will not readily, if at all, dissolve, and consequently the precipitation will not succeed; for the substance to be precipitated separates only by the additional one dissolving and taking its place. The separated

Elements.

Elements.

separated powder oftentimes, instead of falling to the bottom, lodges upon the precipitant; from which it must be occasionally shaken off, for reasons sufficiently obvious.

203. Though in this operation the precipitated powder is generally the part required for use, yet some advantage may frequently be made of the liquor remaining after the precipitation. Thus when fixed alkaline salt is dissolved in water, and sulphur dissolved in this/ixivium, the addition of acids separates and throws down the sulphur, only in virtue of the acid uniting with and neutralizing the alkali by which the sulphur was held dissolved; consequently, if the precipitation is made with the vitriolic acid, and the acid gradually dropped in till the alkali is completely saturated, that is, so long as it continues to occasion any precipitation or turbidness, the liquor will yield, by proper evaporation and crystallization, a neutral salt, composed of the vitriolic acid and fixed alkali, that is, vitriolated tartar. In like manner, if the precipitation is made with the nitrous acid, a true nitre may be recovered from the liquor; if with the marine, the salt called *spiritus salis marini coagulatus*; and if with the acid of vinegar, the *sal diureticus*.

#### SECT. VI. Evaporation.

204. This is a third method of recovering solid bodies from their solutions, effected by the means of heat; which evaporating the fluid part, that is, forcing it off in steam, the matter which was dissolved therein is left behind in its solid form.

205. This process is applicable to the solutions of all those substances which are less volatile than the menstruum, or which will not exhale by the heat requisite for the evaporation of the fluid; as the solutions of fixed alkaline salts, of the gummy, gelatinous, and other inodorous parts of vegetables and animals in water, and of many resinous and odorous substances in spirit of wine.

206. Water extracts the virtues of sundry fragrant aromatic herbs almost as perfectly as rectified spirit of wine: but the aqueous infusions are far from being equally suited to this process with those made in spirit; water carrying off the whole odour and flavour of the subject, which that lighter liquor leaves entire behind it. Thus a watery infusion of mint loses in evaporation the smell, taste, and virtues of the herb; whilst a tincture drawn with pure spirit yields, on the same treatment, a thick balsamic liquid, or solid gummy resin, extremely rich in the peculiar qualities of the mint.

207. In evaporating these kinds of liquors, particular care must be had, towards the end of the process, that the heat be very gentle; otherwise the matter as it grows thick will burn to the vessel, and contract a disagreeable smell and taste: this burnt flavour is called an *emphyreuma*. The liquor ought to be kept stirring during the evaporation; otherwise a part of the matter concretes on the surface exposed to the air, and forms a pellicle which impedes the farther evaporation.

#### SECT. VII. Distillation.

208. In the foregoing operation, fluids are rarefied

by heat into steam or vapour, which is suffered to exhale in the air, but which the business of this is to collect and preserve. For this purpose the steam is received in proper vessels, luted to that in which the subject is contained; and being there cooled, condenses into a fluid form again.

209. There are two kinds of distillation: by the one, the more subtle and volatile parts of liquors are elevated from the grosser; by the other, liquids, incorporated with solid bodies, are forced out from them by vehemence of fire.

210. To the first belongs the distillation of the pure inflammable spirit from vinous liquors, and of such of the active parts of vegetables as are capable of being extracted by boiling water or spirit, and at the same time of arising along with their steam.

211. As boiling water extracts or dissolves the essential oils of vegetables whilst blended with the other principles of the subject without saturation, but imbibes only a determinate, and that a small, portion of them in their pure state; as these oils are the only substances contained in common vegetables, which prove totally volatile in that degree of heat; and as it is in them that the virtues of aromatics, and the peculiar odour and flavour of all plants, reside; it is evident that water may be impregnated, by distillation, with the more valuable parts of many vegetables: that this impregnation is limited, the oil arising in this process pure from those parts of the plant which before rendered it soluble in water without limitation; hence greatest part of the oil separates from the distilled aqueous liquor, and, according to its greater or less gravity, either sinks to the bottom or swims on the surface: that consequently infusions and distilled waters are greatly different from one another: that the first may be rendered stronger and stronger by pouring the liquor on fresh parcels of the subject; but that the latter cannot be in like manner improved by *cobobating*, or redistilling them from fresh ingredients.

212. As the oils of many vegetables do not freely distil with a less heat than that in which water boils, as rectified spirit of wine is not susceptible of this degree of heat, and as this menstruum totally dissolves these oils in their pure state; it follows, that spirit elevates far less from moist vegetables than water; but that nevertheless the distilled spirit, by keeping all that it does elevate perfectly dissolved, may, in some cases, prove as strong of the subject as the distilled water.

213. The apparatus made use of for distilling spirits, waters, and oils, consists of a *still*, or copper vessel, for containing the subject, on which is luted a large head with a *swan neck*. The vapour arising into the head, is thence conveyed through a *worm*, or long spiral pipe, placed in a vessel of cold water called a *refrigeratory*; and being there condensed, runs down into a receiver.

214. It may be observed, that as the parts which are preserved in evaporation cannot arise in distillation, the liquor remaining after the distillation, properly depurated and inspissated, will yield the same extracts as those prepared from the tincture or decoction of the subject made on purpose for that use: the one of these operations collecting only the volatile parts, and the

the other the more fixed; so that where one subject contains medicinal parts of both kinds, they may thus be obtained distinct, without one being injured by the process which collects the other.

215, 216, 217. The subjects of the second kind of distillation are, the gross oils of vegetables and animals, the mineral acid spirits, and the metallic fluid quicksilver; which as they require a much stronger degree of heat to elevate them than the foregoing liquors can sustain, so they likewise condense without arising so far from the action of the fire. The distillation of these is performed in low glass-vessels, called, from their neck being bent to one side, *retorts*: to the farther end of the neck a *receiver* is luted, which standing without the furnace, the vapours soon condense in it, without the use of a refrigeratory: nevertheless, to promote this effect, some are accustomed, especially in warm weather, to cool the receiver, by occasionally applying wet cloths to it, or keeping it partly immersed in a vessel of cold water.

### SECT. VIII. Sublimation.

218. As all fluids are volatile by heat, and consequently capable of being separated, in most cases, from fixed matters by the foregoing process; so various solid bodies are subjected to a similar treatment. Fluids are said to *distil*, and solids to *sublime*; though sometimes both are obtained in one and the same operation. If the subliming matter concretes into a mass, it is commonly called a *sublimate*; if into a powdery form, *flowers*.

219. The principal subjects of this operation are, volatile alkaline salts; neutral salts, composed of volatile alkalis and acids, as sal ammoniac; the salt of amber, and flowers of benzoil; mercurial preparations; and sulphur. Bodies of themselves not volatile are frequently made to sublime by the mixture of volatile ones: thus iron is carried up by sal ammoniac in the preparation of the *fores martiales*.

220. The fumes of solid bodies in close vessels rise but little way, and adhere to that part of the vessel where they concrete. Hence a receiver or condenser is less necessary here than in the preceding operation; a single vessel, as a matras, or tall vial, or the like, being frequently sufficient. The most commodious apparatus for the sublimation of particular substances, and the most advantageous method of conducting the several processes, will be afterwards delivered.

### SECT. IX. Expression.

221. The *press* is chiefly made use of for forcing out the juices of succulent herbs and fruits, and the insipid oils of the unctuous seeds and kernels.

222. The harder fruits, as quinces, require to be previously well beat or ground; but herbs are to be only moderately bruised. The subject is then included in a hair-bag, and pressed betwixt wooden plates, in the common screw-press, as long as any juice runs from it.

223. The expression of oils is performed nearly in the same manner as that of juices; only here, iron plates are substituted to the wooden ones there made use of. The subject is well pounded, and included in a strong canvas-bag, betwixt which and the plates of the press a hair-cloth is interposed.

224. The insipid oils of all the unctuous seeds are obtained, uninjured, by this operation, if performed without the use of heat, which though it greatly promotes the extraction of the oil, at the same time imparts an ungrateful flavour, and increases its disposition to grow rancid.

225. The oils expressed from aromatic substances generally carry with them a portion of their essential oil: hence the smell and flavour of the expressed oils of nutmegs and mace. They are very rarely found impregnated with any of the other qualities of the subject: oil of mustard seed, for instance, is as soft and void of acrimony as that of almonds, the pungency of the mustard remaining entire in the cake left after the expression.

### SECT. X. Exsiccation.

226. THERE are two general methods of *exsiccating* or drying moist-bodies: in one, their humid parts are exhaled by heat; in the other, they are imbibed or absorbed by substances whose soft and spongy texture adapts them to that use. Bodies intimately combined with or dissolved in a fluid, as recent vegetables and their juices, require the first; such as are only superficially mixed, as when earthy or indissoluble powders are ground with water, are commodiously separated from it by the second.

227. Vegetables and their parts are usually exsiccated by the natural warmth of the air; the assistance of a gentle artificial heat may, nevertheless, in general, be not only safely, but advantageously had recourse to. By a moderate fire, even the more tender flowers may be dried in a little time, without any loss either of their odour or lively colour; which would both be greatly injured or destroyed by a more slow exsiccation in the air. Some plants indeed, particularly those of the acid kind, as horic-radish, fennel, grass, and arum, lose their virtues by this process, however carefully performed; but far the greater number retain them unimpaired, and oftentimes improved.

228. The thicker vegetable juices may be exsiccated by the heat of the sun; or, where this is not sufficient, by that of a water-bath, or an oven moderately warm. The thinner juices may be gently boiled till they begin to thicken, and then treated as the foregoing: this process, termed *inspiration* or *evaporation*, has been spoken of already. The juices of some plants, as arum-root, briony-root, orris-root, wild cucumbers, &c. separate, upon standing for some time, into a thick part which falls to the bottom, and a thin aqueous one which swims above it: this last is to be poured off, and the first exsiccated by a gentle warmth: preparations of this kind have been usually called *saecula*; that of the wild cucumber, is the only one which practice now retains.

229. Indissoluble bodies mixed with water into a thick consistence, may be easily freed from the greatest part of it, by dropping them on a chalk-stone, or some powdered chalk pressed into a smooth mass, which readily imbibes their humidity. Where the quantity of fluid is large, as in the edulcoration of precipitates, it may be separated by decantation or filtration.

### SECT. XI. Comminution.

230. COMMINATION is the bare reduction of solid coherent

*Elements.* coherent bodies into small particles or powder. The methods of effecting this are various, according to the texture of the subject.

231. Dry friable bodies, or such as are brittle and not very hard, and mixtures of these with somewhat moist ones, are easily *pulverized* in a mortar.

232. For very light dry substances, resins, and the roots of a tenacious texture, the mortar may in some cases be previously rubbed with a little sweet oil, or a few drops of oil be occasionally added: this prevents the finer powder of the first from flying off, and the others from cohering under the pestle. Camphor is most commodiously powdered, by rubbing it with a little rectified spirit of wine.

233. Tough substances, as woods, the peels of oranges and lemons, &c. are most conveniently *rasped*; and soft oily bodies, as nutmegs, passed through a *grater*.

234. The comminution of the harder minerals, as calamine, crystal, flint, &c. is greatly facilitated by *extinction*; that is, by heating them red hot, and quenching them in water: by repeating this process a few times, most of the hard stones becomes easily pulverable. This process, however, is not to be applied to any of the alkaline or calcareous stones; lest, instead of an insipid powder, we produce an acrimonious calx or lime.

235. Some metals, as tin, though strongly cohering in their natural state, prove extremely brittle when heated, inasmuch as to be easily divided into small particles by dextrous agitation. Hence the official method of pulverising tin, by melting it, and, at the instant of its beginning to return into a state of solidity, briskly shaking it in a wooden box. The comminution of metals in this manner is termed by the metallurgists *granulation*.

236. On a similar principle, certain salts, as nitre, may be reduced into powder in large quantity, by dissolving them in boiling water, setting the solution over a moderate fire, and keeping the salt constantly stirring during its exsiccation, so as to prevent its particles, disjoined by the fluid, from re-uniting together into larger masses.

237. Powders are reduced to a great degree of fineness by *trituration* or rubbing them for a length of time in a mortar. Such as are not dissoluble in water, or injured by the admixture of that fluid, are moistened with it into the consistence of a paste, and *levigated* or ground on a flat smooth marble or iron plate; or where a large quantity is to be prepared at times, in mills made for that use.

238. Comminution, though one of the most simple operations of pharmacy, has, in many cases, very considerable effects. The resinous purgatives, when finely triturated, are more easily soluble in the animal fluids, and consequently prove more cathartic and less irritating than in their grosser state. Crude antimony, which when reduced to a tolerably fine powder discovers little medicinal virtue, if levigated to a great degree of subtlety, proves a powerful alterative in many chronic disorders.

239. By comminution, the heaviest bodies may be made to float in the lightest fluids, for a longer or shorter time, according to their greater or less degree of tenacity. Hence we are furnished with an excellent

criterion of the fineness of certain powders, and a method of separating the more subtle parts from the grosser, distinguished by the name of *elutriation*, or *washing over*. See 275, &c.

## SECT. XII. Fusion.

240. Fusion is the reduction of solid bodies into a state of fluidity by fire. Almost all natural substances, the pure earths and the solid parts of animals and vegetables excepted, melt in proper degrees of fire; some in a very gentle heat, whilst others require its utmost violence.

241. Turpentine, and other soft resinous substances, liquify in a gentle warmth; wax, pitch, sulphur, and the mineral bitumens, require a heat too great for the hand to support; fixed alkaline salts, common salt, and nitre, require a red or almost white heat to melt them; and glass, a full white heat.

242. Among metallic substances, tin, bismuth, and lead, flow long before ignition: antimony likewise melts before it is visibly red-hot, but not before the vessel is considerably so: the regulus of antimony demands a much stronger fire. Zinc begins to melt in a red heat; gold and silver require a low white heat; copper, a bright white heat; and iron, an extreme white heat.

243. One body, rendered fluid by heat, becomes sometimes a menstruum for another not fusible of itself in the same degree of fire. Thus red-hot silver melts on being thrown into melted lead less hot than itself: and thus if steel, heated to whiteness, be taken out of the furnace, and applied to a roll of sulphur; the sulphur instantly liquefying, occasions the steel to melt with it; hence the *chalybs cum sulphure* of the shops. This concrete, nevertheless, remarkably impedes the fusion of some other metals, as lead, which, when united with a certain quantity of sulphur, is scarce to be perfectly melted by a very strong fire: hence the method, described in its place, of purifying zinc, a metal which sulphur has no effect upon, from the lead so frequently mixed with it.

244. Sulphur is the only unmetallic substance which mingles in fusion with metals. Earthy, saline, and other like matters, even the calces and glasses prepared from metals themselves, float distinct upon the surface, and form what is called *scoria* or dross. Where the quantity of this is large in proportion to the metal, it is most commodiously separated by pouring the whole into a conical mould: the pure metal or *regulus*, tho' small in quantity, occupies a considerable height in the lower narrow part of the cone, and when congealed may be easily freed from the scoria by a hammer. The mould should be previously greased, or rather smoked, to make the metal come freely out; and thoroughly dried and heated, to prevent the explosion which sometimes happens from the sudden contact of melted metals with moist bodies.

## SECT. XIII. Calcination.

245. By calcination is understood the reduction of solid bodies by the means of fire, from a coherent to a powdery state, accompanied with a change of their quality; in which last respect this process differs from comminution.

246. To this head belong the burning of vegetable

table and animal matters, otherwise called *ufluxion*, *incineration*, or *concremation*; and the change of metals into a powder, which in the fire either does not melt, or *vittrifies*, that is, runs into glass.

247. The metals which melt before ignition, are calcined by keeping them in fusion for some time. The free admission of air is essentially necessary to the success of this operation; and hence, when the surface of the metal appears covered with calx, this must be taken off or raked to one side; otherwise, the remainder, excluded from the air, will not undergo the change intended. If any coal, or other inflammable matter that does not contain a mineral acid, be suffered to fall into the vessel, the effect expected from this operation will not be produced, and part of what is already calcined will be *revived* or *reduced*; that is, it will return into its metallic form again.

248. Those metals which require a strong fire to melt in, calcine with a much less heat than is sufficient to make them flow. Hence the burning or *scorification* of such iron or copper vessels as are long exposed to a considerable fire without defence from the air. Gold and silver are not calcinable by any degree of fire.

249. In calcination, the metals visibly emit fumes; nevertheless, the weight of the calx proves greater than that of the metal employed. The antimonial regulus gains about one-eleventh part of its weight; zinc, sometimes one-tenth; tin, above one-sixth; and lead, in its conversion into minium, oftentimes one-fourth.

250. The calcination of metallic bodies (gold, silver, and mercury excepted) is greatly promoted by nitre. This salt, exposed to the fire in conjunction with any inflammable substances, extricates their inflammable matter, and burks with it into flame, accompanied with

a hissing noise: this process is usually termed *deflagration* or *detonation*.

251. All the metallic calces and scorix are revived into their metallic state, by fusion with any vegetable or animal inflammable matter. They are all more difficult of fusion than the respective metals themselves; and scarcely any of them, those of lead and bismuth excepted, can be made to melt at all, without some addition, in the strongest fire that can be produced in the common furnaces. The additions called *fluxes*, employed for promoting the fusion, consist chiefly of fixed alkaline salts: a mixture of alkaline salt with inflammable matter, as powdered charcoal, is called a *reducing flux*, as contributing at the same time to bring the calx into fusion and to revive it into metal. Such a mixture is commonly prepared from one part of nitre and two parts of tartar; by grinding them well together, setting the powders on fire with a bit of coal or a red-hot iron, then covering the vessel, and suffering them to deflagrate or burn, till they are changed into a black alkaline coaly mass. This is the common reducing flux of the chemists; and is called from its colour, the *black flux*. Metallic calces, or scorix, mingled with twice their weight of this compound, and exposed to a proper fire, in a close-covered crucible, melt, and resume their metallic form: but tho' they received an increase of weight in the calcination, the revived metal is always found to weigh considerably less than the quantity which the calx was made from.

For a more particular account of all these processes, and an explanation of the principles on which they depend, see *CHEMISTRY passim*, and the articles themselves as they occur in the order of the alphabet.

## PART II. PREPARATIONS AND COMPOSITIONS;

Containing those of the LONDON and EDINBURGH PHARMACOPOEIAS, as directed in the LAST editions.

### C H A P. I.

#### Pharmaceutical PREPARATIONS.

##### SECT. I. *The more Simple Preparations.*

*The preparation of EARTHY and such other pulverable bodies as will not dissolve in water.*

252. These substances are first to be pulverised in a mortar, and then levigated with a little water, upon a hard and smooth marble, into an impalpable powder: this is to be dried upon a chalk-stone, and afterwards set by for a few days, in a warm, or at least very dry place. *L.*

253. After this manner are to be prepared,

254. *Verdegriis.* *L.*

255. *Antimony.* *L. E.*

256. *Crab's claws.* *L. E.*

257. *Coral.* *L. E.*

258. *Chalk.* *L. E.* This is first to be powdered, and then well washed with water, till the latter comes off without either colour or taste. *E.*

259. *Bezoar stone*; which is to be moistened in the levigation with spirit of wine instead of water. *L.*

VOL. VIII.

260. *Calamine stone*, previously calcined, is to be had from those who make brasi. *L. E.*

261. *Blood-stone.* *L. E.*

262. *Lapis lazuli.* *E.*

263. *Pearls.* *L. E.*

264. *Crab's eyes*, so called. *L. E.*

265. *Oyster-shells*, washed clean from dirt, (*L.*) The hollow shells are to be preferred to the plain, (*E.*) because they contain more of the fine white earth in proportion to the rough outward coat; which last appears to be largely impregnated with marine salt.

266. *Egg-shells*, freed, by boiling, from the skin that adheres to them. *L.*

267. *Amber.* *L.*

268. *Tutty.* *L. E.*

269. In preparing antimony, calamine, and tutty, particular care ought to be taken to reduce them into the most subtle powder possible. *L.*

270. Some few substances are more advantageously levigated with spirit of wine than with water. Thus bezoar has the green colour, usually expected in this costly preparation, considerably improved thereby. A little spirit may be added to the other animal-substances, if the weather is very hot, and large

Prepara-  
tions.Prepara-  
tions.

quantities of them are prepared at once, to prevent their running into putrefaction; an accident which, in those circumstances, sometimes happens when they are levigated with water only. Crab's eyes, which abound with animal gelatinous matter, are particularly liable to this inconvenience.

273. The caution given above for reducing antimony, calamine, and tutty, to the greatest subtilty possible, demands particular attention. The tenderness of the parts to which the two last are usually applied, requires them to be perfectly free from any admixture of gross irritating particles. The first, when not thoroughly comminuted, might not only, by its sharp needle-like spicula, wound the stomach, but likewise answers few valuable purposes as a medicine, proving either an useless load upon the viscera, or at best passing off without any other sensible effect than an increase of the grosser evacuations; whilst, if reduced to a great degree of fineness, it turns out to be a medicine of considerable efficacy.

274. The most successful method of obtaining these powders of the requisite tenuity, is to wash off the finer parts by means of water, and continue levigating the remainder till the whole becomes fine enough to remain for some time suspended in the fluid. The process is thus directed in the Edin. Pharm.

A quantity of water is to be poured upon the levigated powder, in a large vessel, and the vessel repeatedly shaken, that the finer parts of the powder may be diffused through the water: the liquor is then to be poured off, and set by till the powder settles. The gross part, which the water would not take up, is to be further levigated, and treated in the same manner.

After this method are prepared antimony, calamine, tutty, bloodstone, chalk, and lapis lazuli.

275. By this method, which is that commonly practised in the preparation of colours for the painter, powders may be obtained of any required degree of tenuity; and without the least mixture of the gross parts, which are always found to remain in them after long continued levigation: all the coarser matter settles at first, and the finer powder continues suspended in the water, longer and longer, in proportion to the degree of its fineness. The same process may likewise be advantageously applied to other hard pulverable bodies of the mineral kingdom, or artificial preparations of them; provided they are not soluble in, or specifically lighter than, water. The animal and absorbent powders, crab's-claws, crab's-eyes, oyster-shells, egg-shells, chalk, pearl, coral, and bezoar, are not well adapted to this treatment; nor indeed do they require it. These substances are readily soluble in acid juices without much comminution: if no acid is contained in the first passages, they are apt to concrete, with the mucous matter usually lodged there, into hard indissoluble masses; the greater degree of fineness they are reduced to, the more are they disposed to form such concretions, and enabled to obstruct the orifices of the small vessels.

276. *The purification or trying of hog's lard and nut-ton suet.* L.

Chop them into small pieces, and melt them by a gentle heat, with the addition of a little water; then strain them from the membranes.

The use of the water is to prevent the fat from burning and turning black; which it does very effectually, though it somewhat prolongs the process, and is likewise apt to be in part imbibed by the fat.

277. *The purification of viper's fat.* L.

Let the fat, separated from the intestines, be melted by a gentle fire, and then pressed thro' a thin linen cloth.

The quantity of this fat usually purified at a time is so small, that the heat may be easily regulated so as to prevent burning, without the addition of any water.

278. *The depuration or clarifying of honey.* L. E.

Let the honey be liquefied in a water-bath, (that is, by setting the vessel containing the honey in a vessel of hot water), and the scum which arises taken off.

The intention of this process is to purify the honey from wax or other drossy matters that have been united with it by the violence of the press in its separation from the comb, and from meal and such like substances which are sometimes fraudulently mingled with it. When the honey is rendered liquid and thin by the heat, these lighter matters rise freely to the surface.

279. *The drying of squills.*

Let the squill, cleared from its outer skin, be cut transversely into thin slices, and dried with a very gentle heat. L. The operation is known to have been successfully performed when the squill becomes brittle without losing its acrimony and bitterness. E.

By this method the squill dries much sooner than when only its several coats are separated, as has been usually directed; the internal part being here laid bare, which, in each of the entire coats, is covered with a thin skin, which impedes the exhalation of the moisture. The root loses, in this process, four fifths of its original weight; the parts which exhale appear to be merely watery: hence six grains of the dry root are equivalent to half a dram of it when fresh; a circumstance to be particularly regarded in the exhibition of this medicine.

280. *The burning of sponge.*

Burn the sponge in a close earthen vessel, until it becomes black and easily friable, then powder it in a glass or marble mortar. L. The sponge is to be cut in small pieces, and well freed from earthy matters previous to the operation, and is to be frequently stirred during the time of burning. E.

This medicine, only lately received in the dispensatory, has been in use for a considerable time, and employed against feropulous disorders and cutaneous foulnesses, in doses of a scruple and upwards. Its virtues seem to depend upon a volatile salt, just formed and combined with its own oil; if the sponge be distilled with a stronger heat, it yields a large proportion of that salt in its proper form. The salt is in this preparation so far extricated, that if the burnt sponge be ground in a brass mortar, it corrodes the metal, so as to contract a disagreeable taint, and sometimes an emetic quality.

A good deal of address is requisite for managing this

this process in perfection. The sponge should be cut small, and beaten for some time in a mortar, that all the stony matters may be got out, which, compared with the weight of the sponge when prepared, will sometimes amount to a considerable quantity. The burning should be discontinued as soon as ever the matter is become thoroughly black. If the quantity put into the vessel at once is large, the outside will be sufficiently burnt before the inside is affected; and the volatile salt of the former will in part escape before that in the latter is begun to be formed. The best method of avoiding this inconvenience seems to be, to keep the sponge continually stirring, in such a machine as is used for the roasting of coffee.

#### 281. *The calcination of hartshorn. L.*

Burn pieces of hartshorn in a potter's furnace, till they become perfectly white; then powder and levigate them after the same manner as the other earthy bodies.

The intention here is, totally to burn out and expel the oil, salt, and other volatile parts, so as to leave only a white insipid animal earth. For this purpose, a strong fire and the free admission of air are necessary. The potter's furnace is directed merely for the sake of convenience; where this is not to be had, any common furnace or stove may be made to serve: on the bottom of the grate spread some lighted charcoal, and above this lay the horns. The whole will burn vehemently; the vegetable matter is reduced to ashes; and the horns are burnt to whiteness, still retaining their original form, by which they are easily distinguished from the other: they ought to be separated as soon as grown cold, to prevent their imbibing any fixed salt from the vegetable ashes moistened by the air. The horns left after the distillation of the volatile salt and oil of hartshorn are as proper for this use as any other; that process only collecting such parts as are here dissipated in the air.

Calcined hartshorn is the purest of the animal absorbent powders; as being perfectly free from any glutinous or oily matter, which most of the others abound with. It appears nevertheless to be one of the weakest in absorbent power, or the most difficult of solution in acids.

#### 282. *The extraction of pulps. L.*

Ureipe pulpy fruits, and ripe ones if they are dry, are to be boiled in a small quantity of water until they become soft; then press out the pulp thro' a strong hair-sieve, and afterwards boil it down to a due consistence, in an earthen vessel, over a gentle fire; taking care to keep the matter continually stirring, to prevent its burning.

283. The pulp of *caña fistularis* is in like manner to be boiled out from the bruised pod, and reduced afterwards to a proper consistence, by evaporating the water.

284. The pulps of fruits that are both ripe and fresh, are to be pressed out thro' the sieve, without any previous boiling.

#### 285. *The straining of storax. L.*

Soften storax calamita in hot water; then press it out betwixt warm iron plates; and separate the storax,

now purified, from the water.

The storax commonly met with, stands greatly in need of purification. It contains a large quantity of woody matter, which this process effectually frees it from, though in other respects liable to some inconveniences. The woody substance in some measure defends the storax from the action of the press, and retains part of it behind; at the same time that the storax is apt to suffer a considerable dissipation of its volatile parts, in which its fragrance and principal virtue consist. To prevent as much as possible this last inconvenience, the operator ought carefully to avoid using a greater heat than is absolutely necessary; and as soon as the storax is sufficiently softened, to be expeditious in the straining of it.

Storax may be excellently purified by means of spirit of wine, which this resin totally dissolves in, so as to pass thro' a filtre, the impurities alone being left. If the storax is afterwards wanted in a solid form, it may be recovered from this solution by gently distilling off the spirit, which will elevate very little of its flavour, or by pouring to it a quantity of water. See Sect. vi. § 3.

#### 286. *Strained opium, or the Thebaic extract. L.*

Take of opium, cut into slices, one pound; dissolve it into the consistence of a pulp, in a pint of boiling water, with care to prevent its burning; and whilst it remains quite hot, strongly press it from the feces, thro' a linen-cloth; the strained opium is then to be reduced, by a water-bath or other gentle heat, to its original consistence.

Opium, thus softened by a small quantity of water, passes the strainer entire, the feces only being left behind. If it was dissolved in a large quantity of water, its resinous and gummy parts would be separated from one another.

Where large quantities of opium are purified at once, the inspissation is most commodiously performed in a water-bath; but small quantities may be very safely inspissated, by placing the vessel immediately over a gentle fire, the matter being kept stirring, and the vessel occasionally removed from the fire whenever there is any suspicion of its becoming too hot. The grosser impurities of the opium are by this process effectually separated; but some of its heterogeneous admixtures, consisting chiefly of dust and farinaceous matters, are so fine, as partly to pass along with it through the pores of the strainer when dilated by the press: this manifestly appears upon boiling the strained opium in water, and afterwards in spirit; when a considerable quantity of earthy matter will be left, which is not soluble in either of those menstrua.

287. The other gums, as ammoniacum, galbanum, asafœtida, and the like, are purified after the same manner; only here a larger quantity of water may be made use of without injury. If the resinous part happens to subside, take it out, and reserve it to be added again towards the end of the inspissation, that it may unite with the rest into one uniform mass.

Any gum that melts easily, as galbanum, may likewise be purified by including it in a bladder, and keeping it in boiling water, until the gum becomes soft enough to be pressed from its impurities through a canvas strainer. L.

288. *Preparation of millepedes, &c.*

The millepedes are to be inclosed in a thin canvas-cloth, and suspended over hot spirit of wine, in a close vessel, till they are killed by the steam, and rendered friable. *L. E.*

*Purification of iron filings.*—Let the filings be laid upon a sieve, and a magnet applied below, so that they may be gradually attracted through it. *E.*

*Preparation of iron filings.*—Let purified filings of iron be laid in a moist place till they fall down in rust, which is to be rubbed into an exceeding fine powder. *E.*

SECT. II. *Substances extracted from Vegetables by Expression.*

## §. I. JUICES.

289. JUICES are obtained from the succulent parts of plants, by including them, after being properly cut, bruised, &c. in a hair-bag, and pressing them, betwixt wooden checks, in the common screw-press, as long as any liquor drops from them.

290. The harder fruits require to be previously well beaten or ground; but herbs are to be only moderately bruised; for if these are over bruised, a large quantity of the herbaceous matter will be forced out along with the juice. Hempen or woollen bags are apt to communicate a disagreeable flavour; the threads of these likewise swell in proportion as they imbibe moisture, so as in great measure to prevent the free percolation of the juice.

291. The fluids thus extracted from succulent fruits, both of the acid and sweet kind; from most of the acrid herbs, as scurvy-grafs and water-cresses; from the acid herbs, as sorrel and wood-sorrel; from the aperient lactescent plants, as dandelion and hawkweed; and from sundry other vegetables, contain great part of the peculiar taste and virtues of the respective subjects. The juices, on the other hand, extracted from most of the aromatic herbs, as those of mint and the fragrant Turkey balm, commonly called *balm of gilead*, have scarce any thing of the flavour of the plants, and seem to differ little from decoctions of them, made in water, boiled till the volatile odoriferous parts have been dissipated. Many of the odoriferous flowers, as the lily, violet, hyacinth, not only impart nothing of their fragrance to their juice, but have it totally destroyed by the previous bruising. From want of sufficient attention to these particulars, practitioners have been frequently deceived in the effects of preparations of this class: juice of mint has been often prescribed as a stomachic, though it wants those qualities by which mint itself, and its other preparations, operate in that intention.

292. The juices thus forcibly pressed out from plants, differ from those which flow spontaneously or from incisions; these last consisting chiefly of such fluids as are not diffused through the whole substance of the vegetable subject, but elaborated in distinct vessels, or secreted into particular receptacles. From poppy-heads, slightly wounded, there issues a thick milky liquor, which dries, by a moderate warmth, into opium; whilst the juice obtained from them by pressure is of a dark green colour, and far weaker virtue.

293. Juices newly expressed are generally thick,

viscid, and very impure: by colature, a quantity of gross matter is separated, the juice becomes thinner, limpid, and better fitted for medicinal purposes, though as yet not entirely pure: on standing, it becomes again turbid, and apt to run into a fermentative or putrefactive state. Clarification with whites of eggs renders the juices more perfectly fine; but there are few that will bear this treatment without a manifest injury to their flavour, taste, and virtue.

294. The most effectual method of purifying and preserving these liquors is, to let the strained liquors stand in a cool place till they have deposited their grosser feces, and then gently pass them several times thro' a fine strainer till perfectly clear; when about  $\frac{1}{10}$ th part their weight of good spirit of wine may be added, and the whole suffered to stand as before: a fresh sediment will now be deposited, from which the liquor is to be poured off, strained again, and put into small bottles that have been washed with spirits and dried. A little oil is to be poured on the surface, so as very nearly to fill the bottles, and the mouths closed with leather, paper, or stopped with straw, as the flasks in which Florence wine is brought to us: this serves to keep out dust, and suffers the air, which in process of time arises from all vegetable liquors, to escape; which air would otherwise endanger the bursting of the glasses, or, being imbibed afresh, render their contents vapid and foul. The bottles are to be kept on the bottom of a good cellar or vault, placed up to the necks in sand. By this method, juices may be preserved a year or two; and some for much longer time.

295. *The scorbutic juices, &c.*

Take of the juice of garden scurvy-grafs, two pints; brooklime, water-cresses, each one pint; Seville oranges, a pint and quarter. Mix them together, let them stand till the feces have subsided, and then either pour the liquor off clear, or pass it through a strainer. *L.*

Take of juice of garden scurvy-grafs, oranges, water-cresses, each two pints; spirituous nutmeg-water, half a pint. Mix all together, and set by the liquor till the feces have subsided; then pour off the clear. *E.*

These juices are of considerable use for the purposes expressed in the title; and may be taken, from an ounce or two to a quarter of a pint, two or three times a day. They generally increase the urinary secretion, and sometimes introduce a laxative habit.

296. *Insipidated juice, commonly called extract, of wolsfbane.*

Let the fresh leaves of wolsfbane be included in a canvas bag, and strongly squeezed in a press, in order to give out their juice, which is to be insipidated to the consistence of thick honey, in vessels exposed to the steam of boiling water, keeping it carefully stirring towards the end.

After the same manner are prepared the insipidated juices or extracts of belladonna, flammula jovis, hyosciamus, and stramonium. *E.*

297. *Insipidated juice, or extract, of hemlock.*

Having expressed the juice of the fresh leaves and stalks of hemlock while in flower, as directed for wolsfbane,

bane, and inspissated it to the consistence of honey; let the whole cool, and then add as much of the powder of dried hemlock-leaves as is sufficient to make the mass of a due consistency for pills. Care, however, must be taken, that the evaporation proceed only as far as to admit about a fifth part of the powder.

### § 2. EXPRESSED OILS.

298. EXPRESSED oils are obtained chiefly from certain seeds and kernels of fruits, by thoroughly pounding them in a stone-mortar, or, where the quantities are large, grinding them in mills, and then including them in a canvas bag, which is wrapped in a hair-cloth, and strongly pressed betwixt iron plates. The canvas, if employed alone, would be squeezed so close to the plates of the press as to prevent the oil from running down: by the interposition of the hair-cloth, a free passage is allowed it.

299. Sundry machines have been contrived both for grinding the subject and pressing out the oil, in the way of business. To facilitate the expression, it is customary to warm either the plates of the press, or the subject itself after the grinding, by keeping it stirring in a proper vessel over the fire: the oil, liquefied by the heat, separates more freely and more plentifully. When the oil is designed for medicinal purposes, this practice is not to be allowed: for heat, especially if its degree is sufficient to be of any considerable advantage for promoting the separation, renders the oil less soft and palatable, imparts a disagreeable flavour, and increases its disposition to grow rancid: hence the colleges both of London and Edinburgh expressly require the operation to be performed without heat.

Nor are the oils to be kept in a warm place after their expression. Exposed but for a few days to a heat no greater than that of the human body, they lose their emollient quality, and become highly rancid and acrimonious. Too much care cannot be taken for preventing any tendency to this acid irritating state, in medicines so often used for abating immoderate irritation.

So much are these oils disposed to this injurious alteration, that they frequently contract an acrimony and rancidity while contained in the original subjects. Hence great care is requisite in the choice of the unctuous seeds and kernels, which are often met with very rancid: almonds are particularly liable to inconveniences of this kind.

300. Expressed oils are prepared for mechanic uses from sundry different subjects, as nuts, poppy-seed, hemp-seed, rape-seed, and others. Those directed for medicinal purposes in the London and Edinburgh Pharmacopœias, are,

301. *Oil of almonds.* L. E.

302. *Oil of linseed.* L. E.

303. *Oil of mustard seed.* L.

304. *Oil of ricinus.* E.

305. The oil of almonds is prepared from the sweet and bitter almonds indifferently; the oils obtained from both sorts being altogether the same. Nor are the differences of the other oils very considerable, the discriminating qualities of the subjects not residing in the oils that are thus obtained by expression: the oil of mustard-seed is as soft, insipid, and void of pungency,

as that of sweet almonds, the pungency of the mustard remaining entire in the cake left after the expression. The several oils differ in some of their properties from one another; but in medicinal qualities they appear to be all nearly alike, and agree in one common emollient virtue. They soften and relax the solids, and obtund acrimonious humours: and thus become serviceable, internally, in pains, inflammations, heat of urine, hoarseness, tickling coughs, &c.; in glysters, for lubricating the intestines, and promoting the ejection of indurated feces; and in external applications for tension and rigidity of particular parts. Their common dose is half an ounce: in some cases, they are given to the quantity of three or four ounces. The most commodious forms of their exhibition we shall see hereafter, in the section of *Emulsions*.

306. The oils expressed from aromatic substances differ from the foregoing, in retaining for the most part an admixture of the aromatic matter of the subject. Thus nutmegs and mace yield, upon expression, an oil impregnated with the flavour of the spices; and an oil expressed from aniseeds, has a great share of the peculiar smell of the seeds. A purgative oil also is extracted in America from the purgative seeds of the ricinus. It does not appear that other qualities of vegetables are communicated to their expressed oils.

307. The rinds of the several varieties of oranges, lemons, and citrons, yield by a kind of expression their essential oils almost pure, and nearly similar to those which are obtained from them by distillation. The essential oils, in which the fragrance and aromatic warmth of these fruits reside, are contained in numerous little vesicles, which may be distinguished by the naked eye, spread all over the surface of the peel. If the rind is cut in slices, and the slices separately doubled or bent in different parts, and squeezed between the fingers, the vesicles burst at the bending, and discharge the oil in a number of fine slender jets. A glass-plate being set upright in a glass or porcelain vessel, and the slices squeezed against the plate, the little jets unite into drops upon the plate, and trickle down into the vessel beneath. But though this process affords the true native oil, in the same state wherein it existed in the subject, unaltered by fire or other agents, it is not practicable to advantage, unless where the fruit is very plentiful, as only a small part of the oil it contains can thus be extracted or collected.

The oil is more perfectly separated by rubbing the rind upon a lump of sugar. The sugar, by the inequality of its surface, produces the effect of a rasp in tearing open the oily vesicles; and in proportion as the vesicles are opened, the sugar imbibes the oil. When the outward part of the lump is sufficiently moistened, it is scraped off, and the operation continued on the fresh surface. The oil thus combined with the sugar, is fit for most of the uses to which it is applied in a fluid state. Indeed, the pure essential oils obtained by distillation are often purposely mixed with sugar, to render their use the more commodious.

### SECT. III. *Infusions in different Menstrua.*

#### § 1. INFUSIONS and DECOCTIONS in WATER.

WATER, the direct menstruum of gums and salts, extracts readily the gummy and saline parts of vegetables. Its action, however, is not limited to these; the

the refinous and oily principles being, in most vegetables, so intimately blended with the gummy and saline, as to be in great part taken up along with them: some of the refinous cathartics, and most of the aromatic herbs, as well as bitters and astringents, yield to water the greatest part of their smell, taste, and medicinal virtue. Even of the pure essential oils and odorous refinings of vegetables, separated from the other principles, water imbibes a part of the flavour; and by the artificial admixture of gummy or saline matter, the whole substance of the oil or resin is made dissoluble in water.

308. Of pure salts, water dissolves only certain determinate quantities, (see n° 162): by applying heat, it is generally enabled to take up more than it can do in the cold, and this in proportion to the degree of heat; but as the liquor cools, this additional quantity separates, and the water retains no more than it would have dissolved without heat. With gummy substances, on the other hand, it unites unlimitedly, dissolving more and more of them till it loses its fluidity: heat expedites the action of the water, but cannot enable it to take up more than it would do, by allowing it longer time in the cold. The active parts extracted from most vegetables by water, and oils and refinings made soluble in water by the artificial admixture of gum, partake of this property of pure gums, being dissoluble without saturation.

309. It has been imagined that vegetables in a fresh state, while their oily, refinous, and other active parts, are already blended with a watery fluid, would yield their virtues to water more freely and more plentifully than when their native moisture has been dissipated by drying. Experience however shews, that dry vegetables in general give out more than fresh ones, water seeming to have little action upon them in their recent state. If, of two equal quantities of mint, one be infused fresh in water, and the other dried and then infused in the like quantity of water for the same length of time, the infusion of the dry herb will be remarkably the strongest: and the case appears to be the same in all the vegetables that have been tried.

310. In all the preparations described in this section, it is to be understood that the subjects must be moderately and newly dried; unless when they are expressly ordered to be taken fresh; in which case it is to be judged that their virtues are destroyed or impaired by drying.

311. The native colours of many vegetables are communicated to water along with their medicinal matter: many impart a colour different from their own; and others, tho' of a beautiful and deep colour themselves, give scarcely any to the menstruum. Of the first kind are the yellow and red flowers; of the second, the leaves of most plants; of the third, some of the blue flowers, as those of cyanus and larkspur. Acid liquors change the infusions of most flowers, the yellow ones excepted, to a red; and alkalies, both fixed and volatile, to a green.

312. From animal-substances, water extracts the gelatinous and nutritious parts, whence glues, gellies, broths, &c.; and along with these, it takes up principles of more activity, as the acrid matter of cantharides. It dissolves also some portion of calcined calcareous earths, both of the animal and of the mineral

kingdom, but has no action on any other kind of earthy matter.

### Art. i. *Infusions in COLD Water.*

#### 313. *Infusion of carduus.*

Take an ounce of the dried leaves of carduus benedictus, and a pint of common water; let them steep for six hours without heat, and then filter the liquor through paper.

By this management, only the finer parts of the carduus are extracted, and the infusion proves an agreeable light bitter: it fits easier on the stomach than any other medicine of the bitter kind; whereas, by long continued maceration, or by the application of heat, the grosser and more ungrateful parts are taken up, and the liquor becomes nauseous, so as to provoke vomiting. The light infusion is often given with great benefit in weaknesses of the stomach, where the common bitters do not agree. It may be flavoured at pleasure with aromatic materials; instead of pure water, a mixture thereof with some grateful distilled spirituous water, as 12 ounces of common water, and four of the spirituous water of orange-peel, may be used for the menstruum. The little quantity of spirit contained in this compound will not considerably vary the dissolving power of the water.

314. Many other vegetables may be advantageously treated in the same manner. From those which are weak in virtue, rich infusions may be obtained, by returning the liquor upon fresh quantities of the subject, the water loading itself more and more with the active parts. These loaded infusions are doubtless applicable to valuable purposes in medicine, as they contain, in a small compass, the finer, more subtle, and active principles of vegetables, in a form readily miscible with the fluids of the human body.

#### 315. *Tincture of mint. E.*

Take half an ounce of the dry leaves of spearmint, and a pint of simple mint-water. Steep them in a close vessel, in a warm place, for four hours, and then strain out the tincture.

The distilled water of mint is impregnated with as much of the volatile parts of the herb, as water can be made to retain by distillation. By infusion, however, it still takes up more, being equally effectual, as a menstruum, with fresh water; hence the tincture proves very rich in the virtue of the mint. This is another useful method of obtaining strong infusions from vegetables, and it may be varied at discretion; the distilled water of one plant may be employed as a menstruum for another.

#### 316. *Infusion of Peruvian bark.*

Take an ounce of Peruvian bark reduced into fine powder, and twelve ounces of water. Macerate without heat for twenty-four hours, occasionally shaking the vessel; then pour off the clear liquor, and pass it through a fine strainer.

The infusion appears to be one of the best preparations of the bark for weak stomachs, and may be given in doses of two or three ounces, in intermitting fevers, and in other disorders where the corroborating virtues of bark are required.

317. *Tar-water.*

Take of tar, two pounds; water, one gallon. Stir them strongly together with a wooden rod; and after standing to settle for two days, pour off the water for use.

Tar-water was some time ago recommended to the world as a certain and safe medicine in almost all diseases; a flow yet effectual alterative in cachexies, feurries, chlorotic, hysterical, hypochondriacal, and other chronic complaints; and a sudden remedy in acute distempers which demand immediate relief, as pleurifies, peripneumonies, the small-pox, and all kinds of fevers in general. The medicine, though certainly far inferior to the character that has been given of it, is doubtless, in many cases, of considerable utility: it sensibly raises the pulse, and occasions some considerable evacuation, generally by perspiration or urine, though sometimes by stool or vomit: hence it is supposed to act by increasing the vis vitæ, and enabling nature to expel the morbid humors.

318. *Lime-water.*

Take a pound of quicklime, and a gallon and a half of water. Pour the water gradually upon the lime; and when the ebullition is over, let the whole stand to settle; then filter the liquor through paper. *L.*

Take a pound of fresh burnt quicklime, and two gallons of water. Pour the water by little and little upon the lime; and when the ebullition is over, strongly shake the vessel; then let the whole stand at rest, that the lime may settle; and after two days filter the liquor, which is to be kept in vessels closely stoppered. *E.*

A lime-water may be prepared in the same manner from calcined oyster-shells.

321. Lime-water has been found of great service in scrophulous and scorbutic complaints; in some kinds of alvine fluxes, female weaknesses, and other disorders proceeding from a laxity and debility of the solids; particularly in corpulent and phlegmatic habits. It appears likewise to be possessed of a lithontriptic power, and in sundry calculous cases has procured considerable relief: the lime-water prepared from calcined oyster-shells is found to be, in this intention, more efficacious than that of the common stone or chalk lime. It is given internally, in the dose of a quarter of a pint, three or four times a-day; and likewise used externally for washing foul ulcers.

*Compound lime-water. E.*

Take of saffaras, root and bark, shaved, two ounces; nutmegs, well bruised, three drams; liquorice, sliced, one ounce; lime-water, fresh prepared, four pints. Digest them together for two days, in a very close vessel; and then strain the liquor.

*Lime-water left compounded. L.*

Take of liquorice, one ounce; saffaras-bark, half an ounce; simple lime-water, six pints. Macerate without heat for two days; and then strain the liquor.

*Lime-water more compounded. L.*

Take of guaiacum wood, shaved, half a pound; li-

quorice, one ounce; saffaras-bark, half an ounce; coriander-seeds, three drams; simple lime-water, six pints. Macerate without heat for two days; and then strain off the liquor.

In all these compositions, the additional articles take off the ill flavour of the lime-water, render it more grateful both to the palate and stomach, and at the same time considerably promote its medicinal efficacy, especially when intended against cutaneous disorders, and foulness of the blood and juices. They may be taken in the same quantities as the simple lime-water, and continued for some time; the patient keeping moderately warm during their use.

319. *The Cretaceous potion.*

Take of prepared chalk, gum arabic, of each one ounce; fine sugar, half an ounce; common water, two pints; spirituous nutmeg-water, two ounces. Mix them together. *E.*

Art. ii. *Infusions in BOILING Water.*320. *Simple bitter infusion. L.*

Take of gentian root, fresh yellow rind of lemon-peel, carefully freed from the inner white part, each half an ounce; dry yellow rind of Seville orange-peel, freed in like manner from the white, one dram and a half; boiling water, three quarters of a pint. Macerate for an hour or two; then filter the liquor through paper, or pass it through a strainer, without pressure.

This is a very elegant and useful bitter; as agreeable to the taste as can well be contrived, the pills communicating a fine flavour; which is the only addition that the gentian stands in need of.

321. *Purging bitter infusion. L.*

Take of senna, yellow rind of lemon-peel, fresh, each three drams; gentian root, yellow rind of Seville orange-peel, dry; lesser cardamom-seeds, freed from the husks, each half a dram; boiling water, five ounces by measure. Macerate them together; and when cold, strain off the liquor.

322. *Bitter infusion with senna. E.*

Take of senna, one dram; gentian root, sweet fennel-seeds, each half a dram; boiling water, a quarter of a pint. Infuse them for four hours, and then strain the liquor.

This infusion may likewise be prepared with two, three, or more times the quantity of senna.

Both these are useful purging bitters. The quantities here prescribed are intended for one dose; the first is the largest, and the other the smallest dose in which senna is usually given.

323. *Common infusion of senna. L.*

Take of senna, an ounce and a half; crystals of tartar, three drams; lesser cardamom-seeds, freed from the husks, two drams; water, one pint. Boil the crystals of tartar in the water until they are dissolved; then pour the water, whilst it continues boiling, upon the other ingredients; and when cold, strain off the liquor for use.

In the former *L. Pharmacopœia*, an alkaline salt was used

used in the infusion of fena, instead of the acid one here directed. The first was supposed to promote the operation of the medicine, by superadding a degree of purgative virtue of its own, and by enabling the water to extract somewhat more from the capital ingredient than it would be capable of doing by itself; whilst acids have rather a contrary effect. Experience, however, has sufficiently shown, that this infusion, and the following one with lemon-juice, do not fail in their intention; and, in a medicine very nauseous to many, it is of principal consequence to prepare it so, that the lightest and least disgusting parts may be extracted. Alkaline salts increase the offensiveness of the fena; whilst crystals of tartar considerably improve the colour of the infusion, and likewise render the taste to some persons less disagreeable. Soluble tartar should seem a good ingredient in these kinds of compositions, as it not only improves the taste, but promotes the purgative virtue of the medicine: this addition also renders the infusion less apt to gripe or occasion flatulencies.

### 324. *Infusion of fena with lemon.* L.

Take of fena, an ounce and a half; yellow rind of lemon-peel, fresh, one ounce; lemon-juice, one ounce by measure; boiling water, one pint. Macerate them together; and when cold, strain off the infusion.

This is a very pleasant and sufficiently efficacious purge: the Committee observe, that it is the most agreeable form they have been able to contrive for the exhibition of fena to such as are more than ordinarily offended with its flavour. The dose is from two ounces to four.

### 325. *Infusion of tamarinds with fena.* L.

Take of tamarinds, six drams; crystals of tartar, fena-leaves, of each one dram; coriander-seeds, half a dram; brown sugar, half an ounce; boiling water, eight ounces. Macerate the ingredients in a close earthen vessel unglazed, shaking it now and then. After four hours strain off the liquor. This infusion may be made with a double or triple quantity of fena.

### 326. *Infusion of rhubarb.* E.

Take of rhubarb, half an ounce; boiling water, half a pint. Infuse them for a night, and to the strained liquor add one ounce of spirituous cinnamon-water.

This appears to be one of the best preparations of rhubarb when designed as a purgative; water extracting its virtue more effectually than either vinous or spirituous menstrua: in this respect rhubarb differs from most of the other vegetable cathartics.

### 327. *Infusion of flammula jovis.* E.

Take of the dried leaves of the flammula jovis, two drams; boiling water, one pint. Macerate for a quarter of an hour; then let the liquor boil a little, and strain it. This may be made also with three or four drams of flammula jovis.

### 328. *Tincture of roses.*

Take of red rose-buds, freed from the white heels,

half an ounce; strong spirit (called *oil*) of vitriol, one scruple; boiling water, two pints and a half; double-refined sugar, one ounce and a half. First mingle the spirit of vitriol with the water in a glass or glazed earthen vessel, and in this mixture macerate the roses; when the liquor is grown cold, strain it, and add the sugar. L.

Take of red roses, cleared from the heels and dried, one ounce; spirit of vitriol, one dram; boiling water, four pints; white sugar, two-ounces. Macerate the roses with the boiling water for four hours in an unglazed earthen vessel; then add the acid, and, after the liquor is strained, the sugar. E.

This tincture is of an elegant red colour, and makes a very grateful addition to juleps in hemorrhages, and all cases that require mild coolers and subastringents: it is sometimes taken with boluses or electuaries of the bark; and likewise makes a good gargle.

### 329. *Mucilage of gum-arabic.* E.

Take of gum-arabic in powder, four ounces; hot water, six ounces; mix them, diligently rubbing them together all the time, and strain through a linen cloth.

### 330. *Mucilage of gum tragacanth.* E.

Take of gum tragacanth in powder, one ounce; hot water, half a pint. Macerate for 24 hours; then rub the ingredients well together, and squeeze the mucilage through a linen-cloth.

## Art. iii. DECOCTIONS.

331. THE effect of boiling differs from that of infusion in some material particulars. One of the most obvious differences is, that as the essential oils of vegetables, in which their specific odours reside, are volatile in the heat of boiling water, they exhale in the boiling along with the watery stream, and thus are lost to the remaining decoction; whereas both in cold and hot infusions they are preserved. Odorous substances, and those in general whose virtues depend on their volatile parts, are therefore unfit for this treatment. The soluble parts of these may, nevertheless, be united in this form with those of bodies of a more fixed nature, by boiling the latter till their virtues are sufficiently extracted, and then infusing the former in this decoction.

332. The extraction of the virtue of the subject is usually promoted or accelerated by a boiling heat; but this rule is less general than it is commonly supposed to be. We have already observed, that Peruvian bark gives out its virtue more perfectly by cold infusion than by coction. In some cases, boiling occasions a manifest disunion of the principles of the subject: thus, when almonds are triturated with cold water, their oil, blended with the mucilaginous or other soluble matter of the almond, unites with the water into a milky liquor called an *emulsion*; but on boiling them in water, the oil separates and rises to the surface; and if the most perfect emulsion be made to boil, a like separation happens.

### 333. *The white decoction.* L.

Take of calcined hartshorn, prepared, two ounces; gum-arabic, two drams; water, three pints. Boil them till only two pints remain; and then strain off the liquor.

This

This decoction is used as common drink in acute diseases attended with a looseness, and where acrimonious humours abound in the *prime viæ*. The gum is added in order to render the liquor lightly glutinous, and thus enable it to sustain more of the calx; which is the ingredient that the colour, but probably not the virtue, of the medicine depends upon. Calcined hartshorn has no quality from which it seems capable either of constringing and strengthening the vessels, giving a greater degree of consistency to thin fluids, or obtunding acrimonious humours. It blunts and absorbs acid juices; but acrimony and acidity are very different: there are few (perhaps none of the acute) disorders of adults attended with the latter; and few of infants are unaccompanied therewith. Some have proposed starch as an ingredient in these kinds of decoctions; a small quantity of this soft gelatinous, farinaceous substance should seem to be greatly preferable to the earthy calx. It may be observed, that the water is not enabled by the boiling to dissolve any part of the calx; and that in the decoction the calx is only diffused in substance thro' the water, as it would be by agitation.

### 334. Decoction of the woods. E.

Take of guaiacum shavings, three ounces; raisins of the sun, stoned, two ounces; saffraas wood sliced, liquorice sliced, of each one ounce; water, one gallon. Boil the guaiacum and raisins with the water, over a gentle fire, to the consumption of one half; adding towards the end, the saffraas and liquorice. Strain out the liquor without pressure.

This decoction is very well contrived; and if its use is duly continued, will do great service in some cutaneous diseases, foulness of the blood and juices, and some disorders of the breast; particularly in cold phlegmatic habits. It may be taken by itself in the quantity of a quarter of a pint, two or three times a-day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient in either case keeping warm, in order to promote the operation of the medicine.

### 335. Decoction of marshmallows root. E.

Take of marshmallow root, moderately dried, six ounces; large raisins, stoned, two ounces; common water, six pints. Boil to four pints, adding the other ingredients towards the end. Strain out the liquor, and let it settle till fine.

This decoction is intended chiefly as an emollient, to be liberally drank of in nephritic paroxysms; in which cases, by softening and relaxing the parts, it frequently relieves the pain, and procures an easy passage for the fabulous matter. Two or three ounces of this decoction may be taken for a dose.

### 336. Pectoral decoction. L.

Take common barley, stoned raisins, figs, each two ounces; liquorice, half an ounce; water, four pints. First boil the water with the barley, then add the raisins, and lastly (just before the end of the process) the figs and liquorice; the boiling is to be continued so long, that the liquor, when strained, may be no more than two pints. L.

VOL. VIII.

I

This decoction is an useful soft pectoral; and very agreeable to the palate. It is a good auxiliary in sharp defluxions on the breast and lungs, and has sometimes done service by itself. It may be drank at pleasure.

### 337. Barley-water. L. E.

Take of pearl-barley, two ounces; water, four pints. First wash the barley from the mealy matter that adheres to it, with some cold water; then boil it a little with about half a pint of fresh water, which will acquire a considerable tinge from it. Throw away this tinged water; put the barley into the water prescribed, made first to boil; and continue the boiling till half the water is wasted; then strain.

This liquor is to be drank freely, as a diluter, in fevers and other disorders. However trivial medicines of this class may appear to be, they are of greater importance in the cure of acute diseases, than many more laborious preparations.

### 338. Mucilage of quince-seeds. L.

Take of quince-seeds, one dram; water, six ounces by measure. Boil them over a soft fire, till the water grows slimy almost like the white of an egg; then pass it through a linen cloth.

This is a pleasant soft mucilage, of a somewhat sweetish taste, and a light agreeable smell: in these respects, and in its easy solubility in water, it differs from the mucilage of gum-tragacanth, to which some have supposed it similar: it has another difference, to its disadvantage, being apt to grow mouldy in keeping.

### [339]—349. Viper-broth. L.

Take a middle-sized viper, freed from the head, skin, and intestines, and two pints of water. Boil them to a pint and a half; then remove the vessel from the fire; and when the liquor is grown cold, let the fat, which congeals upon the surface if the viper was fresh, be taken off. Into this broth, whilst warm, put a pullet of a moderate size, drawn and freed from the skin, and all the fat, but with the flesh entire. Set the vessel on the fire again, that the liquor may boil; then remove it from the fire, take out the chicken, and immediately chop its flesh into little pieces: put these into the liquor again, set it over the fire, and as soon as it boils up, pour out the broth, first carefully taking off the scum.

Here all the circumstances subservient to the perfection of the broth are carefully set down: and even plain chicken-broth, for the use of the sick, ought to be made in a similar manner.

This seems to be one of the best preparations of the viper; all the benefit that can be expected from that animal being by this means obtained. It is very nutritious and restorative food: continued for a length of time, it has sometimes done good service in leprous and other obstinate cutaneous diseases. The dried flesh of the vipers brought from abroad is not at all superior to the fresh vipers of our own country; the wines and tincture of the animal, probably, have little virtue; the volatile salt, however strongly recommended by

34 A

some

Prepara-  
tions.

some, does not appear to differ from that producible from every animal-substance.

### 350. Decoction of feneka. E.

Take of feneka, rattlesnake root, one ounce; water, a pint and a half. Boil to one pint, and strain.

The virtues of this decoction will be easily understood from those of the root which it is prepared from. The dose, in hydropic cases, and rheumatic or arthritic complaints, is two ounces; to be repeated three or four times a-day, according to its effect.

### 351. The common fomentation. L.

Take of abrotanum leaves dried, sea-wormwood tops dried, camomile-flowers dried, each one ounce; bay-leaves dried, half an ounce; water, six pints. Lightly boil them, and strain out the decoction for use.

It is left to the choice of the apothecary to take either the male or female abrotanum, that is, southernwood or lavender-cotton: which, though differing from one another, in some respect may be looked upon as similar with regard to the purposes for which this composition is intended: nor indeed can either of them give much assistance to camomile-flowers and wormwood. The use of this decoction is expressed in its title: spirit of wine, which is commonly added in fomentations, is left to be directed by the prescriber, in such quantity as particular cases may require.

### 352. The common decoction for gylsters. L.

Take of mallow-leaves dried, one ounce; camomile flowers dried, sweet fennel-seeds, each half an ounce; water, one pint. Boil them together, and strain out the decoction for use.

The title of this decoction sufficiently expresses its use, as the basis of gylsters.

### 353. The common decoction. E.

Take of camomile-flowers, one ounce; carway-seeds, half an ounce; water, two quarts. Boil for a quarter of an hour, and then strain out the liquor.

This decoction is intended to answer the purposes of both the foregoing. It is less loaded with ingredients than either, but not perhaps for that reason the less useful.

## § 2. WHEYS.

### 356. Mustard-whcy.

Take milk and water, of each a pint; bruised mustard-seed, an ounce and a half. Boil them together till the curd is perfectly separated; afterwards strain the whey through a cloth.

This is the most elegant, and by no means the least efficacious method of exhibiting mustard. It warms and invigorates the habit, and promotes the different secretions. Hence, in the low state of nervous fevers, it will often supply the place of wine. It is also of use in the chronic rheumatism, palsy, dropsy, &c. The addition of a little sugar will render it more agreeable. — The dose is an ordinary tea-cupful four or five times a-day.

### 537. Alum-whcy.

Boil two drams of powdered-alum in a pint of milk

till it is curdled; then strain out the whey.

This whey is beneficial in an immoderate flow of the menses, and in a diabetes or excessive discharge of urine. — The dose is two, three, or four ounces, according as the stomach will bear it, three times a-day. If it should occasion vomiting, it may be diluted.

### 583. Scorbutic whey.

This whey is made by boiling half a pint of the scorbutic juices in a quart of cow's milk. More benefit, however, is to be expected from eating the plants than from their expressed juices.

The scorbutic-plants are, bitter-oranges, brooklime, garden scurvy-grafs, and water-creffes.

## § 3. VINEGARS.

359. VINEGAR extracts the virtues of several medicinal substances in tolerable perfection: but at the same time its acidity makes a notable alteration in them, or superadds a virtue of a different kind; and hence it is more rarely employed in this intention than purely aqueous or spirituous menstrua. Some drugs, however, vinegar, for particular purposes, excellently assists or coincides with, as squills, garlic, ammoniacum, and others: and in many cases, where this acid is itself principally depended on, it may be advantageously impregnated with the flavour of certain vegetables; most of the odoriferous flowers impart to it their fragrance, together with a fine purplish or red colour. Violets, for instance, if fresh parcels of them are infused in vinegar in the cold for a little time, communicate to the liquor a pleasant flavour, and deep purplish red colour. Vinegar, like other acids, added to watery infusions or decoctions, generally precipitates a part of what the water had dissolved.

### 360. Vinegar of squills.

Take of dried squills, one pound; vinegar, six pints. Macerate the squills in the vinegar with a gentle heat; then press out the liquor, and set it by till the faeces have subsided: the vinegar being afterwards poured off, add to it about one-twelfth its quantity of proof-spirit, that it may keep the longer from growing mothery. L.

Take of the dried root of squills, four ounces; distilled vinegar, two pints; proof-spirit, two ounces. Macerate the root with the vinegar for eight days; then add the spirit; and when the faeces have subsided, pour off the clear liquor. E.

This is a medicine of great antiquity: we find, in a treatise attributed to Galen, an account of its preparation, and of many particular virtues then ascribed to it. It is a very powerful stimulant, aperient, and attenuant of tenacious juices; and hence is frequently used with good success in disorders of the breast occasioned by a load of thick viscid phlegm, for promoting urine in hydropic cases, &c. The dose of this medicine is from a dram to half an ounce. Where crudities abound in the first passages, it may be given at first in a larger dose, to evacuate them by vomit. It is most conveniently exhibited along with cinnamon or other agreeable aromatic waters, which prevent the nausea it would otherwise, even in small doses, be apt to occasion.

Prepara-  
tions.

## § 4. WINES.

361. The original intention of medicated wines was, that medicines, which were to be continued for a length of time, might be taken in the most familiar and agreeable form; by this means a course of remedies was complied with, notwithstanding the repugnance and aversion which the sick often manifest to those directly furnished from the shops; and hence the inferior sort of people had their medicated ales. Nevertheless, as vinous liquors excellently extract the virtues of several simples, and are not ill fitted for keeping, they have been employed as official menstrua also; and substances of the greatest efficacy are trusted in this form. As compounds of water and inflammable spirit, they take up such parts of vegetables and animals as are soluble in those liquors; though most of them abound at the same time with a mucilaginous or viscous substance, which renders them less effectual menstrua than purer mixtures of water and spirit. They contain likewise a fusible acid, which somewhat further obstructs their action on certain vegetable and animal matters, but enables them, in proportion to its quantity, to dissolve some bodies of the metallic kind, and thus impregnate themselves with the corroborating virtues of steel, the alterative and emetic powers of antimony, and the noxious qualities of lead.

*Note.* To all the medicated wines, after they have been strained, you may add about one-twentieth their quantity of proof-spirit to preserve them from fermentation. They may be conveniently kept in the same kind of glass-bottles that wines generally are for common uses, which should likewise be corked with the same care. *L.*

362—364. *Alkaline aloetic wine. L.*

Take of any fixed alkaline salt, eight ounces; fopoc-torine aloes, saffron, myrrh, each one ounce; sal ammoniac purified, six drams; mountain wine, two pints. Macerate without heat for a week or longer; then filter the wine through paper.

This is the *elixir proprietatis Helmontii*, with some little variations which affect the compounder rather than the composition.

Helmont and others have entertained a very high opinion of this medicine, and looked upon it as “a vivifying and preserving balsam, capable of continuing health and prolonging life to the utmost possible limits.” The medicine is doubtless a very efficacious and useful one for many purposes: it may be so managed as to attenuate viscid juices and open obstructions in the remoter parts, and promote evacuation by almost all the emunctories. In doses of one, two, or three drams, it increases the urinary secretion; and if the patient is kept moderately warm, generally proves diaphoretic or sudorific; in larger doses, it gently loosens the belly.

365, a. *Bitter wine. L.*

Take of gentian root, yellow rind of lemon-peel, fresh, each one ounce; long pepper, two drams; mountain wine, two pints. Macerate without heat, and strain out the wine for use.

This is a very elegant bitter, which the addition of the long pepper renders considerably warmer than the

watery infusion. Gentian and lemon-peel, as we have already seen, make a bitter of a very grateful flavour. “The spice here added was selected, after the trial of many other materials.”

365, b. *Bitter wine. E.*

Take of gentian root, half an ounce; Peruvian bark, one ounce; dried orange-peel, two drams; canella alba, one dram; proof-spirit, four ounces; white-wine, two pints. First pour on the proof-spirit, then the wine; macerate four days, and strain.

This wine supplies the place of the stomachic tincture of the former pharmacopœia.

366. *Antimonial or emetic wine.*

Take of crocus of antimony, washed, one ounce; mountain wine, a pint and a half. Digest without heat, and filter the wine through paper. *L.*

Take of glass of antimony, levigated, one ounce; white wine, one pint. Digest for three days, shaking the mixture now and then, and filter the liquor through paper. *E.*

The antimonial wine possesses the whole virtues of that mineral, and may be so dosed and managed as to perform all that can be effected by any antimonial preparation; with this advantage, that as the active part of the antimony is here already dissolved and rendered miscible with the animal-fluids, its operation is more certain. Given from 10 to 50 or 60 drops, it acts generally as an alterative and diaphoretic; in larger doses, as a diuretic and cathartic; whilst three or four drams prove for the most part violently emetic. It has been chiefly used in this last intention, in some maniacal and apoplectic cases; and hence gained the name of *emetic wine*.

367. *Steel-wine.*

Take of iron filings, four ounces; cinnamon, mace, each half an ounce; Rhenish wine, four pints. Macerate without heat for a month, frequently shaking the vessel; then strain off the wine for use. *L.* Take of iron-filings, three ounces; cochineal, half a dram; Rhenish wine, two pints. Digest them together for twenty days, frequently shaking the vessel; and then pass the wine through a filter. *E.*

Both these wines are sufficiently elegant ones. Rhenish is an excellent menstruum for steel, and dissolves a considerable quantity of it: the cochineal, in the second, imparts a fine colour; and the spices, in the first, give the liquor an agreeable flavour, make it sit easier on the stomach, and likewise promote its medicinal efficacy.

368. Steel-wine is a very useful preparation of this metal, and frequently exhibited in chlorotic and other indispositions where chalybeates are proper. Boerhaave recommends it as one of the noblest medicines he was acquainted with, for promoting that power in the body by which blood is made, when weakened by a bare debility of the over-relaxed solids, and an indolent, cold, aqueous indisposition of the juices; for in this case, says he, no virtue of any vegetable or animal substance, no diet or regimen can effect that, which is effected by iron; but it proves hurtful where the vital powers are already too strong, whether this pro-

ceeds from the fluids or the solids. The dose is from a dram to half an ounce; which may be repeated two or three times a-day.

### 369. *Saffron-wine.* L.

Take of saffron, one ounce; canary, one pint. Macerate without heat, and strain off the wine.

Canary has been objected to by some as an improper menstruum for medicinal simples, since it contains a large quantity of unctuous matter, which impedes its dissolving power: a pint of this sort of wine left, upon evaporation, two ounces of a melluginous substance, not unlike honey boiled hard. It is nevertheless, for saffron, a very well adapted menstruum, as not only sufficiently loading itself with its virtues, but likewise coinciding in the general intention of the medicine, that of a cordial. The preparation made with Canary is also better fitted for keeping than when wines that have any tendency to acidity are employed; for tinctures of saffron drawn with these last soon lose their fine colour; whilst those made with the first retain it for a much longer time. The dose of this tincture is from one dram to three or more.

### 370. *Wine of ipecacuanha.* L.

Take of ipecacuanha, two ounces; yellow rind of Seville orange-peel, dried, half an ounce; Canary, two pints. Macerate without heat, and strain out the wine.

### 371. *Tincture of ipecacuanha.* E.

Take of ipecacuanha in powder, one ounce; mountain wine, one pint. After three days digestion, let the tincture be filtered for use.

Both these wines are very mild and safe emetics, and equally serviceable in dysenteries also, with the ipecacuanha in substance; this root yielding nearly all its virtues both to the mountain and Canary wines here ordered, as it does a good share of them even to aqueous liquors. The common dose is an ounce, more or less, according to the age and strength of the patient.

### 372. *Viper-wine.* L.

Take of dry vipers, two ounces; mountain, three pints. Macerate with a gentle heat for a week; and then strain off the wine.

It has been disputed, whether live or dry vipers are preferable for making this medicine: such as are moderately and newly dried, are perhaps the most eligible, since, by exsiccation, they seem to lose only their phlegmatic or aqueous parts. Whether they communicate to the wine, either when used fresh or dry, so much virtue as they are supposed to do, is greatly to be doubted. Some compositions under this name have been highly celebrated, as restoratives, in debilities and decays of constitution; but what virtues of this kind they possessed, were supplied chiefly from other ingredients.

### 373. *Wine of millepedes.* E.

Take of live millepedes, bruised, two ounces; Rhenish wine, one pint. Pour the wine on the millepedes bruised a little; infuse for twelve hours, and strain

off the liquor, and squeeze it out from the residuum.

This wine has been commended as an admirable cleanser of all the viscera, yielding to nothing in the jaundice and obstructions of the kidneys or urinary passages, of excellent service in almost all chronic distempers, even in serophulous and stumous swellings, and in defluxions of rheum upon the eyes. But those who expected these extraordinary virtues from it, have often been deceived; and at present there are few who have any great dependence on it. It is directed to be given from half an ounce to two ounces.

### 374. *Cephalic tincture.* E.

Take of wild valerian root, four ounces; Virginian snakeroot, one ounce; rosemary tops, half an ounce; French white-wine, six pints. Digest them together for three days, and then filter the tincture.

This preparation promises to be a medicine of considerable utility as a cephalic, that is, in disorders of the nervous system, wherein the membranes of the brain are often principally affected, as in vertiginous, epileptic, and paralytic complaints.

### 375. *Vinous tincture of rhubarb.* L.

Take of rhubarb, two ounces; lesser cardamom seeds, freed from the husks, half an ounce; saffron, two drams; mountain wine, two pints. Macerate without heat, and then strain off the tincture.

This is a warm, cordial, laxative medicine. It is used chiefly in weakness of the stomach and bowels, and some kinds of looseness, for evacuating the offending matter, and strengthening the tone of the viscera. It may be given from half a spoonful to three or four spoonfuls or more, according to the circumstances of the disorder, and the purposes it is intended to answer.

### 376. *Tinctura sacra.*

Take of socotorine aloes, eight ounces; canella alba, two ounces; mountain wine, ten pints. Reduce the aloes and canella separately into powder; then mix, and pour on them the wine; afterwards macerate without heat, for a week or longer, occasionally shaking the vessel; lastly, strain off the wine. It will be convenient to mix with the powders some white sand, well washed from dirt, to prevent the aloes from concreting, which it is apt to do upon being moistened. L.

Take of socotorine aloes in powder, one ounce; Ginger, Jamaica pepper, each one dram; mountain wine, a pint and a half. Digest for seven days, shaking the mixture now and then, and then strain off the tincture. E.

This medicine has long been in great esteem, not only as a cathartic, but likewise as a stimulus; the wine dissolving all that part of the aloes in which these qualities reside, a portion only of the less active resinous matter being left. The aromatic ingredients are added to warm the medicine, and somewhat alleviate the ill flavour of the aloes: canella alba, or cloves, are said, among numerous materials that have been made trial of, to answer this end the most successfully.

The tinctura sacra appears from long experience, to

to be a medicine of excellent service in languid, phlegmatic habits, not only for cleansing the primæ viæ, but likewise for attenuating and dissolving viscid juices in the remoter parts, for stimulating the solids, warming the habit, promoting or exciting the uterine purgations, and the hæmorrhoidal flux. The dose, as a purgative, is from one to two ounces, or more: it may be introduced into the habit, so as to be productive of excellent effects as an alterant, by giving it in small doses at proper intervals: thus managed, it does not for a considerable time operate remarkably by stool; but at length proves purgative, and occasions a lax habit of much longer continuance than that produced by the other common cathartics.

### 377. *Thebaic tincture.* L. [See n° 418.]

Take of strained opium, two ounces; cinnamon, cloves, each one dram; mountain wine, one pint. Macerate without heat for a week, and then filter the tincture through paper.

This is the liquid laudanum of Sydenham, with the exchange of Canary wine for mountain, and the omission of an ounce of saffron. The aromatics in the form above are in so small quantity, that the prescriber can scarce expect any considerable effect from them, the proportion of each that goes to a grain of opium, amounting to no more than the sixteenth part of a grain: even these minute proportions, however, are in good measure sufficient to take off the ill odour of the opium; which seems to be all that is intended by them.

378, 379. The principal advantages of exhibiting opium in this form are, that by being already dissolved, it exerts itself the sooner in the body; and that by some persons, liquids are more commodiously taken, than a bolus or pill. The common doses of the tincture are from ten drops to forty, fifty, or more, according to the exigencies of the case. It were to be wished, that the dose could be more exactly ascertained, by weight or measure: as the drops may, according to different circumstances, vary in quantity, though in number the same; and as an error therein may, in some cases, be of mischievous consequences. Twenty drops contain at a medium about one grain of opium, or rather so much as that quantity of wine will extract from one grain; for the liquor does not dissolve the whole substance of the opium, nor is the solution equivalent in its effect to the full quantity of opium employed in it.

A liquid opiate, free from the inconveniences here complained of, will be described under the the head of spirituous tinctures.

### 380. *White dittany wine.* E.

Take of white dittany root, one ounce; iron filings free from rust, three drams; white wine, one pint. Digest 25 hours, and then strain of the liquor.

### § 5. ALES.

381. THERE are two ways of impregnating malt-liquors with the virtues of medicinal substances: Macerating the subject in the liquor after the fermentation is completely finished; and fermenting it along with the liquor, or at least adding it towards the end of the fermentation, that, by the resolute power

of that process, its texture may be opened, and its medicinal parts more fully extracted. Neumann observes, that the active powers of many vegetables are not only effectually extracted, but extended, as it were, by fermentation: that so much pounded nutmeg as will lie on the point of a knife, gives a flavour to a large vat of fermenting ale; whereas, when the fermentation is finished, the quantity of liquor to which it gives a like impregnation, is comparatively inconsiderable.

As the medicinal ales are chiefly intended for diet-drinks, it is not necessary to be very exact with regard to their doses. In general, they may be taken to a pint or more in the day, and continued as long as necessary. They should not, however, be long used at a time, as all bitters are apt to affect the head when their use is persisted in.

### 382. *Antiscorbutic ale.*

Take of horse-radish root, fresh, one pound; great water-dock root, sliced and dried, two pounds; water-trefoil, dried, four ounces. Infuse them in ten gallons of new ale.

In scorbutic disorders, this ale, used as common drink, generally does service.

### 383. *Bitter ale.*

Take of gentian root, four ounces; lemon peel, three ounces; canella alba, two ounces; ale, two gallons. Let the ingredients be cut small, and steeped in the ale without heat.

This is an agreeable stomachic ale, superior to the common purls and most other preparations of that kind.

### 384. *Diuretic ale.*

Take of mustard-seed and juniper-berries, each eight ounces; seeds of the wild carrot, six ounces; new small ale, ten gallons.

In gravelly complaints, and dropical habits, this is an useful diet-drink.

### 385. *Opening ale.*

Take of fena, four ounces; tops of lesser centaury, and wormwood, each three ounces; of focotorine aloes, half an ounce. Infuse in ten gallons of ale.

Half a pint of this ale may be taken twice a-day, or oftener if necessary, to keep the body open.

### 386. *Dr Butler's ale.*

Take of betony, sage, agrimony, garden scurvy-grass, Roman wormwood, each three handfuls; elecampane roots, each four ounces; new ale, four gallons. The herbs and roots are to be put in a bag, and hung in the ale while it works.

This liquor has so far obtained among the common people, as to have been frequently made and sold in public houses. It is used in the spring, for purifying the blood, and preventing scorbutic disorders.

### 387. *Cephalic ale.*

Take of wild valerian root, ten ounces; mustard seed, whole, six ounces; Virginian snakeroot, two ounces; rosemary, or sage, three ounces; new small ale, ten gallons.

The ingredients of this composition are all of the warm and stimulating kind; and consequently tend to invigorate the nervous system, and promote the circulation of the fluids. In palsies, epilepsies, and vertiges, some benefit may be expected from this liquor used as common drink.

#### § 6. SPIRITUOUS TINCTURES.

388. RECTIFIED spirit of wine is the direct menstruum of the resins and essential oils of vegetables; and totally extracts these active principles from sundry vegetable matters, which yield them to water either not at all, or only in part. It dissolves likewise the sweet saccharine matter of vegetables; and generally those parts of animal-bodies in which their peculiar smells and tastes reside.

389. The virtues of many vegetables are extracted almost equally by water and rectified spirit; but in the watery and spirituous tinctures of them there is this difference, that the active parts in the watery extractions are blended with a large proportion of inert gummy matter, on which their solubility in this menstruum in great measure depends, while rectified spirit extracts them almost pure from gum. Hence, when the spirituous tinctures are mixed with watery liquors, a part of what the spirit had taken up from the subject generally separates and subsides, on account of its having been freed from that matter which, being blended with it in the original vegetable, made it soluble in water. This, however, is not universal; for the active parts of some vegetables, when extracted by rectified spirit, are not precipitated by water, being almost equally dissoluble in both menstrua.

390. Rectified spirit may be tinged by vegetables of all colours, except blue: the leaves of plants in general, which give out but little of their natural colour to watery liquors, communicate to spirit the whole of their green tincture, which for the most part proves elegant, though not very durable.

Fixed alkaline salts deepen the colour of spirituous tinctures; and hence have been supposed to promote the dissolving power of the menstruum, tho' this does not appear from experience: in the trials that have been made to determine this affair, no more was found to be taken up in the deep-coloured tinctures than in the paler ones, and often not so much: if the alkali be added after the extraction of the tincture, it will heighten the colour as much as when mixed with the ingredients at first. Nor is the addition of these salts in making tinctures useless only, but likewise prejudicial, as they in general injure the flavour of aromatics, and superadd a quality sometimes contrary to the intention of the medicine.—Volatile alkaline salts, in many cases, promote the action of the spirit. Acids generally weaken it, unless when the acid has been previously combined with the vinous spirit into a compound of new qualities, called *dulcified spirit*.

#### 391. General rules for extracting tinctures.

- I. The vegetable substances ought to be moderately and newly dried, unless they are expressly ordered otherwise. They should likewise be cut and bruised before the menstruum is poured on them.
- II. If the digestion is performed in balneo, the whole

success depends upon the proper management of the fire: it ought to be all along gentle, unless the hard texture of the subject should require it to be augmented; in which case the heat may be increased, so as to make the menstruum boil a little towards the end of the process.

III. Very large circulatory vessels ought to be employed for this purpose, which should be heated before they are luted together.

Circulatory vessels are those which are so contrived, and of such a height, that the vapour which arises during the digestion may be cooled and condensed in the upper part, and fall down again into the liquor below: by this means the dissipation both of the spirit and of the volatile parts of the ingredients is prevented. They are generally composed of two long-necked matrasses or bolt-heads; the mouth of one of which is to be inserted into that of the other, and the juncture secured by a piece of wet bladder. The use of heating the vessels is, to expel a part of the air; which otherwise, rarefying in the process, would endanger bursting them or blowing off the uppermost matrass. A single matrass with a long neck, or with a glass-pipe inserted into its mouth, is more commodious than the double vessel. See 182.

IV. The vessel is to be frequently shaken during the digestion.

V. All tinctures should be suffered to settle before they are committed either to the filter or strainer.

VI. In the tinctures (and distilled spirits likewise) designed for internal use, no other spirit (drawn from malt, melasses, or other fermented matter) is to be used than that expressly prescribed.

VII. Resin and resinous gums yield tinctures more successfully, if, after being ground into powder, they be mixed with some white sand well washed and dried, which will prevent their running into lumps by the heat. If the powders prescribed are sufficient for this purpose, such an addition is unnecessary.

#### 392. Bitter tincture. L.

Take of gentian root, two ounces; yellow rind of Seville orange-peel, dried, one ounce; lesser cardomom-seeds, freed from the husks, half an ounce; proof-spirit, two pints. Digest without heat, and strain off the tincture.

#### 393. Bitter tincture, or stomachic elixir. E.

Take of gentian root, two ounces; dried orange-peel, an ounce; canella alba, half an ounce; cochineal, half a dram; French brandy, two pints. Let them steep for four days, and then filter the elixir.

Both this and the preceding composition are very useful stomachic bitters.

#### 394. Tincture of wormwood. E.

Take of the dried tops of wormwood in flower, four ounces; rectified spirit of wine, two pints. Macerate for two days; and strain the liquor, pressing it out from the residuum; then pour it upon other two ounces of wormwood; macerate again for four days, and press through a linen-cloth; and lastly, filter the liquor.

#### 395. Aromatic

395. *Aromatic tincture.*

Take of cinnamon, six drams; lesser cardomom-seeds, freed from the husks, three drams; long-pepper, ginger, each, two drams; proof-spirit, two pints. Digest without heat, and then strain off the tincture. L.

Take of cinnamon, six drams; lesser cardomom-seeds, an ounce; angelica seeds, three drams; long-pepper, two drams; proof-spirit, two pints. Macerate for seven days; and then filtre. E.

This is a very warm aromatic, too much so to be given without dilution. A teaspoonful or two may be taken in wine, or any other convenient vehicle, in languors, weakness of the stomach, flatulencies, and other like complaints. The *stomachic tincture*, described hereafter, is similar in intention to this; but contrived less hot of the spices, that it may be taken by itself.

396. *Balsamic tincture.*

Take of balsam of copaiba, one ounce and a half; balsam of Peru, half an ounce; English saffron, one dram; rectified spirit of wine, one pint. Digest these ingredients together, in a sand-heat, for three days; and then pass the tincture through a strainer.

This tincture is an excellent balsamic, both for internal and external purposes. It is usually given, in doses of 10, 20, or 30 drops, in the fluor albus, gleet, cachexies, some kinds of asthma and nephritic complaints, for strengthening the tone of the viscera, and corroborating the nervous system in general. Some caution is requisite in the use of these refinous warm medicines: in cold, languid, phlegmatic habits, they have for the most part good effects; but in bilious and plethoric constitutions, where there is any tendency to inflammation or immoderate heat, they are manifestly prejudicial, and raise or continue febrile symptoms.

397. *Tincture of cantharides.*

Take of cantharides, bruised, two drams; cochineal, half a dram; proof-spirit, a pint and a half. Digest them together; and afterwards filter the tincture through paper. L.

Take of cantharides, two drams; rectified spirit of wine, a pint and a half. Digest for four days, and then filter the tincture. E.

These tinctures possess the whole virtues of the fly, and are the only preparations of it designed for internal use; tinctures being by far the most commodious and safe form for the exhibition of this active drug. The usual dose of these tinctures is from 10 to 20 drops, which may be taken in a glass of water, or any other more agreeable liquor, twice a-day, and increased by two or three drops at a time, according to the effect.

398. *Tincture of cardomoms.*

Take of lesser cardomom-seeds, husked, half a pound; proof-spirit, two pints. Digest without heat, and strain the tincture. L.

Take of lesser cardomom-seeds, six ounces; proof-spirit, two pints. Macerate for eight days; and then filter. E.

Tincture of cardomoms has been in use for a considerable time, though but lately received into the dispensatory. It is a pleasant, warm cordial, and may be taken, along with any proper vehicle, from a dram to a spoonful or two.

398. *Tincture of castor.*

Take of Russia castor, powdered, two ounces; proof-spirit, two pints. Digest for ten days without heat, and strain off the tincture. L.

Take of Russia castor, an ounce and a half; rectified spirit of wine, one pint. Digest them for six days, and afterwards strain out the liquor. E.

400. *Compound tincture of castor.* E.

Take of Russia castor, one ounce; asafetida, half an ounce; vinous spirit of sal ammoniac, one pint. Digest for six days in a close-stopped phial, and then strain the tincture.

This composition is a medicine of real efficacy, particularly in hysterical disorders, and the several symptoms which accompany them. The vinous spirit of sal ammoniac, now used instead of the volatile oily spirit prescribed, is an excellent menstruum both for the castor and the asafetida, and greatly adds to their virtues.

401, a. *Tincture of cinnamon.* L. E.

Take of cinnamon, an ounce and a half; proof-spirit, a pint. Digest without heat, and strain off the tincture.

The tincture of cinnamon possesses the restraining virtues of the cinnamon, as well as its aromatic cordial ones; and in this respect it differs from the distilled waters of the spice.

401, b. *Volatile tincture of guaiacum.* L.

Take of gum guaiacum, four ounces; volatile aromatic spirit, a pint and a half. Digest, without heat, in a vessel close stopped; and afterwards let the tincture be passed through a strainer.

This is a very elegant and efficacious tincture; the volatile spirit excellently dissolving the gum, and at the same time promoting its medicinal virtue. In rheumatic cases, a tea-spoonful, taken every morning and evening in any convenient vehicle, has proved of singular service.

402. *Simple tincture of Peruvian bark.* L. E.

Take of Peruvian bark, four ounces; proof-spirit, two pints. Digest and strain.

A medicine of this kind has been for a long time pretty much in esteem, and usually kept in the shops, though but lately received into the dispensatory.

For general use, this is the most convenient of the bark-tinctures, the proof-spirit extracting nearly all the virtues of the bark. It may be given from a tea-spoonful to half an ounce, or an ounce, according to the different purposes it is intended to answer.

403. *Volatile tincture of Peruvian bark.* L.

Take of Peruvian bark, four ounces; spirit of sal ammoniac, two pints. Digest without heat in a vessel close stopped; and afterwards strain the tincture.

This tincture is but lightly impregnated with the virtues.

virtues of the bark; and is so acrimonious, that the largest dose which can with safety be given of it, can contain only a very small quantity of the subject. The medicine nevertheless has its uses, and may be serviceable in some cases where the stronger are improper, as in difficulty of breathing, obstructions, and oppressions of the breast. Stronger tinctures of this kind may be obtained by means of dulcified spirit of sal ammoniac, or the spirit prepared with quicklime. All the three may be employed where a large quantity of bark is not required, as at the close of the cure of intermittents; in weakness of digestion, attended with a cold sensation at the stomach; and some fluxes, particularly those from the uterus, where the circulation is languid, the fibres relaxed, and where there is a periodical return of slight febrile complaints. In these cases, Dr Lewis says he has often experienced salutary effects from a tincture in dulcified spirit of sal ammoniac, given to the quantity of a teaspoonful five or six times a-day, in any appropriated vehicle.

#### 404. *Compound tincture of Peruvian bark.* E.

Take of Peruvian bark, in powder, three ounces; Virginian snakeroot, gentian, each two drams; French brandy, two pints. Let them steep together for three days, and afterwards filter the tincture.

The substances here joined to the bark, in many cases, promote its efficacy in the cure of intermittents; and not unfrequently, are absolutely necessary. In some ill habits, particularly where the juices are sluggish and tenacious, the viscera and abdominal glands obstructed, the bark by itself proves unsuccessful, if not injurious; whilst given in conjunction with corroborant stomachics and deobstruents, it rarely fails of the due effect. Gentian and Virginian snakeroot, are among the best additions for this purpose; to which it is often necessary to join chalybeate medicines also.

#### 405. *Tincture of saffron.* E.

Take of English saffron, one ounce; French brandy, one pint. After digesting them for five days, let the tincture be filtered out for use.

This tincture is similar in virtue to the saffron-wine, n° 368. A spirituous menstruum is here preferred to the wine, as a tincture drawn with the former retains its elegant colour longer, and is not apt to deposit in keeping any part of what it had taken up from the saffron.

#### 406. *Tincture or essence of white dittany.* E.

Take of fresh dittany root, two ounces; rectified spirit of wine, 14 ounces. Digest for eight days, and filter.

#### 407. *Fetid tincture.* E.

Take of asafetida, two ounces; vinous spirit of sal ammoniac, one pint. Macerate for six days in a close-stopped phial, and strain.

This tincture possesses the virtues of the asafetida itself, and may be given from 10 drops to 50 or 60.

#### 408. *Tincture of foot.*

Take of wood-foot, two ounces; asafetida, one ounce; proof-spirit, two pints. Digest and strain. L.

Take of shining wood foot, one ounce; asafetida, half

an ounce; French brandy, a pint. Digest for six days, and strain. E.

These medicines are found serviceable, not only in hysterical cases, but likewise in other nervous disorders. They may be given from a tea spoonful to a common spoonful twice a day.

#### 409. *Tincture of jalap.*

Take of jalap-root, eight ounces; proof-spirit, two pints. After proper digestion, strain off the tincture. L.

Take of jalap, in coarse powder, three ounces; French brandy, one pint. Digest them for eight days, and strain the tincture. E.

This tincture is an useful and mild purgative, the menstruum here employed taking up so much of the gummy parts as corrects the griping quality which the resin is attended with. It may be taken by itself from a dram to half an ounce; or mixed in smaller quantity with cathartic infusions, or the like.

#### 410. a. *Tincture of Kino.*

Take of gum kino, two ounces; proof-spirit, one pint. Digest for eight days, and strain.

#### 410. b. *Japanese tincture.* L. E.

Take of Japan earth, three ounces; cinnamon, two ounces; proof spirit, two pints. After proper digestion, let the tincture be passed through a strainer.

This tincture is of good service in all kinds of desfluxions, catarrhs, loosenesses, uterine fluors, and other like disorders, where mild astringent medicines are indicated. Two or three teaspoonfuls may be taken every now and then, in red wine, or any other proper vehicle.

#### 411. *Tincture of gum-lac.* E.

Take of gum-lac, powdered, an ounce; Myrrh, powdered, half an ounce; spirit of scurvygrass, a pint and a half. Digest in a sand-heat for six days; after which strain off the tincture for use.

This tincture is principally employed for strengthening the gums, and in bleedings and scorbutic exacerations of them: it may be fitted for use in these intentions, by mixing it with honey of roses, or the like. Some recommend it internally against scorbutic complaints, and as a corroborant in gleets, female weaknesses, &c. Its warmth, pungency, and manifestly astringent bitterish taste, point out its virtues, in these cases, to be considerable; though common practice among us has not yet received it.

#### 412. *Tincture of the martial flowers.* L.

Take of martial flowers, four ounces; proof-spirit, one pint. Digest and strain.

#### 413. a. *Tincture of iron.* E.

Take of the scales of iron, prepared and reduced to powder, three ounces; muriatic acid, as much as is sufficient for dissolving the powder. Digest with a great heat; and when the iron is totally dissolved, add as much spirit of wine as will make the whole two pounds by measure.

413. b. *Tincture of iron in spirit of salt.* L.

Take of iron filings, half a pound; Glauber's spirit of salt, three pounds; rectified spirit of wine, three pints. Digest the iron filings in the spirit of salt, without heat, as long as the spirit acts upon the iron; after the fæces have subsided, evaporate the liquor to one pound, and add thereto the vinous spirit.

All these tinctures are greatly preferable to the calces or croci of iron, as being not only more speedy, but likewise more certain, in their operation: the latter, in some cases, pass off through the intestinal tube with little effect; whilst the tinctures scarce ever fail. From 10 to 20 drops of either of the tinctures, may be taken two or three times a-day, in any proper vehicle; though it is seldom advisable to extend the dose so far as the last of these quantities, especially in regard to the tincture in the spirit of salt, which is exceeding strong of the iron.

414. *Tincture of meconium.* E.

Take of opium, two drams; simple Jamaica pepper-water, 20 ounces by weight; rectified spirit of wine, 10 ounces by weight. Having rubbed the opium well with the water, add the spirit, digest for eight days, and then filter through paper.

415. *Tincture of melampodium, or black hellebore.* L. E.

Take of black hellebore roots, four ounces; cochineal, two scruples; proof-spirit, two pints. Digest them together, and afterwards filter the tincture through paper.—The Edinburgh college orders only half a dram of cochineal, and desires the digestion to be continued for eight days.

This is perhaps the best preparation of hellebore when designed for an alterative, the menstruum here employed extracting the whole of its virtues. It has been found, from experience, particularly serviceable in uterine obstructions; in sanguine constitutions, where chalybeates are hurtful, it seldom fails of exciting the menstrual evacuations, and removing the ill consequences of their suppression. So great is the power of this medicine, that wherever, from an ill conformation of the parts, or other causes, the expected discharge does not succeed upon the use of it, the blood, as Dr Mead has observed, is so forcibly propelled, as to make its way through other passages. A tea-spoonful of the tincture may be taken twice in a day in warm water, or any other convenient vehicle.

416. *Tincture of musk.* L.

Take of musk, two drams; rectified spirit of wine, one pint. Digest for ten days, and strain.

417. *Tincture of myrrh.*

Take of myrrh, three ounces; proof spirit, two pints. After due digestion, strain off the tincture. L.  
Take of myrrh in powder, an ounce and a half; rectified spirit of wine, a pint. Digest for ten days; then strain off the tincture for use. E.

Tincture of myrrh is recommended internally for warming the habit, attenuating viscid juices, strengthening the solids, opening obstructions, particularly those of the uterine vessels, and resisting putrefaction. Boerhaave greatly esteems it in all languid cases pro-

ceeding from simple inactivity; in those female disorders which are occasioned by an aqueous, mucous, sluggish indispotion of the humours, and a relaxation of the vessels; in the fluor albus, and all diseases arising from a like cause. The dose is from 15 drops to 40 or more. The medicine may doubtless be given in these cases to advantage; tho' with us it is more commonly used externally, for cleansing foul ulcers, and promoting the exfoliation of carious bones.

418. *Thebaic tincture, commonly called liquid laudanum.* E.

Take of opium, two ounces; spirituous cinnamon-water, 20 ounces. Digest for four days, and filter.

This is a very elegant liquid opiate; the menstruum dissolving nearly the whole substance of the opium, and effectually covering its ill flavour. The usual dose is from 15 to 25 or 30 drops.

419. a. *Tincture of rhubarb.* E.

Take of rhubarb, three ounces; lesser cardamom-seeds, half an ounce; proof-spirit two pints. Digest for seven days, and strain.

b. *Spirituous tincture of rhubarb.* L.

Take of rhubarb, two ounces; lesser cardamom seeds, hulled, half an ounce; saffron, two drams; proof-spirit, two pints. Digest without heat, and strain off the tincture for use.

c. *Bitter tincture of rhubarb.* E.

Take of rhubarb, two ounces; gentian root, half an ounce; Virginian snake-root, one dram; French brandy, two pints. Digest for seven days, and then strain off the tincture.

d. *Sweet tincture of rhubarb.* E.

Is made by adding four ounces of sugar-candy to the simple tincture made as above directed, and strained.

All the foregoing tinctures of rhubarb are designed as stomachics and corroborants, as well as purgatives: spirituous liquors excellently extract those parts of the rhubarb in which the two first qualities reside, and the additional ingredients considerably promote their efficacy. In weakness of the stomach, indigestion, laxity of the intestines, diarrhoeas, colicky and other like complaints, these medicines are frequently of good service: the second is also, in many cases, an useful addition to the Peruvian bark, in the cure of intermittents, particularly in cachectic habits, where the viscera are obstructed. In these intentions, a spoonful or two may be taken for a dose, and occasionally repeated.

420. a. *Saturnine tincture.* L.

Take of sugar of lead, green vitriol, each two ounces; rectified spirit of wine, two pints. Reduce the salts separately into a powder; then add the spirit, and digest them together without heat: afterwards filter the tincture through paper.

b. *Antiphthical tincture.* E.

Take of sugar of lead, an ounce and a half; vitriol of iron, an ounce; rectified spirit of wine, a pint. Let a tincture be extracted without heat.

The reducing of the salts separately into powder,

and performing the digestion without heat, are very necessary circumstances: for if the ingredients are attempted to be pulverized together, they will grow soft and almost liquid; and if heat is made use of, scarce any tincture will be obtained.

These tinctures are sometimes given from 20 to 30 drops, for restraining immoderate secretions, particularly the colligative sweats attending hectic fevers and phthical disorders, whence the name *antiphthical tincture*. They are undoubtedly medicines of great efficacy in these cases, but too dangerous ones to be rashly ventured on. Some have supposed that they do not contain any of the sugar of lead; but experiments made for that purpose, have shown that they do: and therefore, the London college has very judiciously changed the title of their tincture into one expression, its being a preparation of lead.

#### 421. a. *Tincture of fena. L.*

Take of raisins, stoned, 16 ounces; fena, one pound; caraway seeds, one ounce and a half; lesser cardamoms, hulked, half an ounce; proof spirit, one gallon. Digest without heat, and then strain the tincture.

#### b. *Compound tincture of fena, commonly called elixir of health. E.*

Take of fena, two ounces; jalap-root, one ounce; coriander seeds, half an ounce; French brandy, three pints. Digest for seven days; then strain off the tincture, and add to it four ounces of powdered sugar-candy.

Both these tinctures are useful carminatives and cathartics, especially to those who have accustomed themselves to the use of spirituous liquors; they oftentimes relieve flatulent and colicky complaints, where the common cordials have little effect: the dose is from one to two ounces. Several preparations of this kind have been offered to the public, under the name of *Daffy's elixir*; the two above are equal to any, and superior to most of them.

#### 422. *Tincture of snakeroot.*

Take of Virginian snakeroot, three ounces; proof spirit, two pints. Digest without heat, and strain off the tincture. *L.*

Take of Virginian snakeroot, two ounces; cochineal, one dram; proof spirit, two pints. Digest in a gentle heat for three days, and then strain the tincture. *E.*

The tincture of snakeroot was in the former pharmacopœia directed with the *tinctura salis tartari*; which being now expunged, it was proposed to the college to employ rectified spirit; but as the heat of this spirit prevents the medicine from being taken in so large a dose as might otherwise be, a weaker spirit was made choice of. The tincture made in this menstruum, which extracts the whole virtues of the root, may be taken to the quantity of a spoonful or more, every five or six hours.

#### 423. *Stomachic tincture. L.*

Take of raisins, stoned, four ounces; cinnamon, half an ounce; caraway seeds, lesser cardamoms, hulked, cochineal, each two drams; proof spirit, two pints. Digest without heat, and strain off the tinctures.

This is a moderately warm stomachic tincture, much more pleasant than the usquebaugh of the former pharmacopœias. It may be taken, without any vehicle, to half an ounce or an ounce, though oftener used in mixture.

#### 424. *Styptic tincture. L.*

Take of green vitriol, calcined, one dram; French brandy (such as has acquired a yellowish tinge from the cask), two pints. Mix them together, that the spirit may grow black; then pass it through a strainer.

The title of this tincture expresses its medicinal intention. The celebrated *styptic of Helvetius*, (which is said to be the same with that of *Eaton*), differs from it no otherwise than in being more operose in composition. They are recommended both for internal use, and for restraining external hæmorrhages: their virtues do not seem to depend so much on the iron as on the menstruum, the quantity of metal dissolved being extremely small. In keeping, the iron is apt to separate, and the liquor to lose its black colour.

#### 425. *Tincture of sulphur.*

Take of rectified spirit of wine, one pint. Hepar sulphuris (that is, a mixture of sulphur and fixed alkaline salt melted together) four ounces. Grind the hepar into powder whilst hot from the fire, add to it the spirit, and digest in a moderate heat for 24 hours; then pour off the tincture from the fæces.

The digestion may be commodiously performed in a glass receiver: put the spirit first into the vessel, and pour the hot powder upon it: then shake them together; and to prevent the exhalation of any part of the spirit during the digestion, insert a glass tube into the mouth of the receiver.

This tincture is of a rich gold colour, a hot aromatic taste, and a particular, not ungrateful smell. Its virtues are those of a warm, attenuating, aperient, and anti-acid medicine. The dose is from 10 to 60 drops. It is most commodiously taken in Canary or other rich wines.

#### 426. *Tincture of balsam of Tolu. E.*

Take of balsam of Tolu, an ounce and a half; rectified spirit of wine, a pint. Digest in a sand-heat, until the balsam is dissolved; and then strain the tincture.

This solution of balsam of Tolu possesses all the virtues of the balsam itself. It may be taken internally, in the several intentions for which this valuable balsam is proper, to the quantity of a tea-spoonful or two, in any convenient vehicle. Mixed with the plain syrup of sugar, it forms an elegant balsamic syrup.

#### 427. *Simple tincture of valerian. L.*

Take of wild valerian root, four ounces; proof spirit, two pints. After due digestion, strain off the tincture.

The valerian root ought to be reduced into fine powder, otherwise the spirit will not sufficiently extract its virtues. The tincture proves of a deep colour, and considerably strong of the valerian; though it has not been found to answer so well in the cure of epileptic

epileptic disorders, as the root in substance, exhibited in the form of powder or bolus. The dose of the tincture is from half a spoonful to a spoonful or more, two or three times a-day.

#### 428. *Volatile tincture of valerian.* L.

Take of wild valerian root, four ounces; volatile aromatic spirit, two pints. Digest without heat in a vessel closely stopped, and afterwards strain off the tincture.—The Edinburgh college orders two ounces of the root to a pint of vinous spirit of sal ammoniac, and the digestion to be continued for six days in a close stopped vial.

The volatile spirit is here an excellent menstruum, and at the same time considerably promotes the virtues of the valerian, which in some cases wants an assistance of this kind. The dose may be a tea-spoonful or two.

#### 429. *Tincture of veratrum, or white hellebore.* L. E.

Take of white hellebore root, eight ounces; proof spirit, two pints. Digest them together for ten days, and filter the tincture through paper.

This tincture is sometimes used for acuating cathartics, &c. and as an emetic in apoplectic and maniacal disorders. It may likewise be so managed, as to prove a powerful alterative and deobstruent, in cases where milder remedies have little effect. But a great deal of caution is requisite in its use: the dose, at first, ought to be only a few drops; if considerable, it proves violently emetic or cathartic.

#### 430. *Balsam of guaiacum.* L.

Take of gum guaiacum, one pound; balsam of Peru, three drams; rectified spirit of wine, two pints and a half. Digest till the gum is dissolved, and then strain off the balsam.

#### 431. *Elixir of guaiacum.* E.

Take of guaiacum, in powder, one pound; balsam of Peru, three drams; rectified spirit of wine, two pounds and a half. Digest for 10 days, and strain.

Both these compositions are medicines of great efficacy, and capable of answering many useful purposes. They warm and strengthen the habit, and promote insensible perspiration. Twenty or thirty drops may be taken two or three times a-day, or oftener, in any proper vehicle, in rheumatic complaints, cutaneous defecations, &c. particularly where the patient is of a cold phlegmatic temperament, and the solids weak and relaxed. In hot bilious constitutions, and tenderness or rigidity of the vessels, like other stimulating medicines, they are evidently improper.

#### 432. *Volatile elixir of guaiacum.* L.

Take of gum guaiacum, four ounces; balsam of Peru, two drams. Distilled oil of saffron, half a dram; vinous spirit of sal ammoniac, a pound and a half. Macerate for six days in a close stopped vial, and strain.

#### 433. *Balsamum commendataris, Beume de commandeur.*

Take of dry Peruvian balsam, one ounce; storax in the tear, two ounces; benjamin, three ounces; so-

cotrine aloes, myrrh, olibanum, angelica roots, St John's-wort flowers, each half an ounce; spirit of wine, two pounds eight ounces by weight. Let them stand together in the sun during the dog-days, in a glass vessel closely stopped; and afterwards strain out the balsam through a linen cloth.

This balsam has been inserted, with little variation, in some foreign pharmacopœias, and likewise kept a secret in private hands, under the titles of *Balsamum Persicum*, *Balsam of Berne*, *Wade's balsam*, *Friar's balsam*, *Jesuits drops*, &c. The form above is taken from the original receipt published by Pomet (*Histoire des Drogues*, edit. 2. tom. ii. p. 56.) It stands greatly recommended, externally, for cleansing and healing wounds and ulcers, for discussing cold tumours, allaying gouty, rheumatic, and other old pains and aches; and likewise internally, for warming and strengthening the stomach and intestines, expelling flatulencies, and relieving colicky complaints. Outwardly, it is applied cold on the part with a feather; inwardly, a few drops are taken at a time, in wine or any other convenient vehicle.

#### 434. *Traumatic or vulnerary balsam.*

Take of benzoin, three ounces; storax, strained, two ounces; balsam of Tolu, one ounce; socotorine aloes, half an ounce; rectified spirit of wine, two pints. Digest, that the gums may as much as possible be dissolved; and then strain off the balsam for use. L.

This is an elegant reformation of the preceding composition, considerably more simple, yet not inferior in efficacy. The balsam of Tolu supplies, with advantage, the dry Peruvian balsam, a drug very rare to be met with in this country: the olibanum, myrrh, and angelica roots, here omitted, were certainly superfluous in a medicine containing so much more powerful materials; and the St John's-wort flowers are as deservedly thrown out, as having little else to recommend them than prejudice or superstition.

Take of benzoin, powdered, three ounces; balsam of Peru, two ounces; hepatic aloes, in powder, half an ounce; rectified spirit of wine, two pints. Digest them in a sand-heat, for the space of three days; and then strain the balsam. E.

This is a further contraction of the *beume de commandeur*, without any injury to it as a medicine, at least with regard to the purposes for which the title shews it designed. Socotorine aloes is here judiciously exchanged for the hepatic, which appears from experience to be the most serviceable in external applications.

#### 436. *Elixir of aloes.* L.

Take of tincture of myrrh, two pints; socotorine aloes, saffron, each three ounces. Digest them together, and strain off the elixir.

#### 437. *Elixir proprietatis.* E.

Take of tincture of myrrh, two pounds; socotorine aloes, three ounces; English saffron, two ounces. Digest for eight days, suffer the fæces to subside, and pour off the clear elixir.

This is the *elixir proprietatis* of Paracelsus, improved with regard to the manner of preparation.

This medicine is greatly recommended, and not undeservedly, as a warm stimulant and aperient. It strengthens the stomach and other viscera, cleanses the first passages from tenacious phlegm, and promotes the natural secretions in general. Its continued use has frequently done good service in cachectic and icteric cases, uterine obstructions, and other like disorders; particularly in cold, pale, phlegmatic habits: where the patient is of a hot, bilious constitution, and florid complexion, this warm stimulating medicine is less proper, and sometimes prejudicial. The dose may be from 20 drops to a tea-spoonful or more, two or three times a-day, according to the purposes which it is intended to answer.

#### 538. *Elixir proprietatis vitriolicum.* E.

Take of myrrh in powder, socotorine aloes in powder, each an ounce and a half; English saffron, one ounce; dulcified spirit of vitriol, one pint. Digest them in a sand-heat for the space of six days; and having then suffered the faeces to subside, pour off the clear elixir.

This elixir possesses the general virtues of the preceding; and is, in virtue of the menstruum, preferred to it in hot constitutions, and weaknesses of the stomach.

#### 439. *Paregoric elixir.*

Take of flowers of benzoin, opium, strained, each one dram; camphor, two scruples; essential oil of aniseeds, half a dram; rectified spirit of wine, two pints. Digest and strain. L.

Take of flowers of benzoin, English saffron, of each three drams; opium, two drams; distilled oil of aniseed, half a dram; vinous spirit of sal. ammoniac, one pint. Digest four days in a close stopped vial, and strain. E.

This elixir is taken from *Le Mort* with the omission of three unnecessary ingredients, honey, liquorice, and alkaline salt. It was originally prescribed under the title of *elixir asthmaicum*, which it does not ill deserve. It contributes to allay the tickling, which provokes frequent coughing; and at the same time is supposed to open the breast, and give greater liberty of breathing: the opium procures (as it does by itself) a temporary relief from the symptoms; whilst the other ingredients tend to remove the cause, and prevent their return. It is given to children against the chin-cough, &c. from five drops to 20; to adults, from 20 to 100.

#### 440. *Acid elixir of vitriol.* L.

Take of the aromatic tincture, one pint; strong spirit called oil of vitriol, four ounces. Mix them together; and after the faeces have subsided, filter the elixir through paper.

441. In the new edition of the Edinburgh pharmacopoeia the *elixir vitrioli* is thus prepared.

Take of cinnamon, one ounce and a half; ginger, one ounce; pepper-mint leaves, dried, half an ounce; oil of vitriol, six ounces; rectified spirit of wine, two pints. Drop the oil of vitriol by little and little into the spirit of wine; and digest them together in a sand-bath, with a very gentle heat, for three days; then add the other ingredients; conti-

nue the digestion, in the same gentle heat for three days longer; and afterwards filter the tincture in a glass funnel.

These compositions are valuable medicines in weakness and relaxations of the stomach, and decays of constitution, particularly in those which proceed from irregularities, which are accompanied with slow febrile symptoms, or which follow the suppression of intermittents. They have frequently taken place after bitters and aromatics, by themselves, had availed nothing: and, indeed, great part of their virtue depends on the vitriolic acid; which, barely diluted with water, has, in these cases, where the stomach could bear the acidity, produced happy effects.

Fuller relates (in his *Medicina gymnastica*) that he was recovered by *Mynsicht's elixir* (of which the above are improved preparations) from an extreme decay of constitution, and continual reachings to vomit. They may be given from 10 to 30 or 40 drops or more, according to the quantity of acid, twice or three a-day, at such times as the stomach is most empty.

#### 442. *Sweet elixir of vitriol.* L.

Take of the aromatic tincture, one pint; dulcified spirit of vitriol, eight ounces by weight. Mix them together.

This is designed for persons whose stomach is too weak to bear the foregoing acid elixir; to the taste, it is gratefully aromatic, without any perceptible acidity. The dulcified spirit of vitriol, here directed, occasions little or no precipitation upon adding to it the tincture.

443. The Edinburgh college directs this to be made of the same ingredients and in the same manner as the aromatic tincture, excepting that dulcified spirit of vitriol is used instead of spirit of wine.

#### 444. *Compound elixir of myrrh.* L.

Take of extract of favin, one ounce; tincture of castor, one pint; tincture of myrrh, half a pint. Digest them together; and then strain the elixir.

This preparation is a medicine of great importance in uterine obstructions, and in hypochondriacal cases; though, possibly, means might be contrived of superadding more effectually the virtues of favin to a tincture of myrrh and castor. It may be given from five drops to twenty or thirty, or more, in pennyroyal water, or any other suitable vehicle.

#### 445. *Elixir sacrum.*

Take rhubarb, cut small, ten drams; socotorine aloes, in powder, six drams; lesser cardamom seeds, half an ounce; French brandy, two pints. Digest for two days; and then strain the elixir.

#### 446. *Camphorated spirit of ruine.* L. E.

Take of camphor, two ounces; rectified spirit of wine, two pints. Mix them together, that the camphor may be dissolved.

This solution of camphor is employed chiefly for external uses, against rheumatic pains, paralytic numbnesses, inflammations; for discussing tumours, preventing gangrenes, or restraining their progress. It is too pungent to be exhibited internally, even when diluted

nor does the dilution succeed well; for on the admixture of aqueous liquors, the champhor gradually ferparates and runs together into little masses.

The most convenient method of uniting camphor with aqueous liquors, for internal use, seems to be by the mediation of almonds, or of mucilages; triturated with those, it readily mingles with water into the form of an emulsion, at the same time that its pungency is considerably abated. It may also be commodiously exhibited in the form of an oily draught, expressed oils totally dissolving it.

#### § 7. OILS by INFUSION and DECOCTION.

447. EXPRESSED oils extract the resinous and oily parts of vegetables, but do not act upon or unite with the gummy and mucilaginous: hence the *oleum e mucilaginis*, or oil of mucilages (n° 450) of the shops, contains nothing of the mucilage which its ingredients abound with. These oils may be tinged, by vegetable matters, of almost all colours: the leaves of most plants communicate a green; yellow flowers, a dilute gold colour; some red flowers, a light red; alkanet root, a beautiful and deep red.

448. In making the official oils from the leaves of plants, a good deal of care is necessary, to give them the fine green colour expected in them. If the boiling of the herb in the oil is not continued till all the aqueous moisture has exhaled (the mark of which is, the herb's being crisp), the oil will have a dingy yellowish hue: if continued longer, it turns black, and contracts an empyreumatic smell. The most convenient method of managing the process seems to be, to strain off the oil when sufficiently impregnated with the virtues of the plant, and afterwards to let it stand in a clean vessel over a gentle fire, until, by frequent trials on a white tile, it appears to have gained the deep green colour required.

#### 449. Oil of St John's wort. L.

Take of the flowers of St John's wort, full blown, fresh gathered, and carefully freed from the cups, four ounces; oil olive, two pints. Pour the oil upon the flowers, and let them stand together till the oil is sufficiently coloured.

#### 450. Oil of mucilages. L.

Take of marshmallow root, fresh, half a pound; linseed, fennugreek-seed, each three ounces; water, two pints; oil olive, four pints. Bruise the roots and seeds, and gently boil them in the water for half an hour; then add the oil, and continue the boiling till all the water is wasted; afterwards let the oil be carefully poured off for use.

#### 451. Oil of elder. L.

Take of elder-flowers, one pound; oil-olive, two pints. Boil the flowers in the oil, till they are almost crisp; then press out the oil, and set it by till the feces have subsided.

#### 452. Green oil. L.

Take of bay leaves, rue leaves, marjoram leaves, feawormwood leaves, chamomile leaves, each, fresh gathered, three ounces; oil olive, two pints. Bruise the herbs, and gently boil them in the oil till

they are almost crisp; then press out the oil, let it stand to settle, and afterwards pour it off from the sediment.

All the foregoing oils are designed for external applications only. They were supposed, besides the general emollient quality of the oil itself, to receive particular virtues from the ingredients. At present there are few who expect much more from these preparations than from common oil itself, which has the advantage of being less offensive. The mucilaginous ingredients, marshmallow root and linseed, in the *oleum e mucilaginis*, make no addition to the virtue of the oil; for mucilages, as already observed, are not soluble in oils. Experience has not discovered any such singular qualities in flowers of St John's wort, that four ounces of them should communicate any remarkable virtue to a quart of oil. Of the other herbs, the more valuable parts are dissipated by the boiling heat: and although the remaining matter, if it was taken internally, either by itself, or dissolved in watery or spirituous liquors, might not be destitute of activity, yet it can scarcely be supposed, when combined with a large quantity of oil, to have any material effect in external applications. The number of these oils has, therefore, been judiciously retrenched at the late reformation: the four, above retained by the London college, are not one-tenth part of those which were formerly ordered to be kept in the shops. The most certain way of answering the purposes intended by these preparations appears to be, by mixing with the expressed oil a suitable quantity either of the native resins of vegetables, or of the essential oils and resinous extracts artificially prepared from them.

#### 452. Camphorated oil. E.

Take of fresh-drawn oil of almonds, or linseed, two ounces; camphor, half an ounce. Dissolve the camphor in the oil.

This oil is designed, like the foregoing ones, for external purposes; particularly against burns, rheumatic pains, &c.

#### 453. Odoriferous oil.

Let some fine carded cotton be dipped in oil of olive, or oil of ben nuts, that it may be thoroughly imbibed with the oil, without retaining so much as to drip spontaneously. Lay a bed of this cotton in the bottom of a tin or porcelain vessel, and lightly spread upon it a pretty thick layer of any odoriferous flowers fresh gathered, as jasmine flowers, violets, lilies of the valley, &c. Above these, spread more of the cotton, and then more flowers, alternately, till the vessel is full; then cover it close, and let it stand for twenty-four hours in a gentle warmth. Great part of the fragrance of the flowers will be communicated to the oil in the cotton, which is to be stratified in the same manner with two or three fresh quantities of the flowers, till it is sufficiently impregnated therewith; after which the oil is to be squeezed out from the cotton in a press.

This appears to be the most effectual method of transferring into expressed oils the odoriferous matter of those tender flowers which yield little or no essential oil: the perfumed oils and essences of those flowers brought

brought from Italy, are prepared in this manner. The odorous parts may be again separated from the oil, and transferred into water or spirit, by distillation with those liquors.

SECT. IV. *Conservation of recent Vegetables and their Infusions, &c. by Sugar and Honey.*

§ 1. CONSERVES.

454. CONSERVES are compositions of recent vegetable matters and sugar beaten together into an uniform mass.

This management was introduced for preserving certain simples, undried, in an agreeable form, with as little alteration as possible in their native virtues; and to some subjects it is very advantageously applied. Vegetables, whose virtues are lost or destroyed in drying, may in this form be kept uninjured for a length of time: for, by carefully securing the mouth of the containing vessel, the alteration, as well as dissipation, of their active principles, is generally prevented; and the sugar preserves them from the corruption which juicy vegetables would otherwise undergo.

There are, however, sundry vegetables whose virtues are impaired by this treatment. Mucilaginous substances, by long lying with sugar, become less glutinous, and astringents sensibly foster upon the palate. Many of the fragrant flowers are of so tender and delicate a texture, as almost entirely to lose their peculiar qualities on being beaten or bruised.

In general, it is obvious, that in this form, on account of the large admixture of sugar, only substances of considerable activity can be taken to advantage as medicines. And indeed, conserves are at present considered chiefly as auxiliaries to medicines of greater efficacy, or as intermediums for joining them together. They are very convenient for reducing into boluses or pills the more ponderous powders, as mercurius dulcis, the calces of iron, and other mineral preparations; which with liquid or less consistent matters, as syrups, will not cohere.

The shops were formerly encumbered with many conserves altogether insignificant; the few now retained have in general either an agreeable flavour to recommend them, or are capable of answering some useful purposes as medicines. Their common dose is the bulk of a nutmeg, or as much as can be taken up at once or twice upon the point of a knife. There is in general no great danger of exceeding in this particular.

455. *General method of preserving conserves.*

Leaves are picked from the stalks, and flowers from their cups. They are beaten in a marble mortar, with a wooden pestle, into a smooth mass; after which thrice their weight of double-refined sugar is added by degrees, and the beating continued till they are uniformly mixed.

The sugar should be pulverised by itself, and passed through a sieve, before it is mixed with the vegetable mass; otherwise it cannot easily be reduced to sufficient fineness, so as to be duly incorporated. Some vegetables are scarce reducible to the requisite fineness by beating in a mortar; such is orange-peel. This is most conveniently rasped or grated off from the fruit, then well mixed with the sugar, and the com-

pound set by in a close vessel for some weeks; after which it may be beaten smooth with considerably less labour than at first. This peel, and red rose-buds, are commonly ground in a wooden mill made for that purpose.

456. *Conserve of the leaves of garden scurvy-grass. L.*

This is the only form that scurvy-grass in substance can be kept in without the total loss of its virtues. The conserve retains the full taste and virtue of the herb for a very considerable length of time, as a year or two, provided the vessel be made perfectly close and set in a cool place. It may be given in scorbutic habits three or four times a-day, or oftener.

457. *Conserve of the leaves of wood-sorrel. L.*

This is a very elegant and grateful conserve; in taste it is lightly acidulous, with a peculiar flavour, which some resemble to that of green-tea. It is taken occasionally for quenching thirst, and cooling the mouth and fauces, in hot distempers. It may be usefully joined to the foregoing preparation, whose virtue it somewhat promotes, at the same time that it improves the taste.

458. *Conserve of the leaves of spearmint. L.*

The conserve of mint retains the taste and virtues of the herb. It is given in weakness of the stomach and retchings to vomit; and not unfrequently does service in some cases of this kind, where the warmer and more active preparations of mint would be less proper.

459. *Conserve of the leaves of rue. L.*

This conserve is given from a dram to half an ounce in crudities of the primæ viæ, for promoting digestion, and in hysterical disorders: it gently stimulates the solids, attenuates viscid juices, and excites the natural secretions. Some have had a great opinion of it, taken in the morning, as a preservative against the effects of contagious air or exhalation.

460. *Conserve of the tops of sea-wormwood. L.*

The conserve of wormwood has been celebrated in dropsies: Matthioli relates, that several persons were cured by it of that distemper, without the assistance of any other medicine. Where the disorder indeed proceeds from a simple laxity or flaccidity of the solids, the continued use of this medicine may be of some service, as it appears to be a not inelegant mild corroborant. It is directed to be given in the dose of half an ounce, about three hours before meals.

461. *Conserve of the buds of red rose. L.*

This is a very agreeable and useful conserve. A dram or two, dissolved in warm milk, are frequently given as a light refrigerant in weakness of the stomach, and likewise in coughs and phthical complaints. In the German Ephemerides, examples are related of very dangerous phtisises cured by the continued use of this medicine: in one of these cases, 20 pounds of the conserve were taken in the space of a month; and in another, upwards of 30. Riverius mentions several other instances of this kind.

462. *Conserve of rosemary-flowers. L.*

Rosemary-flowers in great measure lose their peculiar

liar fragrance by beating; and hence the conserve has very little of their flavour. Some are therefore accustomed to make this preparation from the leaves of the plant, (which retain their virtues under the peltle), or at least to add a portion of these to the flowers. The conserve of rosemary is directed in weakness of the nerves, and as a light cordial.

463. *Conserve of the yellow rind of Seville orange-peel.* L.

This conserve is a very elegant one, containing all the virtues of the peel in a form sufficiently agreeable both with regard to the dose and the convenience of taking. It is a pleasant, warm stomachic, and in this intention is frequently made use of.

464. *Conserve of flos.* L.

Let the flos be put into water, and set over the fire till they grow soft, with care that they do not burst. Then take the flos out of the water, press out their pulp, and mix with it thrice its weight of double-refined sugar.

This preparation is a gentle astringent, and may be given as such in the dose of two or three drams. The degree of its astringency will vary according to the maturity of the flos and the length of time that the conserve has been kept.

§ 2. PRESERVES.

465. PRESERVES are made by steeping or boiling recent simples, first in water, and then in syrup or solution of sugar. The subject is afterwards either kept moist in the syrup; or taken out and dried, that the sugar may candy upon it: this last is the most usual method.

In this process some of the most valuable parts of the subject are extracted by the liquor, and consequently lost to the preparation; greater regard being here had to palatableness than medicinal efficacy. And indeed most of the preparations of this kind are considered rather as sweetmeats than as medicines, as the business of the confectioner rather than of the apothecary. It would be needless therefore to mention the doses of the several articles, or give particular remarks on the manner of preparing them.

466. *Candied eryngo roots.* L.

Boil them in water till the rind will easily peel off; when peeled, slit them through the middle, take out the pith, and wash them three or four times in cold water. For every pound of the roots so prepared, take two pounds of double-refined sugar, which is to be dissolved in a proper quantity of water, and set over the fire: as soon as the liquor begins to boil, put in the roots, and continue the boiling till they are soft.

467. After this manner are candied, *Angelica stalks*, &c.

468. *Candied orange peel.* L.

Steep the fresh peels of Seville oranges in water; which is to be frequently renewed, until they lose their bitterness. Then, having dissolved in water a suitable quantity of double-refined sugar, boil the peels in this liquor till they become soft and transparent.

469. After the same manner are candied, *Lemon-peels*.

470. *Nutmegs and ginger* are brought to us ready candied from the East Indies. E.

471. *Candied steel.*

Put any quantity of clean filings of iron into, a brass kettle, suspended over a very gentle fire. Add to them, by little and little, twice their weight of white sugar, boiled to the consistence of candy, with which powdered starch has been previously mixed in the proportion of a dram to every pound; agitating the kettle continually, that the filings may be cruised over with the sugar, and taking great care to prevent their running into lumps.

This is a very agreeable preparation of steel; but has hitherto been made only by the confectioners. The college of Edinburgh received it in the former editions; but, as there described, it was almost impossible to hinder the matter from concreting into lumps. They have now discovered the intermedium which prevents that inconvenience, and which the confectioners have kept a secret, the addition of a little starch to the sugar. The preparation may be given to the quantity of half a dram, in those cases wherein chalybeate medicines are proper.

§ 3. GELLIES.

472—477. VEGETABLE gellies are composed of the juices of fruits and sugar, boiled to a thick consistence. Independently of the admixture of sugar, the boiling appears to occasion some alteration in the quality of the juices themselves. The recent juices of the summer fruits are prone to fermentation: after they have been boiled, they are less disposed to ferment, and at the same time they are much less liable to produce, in the human body, flatulencies, gripes, or fluxes; tho' they still retain, in no small degree, their original antiseptic, anti-inflammatory, and aperient or restraining virtues.

§ 4. SYRUPS.

478. SYRUPS are saturated solutions of sugar made in water, or watery or vinous infusions, or in juices. They were formerly considered as medicines of much greater importance than they are thought to be at present. Syrups and distilled waters were for some ages made use of as the great alteratives; inasmuch that the evacuation of any peccant humour was never attempted till, by a due course of these, it had first been regularly prepared for expulsion. Hence arose the exuberant collection of both which we meet with in pharmacopoeias; and like errors have prevailed in each. As multitudes of distilled waters have been compounded from materials unfit to give any virtue over the helm, so numbers of syrups have been prepared from ingredients which in this form cannot be taken in sufficient doses to exert their virtue; for two thirds of a syrup consist of sugar, and greatest part of the remaining third is an aqueous fluid.

479. Syrups are at present chiefly regarded as convenient vehicles for medicines of greater efficacy; and made use of for sweetening draughts and juleps, for reducing the lighter powders into boluses, pills, or electuaries, and other like purposes. Some likewise may not improperly be considered as medicines themselves; as those of saffron and buckthorn-berries.

480. *General rules for preparing syrups.*

I. All the rules laid down for making decoctions are likewise to be observed in the decoctions for syrups. Vegetables, both for decoctions and infusions, ought to be dry, unless they are expressly ordered otherwise.

II. Only the purest or double-refined sugar ought to be used.

In the syrups prepared by boiling, it has been customary to perform the clarification with whites of eggs after the sugar had been dissolved in the decoction of the vegetable. This method is apparently injurious to the preparation; since not the impurities only of the sugar are thus discharged, but a considerable part likewise of the medicinal matter, which the water had before taken up from the ingredients, is separated along with them. Nor indeed is the clarification and depuration of the sugar, by itself, very advisable; for its purification by this process is not so perfect as might be expected: after it has undergone this process, the refiners still separate from it a quantity of oily matter, which is disagreeable to weak stomachs. It appears therefore most eligible to employ fine sugar for all the syrups; even the purgative ones (which have been usually made with coarse sugar, as somewhat coinciding with their intention) not excepted; for as the purgative medicines are in general ungrateful to the stomach, it is certainly improper to employ an addition which increases their offensiveness.

III. Where the weight of the sugar is not expressed, 29 ounces thereof are to be taken to every pint of liquor. The sugar is to be reduced into powder, and dissolved in the liquor by the heat of a water-bath, unless ordered otherwise. *L.*

Although in the formulæ of several of the syrups, a double weight of sugar to that of the liquor is directed, yet less will generally be sufficient. First, therefore, dissolve in the liquor an equal weight of sugar; then gradually add some more in powder till a little remains undissolved at the bottom, which is to be afterwards incorporated by setting the syrup in a water-bath.

The quantity of sugar should be so much as the liquor is capable of keeping dissolved in the cold: if there is more, a part of it will separate and concrete into crystals or candy; if less, the syrup will be subject to ferment, especially in warm weather, and change into a vinous or sour liquor. If, in crystallizing, only the superfluous sugar separated, it would be of no inconvenience; but when part of the sugar has candied, the remaining syrup is found to have an under proportion, and is as subject to fermentation as if it had wanted sugar at first.

IV. Copper-vessels, unless they are well tinned, should not be employed in the making of acid syrups, or such as are composed of the juices of fruits.

The confectioners, who are the most dextrous people at these kinds of preparations, to avoid the expence of frequently new-tinning their vessels, rarely make use of any other than copper ones untinned, in the preparation even of the most acid syrups, as of oranges and lemons. Nevertheless, by taking due care that their coppers be well scoured and perfectly clean, and that the syrup remain no longer in them than is abso-

lutely necessary, they avoid giving it any ill taste or quality from the metal. This practice, however, is by no means to be recommended to the apothecary.

V. The syrup, when made, is to be set by till next day: if any saccharine crust appears upon the surface, take it off. *L.*

481. *Syrup of garlic.* *L.*

Take of garlic, sliced, one pound; boiling water, two pints. Macerate them in a close vessel for twelve hours; then strain off the liquor, and dissolve in it a proper quantity of sugar, so as to make a syrup.

This syrup is occasionally made use of for attenuating viscid phlegm, and promoting expectoration in humoral asthma and oppressions of the breast: in these cases, it proves a medicine of considerable efficacy, though a very unpleasant one; it tastes and smells strongly of the garlic. The college have received it as an alternative to the oxymel of garlic, for the use of those with whom honey disagrees.

482. *Syrup of marshmallows.*

Take of marshmallow roots, fresh, one pound; double-refined sugar, four pounds; water, one gallon. Boil the water with the roots to one half: when grown thoroughly cold, pour off and press out the decoction, and set it by for a night to settle: next morning pour off the clear liquor, and, adding to it the sugar, boil the whole to the weight of six pounds. *L.*

Take of moderately dried marshmallow-roots, nine ounces; white sugar, four pounds; water, a gallon. Boil the water with the marshmallow-roots to the consumption of one half; then strain out the remaining decoction, and suffer it to rest for some time. Pour off the clear liquor from the sediment, and boil it with the sugar over a gentle fire, keeping the matter continually stirring till it becomes a syrup. *E.*

The syrup of marshmallows is used chiefly in nephritic cases, for sweetening emollient decoctions, and the like: of itself it can do little service, notwithstanding the high opinion which some have entertained of it; for what can be expected from two or three spoonfuls of the syrups, when the decoction, from which two or three pounds are made, may be taken at a draught or two? The college of Edinburgh has very properly united this and the *pectoral syrup* into one; for the syrup of marshmallows has always, till the late reformation, contained the principal ingredients of the pectoral syrup, and its own capital ingredient coincides in the same intention.

483. *Syrup of orange-peel.*

Take of the yellow rind of Seville orange-peel, fresh, eight ounces; boiling water, five pints. Macerate them for a night in a close vessel; next morning strain out the liquor, and dissolve in it the proper quantity of sugar for making it into a syrup. *L.*

Take of the yellow rind of orange-peel, fresh, six ounces; boiling water, three pints. Infuse them for a night in a close vessel: then strain the liquor; let it stand to settle; and, having poured it off clear from the sediment, dissolve therein seven pounds and

a quarter of white sugar, so as to make it into a syrup without boiling. *E.*

In making this syrup, it is particularly necessary that the sugar be previously powdered, and dissolved in the infusion with as gentle a heat as possible, to prevent the exhalation of the volatile parts of the peel. With these cautions, the syrup proves a very elegant and agreeable one, possessing great share of the fine flavour of the orange-peel.

#### 484. a. *Balsamic syrup.*

Take of balsam of Tolu, eight ounces; water, three pints. Boil them for two or three hours in a circulatory vessel, or at least in a long-necked matrass, having its mouth lightly covered. When grown cold, strain out the liquor, and mix therewith a proper quantity of sugar to make it into a syrup. *L.* The coction may be conveniently performed in a retort, with a receiver adapted to it, the liquor which comes over being occasionally poured back; or the water may be entirely drawn off, and the sugar dissolved in the distilled liquor.

Take of the syrup of sugar, just made, and warm from the fire, two pounds; tincture of balsam of Tolu, one ounce. When the syrup has grown almost cold, stir into it the tincture by little at a time, agitating them well together till perfectly united. The mixture is then to be kept in the heat of a water-bath until the spirit has exhaled. *E.*

The intention of the contrivers of the two foregoing processes seems to have been somewhat different. In the first, the more subtle and fragrant parts of the balsam are extracted from the grosser resinous matter, and alone retained in the syrup: the other syrup contains the whole substance of the balsam in larger quantity. They are both moderately impregnated with the agreeable flavour of the balsam.

In some pharmacopœias, an elegant syrup of this kind is prepared from a tincture of balsam of Peru, with rose-water and a proper quantity of sugar.

#### 484. b. *Syrup of clove-julyflowers.*

Take of clove-julyflowers, fresh gathered, and freed from the heels, three pounds; boiling water, five pints. Macerate them for a night in a glass or glazed earthen vessel; then strain off the liquor, and dissolve therein its due proportion of sugar to make it into a syrup. *L.*

One pound of the flowers is to be infused in three pints of water, and the syrup made as above without boiling. *E.*

This syrup is of an agreeable flavour, and a fine red colour; and for these it is chiefly valued. Some have substituted to it one easily parable at seasons when the flowers are not to be procured: An ounce of clove spice is infused for some days in 12 ounces of white-wine, the liquor strained, and, with the addition of 20 ounces of sugar, boiled to a proper consistence: a little cochineal renders the colour of this syrup exactly similar to that prepared from the clove-julyflower; and its flavour is of the same kind, though not so pleasant. The abuse may be readily detected, by adding to a little of the syrup some alkaline salt or

VOL. VIII.

1

ley, which will change the genuine syrup to a green colour; but in the counterfeit, it will make no such alteration, only varying the shade of the red.

#### 484. c. *Syrup of colchicum.* *E.*

Take of the root of colchicum, cut into thin slices, one ounce; vinegar, one pint; fine sugar, 26 ounces. Digest the root for two days in the vinegar, shaking the vessel now and then; then strain, pressing out the liquor slightly. Add the sugar to the strained liquor, and boil it gently to the consistence of a syrup.

#### 485. *Syrup of saffron.* *L.*

Take of saffron wine, one pint; double-refined sugar, 15 ounces. Dissolve the sugar in the wine, so as to make a syrup thereof.

Saffron is very well fitted for making a syrup, as in this form a sufficient dose of it is contained in a reasonable compass. This syrup is at present more frequently prescribed than the wine from which it is made: it is a pleasant cordial, and gives a fine colour to juleps.

#### 486. *Syrup of quinces.* *L.*

Take of quince-juice, depurated, three pints; cinnamon, one dram; cloves, ginger, each half a dram; red port wine, one pint; double-refined sugar, nine pounds. Digest the juice with the spices, in the heat of ashes, for six hours; then adding the wine, pass the liquor through a strainer; and afterwards dissolve in it the sugar, so as to make a syrup.

If the quinces are kept for some time in an airy place before the juice is pressed out, the syrup proves rather more elegant, and richer of the fruit than when they are taken fresh from the tree. In either case, the preparation is a very agreeable, mild, cordial refringent; and in some kinds of loosenesses and disorders of the stomach, may be either taken by itself in the quantity of a spoonful or two at a time, or employed for reconciling to the palate and stomach medicines of the more ungrateful kind.

#### 487. *Syrup of kermes.*

This syrup, which is brought to us ready made, from the southern parts of France, is of an agreeable taste, and a fine red colour. It is accounted cordial and corroborant, and supposed to be particularly serviceable in weaknesses and other disorders of pregnant women.

#### 488. *Syrup of lemon-juice.* *L. E.*

Take of juice of lemons, suffered to stand till the sedes have subsided, and afterwards strained, two pints; double-refined sugar, 50 ounces. Dissolve the sugar in the juice, so as to make a syrup thereof. *L.*

After the same manner are prepared,

#### 489. *Syrup of mulberries.* *L.*

#### 490. *Syrup of raspberries.* *L.*

All these are very pleasant, cooling syrups; and in this intention are occasionally made use of in draughts and juleps, for quenching thirst, abating heat, &c. in bilious or inflammatory distempers. They are sometimes likewise employed in gargarisms for inflammations of the mouth and tonsils.

34 C

491. *Syrup*

491. a. *Syrup of meconium, or diacodium. L.*

Take of white poppy heads, dried and cleared from the seeds, three pounds and a half; water, six gallons. Cut the heads, and boil them in the water, stirring them now and then, to prevent their burning, till only about one third part of the liquor remains, which will be almost entirely soaked up by the poppies. Then remove the vessel from the fire, strongly press out the decoction, and boil it down to about four pints: strain it whilst hot, first through a sieve, and afterwards through a fine woollen cloth; and set it by for a night, that the fæces may subside. Next morning pour the liquor off clear, and boil it with six pounds of double-refined sugar, until the weight of the whole is nine pounds, or a little more, that it may become a syrup of a proper consistence.

This syrup, impregnated with the opiate matter of the poppy-heads, is given to children in doses of two or three drams, to adults from half an ounce to an ounce and upwards, for obtunding and incrassating acrimonious humours, easing pain, procuring rest, and answering the other intentions of mild opiates. Particular care is requisite in its preparation, that it may be always made, as nearly as possible, of the same strength; and accordingly the college has been very minute in their description of the process.

491. b. *Syrup of white poppies, or of meconium, commonly called diacodium. E.*

Take of white poppy heads, just ripe, and moderately dried, two pounds; boiling-water, three gallons. Let these be steeped together for a night, and then boiled until half the liquor is wasted: strain, and strongly press out the remainder; and boil it, with the addition of four pounds of white sugar, to the consistence of a syrup.

This process is considerably different from the preceding. The poppy-heads are not boiled so long; and their quantity, in proportion to the produce of syrup, is much less. How far these differences may affect the strength of the preparations, we shall not take upon us to determine.

492. *Syrup of wild poppies. L.*

Take of wild poppy flowers, fresh, four pounds; boiling-water, four pints and a half. Pour the water on the poppies, set them over the fire, and frequently stir them, until the flowers are thoroughly moistened: as soon as they have sunk under the water, let the whole be set by to steep for a night; next day pour off, and press out the liquor, and set it by for a night longer to settle; afterwards add the proper quantity of double-refined sugar to make it into a syrup.

The design of setting the flowers over the fire, is, (as Dr Pemberton observes), that they may be a little scalded, so as to shrink enough to be all immersed in the water; without this artifice, they can scarce be all got in: but they are no longer to be continued over the fire than till this effect is produced, lest the liquor become too thick, and the syrup be rendered ropy.

This syrup has been recommended in disorders of the breast, coughs, spitting of blood, pleurifies, and other diseases, both as an emollient and as an opiate.

It is one of the lightest of the opiate medicines, and in this respect too weak, that some have doubted of its having any anodyne quality.

493. *Pectoral syrup. L. [See 482.]*

Take of English maidenhair, dried, five ounces; liquorice, four ounces; boiling-water, five pints. Macerate them for some hours: then strain out the liquor, and with a proper quantity of double-refined sugar make it into a syrup.

The title of this composition expresses its medicinal intention: it is supposed to soften acrimonious humours, allay tickling coughs, and promote the expectoration of tough phlegm.

494. a. *Solutive Syrup of roses. L.*

Take the liquor that remains after the distillation of six pounds of damask roses; double-refined sugar, five pounds. Having pressed out the liquor from the roses, boil it down to three pints, and set it by for a night to settle: next morning pour it off clear from the sediment; and adding the sugar, boil the mixture to the weight of seven pounds and a half.

494. b. *Syrup of pale roses. E.*

Take of pale roses, fresh gathered, one pound; boiling-water, three pints; white sugar, three pounds. Macerate the roses in the water for a night: then strain the liquor; and adding to it the sugar, boil them into a syrup. This syrup may likewise be made from the liquor remaining after the distillation of rose-water, depurated from its fæces.

The liquor remaining after the distillation of roses (provided the still has been perfectly clean) is as proper for making this syrup as a fresh infusion; for the distillation only collects those volatile parts which are dissipated in the air, whilst the infusion is boiling to its consistence. This syrup is an agreeable and mild purgative for children, in the dose of half a spoonful, or a spoonful. It likewise proves gently laxative to adults, and in this intention may be of service in costive habits. Its principal use is in solutive glysters.

494. c. *Syrup of dry roses. E.*

Take of red roses, dried, seven ounces; white sugar, six pounds; boiling-water, four pints. Infuse the roses in the water for a night; then boil them a little, strain out the liquor, and, adding to it the sugar, boil them to the consistence of a syrup.

This syrup is supposed to be mildly astringent; but is principally valued on account of its red colour.

495. *Syrup of squills.*

Take of vinegar of squills, a pint and a half; cinnamon, ginger, each one ounce; double-refined sugar, three pounds and a half. Steep the spices in the vinegar for three days; then strain out the liquor, and add the sugar so as to make a syrup thereof. E.

Take of vinegar of squills, a pound and an half; white sugar, three pounds and an half. Make them into a syrup, without boiling. E.

The spices, in the first of these compositions, somewhat alleviate the offensiveness of the squills, though not so much as to prevent the medicine from being dis-

disagreeable. It is used chiefly, in doses of a spoonful or two, for attenuating viscid phlegm, and promoting expectoration, which it does very powerfully.

496. *The simple syrup, or syrup of sugar.* E.

Take of white sugar, water, each equal quantities. Boil them into a syrup.

This preparation is a plain liquid sweet, void of flavour or colour. It is convenient for sundry purposes where these qualities are not wanted, or would be exceptionable.

497. a. *Syrup of buckthorn.*

Take of the juice of ripe and fresh buckthorn-berries, one gallon; cinnamon, ginger, nutmegs, each one ounce; double-refined sugar, seven pounds. Set the juice by for some days to settle; then pass it thro' a strainer, and in some part thereof macerate the spices. Boil the rest of the juice, adding towards the end that part in which the spices were macerated, first passed through a strainer: this part of the process must be so managed, that the whole liquor may be reduced to four pints. Lastly, put in the sugar, and make the mixture into a syrup. L.

Take of the juice of ripe buckthorn-berries, depurated, six pounds; white sugar, three pounds and an half. Boil them to the consistence of a syrup. E.

This syrup, in doses of three or four spoonfuls, operates as a brisk cathartic. The principal inconveniences attending it are, its being very unpleasant, and occasioning a thirst and dryness of the mouth and fauces, and sometimes violent gripes: both these may be prevented by drinking liberally of water-gruel, or other warm liquors, during the operation. The ungratefulness of the buckthorn is endeavoured to be remedied by the addition of aromatics, which, however, are scarcely sufficient for that purpose.

497. b. *Syrup of violets.*

Take of violets, fresh, and well coloured, two pounds; boiling-water, five pints. Macerate them for a whole day in a glass, or at least a glazed earthen vessel; then pour out the liquor, and pass it through a thin linen-cloth, carefully avoiding even the lightest pressure: afterwards, adding the due proportion of sugar, make it into a syrup. L.

Take of March violets, fresh, one pound; boiling water, three pints. Steep them together for a night, in a glazed earthen vessel close covered: then strain out the liquor, and dissolve in it seven pounds and a quarter of white sugar, so as to make a syrup without boiling. E.

This syrup is of a very agreeable flavour; and, in the quantity of a spoonful or two, proves to children gently laxative. It is apt to lose, in keeping, the elegant blue colour, for which it is chiefly valued; and hence some have been induced to counterfeit it with materials whose colour is more permanent. This abuse may be readily discovered, by adding to a little of the suspected syrup any acid or alkaline liquor. If the syrup is genuine, the acid will change its blue colour to a red, and the alkali will change it to a green; but if counterfeit, these changes will not happen.

498. *Syrup of ginger.*

Take of ginger, cut into thin slices, four ounces; boil-

ing water, three pints. Macerate them for some hours; then strain out the liquor, and make it into a syrup with a proper quantity of double-refined sugar. L.

Take of ginger, sliced and bruised, three ounces; white sugar, seven pounds and a quarter; boiling-water, three pints. Steep the ginger in the water, in a close vessel, for a night; then boil them a little, and having strained out the decoction set it by to settle. Pour off the clear liquor, add to it the sugar, and make them into a syrup. E.

This is an agreeable and moderately aromatic syrup, lightly impregnated with the flavour and virtues of the ginger.

499. *Confection of kermes.* L.

Take of juice of kermes-grains, warmed and strained, three pounds; damask rose-water, six ounces by measure; oil of cinnamon, half a scruple; double-refined sugar, one pound. Dissolve the sugar in the rose-water, by the heat of a water-bath, into a syrup; then mix in the juice of kermes, and, after it has grown cold, the oil of cinnamon. L.

This is a very elegant and agreeable cordial; the dose, when taken by itself, is from a scruple to a dram or more. Particular care ought to be had in the choice of the essential oil, which for the most part is grievously adulterated: it would be convenient to grind the oil with a little of the sugar, before it is added to the other ingredients; for by this means, it will mix more perfectly, and not be apt to separate in keeping.

500. *Rob of elder-berries.* E.

Take of the juice of ripe elder-berries, four pounds; fine sugar, half a pound. Boil them on a gentle fire to the consistence of thick honey.

§ 5. HONEYS AND OXYMELS.

THE more fixed parts of vegetables, dissolved in watery liquors, may be thence transferred into honey, by mixing the honey with the watery decoction or juice of the plant, and boiling them together till the aqueous part has exhaled, and the honey remains of its original consistence.

501. *Honey of roses.*

Take of rose-buds, freed from the heels, and hastily dried, four ounces; boiling water, three pints; clarified honey, five pounds. Steep the roses in the water for some hours: then strain off the liquor, mix with it the honey, and boil the mixture to the consistence of honey.

This preparation is not unfrequently made use of, as a mild cooling detergent, particularly in gargarisms for ulcerations and inflammation of the mouth and tonsils. The design of hastily drying the roses, is that they may the better preserve their astringency.

502. *Solutive honey.* L.

Take the liquor remaining after the distillation of six pounds of damask-roses; cummin seeds, bruised a little, one ounce; brown sugar, four pounds; honey, two pounds. Having pressed out the liquor, boil it to three pints; adding towards the end, the seeds tied up in a linen cloth. Then put in the sugar and

honey, and boil down the mixture to the consistence of thin honey.

This composition is very well contrived for the purpose expressed in its title. It is principally employed in laxative glysters; and hence brown sugar is here allowed; whilst, for all other uses, the double-refined is directed.

#### 503. *Oxymel of garlic.* L.

Take of garlic, cut in slices, an ounce and a half; caraway seeds, sweet fennel seeds, each two drams; clarified honey, ten ounces by weight; vinegar, half a pint. Boil the vinegar, for a little time, with the seeds bruised, in a glazed earthen vessel; then add the garlic, and cover the vessel close; when grown cold, press out the liquor, and dissolve in it the honey by the heat of a water-bath.

This oxymel is recommended for attenuating viscid juices, promoting expectoration, and the fluid secretions in general. It is doubtless a medicine of considerable efficacy, though very unpleasant, the flavour of the garlic prevailing, notwithstanding the addition of the aromatic seeds.

#### 504. *Pectoral oxymel.*

Take of elecampane roots, one ounce; Florence orris roots, half an ounce; gum ammoniacum, one ounce; vinegar, half a pint; clarified honey, one pound; water, three pints. Let the roots, cut and bruised, be boiled in the water till one-third is wasted: then strain off the liquor; let it stand to settle; and having poured it off clear from the feces, add to it the honey, and the ammoniacum, previously dissolved in the vinegar. Mix them together, by boiling them a little.

This composition is designed for those disorders of the breast that proceed from a load of viscid phlegm (which this medicine attenuates and promotes the expectoration of) and obstructions of the pulmonary vessels. Two or three spoonfuls may be taken every night and morning, and continued for some time.

#### 505. *Oxymel of squills.* L.

Take of clarified honey, three pounds; vinegar of squills, two pints. Boil them in a glazed earthen vessel, over a gentle fire, to the consistence of a syrup.

This is an useful aperient, detergent, and expectorant, and of great service in humoral asthmas, coughs, and other disorders, where thick phlegm abounds. It is given in doses of two or three drams, along with some aromatic water, as that of cinnamon, to prevent the great nausea which it would otherwise be apt to excite. In large doses, it proves emetic.

#### 506. *Simple oxymel.* L.

Take of clarified honey, two pounds; vinegar, one pint. Boil them to a due consistence.

This simple preparation is not inferior in efficacy to many more elaborate compositions. It is an agreeable, mild, cooling, saponaceous, detergent, and attenuating medicine. It is often used in cooling detergent gargarisms, and not unfrequently as an expectorant.

507. The boiling of oxymels in glazed earthen vessels, is not free from danger. Their glazing is procured by a vitrification of lead; and vinegar, by a boiling heat, may corrode so much so much of vitrified lead, as to receive from it noxious qualities.

### SECT. V. *Separation and collection of those parts of Vegetable and Animal substances which are volatile in the heat of boiling water.*

508. THERE are many vegetable, and some animal substances, whose virtues reside, wholly or in part, in a matter which is capable of totally exhaling in the heat of boiling water. In most of the processes hitherto described it is endeavoured, if possible, to preserve this volatile matter along with the more fixed parts; whether those fixed parts were themselves medicinal, or only subservient to the union of the volatile matter with the fluids employed. The aim, in the present section, is, to completely separate this volatile subtle principle, and collect it pure from the grosser fixed parts, either in a concentrated state, or diluted with water or spirit of wine. In its concentrated state, it appears commonly an oil; which, from its containing always the specific odour, and frequently the other medicinal powers of the subject, is called *essential oil*.

#### § I. ESSENTIAL OILS.

509. THESE are drawn by distillation in an alembic, with a large refrigeratory. A quantity of water is added to the subject, sufficient to prevent its burning; and in this water it is likewise macerated a little time before the distillation. The oil comes over along with the water; and either swims on its surface, or sinks to the bottom, according as it is lighter or heavier than that fluid. L.

510. Essential oils are obtained only from odiferous substances; but not equally from all of this class, nor in quantity proportionable to their degree of odour; some, which if we were to reason from analogy should seem very well fitted for this process, yielding extremely little oil, and others none at all. Roses and camomile flowers, whose strong and lasting smell promises abundance, are found upon experiment to contain but a small quantity: the violet and jasmine flowers, which perfume the air with their odour, lose their smell upon the gentlest coction, and do not afford the least perceptible mark of oil upon being distilled, unless immense quantities are submitted to the operation at once: while favin, whose disagreeable scent extends to no great distance, gives out the most oil of almost any vegetable known.

Nor are the same plants equally fit for this operation, when produced in different soils or seasons, or at different times of their growth. Some yield more oil if gathered when the flowers begin to fall off than at any other time; lavender and rue, for instance. Others, as sage, afford the largest quantity when young, before they have sent forth any flowers; and others, as thyme, when the flowers have just appeared. All fragrant herbs yield a larger proportion of oil when produced in dry soils and warm summers, than in the opposite circumstances. On the other hand, some of the disagreeable strong-scented ones, as wormwood,

wood, are said to contain most in rainy seasons and moist rich grounds.

511. With regard to the proportion of water, if whole plants, moderately dried, are used, or the shavings of woods; as much of either may be put into the vessel, as, lightly pressed, will occupy half its cavity; and as much water may be added, as will arise up to two thirds its height. The water and ingredients, all together, should never take up more than three-fourths of the still; there should be liquor enough to prevent any danger of an empyreuma, but not so much as to be too apt to boil over into the receiver.

The maceration should be continued so long, as that the water may fully penetrate the pores of the subject. To promote this effect, woods should be thinly shaved across the grain, roots cut transversely into thin slices, barks reduced into coarse powder, and seeds lightly bruised. Very compact and tenacious substances require the maceration to be continued a week or two, or longer; for those of a softer and looser texture, two or three days are sufficient; whilst some tender herbs and flowers not only stand not in need of any at all, but are even injured by it.

512. The choice of proper instruments is of great consequence to the performance of this process to advantage. There are some oils, which pass freely over the swan-neck of the head of the common still: others, less volatile, cannot easily be made to rise so high. For obtaining these last Dr. Lewis recommends a large low head, having a rim or hollow canal round it; in this canal the oil is detained on its first ascent (and thence conveyed at once into the receiver), the advantages of which are sufficiently obvious.

With regard to the fire, the operator ought to be expeditious in raising it at first, and to keep it up, during the whole process, of such a degree, that the oil may freely distil; otherwise, the oil will be exposed to an unnecessary heat, a circumstance which ought as much as possible to be avoided. Fire communicates to all these oils a disagreeable impression, as is evident from their being much less grateful when newly distilled, than after they have stood for some time in a cool place; the longer the heat is continued, the more alteration it must produce in them.

The greater number of oils require for their distillation the heat of water strongly boiling: but there are many also which rise with a considerably less heat; such as those of lemon-peel, citron-peel, of the flowers of lavender and rosemary, and of almost all the more odoriferous kinds of flowers. We have already observed, that these flowers have their fragrance greatly injured, or even destroyed, by beating or bruising them: it is impaired also by the immersion in water in the present process, and the more so in proportion to the continuance of the immersion and the heat: hence these oils, distilled in the common manner, prove much less agreeable in smell than the subjects themselves. For the distillation of substances of this class, another method has been contrived: instead of being immersed in water they are exposed only to its vapour. A proper quantity of water being put into the bottom of the still, the odoriferous herbs or flowers are laid lightly in a basket, of such a size, that it may enter into the still, and rest against its sides, just above

the water. The head being then fitted on, and the water made to boil, the steam, percolating through the subject, imbibes the oil, without impairing its fragrance, and carries it over into the receiver. Oils thus obtained possess the odour of the subject in an exquisite degree, and have nothing of the disagreeable scent perceivable in those distilled by boiling them in water in the common manner.

The water employed in the distillation of essential oils, always imbibes some portion of the oil; as is evident from the smell, taste, and colour, which it acquires. It cannot, however, retain above a certain quantity; and therefore, such as has been already used and almost saturated itself, may be advantageously employed, instead of common water, in a second, third, or any future distillation of the same subject.

After the distillation of one oil, particular care should be had to duly cleanse the worm before it is employed in the distillation of a different plant. Some oils, those of wormwood and aniseeds for instance, adhere to it so tenaciously, as not to be melted out by heat, or washed off by water: the best way of cleansing the worm from these, is to run a little spirit of wine through it.

513. Essential oils, after they are distilled, should be suffered to stand for some days in vessels loosely covered with paper, till they have lost their disagreeable fiery odour and become limpid: then put them up in small bottles, which are to be kept quite full, closely stoped, in a cool place: with these cautions, they will retain their virtues in perfection for many years.

When carelessly kept, they in time gradually lose of their flavour, and become gross and thick. Some endeavour to recover them again after they have undergone this change, by grinding them with about thrice their weight of common salt, then adding a large proportion of water, and distilling them afresh: the purer part arises thin and limpid, possessing a great degree of the pristine smell and taste of the oils, though inferior in both respects to what the oil was at first. The oils, when thus altered, are nearly in the same state with the turpentine, and other thickened oily juices, which readily yield their purer oil in distillation with water alone.

514. Essential oils, medically considered, agree in the general qualities of pungency and heat; in particular virtues, they differ as much as the subjects from which they are obtained, the oil being the direct principle in which the virtues, or part of the virtues, of the several subjects reside. Thus the carminative virtue of the warm seeds, the diuretic of juniper-berries, the emmenagogue of saffron, the nervine of rosemary, the stomachic of mint, the antiscorbutic of scurvy-grass, the cordial of aromatics, &c. are concentrated in their oils.

There is another remarkable difference in essential oils, the foundation of which is less obvious; that of the degree of their pungency and heat; which are by no means in proportion, as might be expected, to those of the subjects they were drawn from. The oil of cinnamon, for instance, is excessively pungent and fiery; in its undiluted state, it is almost caustic: whereas cloves, a spice which in substance is far more pungent than the other, yields an oil which is far less so.

This.

This difference seems to depend partly upon the quantity of oil afforded, cinnamon yielding much less than cloves, and consequently having its active matter concentrated into a smaller volume; partly, upon a difference in the nature of the active parts themselves: for though essential oils contain always the specific odour and flavour of their subjects, whether grateful or ungrateful, they do not always contain the whole pungency; this resides frequently in a more fixed resinous matter, and does not rise with the oil. After the distillation of cloves, pepper, and some other spices, a part of their pungency is found to remain behind: a simple tincture of them in rectified spirit of wine is even more pungent than their pure essential oils.

415. The more grateful oils are frequently made use of for reconciling to the stomach medicines of themselves disgusting. It has been customary to employ them as correctors for the resinous purgatives; an use which they do not seem to be well adapted to. All the service they can here be of, is to make the resin sit easier at first on the stomach; far from abating the irritating quality upon which the virulence of its operation depends, these pungent oils superadd a fresh stimulus.

Essential oils are never given alone, on account of their extreme heat and pungency; which in some is so great, that a single drop let fall upon the tongue, produces a gangrenous eschar. They are readily imbibed by pure dry sugar, and in this form may be conveniently exhibited. Ground with eight or ten times their weight of the sugar, they become soluble in aqueous liquors, and thus may be diluted to any assigned degree. Mucilages also render them miscible with water into a uniform milky liquor. They dissolve likewise in spirit of wine; the more fragrant in an equal weight, and almost all of them in less than four times their own quantity: these solutions may be either taken on sugar, or mixed with syrups or the like; on mixing them with water, the liquor grows milky, and the oil separates.

The more pungent oils are employed externally against paralytic complaints, numbness, pains, and aches, cold tumours, and in other cases where particular parts require to be heated or stimulated. The toothach is sometimes relieved by a drop of these almost caustic oils, received on cotton, and cautiously introduced into the hollow tooth.

#### 516. *Essential oil of the leaves of wormwood.* L.

This is one of the more ungrateful oils: it smells strongly of the wormwood; and contains its particular nauseous taste, but has little or nothing of its bitterness, this remaining entire in the decoction left after the distillation: its colour, when drawn from the fresh herb, is a dark green; from the dry, a brownish yellow. This oil is employed chiefly as a vermifuge; and for this purpose is both applied externally to the belly, and taken internally: it is most conveniently exhibited in the form of pills, which it may be reduced into by mixing it with crumb of bread.

#### 517. *Essential oil of dill-seeds.* L. E.

This is a very warm oil; of a flavour not very agreeable, less so than that of the seeds. It is sometimes given as a carminative, in flatulencies, colicky pains, hiccups, and the like, from one to three or four drops.

#### 518. *Essential oil of aniseeds.* L. E.

This oil possesses the taste and smell of the aniseeds in perfection. It is one of the mildest of the distilled oils: 15 or 20 drops may be taken at a time without danger, though common practice rarely goes so far as half this number. Its smell is extremely durable and diffusive: milk drawn from the breast after taking it, is found impregnated with its odour; and possibly this may be, in part, the foundation of the pectoral virtues usually ascribed to it: in flatulencies and colics, it is said by some to be less effectual than the seeds themselves.

It is remarkable of this oil, that it congeals, even when the air is not sensibly cold, into a butyaceous consistence: and hence, in the distillation of it, the operator ought not to be over-solicitous in keeping the water in the refrigeratory too cool: it behoves him rather to let it grow somewhat hot, particularly towards the end of the process; otherwise the oil, congealing, may so stop up the worm, as to endanger blowing off the head of the still, at least a considerable quantity of oil will remain in it.

#### 519. *Essential oil of caraway seeds.* L. E.

This is a very hot and pungent oil; a single drop is a moderate dose, and five or six a very large one. It is not unfrequently made use of as a carminative; and supposed by some to be peculiarly serviceable for promoting urine, to which it communicates some degree of its smell.

#### 520. *Essential oil of cloves.* L. E.

This oil is so ponderous as to sink in water, and is not easily elevated in distillation: if the water which comes over be returned on the remaining cloves, and the distillation repeated, some more oil will generally be obtained, though much inferior in quality to the first. The oil of cloves is usually described as being "in taste excessively hot and fiery, and of a gold yellow colour;" (*Boerh. process.* 27.) Such indeed is the composition which we receive under this name from Holland; but the genuine oil of cloves is one of the milder oils: it may be taken with great safety (duly diluted) to the quantity of 10 or 12 drops or more. Nor is its colour at all yellow, unless it has been long and carelessly kept, or distilled by too violent a fire: when in perfection, it is limpid and colourless; of a pleasant, moderately warm and pungent taste; and of a very agreeable smell, much resembling that of the spice itself.

#### 521. *Essential oil of chamomile flowers.* L.

This is a very pungent oil, of a strong not ungrateful smell, resembling that of the flowers; its colour is yellow, with a cast of greenish or brown. It is sometimes given in the dose of a few drops, as a carminative, in hysterical disorders, and likewise as a vermifuge; it may be conveniently made into pills with crumb of bread.

#### 422. *Oil of cinnamon.* L.

This valuable oil is extremely hot and pungent; of a most agreeable flavour, like that of the cinnamon itself. In cold languid cases, and debilities of the nervous system, it is one of the most immediate cordials and

and restoratives. The dose is one, two, or three drops; which must always be carefully diluted by the mediation of sugar, &c. for so great is the pungency of this oil, that a single drop let fall upon the tongue, undiluted, produces, as Becherave observes, a gangrenous eschar. In the distillation of this oil, a smart fire is required; and the low head, with a channel round it, above recommended for the distillation of the less volatile oils (n<sup>o</sup> 512.), is particularly necessary for this, which is one of the least volatile, and which is afforded by the spice in exceeding small quantity.

523. *Essential oil of fennel-seeds.*

The oil obtained from sweet-fennel seeds is much more elegant and agreeable than that of the common fennel. It is one of the mildest of these preparations: it is nearly of the same degree of warmth with that of aniseeds; to which it is likewise similar in flavour, tho' far more grateful. It is given from two or three drops to 10 or 12, as a carminative, in cold indispositions of the stomach; and in some kinds of coughs, for promoting expectoration.

524. *Essential oil of juniper-berries.* L. E.

This oil is a very warm and pungent one; of a strong flavour, not unlike that of the berries. In the dose of a drop or two, it proves a serviceable carminative and stomachic; in one of six, eight, or more, a stimulating, detergent diuretic and emmenagogue: it seems to have somewhat of the nature of the turpentine, or their distilled oil; like which it communicates a violent smell to the urine.

The oil of these berries resides partly in vesicles spread through the substance of the fruit, and partly in little cells contained in the seeds; when the berry is dry, and the oil hardened into a resinous substance, it becomes visible, upon breaking the seeds, in form of little transparent drops. In order therefore to obtain this oil to advantage, we ought, previous to the distillation, to bruise the berry thoroughly, so as to break the seeds, and entirely lay open the oily receptacles.

525. *Essential oil of lavender-flowers.* L. E.

This oil, when in perfection, is very limpid, of a pleasant yellowish colour, extremely fragrant, possessing in an eminent degree the peculiar smell generally admired in the flowers. It is a medicine of great use, both externally and internally, in paralytic and lethargic complaints, rheumatic pains, and debilities of the nervous system. The dose is from one drop to five or six.

526. *Essential oil of bay-berries.*

The oil of bay-berries is thin and limpid, moderately pungent, of a strong and tolerably grateful smell. It is given in flatulent colics, hysterical complaints, and for allaying the pains consequent upon delivery; the dose from two drops to five or six. It is likewise made an ingredient in carminative glysters; and in some hysterical cases, is applied externally.

526. *Essence of lemons.* L.

This is a pleasant oil, of a fine smell, very near as agreeable as that of the fresh peel: it is one of the lightest and most volatile oils we have, perfectly limpid, and almost colourless. It is taken in doses of two

or three drops, as a cordial, in weakness of the stomach, &c. though more frequently used as a perfume.

528. *Essential oil of mace.*

The essential oil of mace is moderately pungent, very subtle and volatile, and of a strong aromatic smell like that of the spice itself: it is thin and limpid, of a pale yellowish colour, with a portion of thicker and darker-coloured oil at the bottom. This oil is celebrated in vomitings, hiccups, colicky pains, &c. both given internally from one to four drops, and applied externally to the stomach and umbilical region. It is, however, but rarely made use of, and not often met with in the shops.

529. *Essential oil of marjoram leaves.* L.

This oil is very hot and penetrating, in flavour not near so agreeable as the marjoram itself: when in perfection, it is of a pale yellow colour; by long keeping, it turns reddish: if distilled with too great a heat, it arises of this colour at first. It is supposed to be peculiarly serviceable in relaxations, obstructions, and mucous discharges of the uterus: the dose is one or two drops.

530. a. *Essential oil of the leaves of common mint.*

L. E.

This oil smells and tastes strongly of the mint, but is in both respects somewhat less agreeable than the herb itself. It is an useful stomachic medicine; and not unfrequently exhibited in want of appetite, weakness of the stomach, retchings to vomit, and other like disorders, when not accompanied with heat or inflammation: two or three drops, or more, are given for a dose.

530. b. *Essential oil of the leaves of pepper-mint.* L.

This possesses the smell, taste, and virtues of the pepper-mint in perfection; the colour is a pale greenish yellow. It is a medicine of great pungency and subtlety; and diffuses, almost as soon as taken, a glowing warmth through the whole system. In colics accompanied with great coldness, and in some hysterical complaints, it is of excellent service. A drop or two are in general a sufficient dose.

331. *Essential oil of nutmegs.* L. E.

The essential oil of nutmegs possesses the flavour and aromatic virtues of the spice in an eminent degree. It is similar in quality to the oil of mace, but somewhat less grateful.

532. *Essential oil of the leaves of origanum.* L. E.

This oil has a very pungent acrimonious taste, and a penetrating smell. It has been chiefly employed externally as an errhine, and for easing pains of the teeth.

533. *Essential oil of Jamaica pepper.* E.

This is a very elegant oil, and may be used as a succedaneum to those of some of the dearer spices. It is of a fine pale colour, in flavour more agreeable than the oil of cloves, and not far short of that of nutmegs. It links in water, like the oils of some of the eastern spices.

534. *Essential oil of rosemary.* L. E.

The oil of rosemary is drawn from the plant in flower.

flower. When in perfection, it is very light and thin; pale, and almost colourless; of great fragrantcy, tho' not quite so agreeable as the rosemary itself. It is recommended, in the dose of a few drops, in nervous and hysterical complaints. Boerhaave holds it in great esteem against epilepsies, and suppressions of the uterine purgations, occasioned by weakness and inactivity.

535. *Essential oil of rue-leaves.* L.

The oil of rue has a very acrid taste, and a penetrating smell, resembling that of the herb, but rather more unpleasant. It is sometimes made use of in hysterical disorders, and as an anthelmintic; as also in epilepsies proceeding from a relaxed state of the nerves.

Rue yields its oil very sparingly. The largest quantity is obtained from it when the flowers are ready to fall off, and the seeds begin to show themselves: suitable maceration, previous to the distillation, is here extremely necessary.

536. *Essential oil of savin leaves.* L. E.

This oil is a celebrated uterine and emmenagogue; in cold phlegmatic habits, it is undoubtedly a medicine of good service, though not capable of performing what it has been usually represented to do. The dose is, two or three drops or more.

537. *Essential oil of saffraas.* L. E.

This is the most ponderous of all the known essential oils, but rises in distillation with sufficient ease: it appears limpid as water, has a moderately pungent taste, a very fragrant smell, exactly resembling that of the saffraas. It stands greatly commended as a sudorific, and for purifying the blood and juices: it is likewise supposed to be of service in humoral asthma and coughs. The dose is from one drop to eight or ten; though Geoffroy goes as far as 20.

The decoction remaining after the distillation of the oil, affords, by inspissation, an useful extract, of a mild, bitterish, subastringent taste. Hoffman says, he has given it with great benefit, in doses of a scruple, as a corroborant in cachectic cases, in the decline of intermitting fevers, and for abating hypochondriacal spasms.

538. *Oil of turpentine.* L. E.

This is distilled in the same manner as the foregoing oils, and is strictly an essential one, though not usually ranked in this class: it is commonly, but improperly, called *spirit of turpentine*. It is employed in large quantities for some mechanic purposes, and hence the distillation of it is become a particular business.

This oil is a very hot, stimulating medicine. It is sometimes given as a sudorific and diuretic, in the dose of two or three drops: in larger doses, it is apt to greatly heat the body, occasion pain of the head, an effusion of the semen and liquor of the prostate glands. It has nevertheless been of late taken in considerable doses (along with honey or other convenient vehicles) against the sciatica; and, as is said, with good success. Some have recommended it against venereal runnings: but here it has produced mischievous consequences, inflaming the parts and aggravating the disorder. Externally it is not unfre-

quently employed against rheumatic pains, aches, sprains, for disussing cold tumours, and restraining hæmorrhages.

539. After the distillation of the turpentine, there remains in the still a brittle resinous substance, of a yellow colour, called *yellow resin* [L.]

The only use of this is in external applications, for giving consistence to plasters, and the like purposes.

540. Most of the foregoing oils are drawn by our chemists, and easily procurable in a tolerable degree of perfection; those of cinnamon, cloves, nutmegs, and mace, excepted. These are usually imported from abroad; and are for the most part so much adulterated, that it is difficult to meet with such as are at all fit for use.

Nor are the adulterations of these kinds of preparations easily discoverable. The groffer abuses indeed may be readily detected: thus if the oil is mixed with spirit of wine, it will turn milky on the addition of water; if with expressed oils, rectified spirit will dissolve the essential, and leave the other behind; if with oil of turpentine, on dipping a piece of paper in the mixture, and drying it with a gentle heat, the turpentine will be betrayed by its smell. But the more subtle artifices have contrived other methods of sophistication, which elude all trials of this kind.

Some have looked upon the specific gravity of oils, as a certain criterion of their genuineness. This, however, is not to be absolutely depended on; for the genuine oils, obtained from the same subject, oftentimes differ in gravity as much as those drawn from different ones. Cinnamon and cloves, whose oils usually sink in water, yield, if slowly and warily distilled, an oil of great fragrantcy, which is nevertheless specifically lighter than the aqueous fluid employed in the distillation of it; whilst, on the other hand, the last runnings of some of the lighter oils prove sometimes so ponderous as to sink in water.

As all essential oils agree in the general properties of solubility in spirit of wine, indissolubility in water, miscibility with water by the intervention of certain intermedia, volatility in the heat of boiling water, &c. it is plain that they may be variously mixed with one another, or the dealer sophisticated with the cheaper, without any possibility of discovering the abuse by any trials of this kind. And indeed, it would not be of much advantage to the purchaser if he had infallible criteria of the genuineness of every individual oil. It is of as much importance, that they may be good, as that they may be genuine; for we have often seen genuine oils, from incautions distillation, and long and careless keeping, weaker both in smell and taste than the common sophisticated ones.

The smell and taste seem to be the only certain tests that the nature of the thing will admit of. If a bark should have in every respect the appearance of good cinnamon, and should be proved indisputably to be the genuine bark of the cinnamon tree; yet, if it wants the cinnamon flavour, or has it but in a low degree, we reject it: and the case is the same with the oil. It is only from use and habit, or comparison with specimens of known quality, that we can judge of the goodness, either of the drugs themselves, or of their oils.

Most of the essential oils, indeed, are too hot and pungent to be tasted with safety; and the smell of the subject is so much concentrated in them, that a small variation in this respect is not easily distinguished. But we can readily dilute them to any assignable degree. A drop of the oil may be dissolved in spirit of wine; or received on a bit of sugar, and dissolved by that intermedium in water. The quantity of liquor which it thus impregnates with its flavour, or the degree of flavour which it communicates to a certain determinate quantity, will be the measure of the degree of goodness of the oil.

## § 2. SIMPLE DISTILLED WATERS.

541. THE effluvia which exhale in the air from many vegetables, particularly from those of the odorous kind, consist apparently of principles of great subtilty and activity, capable of strongly and suddenly affecting the brain and nervous system, especially in those whose nerves are of great sensibility; and likewise of operating, in a slower manner, upon the system of grosser vessels. Thus Boerhaave observes, that, in hysterical and dropical persons, the fragrant odour of the Indian hyacinth excites strange spasms, which the strong scent of rue relieves; that the effluvia of the walnut-tree occasion head-achs, and make the body costive; that those of poppies procure sleep; and that the smell of bean-blossoms, long continued, disorders the senses. Lemery relates, from his own knowledge, that several persons were purged, by staying long in a room where damask-roses were drying.

Some of the chemists have indulged themselves in the pleasing survey of these *presiding spirits*, as they are called, of vegetables; their peculiar nature in the different species of plants; their exhalation into the atmosphere by the sun's heat, and dispersion by winds; their rendering the air of particular places medicinal, or otherwise, according to the nature of the plants that abound. They have contrived also different means for collecting these fugitive emanations, and concentrating and condensing them into a liquid form; employing either the native moisture of the subject, or an addition of water, as a vehicle or matrix for retaining them.

542. The process which has been judged most analogous to that of nature is the following: The subject, fresh gathered at the season of its greatest vigour, with the morning-dew upon it, is laid lightly and unbruised in a shallow vessel, to which is adapted a low head with a recipient: under the vessel a live coal is placed, and occasionally renewed, so as to keep up a uniform heat, no greater than that which obtains in the atmosphere in summer, viz. about 85 degrees of Fahrenheit's thermometer. In this degree of heat, there arises, exceedingly slowly, an invisible vapour, which condenses in the head into dewy drops, and falls down into the receiver, and which has been supposed to be the very substance that the plant would have spontaneously emitted in the open air.

But on submitting to this process many kinds of odoriferous vegetables, liquors obtained by it have been always found to be very different from the natural effluvia of the respective subjects: they had very little smell, and no remarkable taste. It appeared,

that a heat, equal to that of the atmosphere, is incapable of raising in close vessels those parts of vegetables which they emit in the open air. It may therefore be presumed, that in this last case some other cause concurs to the effect: that it is not the sun's heat alone which raises and impregnates the air with the odorous principles of vegetables; but that the air itself, or the watery humidity with which it abounds, acting as a true dissolvent, extracts and imbibes them; so that the natural effluvia of the plant may be looked upon as an infusion of the plant made in air. The purgative virtue of the damask-rose, and the astringency of the walnut-tree, which, as above observed, are in some measure communicated to the air, may be totally extracted by infusion both in watery and spirituous menstrua, but never rise in distillation with any degree of heat: and the volatile odours of aromatic herbs, which are diffused through the atmosphere in the lowest warmth, cannot be made to distil without a heat much greater than is ever found to obtain in a shaded air.

The above process therefore, and the theory on which it is built, appear to be faulty in two points: (1.) In supposing, that all those principles which naturally exhale from vegetables, may be collected by distillation; whereas there are many which the air extracts in virtue of its dissolving power, and which are artificially separable also by dissolvents only: (2.) In employing a degree of heat insufficient for separating even those parts which are truly exhaleable by heat.

543. The foregoing method of distillation is commonly called *distillation by the cold still*; but those who have practised it, have generally employed a considerable heat. A shallow leaden vessel is filled with the fresh herbs, flowers, &c. which are heaped above it, so that, when the head is fitted on, this also may be filled a considerable way: a little fire is made under the vessel, sufficient to make the bottom much hotter than the hand can bear, care being taken only not to heat it so far as to endanger scorching any part of the subject. If the bottom of the vessel is not made so hot as to have this effect on the part contiguous to it, it is not to be feared that the heat communicated to the rest of the included matter will be great enough to do it any injury. By this management, the volatile parts of several odorous plants, as mint, are effectually forced over; and if the process has been skillfully managed, the distilled liquor proves richly impregnated with the native odour and flavour of the subject, without having received any kind of disagreeable impression from the heat made use of.

This process has been chiefly practised in private families; the slowness of the distillation, and the attendance and care necessary for preventing the scorching of some part of the plant so as to communicate an ungrateful burnt flavour to the liquor, rendering it inconsistent with the dispatch requisite in the larger way of business.

544. Another method has therefore been had recourse to; that by the common still, called, in distinction from the foregoing, the *hot still*. Here a quantity of water is added to the plant, to prevent its burning: and the liquor is kept nearly of a boiling heat, or made fully to boil, so that the vapour rises plentifully into the head, and passing thence into a spiral pipe

or worm, placed in a vessel of cold water, is there condensed, and runs out into drops quickly succeeding one another, or in a continued stream. The additional water does not at all weaken the produce: for the most volatile parts of the subject rise first, and impregnate the liquor that first distils: as soon as the plant has given over its virtue sufficiently, which is known by examining from time to time the liquor that runs from the nose of the worm, the distillation is to be stopped.

This is the method of distillation commonly practised for the official waters. It is accompanied with one imperfection, affecting chiefly those waters whose principal value consists in the delicacy of their flavour; this being not a little injured by the boiling heat usually employed, and by the coagitation of the odorous particles of the subject with the water. Sometimes also a part of the plant sticks to the sides of the still, and is so far scorched as to give an ungrateful taint to the liquor.

545. There is another method of managing this operation, which we have already recommended for the distillation of the more volatile essential oils, and which is equally applicable to that of the waters. In this method, the advantages of the foregoing ones are united, and their inconveniences obviated. A quantity of water being poured into the still, and the herbs or flowers placed in a basket over it, there can be no possibility of burning; the water may be made to boil, but so as not to rise up into the basket, which would defeat the intention of this contrivance. The hot vapour of the water passing lightly through all the interstices of the subject matter, imbibes and carries out the volatile parts unaltered in their native flavour. By this means the distilled waters of all those substances, whose oils are of the more volatile kind, are obtained in the utmost perfection, and with sufficient dispatch; for which last intention the still may be filled quite up to the head.

546. In the distillation of essential oils, the water, as observed in the foregoing section, imbibes always a part of the oil. The distilled liquors here treated of, are no other than water thus impregnated with the essential oil of the subject; whatever smell, taste, or virtue, is here communicated to water, or obtained in the form of a watery liquor, being found in a concentrated state in the oil. The essential oil, or some part of it, more attenuated and subtilized than the rest, is the direct principle on which the title of *spiritus rectior*, or presiding spirit, has been bestowed.

All these vegetables therefore which contain an essential oil, will give over some virtue to water by distillation: but the degree of the impregnation of the water, or the quantity of water which a plant is capable of satiating with its virtue, are by no means in proportion to the quantity of its oil. The oil satiates only the water that comes over at the same time with it: if there be more oil than is sufficient for this satiation, the surplus separates, and concretes in its proper form, not miscible with the water that arises afterwards. Some odoriferous flowers, whose oil is in so little quantity, that scarcely any visible mark of it appears, unless 50 or 100 pounds or more are distilled at once, give nevertheless as strong an impregnation to

water, as those plants which abound most with oil. Preparations.

### 547. General rules for the distillation of the official simple waters.

I. Plants and their parts ought to be fresh gathered.

Where they are directed fresh, such only must be employed; but some are allowed to be used dry, as being easily procurable in this state at all times of the year, though rather more elegant waters might be obtained from them whilst green [L.]

II. Having bruised the subject a little, pour thereon thrice its quantity of spring-water: this quantity is to be diminished or increased, according as the plants are more or less juicy than ordinary.

When fresh and juicy herbs are to be distilled, thrice their weight of water will be fully sufficient: but dry ones require a much larger quantity. In general, there should be so much water, that after all intended to be distilled has come over, there may be liquor enough left to prevent the matter from burning to the still.

III. The distillation may be performed in an alembic with a refrigeratory, the junctures being luted.

IV. The distillation is to be continued as long as the water which comes over is perceived to have any smell or taste of the plant.

Plants differ so much, according to the soil and season of which they are the produce, and likewise according to their own age, that it is impossible to fix the quantity of water to be drawn from a certain weight of them, to any invariable standard. The distillation may always be continued as long as the liquor runs well flavoured of the subject, and no longer.

If the herbs are of prime goodness, they must be taken in the weights prescribed. But when fresh ones are substituted to dry, or when the plants themselves are the produce of unfavourable seasons, and weaker than ordinary, the quantities are to be varied according to the discretion of the artist [L.]

After the odorous water, alone intended for use, has come over, an acidulous liquor arises, which has sometimes extracted so much from the copper-head of the still, as to prove emetic. To this are owing the anthelmintic virtues attributed to certain distilled waters.

V. If any drops of oil swim on the surface of the water, they are to be carefully taken off.

VI. That the waters may keep the better, about one-twentieth part their weight of proof-spirit may be added to each, after they are distilled. L.

548. A great number of distilled waters were formerly kept in the shops, and are still retained in foreign pharmacopœias. The faculty of Paris direct, in the last edition of their *codex medicamentarius*, no less than 125 different waters, and 130 different ingredients in one single water. Near one half of these preparations have scarcely any virtue or flavour from the subject, and many of the others are insignificant.

The colleges of London and Edinburgh have rejected these ostentatious superfluities: and given an elegant and compendious set of waters, sufficient for answering such purposes as these kinds of preparations are applied to in practice. Distilled waters are employed chiefly as grateful diluents, as suitable vehicles for medicines of greater efficacy, or for rendering disgusting ones more acceptable to the palate and stomach:

Prepara-  
tions.

mach: few are depended on, in any intentions of consequence, by themselves.

549. *Simple alexeterial water.* L.

Take of spearmint leaves, fresh, a pound and a half: sea-wormwood tops fresh, angelica-leaves fresh, each one pound; water, as much as is sufficient to prevent an empyreuma. Draw off by distillation three gallons.

This water is sufficiently elegant with regard to taste and smell; though few expect from it such virtues as the title seems to imply. It is used occasionally for vehicles of alexipharmac medicines, or in juleps to be drank after them, as coinciding with the intention; but in general this water is not supposed to be itself of any considerable efficacy.

550. *Simple orange-peel water.* L.

Take of yellow peel of Seville oranges, dried, four ounces; water, as much as is sufficient to prevent burning. Distill off one gallon.

This water proves very weak of the orange-peel. It is designed for a diluter, in fevers, and other disorders where the stomach and palate are subject to receive quick disgust; in which cases (as the committee observe) cordial waters, especially if their use is to be long continued, ought to be but lightly impregnated with any flavour, however agreeable.

551. *Black cherry water.*

Let any quantity of black cherries be bruised, so as the stones may be broken; and then distilled according to art, with only a small proportion of water.

This is a very grateful water, and has long maintained a place in the shops. It has frequently been employed by physicians as a vehicle, in preference to the other distilled waters; and, among nurses and others who have the care of young children, has been the first remedy against the convulsive disorders to which children are so often subject.

This water has nevertheless of late been brought into disrepute; being, in consequence of certain experiments, looked upon by some as poisonous, and by most as at least suspicious. Wherefore both the London and Edinburgh colleges have chosen to lay it aside; more especially as it has been too often counterfeited with a water distilled from bitter almonds, which are known to communicate a poisonous quality.

552. a. *Simple cinnamon-water.* L.

Take of cinnamon, one pound; water, as much as will prevent burning. Distil off a gallon.

552. b. *Cinnamon-water without wine.* E.

Take of cinnamon, half a pound; water, one gallon and a half. Steep them together for two days; and then distil off one gallon.

This is a very grateful and useful water, possessing in an eminent degree the fragrance and aromatic cordial virtues of the spice. Great care should be had, in the choice of the cinnamon, to avoid the too common imposition of casia being substituted in its room: this latter yields a water much less agreeable than that of cinnamon, and whose flavour is manifestly empyreumatic.

Prepara-  
tions.

The virtues of all these waters depend upon their containing a portion of the oil of the subject. The oil of cinnamon is very ponderous, and arises more difficultly than that of any of the other vegetable matters from which simple waters are ordered to be drawn. This observation directs us, in the distillation of this water, to make use of a quick fire, and a low vessel. For the same reason, the water does not keep so well as might be wished; the ponderous oil parting from it in time, and falling to the bottom, when the liquor loses its milky hue, its fragrant smell and aromatic taste. Some recommend a small proportion of sugar to be added, in order to keep the oil united with the water.

553. *Fennel water.* L.

Take of sweet-fennel seeds, one pound; water, as much as is sufficient to prevent an empyreuma. Distil off one gallon.

This water is a sufficiently grateful one. The leaves should be taken before the plant has run into flower; for after this time, they are much weaker and less agreeable. Some have observed, that the upper leaves and tops, before the flowers appear, yield a more elegant water, and a remarkably finer essential oil, than the lower ones; and that the oil obtained from the one swims on water, whilst that of the other sinks. No part of the herb, however, is equal in flavour to the seeds.

554. *Balm water.*

This is prepared by distilling the green leaves of balm, as in the foregoing process.

In a former edition of the Edinburgh pharmacopœia, this water was ordained to be cohobated, or redistilled from fresh quantities of the herb. This management seems to have been taken from Boerhaave, who has a very high opinion of the water thus prepared: he says, he has experienced in himself, extraordinary effects from it, taken on an empty stomach; that it has scarce its equal in hypochondriacs and hysterical cases, the chlorosis, and palpitation of the heart, as often as these diseases proceed from a disorder of the spirits rather than from any collection of morbid matter.

But whatever virtues are lodged in balm, they may be much more perfectly and advantageously extracted by cold infusion in aqueous or spirituous menstrua: in this process, the liquor suffers no injury from being returned on fresh parcels of the herb; a few repetitions will load it with the virtues of subject, and render it very rich. The impregnation here is almost unlimited; but in distilled waters it is far otherwise.

555. *Mint-water.* E.

Take of spearmint leaves, fresh, any quantity; water, three times as much. Distil as long as the liquor which comes over has any taste or smell of the mint.

556. *Simple spearmint-water.* L.

Take of spearmint-leaves, dried, a pound and a half; water, as much as is sufficient to prevent burning. Draw off by distillation one gallon.

These waters smell and taste very strong of the mint; and prove in many cases useful stomachics. Boerhaave commends them (cohobated) as a present and

incomparable remedy for strengthening a weak stomach, and curing vomiting proceeding from cold viscous phlegm; as also in henteries.

557. *Simple peppermint-water.* L. E.

Take of peppermint leaves, dry, a pound and a half; water, as much as will prevent an empyema. Draw off by distillation one gallon.

This is a very elegant and useful water; it has a warm, pungent taste, exactly resembling that of the peppermint itself. A spoonful or two, taken at a time, warm the stomach, and give great relief in cold, flatulent colics. Some have substituted a plain infusion of the dried leaves of the plant, which is not greatly different in virtue from the distilled water.

558. *Water of Jamaica pepper.* L.

Take of Jamaica pepper, half a pound; water, as much will prevent burning. Distil off one gallon.

This distilled water is a very elegant one, and has of late come pretty much into use: the hospitals employ it as a succedaneum to the more costly spice-waters. It is, however, inferior in gratefulness to the spirituous water of the same spice hereafter directed, (591.).

559. a. *Simple pennyroyal-water.* L.

Take of pennyroyal leaves, dry, a pound and a half; water, as much as will prevent burning. Draw off by distillation one gallon.

559. b. *Water of pennyroyal.* E.

Take of pennyroyal leaves, fresh, a pound and a half; water, as much as will prevent burning. Distil off a gallon.

This water possesses, in a considerable degree, the smell, taste, and virtues of the pennyroyal. It is frequently taken in hysteric cases, and not without good effects.

560. *Damask-rose water.*

Take of damask roses, fresh gathered, six pounds; water, as much as will keep them from burning. Distill off a gallon of the water. L.

Take of roses, six pounds; water, a sufficient quantity. Distil off one gallon. E.

This water is principally valued on account of its fine flavour, which approaches to that generally admired in the rose itself. The purgative virtue of the roses remains entire in the liquor left in the still, which has therefore been generally employed for making the solutive honey and syrup, instead of a decoction or infusion of fresh roses prepared on purpose: and this piece of frugality the college have now admitted.

561. *Rue-water.*

This is to be distilled from the fresh leaves of rue, and cohobated on fresh parcels of them, after the same manner as the balm-water, (554.)

Rue gives over in this process the whole of its smell, and great part of its pungency. The distilled water stands recommended in epileptic cases, the hysteric passion, for promoting perspiration and other natural secretions.

562. *Savin-water.*

Savin leaves, fresh, any quantity; water, three times

as much. Distil as long as the liquor runs well-flavoured of the plant.

This water is by some held in considerable esteem for the same purpose as the distilled oil of savin. Boerhaave relates, that he found it (when prepared by cohobation) to give an almost incredible motion to the whole nervous system; and that, when properly used, it proves eminently serviceable for promoting the menses, and the hæmorrhoidal flux.

§ 3. *SPIRITUOUS* DISTILLED WATERS and SPIRITS.

563. THE flavour and virtues of the distilled waters are owing, as observed in the preceding section, to their being impregnated with a portion of the essential oil of the subject from which they are drawn. Spirit of wine, considered as a vehicle for these oils, has this advantage above water, that it is their proper menstruum, and keeps all the oil, that rises from it, perfectly dissolved into an uniform limpid liquor.

Nevertheless, many substances, which, on being distilled with water, impart to it their virtues in great perfection; if treated in the same manner with spirit of wine, scarce give over to it any smell or taste. This difference proceeds from hence; that spirit is not susceptible of so great a degree of heat as water. Liquids in general, when made to boil, have received as great a heat as they are capable of sustaining: now, if the extent of the heat between freezing and boiling water, as measured by thermometers, be taken for a standard, spirit of wine will be found to boil with less than four-fifths of that heat, or above one-fifth less than the heat of boiling water. It is obvious therefore, that substances may be volatile enough to rise with the heat of boiling water, but not with that of boiling spirit.

Thus if cinnamon, for instance, be committed to distillation with a mixture of spirit of wine and water, or with a pure proof-spirit, which is no other than a mixture of about equal parts of the two; the spirit will arise first, clear, colourless, and transparent, and almost without any taste of the spice; but as soon as the more ponderous watery fluid begins to arise, the oil comes freely over with it, so as to render the liquor highly odorous, sapid, and of a milky hue.

The proof-spirits usually met with in the shops are accompanied with a degree of ill flavour; which, though concealed by means of certain additions, plainly discovers itself in distillation. This nauseous relish does not begin to arise till after the purer spirituous part has come over; which is the very time that the virtues of the ingredients begin also most plentifully to distil: and hence the liquor receives an ungrateful taint. To this cause principally is owing the general complaint, that the cordials of the apothecary are less agreeable than those of the same kind prepared by the distiller; the latter being extremely curious in rectifying or purifying the spirits (when designed for what he calls *fine goods*) from all ill flavour.

564. *Rectified spirit of wine,*

In the former edition of the Edinburgh pharmacopœia, was thus ordered:

Take any quantity of French brandy, and with a very gentle

gentle heat distil it to one half.

This rectified spirit, being digested for two days with one-fourth its quantity of dry salt of tartar in powder, and then distilled in a glass cucurbit, with a very gentle heat, becomes alcohol.

Spirits distilled from malt liquors, or other fermented substances, after being rectified in the above method, require further purification; namely, repeated distillation from an equal quantity of spring water.

565. French brandy is rather too dear an article in this country, for distillation; nor is the spirit obtained from it any ways preferable to one procurable from cheaper liquors. The coarser inflammable spirits may be rendered perfectly pure and fit for the nicest purposes, by the following method.

If the spirit is exceedingly foul, mix it with about an equal quantity of water, and distil with a slow fire; discontinuing the operation as soon as the liquor begins to run milky, and discovers, by its nauseous taste, that the impure and phlegmatic part is arising. By this treatment, the spirit leaves a considerable portion of its foul oily matter behind it in the water, which now appears milky and turbid, and proves highly disagreeable in taste. If the spirit was not very foul at first, this ablation is not necessary; if extremely so, it will be needful to repeat it once, twice, or oftener.

566. As vinous spirits arise with a less degree of fire than watery liquors, we are hence directed to employ, in the distillation of them, a heat less than that in which water boils: and if due regard be had to this circumstance, very weak spirits may, by one or two wary distillations, be tolerably well freed from their aqueous phlegm; especially if the distilling vessels are of such a height, that the spirit, by the heat of a water-bath, may but just pass over them: in such case, the phlegmatic vapours, which arise for a little way along with the spirit, will condense and fall back again before they can come to the head. Very pompous instruments have been contrived for this purpose, and carried in a spiral or serpentine form to an extraordinary height. The spirit, ascending through these, was to leave all the watery parts it contained, in its passage, and come over perfectly pure and free from phlegm. But these instruments are built upon erroneous principles, their extravagant height defeating the end it was designed to answer: if the liquor is made to boil, a considerable quantity of mere phlegm will come over along with the spirit; and if the heat is not raised to this pitch, neither phlegm nor spirit will distil. The most convenient instrument is the common still, betwixt the body of which, and its head, an adaptor or copper tube may be fixed.

567. The spirit being washed, as above directed, from its foul oil, and freed from the greatest part of the phlegm by gentle distillation in a water-bath, add to every gallon of it a pound or two of pure, dry, fixed alkaline salt. Upon digesting these together for a little time, the alkali, from its known property of attracting water and oils, will imbibe the remaining phlegm, and such part of the disagreeable unctuous matter as may still be left in the spirit, and sink with them to the bottom of the vessel. If the spirit be now again gently drawn over, it will arise entirely free

from its phlegm and nauseous flavour; but some particles of the alkaline salt are apt to be carried up with it, and give what the workmen call an *urinous relish*: This may be prevented, by adding, previous to the last distillation, a small proportion of calcined vitriol, alum, or sal catharticus amarus; the acid of these salts will unite with and neutralize the alkali, and effectually prevent it from arising; while no more of the acid of the salts is extricated than what the alkali absorbs.

The spirit obtained by this means is extremely pure, limpid, perfectly flavourless, and fit for the finest purposes. It may be reduced to the strength commonly understood by proof, by mixing 20 ounces of it (by weight) with 17 ounces of water. The distilled cordials made with these spirits, prove much more elegant and agreeable, than when the common rectified or proof spirits of the shops are made use of.

If the rectified spirit be distilled afresh from dry alkaline salt with a quick fire, it brings over a considerable quantity of the salt; and in this state is supposed to be a more powerful menstrum for certain substances than the pure spirit. This alkalinized spirit is called *tartarized spirit of wine*.

568. The general virtues of vinous spirits have been already mentioned; (see MATERIA MEDICA, the Table.) The spirits impregnated with the volatile oils of vegetables, to be treated of in this section, have joined to those the aromatic, cordial, or other virtues which reside in the oils.

#### Art 1. Distilled Spirits.

569. *Compound balm-water, commonly called Eau de carmes.*

Take of balm in flower, fresh gathered and cleared from the stalks, two pounds; lemon peel, fresh, as soon as pared from the fruit, four ounces; coriander seeds, eight ounces; nutmegs, cloves, cinnamon, each, bruised, two ounces; angelica roots, dried and bruised, one ounce; spirit of wine, highly rectified, ten pints. Steep the several ingredients in the spirit four or five days; and then draw off, in the heat of a water-bath, 10 pints. Rectify the distilled liquor by a second distillation in a water-bath, drawing off only about eight pints and three quarters.

This process is taken from the *Eléments de pharmacie* of M. Baumé, who observes, that all the aromatic spirits ought to be prepared in the same manner. When the common spirits of this kind are rubbed on the hands, &c. they leave, after the more volatile parts have exhaled, a disagreeable empyreumatic smell; and when diluted with water, and taken medicinally, they leave in like manner a nauseous flavour in the mouth. To remedy these imperfections, he made many experiments, which showed, that in order to obtain these liquors of the desirable qualities, the spirit must not only be perfectly pure at first, but that the liquor ought also to be rectified after it has been distilled from the subjects. In this rectification only the more volatile, subtle, aromatic parts of the ingredients arise; there remains behind a white liquor, acrid, bitter, loaded only with the grosser oil, and deprived of all the specific flavour of the subjects. Indeed the very imperfection complained of naturally points out this second distillation for the remedy, as it shows the spi-  
rit:

Prepara-  
tions.

rit to contain a grateful and ungrateful matter; the first of which exhales, while the other is left behind.

Aromatic spirituous waters have in general less smell, when newly distilled, than after they have been kept about six months. M. Baumé suspects, that the preparations of this kind which have been most in vogue were such as had been thus improved by keeping; and found, that the good effects of age might be produced in a short time by means of cold. He plunges quart-bottles of the liquor into a mixture of pounded ice and sea-salt: the spirit, after having suffered for six or eight hours the cold hence resulting, proves as grateful as that which has been kept for several years. Simple waters also, after being frozen, prove far more agreeable than they were before; tho' they are always less so than those which have been drawn with spirit, and exposed to a like degree of cold. This melioration of distilled waters by froit was taken notice of by Geoffroy, *Hist. Acad.* 1713.

#### 570. Spirit of rosemary. L.

Take of rosemary-tops, fresh gathered, a pound and a half; proof spirit, one gallon. Distil in the heat of a water-bath, till five pints are come over.

#### 571. Hungary-water.

Take of rosemary flowers, just gathered, two pounds; rectified spirit of wine, one gallon. Put them together, and immediately distil in a water-bath. It is generally brought to us from abroad.

This spirit is very fragrant, inasmuch as to be in common use as a perfume: that brought from abroad is superior in fragrance to such as is generally made among us. In order to prepare it in perfection, the vinous spirit should be extremely pure, the rosemary-tops gathered when the flowers are full blown upon them, and committed immediately to distillation, particular care being taken not to bruise or press them. The best method of managing the distillation is that formerly recommended for the distillation of the more volatile essential oils and simple waters, viz. first to place the spirit in the still, and then set in above the liquor, either an iron hoop, with a hair-cloth stretched over it, upon which the flowers are to be lightly spread, or rather a basket, supported on three pins, reaching down to the bottom. A gentle heat being applied, just sufficient to raise the spirit, its vapour, lightly percolating through the flowers, will imbibe their finer parts, without making that disagreeable alteration which liquors applied to such tender subjects in their grosser form generally do. Probably the superiority of the French Hungary water to that prepared among us, is owing to some skilful management of this kind, or that recommended for the foregoing preparation, and employing a perfectly pure spirit.

#### 572. Simple spirit of lavender. L.

Take of lavender-flowers, fresh gathered, a pound and a half; proof spirit, one gallon. Draw off, by the heat of a water-bath, five pints.

Take of fresh lavender-flowers, two pounds; rectified spirit of wine, one gallon. Distil off a gallon in a water-bath. E.

The same cautions are to be observed here as in the distillation of the foregoing spirit. Both of them,

Prepara-  
tions.

when made in perfection, are very grateful and fragrant: they are frequently rubbed on the temples, &c. under the notion of refreshing and comforting the nerves; and likewise taken internally, to the quantity of a tea-spoonful, as warm cordials.

#### 573. Compound spirit of lavender. L. E.

Take of simple spirit of lavender, three pints; spirit of rosemary, one pint; cinnamon, one ounce; cloves, nutmegs, each half an ounce; red saunders, three drams. Digest them together for seven days, and then strain out the spirit for use.

The red saunders is of no farther use [in the composition than as a colouring ingredient. If a yellow spirit was liked, the yellow saunders would be an excellent article, as it not only communicates a fine colour, but likewise a considerable share of medicinal virtue. A spirit distilled from the flowers of lavender and sage, in due proportion, and digested in the cold for a little time with some cinnamon, nutmegs, and yellow saunders, proves a very elegant and grateful one.

This medicine has long been held in great esteem, under the name of *palsy-drops*, in all kinds of languors, weakness of the nerves, and decays of age. It may be conveniently taken upon sugar, from 10 to 80 or 100 drops.

#### 574. An odoriferous spirit, called sweet honey-water.

Take of coriander seeds, honey, each one pound; cloves, an ounce and a half; nutmegs, benzoin, storax, each an ounce; vanilloes, in number four; yellow rind of three lemons; French brandy, one gallon. Digest these ingredients together for forty-eight hours; and then distil off the spirit in *balneo marie*. To one gallon of this spirit add orange-flower water, rose-water, of each one pound and a half; ambergris, musk, of each five grains. First grind the musk and ambergris with some of the water, and afterwards put all together in a large matras; shake them well, and let them circulate for three days and nights in a gentle heat; then suffer them to cool, filter the liquor, and keep it close stopped up for use.

#### 575. Another.

Take of coriander seeds, one pound; lemon-peel fresh, nutmegs, each four ounces; ambergris, musk, each five grains; clean mclasses spirit, two gallons. Bruise the nutmegs and coriander seeds, and put them, with the lemon-peel and the spirit, into a small still placed in *balneo marie*: tie a thin cloth over the mouth, and sprinkle thereon the ambergris and musk reduced into fine powder: lute on the head; let the whole stand in digestion for twelve hours, and then distil as much as a boiling heat of the bath can force over. To this add, of rose-water, one pint; orange-flower water, half a pint.

These compositions are designed rather as perfumes than as medicines; though for such as can bear their fragrance, they might be used to advantage in this last intention. The musk and ambergris do not communicate so much of their smell as might be expected; and serve chiefly to heighten the flavour of the other ingredients; which these perfumes excellently do, when

when employed in very small proportion, to all the odoriferous simples, without imparting any thing perceptible of their own. Both the foregoing spirits are very agreeable; a few drops of either give a fine flavour to a large quantity of other liquor. Mr Willon, from whom the first is taken, (*Pract. Chem.* p. 354.), tells us, that he often made it for king James II. and that it gives one of the most pleasant scents that can be smelt to. The other is formed on the same plan, by omitting such articles as appeared superfluous in the first.

#### 576. *Spirit of scurvy-grass.*

Take of fresh scurvy-grass, bruised, 10 pounds; rectified spirit of wine, five pints. Steep the herb in the spirit for 12 hours; then with the heat of a water-bath distil off five pints.

This spirit is very strong of the scurvy-grass; and may be given, in those cases where the use of this herb is proper, from 20 to 100 drops. The virtues of scurvy-grass reside in a very subtle volatile oil, which arises in distillation both with water and pure spirit; and, if the liquors are exposed to the air, soon exhales from both. The spirit, newly distilled, is extremely pungent; but if long kept, even in close vessels, becomes remarkably less so.

#### 577. *Golden or purging spirit of scurvy-grass.*

Take of spirit of scurvy-grass, one pound; gamboge, one ounce. Dissolve the gamboge in the spirit; and if any sediment falls to the bottom, carefully decant the tinged liquor from it. This spirit is otherwise made with scammony, or resin of jalep, instead of gamboge.

This has been in great esteem among the common people, and strongly recommended by the venders, in all kinds of scorbutic disorders. It is nevertheless a very indifferent medicine, and little deserves the pompous title given it. It may be taken from 20 to 60 drops, either upon sugar or mixed with syrup.

#### Art. 2. *Distilled Spirituous Waters.*

578. By *distilled Spirits*, are understood such as are drawn with a spirit that has been previously rectified, or which is reduced nearly to that strength in the operation: by *Spirituous Waters*, those in which the spirit is only of the proof strength, or contains an admixture of about an equal measure of water. These last have been usually called *compound waters*, even when distilled from one ingredient only; as those, on the other hand, which are drawn by common water, tho' from a number of ingredients, are named *simple*; the title *simple*, here, relating not to simplicity in respect of composition, but to the vehicle being plain water. The Edinburgh pharmacopœia denominates those waters *simple* which are drawn from a single ingredient, whether the vehicle be common water or spirituous water, and all those *compounds* which are distilled from more than one.

#### 579. *General rules for the distillation of Spirituous Waters.*

I. The plants and their parts ought to be moderately and newly dried, except such as are ordered fresh gathered.

II. After the ingredients have been steeped in the spirit for the time prescribed, add as much water as will be sufficient to prevent an empyreuma, or rather more.

III. The liquor which comes over first in the distillation, is by some kept by itself, under the title of *spirit*; and the other runnings, which prove milky, fined down by art. But it is better to mix all the runnings together without fining them, that the waters may possess the virtues of the plant entire; which is a circumstance to be more regarded than their fineness or lightness.

IV. In the distillation of these waters, the genuine brandy obtained from wine is directed. Where this is not to be had, take, instead of that proof spirit, half its quantity of a well-rectified spirit prepared from any other fermented liquors: in this steep the ingredients, and then add spring-water enough both to make up the quantity ordered to be drawn off, and to prevent burning.

580. By this method more elegant waters may be obtained than when any of the common proof-spirits, even that of wine itself, are made use of. All vinous spirits receive some flavour from the matter from which they are extracted; and this flavour, which adheres chiefly to the phlegm or watery part, they cannot be divested of without separating the phlegm, and reducing them to a rectified state.

#### 581. *Spirituous alexeterial water.* L.

Take of spearmint leaves, fresh, half a pound; angelica leaves, fresh, sea-wormwood tops, fresh, each four ounces; proof-spirit, one gallon; water, as much as will prevent burning. Distil off one gallon.

This is a tolerably pleasant water; it is looked upon as an alexipharmac and stomachic, and in these intentions is not unfrequently made use of in juleps, &c.

#### 582. *Spirituous alexeterial water with vinegar.* L.

Take of spearmint leaves, angelica leaves, each half a pound; sea-wormwood tops, four ounces; proof-spirit, one gallon; water, as much as is sufficient to prevent burning; vinegar, one pint. Distil the fresh herbs with the spirit and water, drawing off one gallon; to which add the vinegar.

Angelica, after trial of sundry other materials, has been found the most effectually to remove the disagreeable flavour which the vinegar would otherwise communicate, and therefore this plant is ordered in a larger proportion here than in the other alexeterial waters. Perhaps it would be more eligible to add the vinegar occasionally; for when mixed with the liquor at first, it is apt to throw down, upon keeping, some of the more valuable parts which the water received from the herbs.

#### 583. *Compound aniseed water.* L.

Take of aniseeds, angelica seeds, each half a pound; proof-spirit, one gallon; water, as much as is sufficient to prevent burning. Draw off by distillation one gallon.

This is a very elegant aniseed water, the angelica seeds greatly improving the flavour of the anise: it is apt to turn out milky, if drawn so low as here ordered.

584. *Spirituus orange-peel water.* L.

Take of the outer rind of Seville-orange-peel, dried, half a pound; proof-spirit, one gallon; water, as much as is sufficient to prevent an empyreuma. Distill off one gallon.

This is considerably stronger of the orange-peel than the simple water. It is used as a cordial, stomachic, and carminative.

585. *Cardamom-feed water.* L.

Take of lesser cardamom seeds, freed from the husks, four ounces; proof-spirit, one gallon; water, as much as is sufficient to prevent burning. Distill off one gallon.

This water is a grateful cordial and carminative, the cardamom seeds giving over in this process the whole of their flavour. It is not perhaps very necessary to be at the trouble of separating the husks, for these communicate nothing disagreeable; the only difference is, that if employed unhusked, a proportionably larger quantity of them must be taken.

586. *Caraway-water.* L. E.

Take of caraway seeds, half a pound; proof-spirit, one gallon; water, as much as will prevent burning. Distill off one gallon.

This is a cordial in common use; it contains the flavour of the caraway seeds in perfection.

587. *Spirituus cinnamon-water.* L.

Take of cinnamon, a pound; proof-spirit, a gallon; water, so much as will prevent burning. Draw off by distillation one gallon.

588. *Cinnamon-water with wine.* E.

Take of cinnamon, half a pound; proof-spirit, one gallon. Distill off one gallon.

This is a very agreeable and useful cordial-water, but not so strong of the cinnamon as might be expected; for very little of the virtues of the spice arise till after the pure spirituous part has distilled.

In the *pharmacopœia reformata*, it is proposed to make this water, by mixing the simple cinnamon water (553, a.) with somewhat less than an equal quantity of rectified spirit: on shaking them together, the liquor loses its milky hue, soon becomes clear, and more elegant than the water distilled as above; it is equally strong of the cinnamon, and free from the nauseous taint which the common proof-spirits are impregnated with.

589. *Compound juniper-water.* L. E.

Take of juniper-berries, one pound; sweet-fennel seeds, caraway seeds, each an ounce and a half; proof-spirit, one gallon; water, as much as is sufficient to prevent burning. Distill off one gallon.

This water, mixed with about an equal quantity of the rob of juniper-berries, proves an useful medicine in catarrhs, debility of the stomach and intestines, and difficulty of urine. The water by itself is a good cordial and carminative: the service which this and other spirituous waters do in these intentions, is too commonly known; though the ill consequences that follow their constant use, are too little regarded.

590. a. *Spirituus pepper-mint water.* L.

Take of peppermint-leaves, dry, a pound and a half; proof-spirit, a gallon; water, as much as is sufficient to prevent an empyreuma. Draw off by distillation one gallon.

This water is made use of in flatulent colics and other like disorders; in which it oftentimes gives immediate relief. It smells and tastes strongly of the pepper-mint.

590. b. *Spirituus mint-water.* L.

Take of peppermint leaves, dry, a pound and a half; proof-spirit, a gallon; water, as much as will prevent burning. Distill off one gallon.

This water, if the spirit be good, turns out a very elegant one, and preferable, in weakness of the stomach, retching to vomit, and the like, to many more elaborate preparations. Where the disorder is not accompanied with heat or inflammation, half an ounce of this water may be given diluted with some agreeable aqueous liquor.

591. *Spirituus Jamaica-pepper water.*

Take of Jamaica pepper, half a pound; proof-spirit, three gallons; water, a sufficient quantity to prevent an empyreuma. Draw off by distillation three gallons.

This water is far more agreeable than a simple water drawn from the same spice; and has long had a place among the cordials both of the distiller and apothecary; though it has not yet been received into any public pharmacopœia.

592. *Nutmeg water.* L.

Take of nutmegs, two ounces; proof-spirit, a gallon; water, as much as will prevent burning. Draw off by distillation one gallon.

This water (with the addition only of some hawthorn flowers, an article of very little significance) was formerly celebrated in nephritic disorders, under the name of *aqua nephritica*. At present, it is regarded only as an agreeable spirituous liquor, lightly impregnated with the nutmeg flavour.

593. *Spirituus pennyroyal water.* L.

Take of pennyroyal leaves, dry, a pound and a half; proof-spirit, a gallon; water, as much as will prevent burning. Distill off one gallon.

This water has a good share of the flavour of the pennyroyal, and is pretty much in use as a carminative and antihysteric.

594. *Compound horseradish water.*

Take of garden scurvygrass leaves, fresh, four pounds; horseradish root fresh, orange-peel fresh, each two pounds; nutmegs, nine ounces; proof-spirit, two gallons; water, a sufficient quantity to prevent burning. Draw off by distillation two gallons. L.  
Take of horseradish root, three pounds; rectified spirit of wine, four pints. Distill off four pints in a water-bath, and to the distilled liquor add eight pints of simple Jamaica-pepper water. E.

Both these waters are very elegant ones, and as well adapted

adapted for the purposes of an antiscorbutic, as any thing that can well be contrived in this form.

Mustard-seed, though not hitherto employed in these kinds of compositions, should seem to be an excellent ingredient ; it gives over the whole of its pungency, and is likewise less perishable than most of the other substances of this class : this seed wants no addition, unless some aromatic material to furnish an agreeable flavour.

#### SECT. VI. Concentration of the medicinal parts of Juices and Infusions by Evaporation.

595. WHEN vegetable juices, or watery or spirituous decoctions or infusions, are exposed to a continued heat, the fluid, gradually evaporating, carries off with it such volatile matters as it was impregnated with, and leaves the more fixed united together into one mass. As the object of the preceding section was the collection of the volatile principle which exhales along with the fluid, that of the present is this re-union and concentration of the fixed matter. The mass which remains from the evaporation of the expressed juice of a plant, is called an *inspissated juice*; from watery decoctions or infusions, an *extract*; from spirituous tinctures, a *resin*, or *essential extract*. The term *extract* is frequently used also as a general appellation of all the three kinds. Inspissated juices and watery decoctions, particularly the former, when evaporated no further than to the consistence of oil or honey, are called *rob* or *sapa*; and spirituous tinctures, reduced to a like consistence, are called *balsam*.

##### § I. INSPISSATED JUICES.

596. WHAT relates to the expression of juices, has already been delivered in Sect. ii. with the most effectual means of preserving them in their liquid state, and a general account of what substances do or do not give out their virtues with their juices. In the inspissation of juices, there is further to be considered the volatility or fixity of their medicinal parts: if a plant loses its virtue, or part of its virtue, in being dried, it is obvious that the juice must lose as much in being inspissated to dryness, how gentle soever the heat be with which the inspissation is performed. It is likewise to be observed, that the medicinal parts of some juices are kept in a state of perfect solution by the watery fluid, so as to be completely retained by it after the liquor has been made fine by settling, straining, or other means; while the medicinal parts of others, not diffusible by watery menstrua, are only diffused through the liquor in the same manner as the feculences are, and separate along with these on standing.

##### 597. Rob of elder-berries.

Let the depurated juice of elder-berries be inspissated with a gentle heat. *L.*

This preparation, made with or without sugar, keeps well, and proves a medicine of considerable importance as an aperient, generally promoting the natural excretions by stool, urine, or sweat. The dose is from a dram or two to an ounce or more. A spoonful, diluted with water, is usefully taken in common colds at bed-time.

##### 598. Inspissated juice of sloes, or German acacia.

Let any quantity of the juice of unripe sloes be inspissated over a gentle fire.

This juice is inspissated nearly to dryness, care being taken to prevent its burning, as directed in the following §, for making extracts with water. It is a moderately strong astringent, similar to the Egyptian acacia, for which it has been commonly substituted in the shops. It is given in fluxes and other disorders where styptic medicines are indicated, from a scruple to a dram.

##### 599. Extract of plantane.

Let any quantity of the juice of plantane-leaves be depurated; either by suffering it to settle, and then decanting off the clear liquor; or by straining; or by clarification by whites of eggs. Afterwards evaporate the juice in a sand-heat, to the consistence of honey. After the same manner, extracts may be made from all acid, cooling, styptic, juicy plants.

This is a method of treating plants very little practised; but which promises, if duly prosecuted, to afford medicines of considerable power. There are many common and neglected herbs, as plantane, chickweed, chervil, &c. whose juices in their dilute state, as well as the herbs in substance, seem to be altogether insignificant, but which, when the juice is well depurated from the feculent matter, and concentrated by the evaporation of the fluid, yield extracts which discover to the taste no small activity. These extracts, like those prepared from the juices of most of the summer-fruits, if inspissated to dryness, grow moist again in the air.

##### 600. Extract of hemlock.

See n° 249.

This is the preparation of hemlock lately published at Vienna by Dr Storck; who recommends it as a high resolvent in many obtundate disorders, where the common remedies avail nothing. He observes, that small doses should always be begun with, as two grains, made into a pill, twice a-day; and that, by gradually increasing the dose, it may be given to two, three, or even four drams a-day, and continued in such quantities for several weeks: that it may be used with safety, in infancy, old age, and pregnancy: that it neither accelerates nor disturbs the circulation; neither heats nor cools; nor affects the animal-functions: that it increases the secretions, and renders the mouth moist; seldom purges; very rarely vomits; sometimes augments perspiration; often produces a copious discharge of viscid urine; but in many patients does not increase any of the sensible evacuations: that it removes obstructions and their consequences; relieves rheumatic pains, though of long continuance; dissolves scirrhus tumours, both internal and external; and cures dropsies and consumptions proceeding from scirrhusities; that it often dissolves cataracts, or stops their progress, and has sometimes removed the gutta serena: that it inveterate cutaneous eruptions, scald-heads, malignant ulcers, cancers, the malignant fluor albus and gonorrhœa of long standing, obtundate remains of the venereal disease, and caries of the bones, generally yield to it: that for the most part it is ne-

cessary to continue this medicine for a very considerable time, before the cure is effected, or much benefit perceived from it : that in some cases it failed of giving any relief, and that he met with some persons who could not bear its effects ; and that consequently there must be some latent difference in the habit, the diagnostic signs of which are at present unknown : that though it is by no means infallible, any more than other medicines in their respective intentions, yet the great number of deplorable cases that have been happily cured by it is sufficient to recommend it to further trials. The efficacy of this medicine is confirmed by many eminent practitioners abroad ; though the trials hitherto made of it in this country have not been attended with much success. Somewhat, perhaps, may depend upon the time of the plant's being gathered, and the manner of the preparation of the extract. Dr Storck himself takes notice of some mistakes committed in this respect : some have left the herb in a heap for several days, whence part of it withered, part rotted, and the juice became thick and mucilaginous : others have taken a very large quantity of the juice, and boiled it down in copper vessels with a great heat, by which means a strong fetor was diffused to a considerable distance, and the most efficacious parts dissipated : others, with officious care, have clarified the juice, and thus obtained a black tenacious extract, retaining but a small degree of the specific smell of the plant : the extract duly prepared, according to the prescription above referred to, is of a greenish brown colour, and a very disagreeable smell, like that of mice. But though there is reason to believe, that much of the extract used here had been ill prepared, we can by no means admit that its general inefficacy was owing to this cause ; for though there are few instances of its discovering any valuable medicinal powers, there are several of its having activity enough, even in small doses, to produce alarming symptoms.

#### 601. *Elaterium.*

Slit ripe wild cucumbers, and having very lightly pressed out the juice, pass it thro' a fine hair-sieve into a glazed earthen vessel. After standing for some hours, the thicker part will fall to the bottom ; from which the thinner is to be poured off, and what liquid matter is still left is to be separated by filtration. The remaining thick part is to be covered with a linen cloth, and exposed to the sun, or other gentle heat, till grown thoroughly dry. L.

Preparations of this kind have been commonly called *fecule*. The filtration above directed, for draining off such part of the watery fluid as cannot be separated by decantation, is not the common filtration through paper, for this does not succeed here : the grosser parts of the juice, falling to the bottom, form a viscid cake upon the paper, which the liquid cannot pass through. The separation is to be attempted in another manner, so as to drain the fluid from the top : this is effected by placing one end of some moistened strips of woollen cloth, skins of cotton, or the like, in the juice, and laying the other end over the edge of the vessel, so as to hang down lower than the surface of the liquor : by this management the separation succeeds in perfection.

*Elaterium* is a strong irritating cathartic, and often-

times operates also as an emetic. It is never to be ventured on but in indolent phlegmatic habits, as in dropsies, in which it is by some particularly recommended. Two or three grains are in general a sufficient dose.

#### § 2. EXTRACTS WITH WATER.

602. These extracts are prepared, by boiling the subject in water, and evaporating the strained decoction to a thick consistence.

This process affords us some of the more active parts of plants, free from the useless indissoluble earthy matter, which makes the largest share of their bulk. There is a great difference in vegetable substances, with regard to their fitness for this operation ; some yielding to it all their virtues, and others scarce any. Those parts in which the sweet, glutinous, emollient, cooling, bitter, astringent, virtues reside, are for the most part totally extracted by the boiling water, and remain almost entire upon evaporating it : whilst those which contain the peculiar odour, flavour, and aromatic quality, are either not extracted at all, or exhale along with the menstruum. Thus gentian root, which is almost simply bitter, yields an extract possessing, in a small volume, the whole taste and virtues of the root : wormwood, which has a degree of warmth and strong flavour joined to the bitter, loses the two first in the evaporation, and gives an extract not greatly different from the foregoing ; the aromatic quality of cinnamon, is dissipated by this treatment, its astringency remaining : whilst an extract made from the flowers of lavender and rosemary, discovers nothing either of the taste, smell, or virtues of the flowers.

#### *General rules for making extracts with water.*

I. It is indifferent, in regard to the medicine, whether the subject is used fresh or dry ; since nothing that can be preserved in this process, will be lost by drying. In regard to the facility of extraction, there is a very considerable difference ; vegetables in general giving out their virtues more readily, when moderately dried, than when fresh.

II. Very compact dry substances should be reduced into exceeding small parts, previous to the affusion of the menstruum.

III. The quantity of water ought to be no greater than is necessary for extracting the virtues of the subject. A difference herein will sometimes occasion a variation in the quality of the product : the larger the quantity of liquor, the longer fire will be requisite for evaporating it, and consequently the more of the volatile parts of the subject will be dissipated. A long-continued heat likewise makes a considerable alteration in the matter which is not volatile : sweet substances, by long boiling with water, become nauseous ; and the drastic purgatives lose their virulence, tho' without any remarkable separation of their parts.

IV. The decoctions are to be depurated by colature ; and afterwards suffered to stand for a day or two, when a considerable quantity of sediment is usually found at the bottom. If the liquor, poured off clear, be boiled down a little, and afterwards suffered to cool again, it will deposit a fresh sediment, from which it may be decanted before you proceed to finish the

Prepara-  
tions.

the evaporation. The decoctions of very refinous substances do not require this treatment, and are rather injured by it; the resin subfiding along with the inactive dregs.

V. The evaporation is most conveniently performed in broad shallow vessels: the larger the surface of the liquor, the sooner will the aqueous parts exhale: this effect may likewise be promoted by agitation.

VI. When the matter begins to grow thick, great care is necessary to prevent its burning. This accident, almost unavoidable if the quantity is large, and the fire applied as usual under the evaporating pan, may be effectually secured against, by carrying on the inspissation after the common manner, no farther than to the consistence of a syrup, when the matter is to be poured into shallow tin or earthen pans, and placed in an oven, with its door open, moderately heated; which acting uniformly on every part of the liquid, will soon reduce it to any degree of consistence required. This may likewise be done, and more securely, in *balneo marie*, by setting the evaporating vessel in boiling water; but the evaporation is here exceeding slow and tedious.

VII. Extracts are to be sprinkled with a little spirit of wine, to prevent their growing mouldy. *L.* They should be kept in bladders moistened with sweet oil. *E.*

#### 603. *Extract of wormwood.*

Boil dried wormwood leaves in water, supplying fresh water occasionally till the herb has given out all its virtues to the liquor. Strain the decoction through a woollen cloth, and evaporate it, in a sand-bath, to the consistence of honey.

This extract is almost simply bitter; the peculiar flavour of the wormwood being dissipated in the evaporation. The chemists usually prepare the extract of wormwood from the decoction which remains in the still after the distillation of the essential oil: and, provided the still has been perfectly clean, and the liquor not stood too long in it after the distillation, this piece of frugality is not to be disapproved of; since, whether we catch the exhaling vapour, or suffer it to be dissipated in the air, the remaining extract will be the same.

#### 604. *Extract of lesser centaury.*

This is directed to be prepared in the same manner as the preceding. It is the oldest extract we have any account of: its preparation is very accurately and circumstantially set down in a book usually ascribed to Galen, *De virtute centaureæ*. The author of that treatise recommends the extract as a medicine of excellent service in many cases; and looks upon centaury as a specific against the bite of a mad dog and other venomous animals. It is doubtless an useful bitter, possessing the general virtues of the substances of that class; but cannot well be supposed to have any others.

#### 605. *Extract of chamomile.*

This extract is prepared from the flowers of chamomile, in the same manner as those of the leaves of the two preceding plants. Nor is it greatly different from those extracts in quality; the specific flavour of

Prepara-  
tions.

the chamomile exhaling in the evaporation. The chemists commonly prepare it, like that of wormwood, from the decoction remaining after the distillation of the essential oil.

#### 606. *Extract of elecampane. L.*

Boil the roots of elecampane in water, press out and strain the decoction, and set it by to settle. Then pour off the clear liquor, and boil it down to a pilular consistence; taking care, towards the end, to prevent its burning to the vessel.

This extract retains a considerable share of the virtues of the root: its taste is somewhat warm, and not ungratefully bitterish. It is given, from a scruple to a dram, in a lax state of the fibres of the stomach, and in some disorders of the breast.

#### 607. *Extract of gentian. L. E.*

This extract is prepared from the roots of gentian, in the same manner as the foregoing extracts. It is of a reddish brown colour, and an intensely bitter taste, being one of the strongest of the vegetable bitters.

#### 608. *Extract of liquorice. L.*

Lightly boil fresh liquorice roots in water, press the decoction through a strainer; and after the fibres have subsided, evaporate it until it no longer sticks to the fingers; taking care, towards the end of the operation, to prevent an empyreuma.

It is convenient, before boiling the root, to cut it transversely into small pieces, that it may more readily give out its virtues by light coction: if the boiling is long continued, the rich sweet taste, for which this preparation is valued, will be greatly injured. For the same reason, the quantity of water ought to be no larger than is absolutely necessary to extract the virtues of the root: a quart, or at most three pints, will be fully sufficient for a pound of liquorice. It would be of considerable advantage to the preparation, and probably (when made in quantity) less expensive to the preparer, to use, instead of the decoction, juice of liquorice, pressed out betwixt iron rollers, after the manner practised abroad for obtaining the juice of the sugar-cane.

Large quantities of extract of liquorice have been usually brought to us from Spain and other foreign countries; but it is very rarely met with in the shops in perfection; the makers of this commodity, both at home and abroad, being either very slovenly in its preparation, or designedly mixing it with sand and other impurities. When made with due care, it is exceedingly sweet, not at all bitterish or nauseous, more agreeable in taste than the root itself, of a pleasant smell, a reddish brown colour, and, when drawn out into strings, of a bright golden colour; totally soluble in water, without depositing any fibres.

This preparation would be very convenient for many purposes in the shops, if kept in a somewhat softer consistence than that of an extract. The only inconvenience attending this soft form is, its being apt in a short time to grow mouldy: but this may be effectually prevented, by the addition of a small portion of spirit of wine.

Prepara-  
tions.Prepara-  
tions.609. *Extract of black hellebore.* L. E.

This extract is prepared from the roots of black hellebore, in the same manner as that of elecampane roots above described. It purges with considerably less violence than the hellebore in substance; and appears to be one of the best preparations of that root, when intended to act only as a cathartic. The dose is from 8 or 10 grains to 15 or more.

610. *Extract of logwood.* L.

Take of logwood, reduced to powder, one pound. Boil it in a gallon of water till half the liquor is consumed, repeating the coction with fresh water four times, or oftener: the several decoctions are to be mixed together, passed through a strainer, and evaporated to a due consistence.

This extract has an agreeable sweet taste, with some degree of astringency; and hence becomes serviceable in diarrhoeas, for blunting the acrimony of the juices, and moderately constringing the intestines and orifices of the smaller vessels: It may be given from a scruple to half a dram, and repeated five or six times a-day to advantage. During the use of this medicine, the stools are frequently tinged red by it; which has occasioned some to be alarmed, as if the colour proceeded from blood: the prescriber therefore ought to caution the patient against any surmise of this kind.

611. *Extract of Peruvian bark, soft and hard.* L.

Boil a pound of powdered bark in five or six quarts of water for an hour or two, and pour off the liquor; which whilst hot will be red and transparent, but on growing cold becomes yellow and turbid. The remaining bark is to be boiled again in the same quantity of water as before; and this process repeated till the liquor remains transparent when cold. All the decoctions, strained and mixed together, are to be evaporated over a very gentle fire to a due consistence, care being taken to prevent the matter from burning.

This extract is directed to be kept in the shops, both in a soft and a hard form; the first of a proper consistence for making into pills; the other fit for being reduced into powder.

612. *Extract of guaiacum wood, soft and hard.* L.

Boil a pound of shavings of guaiacum in a gallon of water till half the liquor is wasted, repeating the operation four times, or oftener, with the same quantities of fresh water. The several decoctions, passed through a strainer, are to be mixed and inspissated together; when the aqueous parts are almost entirely exhaled, a little rectified spirit of wine is to be added, that the whole may be reduced into a uniform and tenacious mass. This extract is to be prepared as the foregoing, in a soft and hard form.

Here the resinous parts of the wood, which were boiled out with the water, are apt to separate towards the end of the inspissation: Hence an addition of spirit becomes necessary to keep them united with the rest of the matter. The extract agrees in virtue with the wood. See GUAIACUM.

613. *Extract of rue.* L.

This is prepared from the leaves of rue, in the same manner as that of elecampane roots already described. It retains a considerable share of the warmth and pungency of the rue; for though the principal virtues of rue reside in an essential oil, yet the oil of this plant, as formerly observed under the head of those preparations, is not of a very volatile kind.

614. *Extract of savin.* L.

This extract is prepared from the leaves of savin in the same manner as the preceding. It does not retain so much as that extract does of the virtues of its subject, the oil of savin being more volatile than that of rue.

615. *Gum and resin of aloes.* L.

Boil four ounces of socotorine aloes in two pints of water till as much as possible of the aloes is dissolved. The solution suffered to rest for a night, will deposit the resin to the bottom of the vessel: after which, the remaining liquor, strained, if needful, is to be evaporated, that the gum may be left.

The gum of aloes is somewhat less purgative, and considerably less disagreeable, than the crude juice.

616. *The pills or extract of RADIUS.*

Take of black-hellebore roots, colocynth, socotorine aloes, each two ounces; scammony, one ounce; vitriolated tartar, two drams; distilled oil of cloves, one dram. Bruise the colocynth and hellebore, pour on them two quarts of water, and boil to the consumption of half the liquor: pass the decoction through a strainer, and evaporate it to the consistence of honey, adding the aloes and scammony reduced into fine powder: when the mass is taken from the fire, mix into it the vitriolated tartar and distilled oil.

This preparation is a medicine of great importance as a cathartic.

617. *Rob of juniper-berries.*

Let juniper-berries, thoroughly bruised, be boiled in a sufficient quantity of water, the liquor strained, and inspissated to the consistence of honey.

This preparation may be made also from the decoction that remains after the distillation of the essential oil of the berries. It has a sweet balsamic taste, accompanied with a greater or less bitterness, according as the seeds of the berry were more or less thoroughly bruised. This elegant preparation, though not received in our pharmacopœias, seems not unworthy of a place in the shops. Hoffman has a great opinion of it in debilities of the stomach and intestines, and in the difficulties of urine familiar to persons of an advanced age.

618. Besides the above extracts, there are ordered, in the present edition of the Edinburgh pharmacopœia, one from the heads of puppies; another from the seeds of hemlock scarce come to maturity; and a third from the leaves of *pulsatilla nigricans*. They are to be made in the same manner with the extract of gentian, n° 607.

## § 3. EXTRACTS WITH RECTIFIED SPIRITS.

619. RECTIFIED spirit of wine dissolves the essential oils and resins of vegetables, and does not readily carry off the oil in its exhalation, the heat sufficient to exhale pure spirit being much less than that in which water considerably evaporates, or most essential oils distil. Hence a resinous or spirituous extract of wormwood, contrary to that made with water, contains the warmth and flavour as well as bitterness of the herb; one made from cinnamon possesses its aromatic virtue, as well as its astringency; and one from lavender and rosemary flowers retains great part of their flavour and virtues; the volatile parts, which are carried off by water in its evaporation, being left behind by spirit.

The spirit employed for this purpose should be perfectly free from any ill flavour, which would be communicated in part to the preparation; and from any admixture of phlegm or water, which would not only vary its dissolving power, but, likewise evaporating towards the end of the inspissation, would promote the distillation of the volatile parts of the subject. Hence also the subject itself ought always to be dry: those substances which lose their virtue by drying, lose it equally on being submitted to this treatment with the purest spirit.

The inspissation should be performed from the beginning in the gentle heat of a water-bath. It is not needful to suffer the spirit to evaporate in the air: greatest part of it may be recovered by collecting the vapour in the common distilling vessels. If the distilled spirit is found to have brought over any flavour from the subject, it may be advantageously reserved for the same purposes again.

620. It is observable, that though *rectified spirit* is the proper menstruum of the pure volatile oils and of the grosser resinous matter of vegetables, and *water* of the mucilaginous and saline; yet these principles are, in almost all plants, so intimately combined together, that whichever of these liquors is applied at first, it will take up a portion of what is directly soluble only in the other. Hence sundry vegetables, extremely resinous, and whose virtues consist chiefly in their resin, afford nevertheless very useful extracts with water, though not equal to those which may be obtained by a prudent application of spirit. Hence, also, the extracts made from most vegetables by pure spirit are not mere resins; a part of the gummy matter, if the subject contained any such, being taken up along with the resin, an admixture of great advantage to it in a medicinal view. The spirituous extracts of several vegetable substances, as mint-leaves, rhubarb, saffron, dissolve in water as well as in spirit.

621. Pure resins are prepared by mixing with spirituous tinctures of very resinous vegetables a quantity of water. The resin, incapable of remaining dissolved in the watery liquor, separates and falls to the bottom; leaving in the menstruum such other principles of the plant as the spirit might have extracted at first along with it.

622. *Refin of jalap.*

Take any quantity of jalap-root very well bruised; pour upon it so much rectified spirit of wine as will cover it to the height of four fingers, and digest them together in a sand-heat, that the spirit may

extract the virtue of the root. Filter the tincture through paper, put it into a retort, and distil off one half of the spirit. Add to the remainder a proper quantity of water, and the resin will precipitate to the bottom: divide it into little cakes, and dry it with a very gentle heat.

This preparation is a pure resin; such gummy parts as the spirit might have taken up remaining suspended in the liquor. Its indissolubility in any aqueous fluid, and its tenacious quality, by which it adheres to the coats of the intestines, and occasions great irritation and gripes, forbid its being ever given by itself. It is fitted for use, by thoroughly triturating it with testaceous powders, by grinding it with almonds or powdered gum, and making the compound into an emulsion with water; or by dissolving it in spirit of wine, and mixing the solution with a proper quantity of syrup or of mucilage. Six or eight grains, managed in either of these ways, prove powerfully cathartic, and generally without griping or greatly disordering the body.

623. *Refin of Peruvian bark.*

This resin is made in the same manner as the foregoing, and proves an elegant preparation of the bark, much stronger in taste than the watery extract, (611.) It is nearly equivalent to about ten times its quantity of the bark in substance. There does not, however, appear to be any advantage in separating the pure resin by the addition of water, either in this or in the other articles. In regard to the bark particularly, it is more advisable to endeavour to unite into one compound all that can be extracted from it by watery and spirituous menstrua: and accordingly the Edinburgh college has received a preparation of this kind, n<sup>o</sup> 627.

624. *Extract of saffron.*

Digest saffron in fresh quantities of pure spirit of wine, as long as the spirit extracts any colour from it. Mix the several tinctures together, and distil off the spirit in a tall glass vessel by the heat of a water-bath, till the residuum appears of the consistence of oil or balsam. *Pharm. Bran.*

This is an elegant and high cordial. Boerhaave says it possesses such exhilarating virtues, that if used a little too freely, it occasions an almost perpetual and indecent laughing. He observes, that it tinges the urine of a red colour, and that it mingles with water, spirit, and oils, but is most conveniently taken in a glass of Canary or other rich wine. A few drops are sufficient for a dose.

## § 4. EXTRACTS WITH SPIRIT AND WATER.

625. THERE are sundry vegetables, particularly those of a resinous nature, which are treated, to better advantage, with a mixture of water and spirit, than with either of them singly. The virtues of resinous woods, barks, and roots, may indeed be in great part extracted by long boiling in fresh portions of water; but at the same time they suffer a considerable injury from the continued heat necessary for the extraction, and for the subsequent evaporation of so large a quantity of the fluid. Rectified spirit of wine is not liable to this inconvenience; but the extracts obtained by it, from the substances here intended, being almost purely

purely resinous, are less adapted to general use than those in which the resin is divided by an admixture of the gummy matter, of which water is the direct menstruum.

There are two ways of obtaining these compound or gummy resinous extracts: one, by using proof-spirit, that is, a mixture of about equal parts of spirit and water, for the menstruum; the other, by digesting the subject first in pure spirit, and then in water, and afterwards uniting into one mass the parts which the two menstrua have separately extracted. In some cases, where a sufficiency of gummy matter is wanting in the subject, it may be artificially supplied, by inspissating the spirituous tincture to the consistence of a balsam, then thoroughly mixing with it a thick solution of any simple gum, as mucilage of gum arabic, and exsiccating the compound with a gentle heat. By this method are obtained elegant gummy resins, extemporaneously miscible with water into milky liquors.

#### 626. *Extract of jalap.*

Upon powdered jalap pour some rectified spirit of wine, and with a gentle heat extract a tincture; boil the remaining jalap in fresh parcels of water. Strain the first tincture, and draw off the spirit, till what remains begins to grow thick; boil the strained decoction also to a like thickness; then mix both the inspissated matters together, and with a gentle fire reduce the whole to a pilular consistence. L.

Take of jalap root, one pound; rectified spirit of wine, four pints; water, two pints. Digest them together for eight days, and strain. Distil off the strained liquor in a retort to one half. Evaporate the remainder in a water-bath, keeping the matter constantly stirring towards the end, so as to make it into a smooth extract. E.

This extract is an useful purgative, preferable to the crude root, as being of more uniform strength, and as the dose, by the rejection of the woody parts, is rendered smaller; the mean dose is twelve grains. If the spirituous tincture was inspissated by itself, it would afford a resinous mass, which, unless thoroughly divided by proper admixtures, occasions violent griping, and yet does not prove sufficiently cathartic; the watery decoctions yield an extract, which operates exceeding weakly: both joined together, as in this preparation, compose an effectual and safe purge. This method of making extracts might be advantageously applied to sundry other resinous substances, as the dry woods, roots, barks, &c. A small quantity of spirit takes up the resin, and much less water than would otherwise be necessary extracts all the other soluble parts.

#### 627. *Extract of Peruvian bark.* E.

The college of Edinburgh has directed the extract of bark to be made with water and spirit in the same manner as the preceding. In the bark we may distinguish two kinds of tastes, an astringent and a bitter one; the former of which seems to reside in the resinous matter, and the latter chiefly in the gummy. The watery extract (n° 611) is moderately strong in point of bitterness, but of the astringency it has only a small

degree. The pure resin, on the other hand, (n° 623.) is strong in astringency, and weak in the bitterness. Both qualities are united in the present extract; which appears to be the best preparation of this kind that can be obtained from this valuable drug.

#### 728. *Extract of logwood.* E.

This extract is directed in the Edinburgh pharmacopœia to be prepared as the foregoing; and the same treatment is judiciously ordered for all the resinous drugs in general.

#### 629. *Cathartic extract.*

Take of colocutorie aloes, an ounce and a half; colocynth, six drams; scammony, lesser cardamoms husked, each half an ounce; proof-spirit, one pint. Having cut the colocynth small, and bruised the seeds, pour on them the vinous spirit, and digest with a gentle heat for four days. Press out the tincture, and dissolve therein the aloes and scammony, first separately reduced to powder; then draw off the spirit, and inspissate the remaining mass to a pilular consistence.

This composition answers very effectually the intention expressed in its title, so as to be relied on in cases where the patient's life depends on its taking place; the dose is fifteen grains to half a dram.

#### 530. *Cordial confectio.* L.

Take of rosemary tops fresh, juniper-berries, each one pound; lesser cardamom seeds husked, zedoary, saffron, each half a pound. Extract a tincture from these ingredients with about a gallon and a half of proof-spirit: let the tincture be strained off, and reduced by a gentle heat to the weight of about two pounds and a half; then add the following ingredients very finely pulverized, and make the whole into an electuary: Compound powder of crabs-claws, sixteen ounces; cinnamon, nutmegs, each two ounces; cloves, one ounce; double-refined sugar, two pounds.

This confectio is composed of the more unexceptionable ingredients of a composition formerly held in great esteem, and which was called, from its author, *Confectio Rakeighiana*.

The confectio is a sufficiently grateful and moderately warm cordial; and frequently given in that intention, from eight or ten grains to a scruple or upwards, in boluses and draughts. The extract retains a considerable share of the flavour and virtue of the ingredients, though not near so much as if a rectified spirit had been employed. The operator should be particularly careful to extract as much from the ingredients as the spirit will take up; otherwise the inspissated matter turns out so thin, and of so little tenacity, that the powders are apt to separate and subside from it in keeping. The crabs-claw powder does not appear to be very necessary; and is inserted rather in compliance with the original, than from its contributing any thing to the intention of the medicine.

#### SECT. VII. *Empyreumatic Oils.*

631. VEGETABLE and animal substances, and mineral bitumens, on being urged with a red heat, have their original properties destroyed, and are resolved or changed

changed into products of a different nature from what per-se existed in the subject. By burning them in the open air, a part is changed into ashes, a part into foot, and a part is dissolved by the air. Exposed to the fire in close vessels (as in those called *retorts*, having receivers adapted to them for detaining the volatile parts), they are resolved into fetid oils, and different kinds of saline substances which rise into the receiver; and a black coal which remains behind, and which, though no farther alterable in close vessels, on admitting air burns into white ashes. The oils, called from their fetid burnt smell *empyreamatic*, are the objects of the present section. Some of these however being obtained in the same process with certain saline bodies of more importance than themselves, are referred to the head of saline preparations.

#### 632. Oil of box. L.

Distil pieces of boxwood in a retort, with a sand-heat gradually increased: the oil will come over along with an acid spirit, which is to be separated by a funnel.

#### 633. Oil of guaiacum.

Put any quantity of chips of guaiacum into an earthen long-neck, or a glass retort, and distil either in a sand-bath or an open fire, increasing the heat by degrees. At first an acid liquor will come over; afterwards a light red oil; and at length, in the utmost degree of fire, a thick black oil which sinks through the other liquors to the bottom of the receiver. Oils may be obtained after the same manner from every kind of wood.

The oils obtained by this treatment from different woods and plants are nearly of the same qualities: they have all a very disagreeable acrid taste, and a burnt stinking smell, without any thing of the peculiar flavour, taste, or virtues, of the subject which afforded them. The present practice rarely employs those oils any otherwise than for external purposes, as the cleansing of foul bones, for the tooth-ach, against some kinds of cutaneous eruptions, old pains and aches, and the like; and for these not very often.

#### 634. Compound oil of balsam of Copaiva. L.

Take two pounds of balsam of Copaiva, and four ounces of gum guaiacum. Distil them in a retort, continuing the operation till a pint of oil is come over.

The mixture, undistilled, proves a medicine of considerable efficacy in rheumatic cases, &c. In distillation the guaiacum gives over little. The balsam distilled in a retort, with or without the gum, yields first a light coloured oil, smelling considerably of the subject; this is immediately followed by a darker coloured oil, and afterwards by a blue one, both which have little other smell than the empyreamatic one that distinguishes the oils of this class: their taste is very pungent and acrimonious. This balsam distilled with water yields as much essential oil as above of empyreamatic.

#### 635. The anodyne, commonly called Guido's balsam.

Take of tacamahaca in powder, Venice turpentine, each equal parts. Put them into a retort, whereof they may fill two-thirds, and distil with a fire gradually increased. Separate, according to art, the

red oil, or balsam, from the liquor that swims above it.

This oil is supposed to be anodyne and discutient.

#### 636. Dippel's animal-oil.

Take any quantity of the empyreamatic oil distilled from animal-substances, as that of hartshorn (the preparation of which is described along with that of the volatile salt and spirit in the following section. Put it into a glass retort; and having fitted on a receiver, distil in a sand-heat: the oil will arise paler coloured and less fetid; and a black coally matter will remain behind. Repeat the distillation in fresh retorts, till the oil ceases to leave any faeces, and till it loses its ill smell, and acquires an agreeable one.

a, The quantity of oil employed in this process should be considerable: for it leaves so much black matter behind in the several distillations, that it is reduced, at last, to a small portion of its original quantity. The distillation must be repeated at least 12 times, and frequently the requisite subtilization will scarcely be obtained with less than 20 distillations. It is said, that the effect may be expedited, by mixing the oil with quicklime into a soft paste; the lime keeping down more of the gross matter, than would remain without such an addition.

b, Animal-oils thus rectified, are thin and limpid, of a subtle, penetrating, not disagreeable smell and taste. They are strongly recommended as anodynes and antispasmodics, in doses of from 15 to 30 drops. Hoffman reports, that they procure a calm and sweet sleep, which continues often for 20 hours, without being followed by any languor or debility, but rather leaving the patient more alert and cheerful than before: that they procure likewise a gentle sweat, without increasing the heat of the blood: that given to 20 drops or more, on an empty stomach, six hours before the accession of an intermittent fever, they frequently remove the disorder: and that they are likewise a very generous remedy in inveterate and chronic epilepsies, and in convulsive motions, especially if given before the usual time of the attack, and preceded by proper evacuations.

c, The empyreamatic oils of vegetables, rectified in the same manner by repeated distillations, suffer a like change with the animal; losing their dark colour and offensive smell, and becoming limpid, penetrating, and agreeable: in this state they are supposed, like the animal oils, to be anodyne, antispasmodic, and diaphoretic or sudorific. It is observable, that all the empyreamatic oils dissolve in spirit of wine; and that the oftener they are rectified or re-distilled, they dissolve the more readily; a circumstance in which they differ remarkably from essential oils, which, by repeated distillations, become more and more difficult of solution.

d, How far these preparations really possess the virtues that have been ascribed to them, has not yet been sufficiently determined by experience; and the tediousness and trouble of the rectification having prevented their coming into general use, or being often made. They are liable also to a more material inconvenience in regard to their medicinal use, precariousness in their quality: for how perfectly soever they be rectified, they

they generally lose, in keeping, the qualities they had received from that process, and return more and more towards their original fetidness.

## SECT. VIII. *Salts and Saline Preparations.*

### § I. FIXED ALKALINE SALTS.

637. THE ashes of most vegetables, steeped or boiled in water, give out to it a saline substance, separable in a solid form by evaporating the water. This kind of salt never pre-exists in the vegetable, but is always generated during the burning. It is called *fixed alkaline salt*.

#### 638. *Salt of tartar.*

Let any kind of tartar be wrapped up in strong brown paper, first made wet, or included in a proper vessel, and exposed to the fire, that its oil may be burnt out: then boil it in water, filter the solution, and evaporate it, till there remains a dry salt, which is to be kept in a vessel closely stopp'd. *L.*  
Take of tartar any quantity, and having wrapped it up in brown paper, or put it into a crucible, let it be surrounded with a gentle fire, till reduced to a coal. Having reduced this to powder, calcine it again in an open crucible, with a fire not sufficient to melt it till the salt becomes white, or at least ash-coloured. Dissolve it in water, and strain thro' a linen cloth; after which it is to be evaporated in a clean iron vessel, till all the moisture is exhaled. Continue to keep it over the fire, till the bottom of the vessel is almost red. Then put it up in glass bottles well stopp'd. *E.*

This salt has a pungent fiery taste; and occasions in the mouth a kind of urinous flavour, probably from the resolution which it produces in the saliva. It readily dissolves in water, and deliquesces in the air; but is not acted upon by pure vinous spirits. Instead of being dissolved by vinous spirits, if a saturated solution of it in water be dropt into the pure spirit, it will not mix therewith, but fall distinct to the bottom: if water be mixed with the spirit, the addition of fixed alkaline salt will imbibe the water, and form with it, as in the other case, a distinct fluid at the bottom; this property affords a commodious method of dephlegmating vinous spirits, or separating their watery part, as we have already seen.

639. Salt of tartar, or solutions of it in water, raise an effervescence on the admixture of acid liquors, and destroy their acidity, the alkali and acid uniting together into a compound of new qualities called *neutral*: earthy substances, and most metallic bodies, previously dissolved in the acid, are precipitated from it by the alkali. The alkaline salt changes the colours of the blue flowers of plants, or their infusions, to a green: it has the same effect on the bright red flowers, and on the colourless infusions of white ones; but in many of the dark red, as those of the wild poppy, and of the yellow ones, it produces no such change.

640. Solutions of this salt liquefy all the animal juices, except milk; corrode the fleshy parts into a kind of mucous matter; concrete with animal fats, and vegetable oils, into soap; and dissolve sulphur into a red liquor; especially if assisted by a boiling heat, and mingled with quicklime, which greatly promotes their

activity. On pure earths and stones, these liquors have no sensible action; but if the earth or stones be mixed with four or five times the weight of the dry salt, and urged with a strong fire, they melt along with it, and become afterwards perfectly soluble both in water and by the moisture of the air: with a smaller proportion of the salt, as an equal weight, they run into an indissoluble glassy matter.

641. The medical virtues of this salt are, to attenuate the juices, resolve obstructions, and promote the natural secretions. A dilute solution of it, drank warm in bed, generally excites sweat: if that evacuation is not favoured, its sensible operation is by urine. It is an excellent remedy in colic habits, especially if a few grains of aloes be occasionally interposed; with this advantage above other purgatives and laxatives, that when the complaint is once removed, it is not apt to return. Where acidities abound in the first passages, this salt absorbs the acid, and unites with it into a mild aperient neutral salt. As one of its principal operations is to render the animal fluids more thin, it is obvious, that where they are already colliquated, as in scurvy, and in all putrid disorders in general, this medicine is improper. The common dose of the salt is from two or three grains to a scruple; in some circumstances it has been extended to a dram, in which case it must always be largely diluted with watery liquors.

#### 642. *Salt of wormwood.*

Let ashes of wormwood (which the shops are usually supplied with from the country) be put into an iron pot, or any other convenient vessel; and kept red-hot over the fire for some hours, often stirring them, that what oily matter remains may be burnt out; then boil the ashes in water, filter the ley through paper, and evaporate it till a dry salt remains; which is to be kept in a vessel close stopp'd. *L.* After the same manner a fixed alkaline still may be prepared from all those vegetables which yield this kind of salt, *L.* as bean-stalks, broom, &c. *E.*

These salts are obtained to greater advantage from dry plants than from green ones; they must not, however, be too dry, or too old; for in such case, they afford but a small quantity of salt. The fire should be so managed, as that the subject may burn freely, yet not burst into violent flame; this last circumstance would greatly lessen the yield of the salt; and a very close smothering heat would have this effect in a greater degree: hence the ashes of charcoal scarce yield any salt, whilst the wood it was made from, if burnt at first in the open air, affords a large quantity.

Tachenius, Boerhaave, and others, have entertained a very high opinion of these oily salts, and endeavour as much as possible to retain the oil in them. They are nevertheless liable to a great inconvenience, uncertainty in point of strength, without promising any advantage to counterbalance it; if the common alkalis are required to be made milder and less acrimonious (which is the only point aimed at in the making of these medicated salts as they are called), they may be occasionally rendered so by suitable additions. Pure alkalis, united with a certain quantity of expressed oil, compose (as we shall see hereafter) a perfect

fect soap, in which the pungent taste of the alkaline salt is totally suppressed: it is obvious, therefore, that on the same principle the pungency may be covered in part, and this proportionably to the quantity of oily matter combined.

#### 643. Fixed nitre.

Take of powdered nitre, four ounces; charcoal in powder, five drams. Mix them thoroughly together, by rubbing them in a mortar, and inject the mixture, by a little at a time, into a red-hot crucible. A deflagration, or a bright flame with a hissing noise, happens on each injection; the whole quantity being thus deflagrated, continue the fire strong for half an hour.

Nitre is composed of the common vegetable fixed alkaline salt, and a peculiar acid. In this process, the acid is destroyed, or changed to another nature; and the remaining salt proves merely alkaline, not different in quality from the salt of tartar, except that a very minute portion of the nitre generally remains unchanged; the salt is purified by solution in water, filtration, and evaporation.

#### 644. The alkaline salt of sea-salt.

Take of cubical nitre (prepared as hereafter described in § 6.) four ounces; charcoal, five drams. Mix and deflagrate as in the preceding process.

a, Cubical nitre is composed of the nitrous acid united with the alkaline basis of sea-salt: the acid being here separated in the deflagration, that alkali remains nearly pure. It possesses the general properties of the foregoing preparation; changing blue flowers, green; dissolving oils, salts, and sulphur; bringing earths and stones into fusion, and forming with them, according to its quantity, either a vitreous, or a soluble compound; effervescing with acids, precipitating earths, and metals dissolved in them, and uniting with the acid into a neutral salt. It differs from the foregoing alkalies, in being much milder in taste; not so readily dissolving in water; not at all deliquating in the air; easily assuming, like neutral salts, a crystalline form; and yielding, with each of the common acids, compounds very sensibly different, both in their form and qualities, from those which result from the coalition of the vegetable alkalies with the respective acids. The crystals of this salt itself are prismatic, greatly resembling those of the salt called *sal mirabile*; (see § 6.) Exposed to a warm air, they fall into a porous, friable mass, and lose above two-thirds of their weight.

b, How far this salt differs in medical virtue from the other alkalies, is not well known. It apparently possesses the same general virtues; and, as it is far milder, may be given in more considerable doses.

c. A salt of the same nature with this, but less pure, as containing an admixture of the common vegetable alkali, is prepared at Alicante, and some other places, from the ashes of certain marine plants, called *kali*; which plants are supposed to have given rise to the name *alkali*. The salt of the kali plants is called *soda*, or *bariglia*: it has been long used medicinally in France, and begins now to be introduced into practice in this country; but the above pure alkali extracted from sea-salt is doubtless preferable to it.

645. *Ley of tartar, or oil of tartar per deliquium.*  
Put any quantity of salt of tartar in a flat glass dish, and expose it to the air, for some days, in a moist place: it will run into a liquor, which is either to be filtered through paper, or separated from the fæces by decantation. The higher the salt has been calcined, the more readily will it relent in the air.

The solutions of fixed alkaline salts, effected by exposing them to a moist air, are generally looked upon as being purer than those made by applying water directly: for though the salt be repeatedly dissolved in water, filtered, and exsiccated; yet, on being liquesfied by the humidity of the air, it will still deposit a portion of earthy matter: but it must be observed, that the exsiccated salt leaves always an earthy matter on being dissolved in water, as well as on being deliquated in the air. The deliquated lixivium is said to contain nearly one part of alkaline salt to three of an aqueous fluid. It is indifferent, in regard to the lixivium itself, whether the white ashes of tartar, or the salt extracted from them, be used: but as the ashes leave a much greater quantity of earth, the separation of the ley proves more troublesome.

#### 646. Purified potash. E.

Take of the lixivial salt, commonly called *pearl-ashes*, any quantity; and let it be made red-hot in a crucible, that the oily matter, if any is contained in it, may be burnt out. Then powder and mix it with an equal quantity of water; let the liquor settle, and pour it off from the fæces. Evaporate to dryness in an iron vessel. The salt is known to be perfectly purified, when it totally dissolves in an equal weight of water into a liquor without smell or taste.

#### 647. Soap leys.

Take of Russia potash, quicklime, of each equal weights. Gradually sprinkle on them as much water as will slake the lime; then pour on more water, stirring the whole together, that the salt may be dissolved: let the ley settle, pour it off into another vessel, and, if there is occasion, filter it. A wine pint of this ley, measured with the greatest exactness, ought to weigh just 16 ounces Troy. If it proves heavier, for every dram that it exceeds this weight, add to each pint of the liquor an ounce and a half of water by measure: if lighter, boil it till the like quantity is wasted, or pour it upon fresh lime and ashes. L.

Take of quicklime, eight ounces; purified potash, six ounces. Put the lime into a glazed earthen or iron vessel, with 28 ounces of warm water. Add the potash as soon as the lime is slaked; and having mixed them well together, let the vessel be covered till it cools. When the mixture has become cold, pour the whole into a glass funnel, having the pipe stopped with a clean linen rag. Cover the upper part of the funnel, and insert its pipe into another glass vessel, that the ley may drop from it. When it has ceased to drop, pour some ounces of water cautiously into the funnel, that it may lie above the thick matter. The ley will again begin to drop: and this operation is to be repeated till 32 ounces by measure, or 36 by weight,

weight, have passed through; which will take up the space of two or three days. Then mix the upper and under parts of the ley together by shaking the vessel, and keep it in a glass bottle well stoppered. *E.*

Quicklime greatly increases the strength of alkaline salts; and hence this ley is much more acrimonious, and acts more powerfully as a menstruum on oils, fats, &c. than a solution of the potash alone; the lime should be used fresh from the kiln; by long keeping, even in close vessels, it loses of its strength; such should be made choice of as is thoroughly burnt or calcined, which may be known by its comparative lightness.

All the instruments employed in this process should be either of wood, earthen ware, or glass: the common metallic ones would be corroded by the ley, so as either to discolour, or communicate disagreeable qualities to it. If it should be needful to filter or strain the liquor, care must be taken that the filter or strainer be of vegetable matter; woollen, silk, and that sort of filtering paper which is made of animal substances, are quickly corroded and dissolved by it.

The liquor is most conveniently weighed in a narrow-necked glass bottle, of such a size, that the measure of a wine-pint may arise some height into its neck; the place where it reaches to, being marked with a diamond. A pint of the common leys of our soft-soap makers weighs more than 16 ounces; it has been found that their soap-ley will be reduced to the standard here proposed, by mixing it with something less than an equal measure of water.

#### 648. *The septic stone, or potential cautery. E.*

Take any quantity of soap-ley; evaporate it over a gentle fire in a very clean iron vessel, till the ebullition ceases, and the matter flows smooth like oil, which will happen before it is red-hot. Then pour it out on a clean iron plate, and cut it into slips before it grows cold; then keep it in a glass well stoppered.

This preparation is a strong and a sudden caustic. It has an inconvenience of being apt to liquefy too much upon the part to which it is applied, so that it is not easily confined within the limits in which it is intended to operate: and indeed the suddenness of its action depends on this disposition to liquefy.

#### 649, a. *The stronger common caustic. L.*

Boil any quantity of the soap-leys above described, to one-fourth part: then, whilst it continues boiling, some lime, that has been kept for several months in a glass vessel stoppered with a cork, is to be sprinkled in by little and little, till it has absorbed all the liquor, so as to form a kind of paste; which keep for use in a vessel very closely stoppered.

Here the addition of lime in substance renders the preparation less apt to liquefy than the foregoing, and consequently more easily confineable within the intended limits, but proportionably slower in its operation. The design of keeping the lime is, that its acrimony may be somewhat abated.

#### 649, b. *The milder common caustic. L.*

Take of fresh quicklime, soft soap, of each equal parts.

Mix them well together at the time of using.

This caustic, notwithstanding the lime is used fresh, proves much milder than the former; the acrimony of the salt being here covered by the oil and tallow by which it is reduced into soap. The mild caustic of the Edinburgh pharmacopoeia is only soap-ley made into a paste with quicklime.

### § 2. VOLATILE ALKALINE SALTS.

650. As fixed alkalies are produced in the burning of vegetables, and remain behind in the ashes; volatile ones are produced by a like degree of heat from animal substances, and rise in distillation along with the other volatile principles; the admission of air, necessary for the production of the former, is not needful for the latter. These salts are obtainable also from some vegetable matters; and from vegetable and animal foot. Though a strong fire is requisite for their production, yet when once completely formed, they are dissipated by the gentlest warmth: in distillation, they rise sooner than the most highly rectified spirit of wine. They are produced in urine, by putrefaction, without fire; and without fire also they exhale from it.

#### 651. *Spirit, salt, and oil of hartshorn. L.*

Distil pieces of hartshorn by a fire gradually raised almost to the highest: a spirit, salt, and oil, will ascend.

If the oil be separated, and the spirit and salt distilled again together with a very gentle heat, they will both arise more pure. If this be carefully repeated several times, the salt will become exceedingly white, the spirit limpid as water, and of a grateful odour.

The salt, separated from the spirit, and sublimed first from an equal weight of pure chalk, and afterwards from a little rectified spirit of wine, becomes the sooner pure.

Calcined hartshorn is generally made by burning the horns left after this distillation.

After the same manner; a spirit, salt, and oil, may be obtained from every kind of animal substance.

652. In the former edition of the Edinburgh dispensatory the following directions were given.

Put pieces of hartshorn into a large iron pot furnished with an earthen head; and having fitted on a capacious receiver, and luted the junctures, distil in an open fire gradually increased. At first a phlegm arises, then a spirit, and afterwards a volatile salt, accompanied with an oil: the oil that comes over first is of a yellowish colour, but on protracting the distillation, there succeeds a reddish one verging to black. In the bottom of the iron pot there remains a black coal, which being burnt to whiteness in the open air, is called *calcined hartshorn*.

Having poured out of the recipient all the different matters which have come over into it, they may be separated from one another in the following manner; the oil separates from the phlegm and spirit in filtration: the latter two will pass through, and the oil remain on the filter.

The phlegm may be separated from the spirit by distilla-

distillation in a tall vessel, with a gentle heat; the spirit will come over into the recipient, and the phlegm remain at the bottom of the distilling vessel.

The spirit may be divided into a volatile salt and phlegm, by distilling it in a very tall and narrow cucurbit; the salt will arise, and adhere to the head in a dry form; the phlegm remaining behind.

The salt may be freed from the oil, by subliming it from twice its quantity of potash; for the oil is kept down by the potash, whilst the salt arises.

The spirit also is rendered purer, by adding, to every pint, two ounces of potash, and distilling in a glass retort.

The remaining potash may be again purified for use, by calcining it in an open fire, so as to burn out the oil it had absorbed from the salt or spirit.

A spirit, salt, and oil, may be obtained in the same manner from all the solid parts of animals.

653. The wholesale dealers have very large pots for the distillation of hartshorn, with earthen heads almost like those of the common still: for receivers, they use a couple of oil-jars, the mouths of which are luted together; the pipe that comes from the head enters the lowermost jar, through a hole made on purpose in its bottom. When a large quantity of the subject is to be distilled, it is customary to continue the operation for several days successively; only unluting the head occasionally to put in fresh materials.

When only a small quantity of spirit or salt is wanted, a common iron pot, such as is usually fixed in sand furnaces, may be employed, an iron head being fitted to it. The receiver ought to be large, and a glass, or rather tin adaption, inserted betwixt it and the pipe of the head.

The distilling vessel being charged with pieces of the horn, a moderate fire is applied, which is slowly increased, and raised at length almost to the utmost degree. At first a phlegmatic liquor arises; the quantity of which will be less or greater according as the horns were more or less dry: this is succeeded by the salt and oil; the salt at first dissolves as it comes over in the phlegm, and thus forms what is called *spirit*: when the phlegm is saturated, the remainder of the salt concretes in a solid form to the sides of the recipient. If it is required to have the whole of the salt solid and undissolved, the phlegm should be removed as soon as the salt begins to arise, which may be known by the appearance of white fumes: and that this may be done the more commodiously, the receiver should be left unluted till this first part of the process is finished. The white vapours which now arise sometimes come with such vehemence as to throw off or burst the receiver: to prevent this accident, it is convenient to have a small hole in the luting, which may be occasionally stopped with a wooden peg, or opened as the operator shall find proper. After the salt has all arisen, a thick dark-coloured oil comes over: the process is now to be discontinued, and the vessels, when grown cold, unluted.

All the liquid matters being poured out of the receiver, the salt which remains adhering to its sides is to be washed out with a little water, and added to the rest. It is convenient to let the whole stand for a few hours, that the oil may the better disengage itself from the liquor, so as to be first separated by a fun-

nel, and afterwards more perfectly by filtration thro' wetted paper. The salt and spirits are then to be farther purified as above directed.

654. The spirit of hartshorn met with in the shops is extremely precarious in point of strength; the quantity of salt contained in it (on which its efficacy depends) varying according as the distillation in rectifying it is continued for a longer or shorter time. If after the volatile salt has arisen, so much of the phlegm or watery part be driven over after it as is just sufficient to dissolve it, the spirit will be fully saturated, and as strong as it can be made: if the process is not at this instant stopped, the phlegm continuing to arise must render the spirit continually weaker and weaker. The distillation therefore ought to be discontinued at this period, or rather whilst some of the salt still remains undissolved: the spirit will thus prove always equal, and the buyer be furnished with a certain criterion of its strength. Very few have taken any notice of the above-mentioned inconvenience of these kinds of spirits; and the remedy is first hinted at in the *pharmacopœia reformata*. The purity of the spirits is easily judged from its clearness and grateful odour.

655. Volatile alkaline salts, and their solutions called *spirits*, agree in many respects with fixed alkalies and their solutions or leys; as in changing the colour of blue flowers to a green; effervescing with and neutralizing acids; liquefying the animal juices, and corroding the fleshy parts, so as, when applied to the skin, and prevented from exhaling by a proper covering, to act as caustics; dissolving oils and sulphur, though less readily than the fixed alkalies, on account probably of their not being able to bear any considerable heat, by which their activity might be promoted. Their principal difference from the other alkalies seems to consist in their volatility: they exhale or emit pungent vapours in the coldest state of the atmosphere; and by their stimulating smell, they prove serviceable in languors and faintings. Taken internally, they discover a greater colliquating as well as stimulating power; the blood drawn from a vein, after their use has been continued for some time, being found to be remarkably more fluid than before: they are likewise more disposed to operate by perspiration, and to act on the nervous system. They are particularly useful in lethargic cases; in hysterical and hypochondriacal disorders, and in the languors, headaches, inflations of the stomach, flatulent colics, and other symptoms which attend them: they are generally found more serviceable to aged persons, and in phlegmatic habits, than in the opposite circumstances. In some fevers, particularly those of the low kind, accompanied with a cough, hoarseness, redundancy of phlegm, and siziness of the blood, they are of great utility; liquefying the viscid juices, raising the *vis vita*, and exciting a salutary diaphoresis; but in putrid fevers, scorbutics, and wherever the mass of blood is thin and acrimonious, they do harm. As they are more powerful than the fixed in liquefying sisy blood and tenacious humours, so they prove more hurtful where the fluids are already in a colliquated state. In vernal intermittents, particularly those of the slow kind, and where the blood is dense or sisy, they are often the most efficacious remedy. Mr Bisset observes, in his Essay

on the medical constitution of Great Britain, that tho' many cases occur which will yield to no other medicine than the bark, yet he has met with a pretty many that were only suppressed from time to time by the bark, but were completely cured by alkaline spirits: that these spirits will often carry off vernal intermittents without any previous evacuation; but that they are generally more effectual if a purge is premised: and in plethoric or inflammatory cases, or where the fever personates a remittent, venesection.

These salts are most commodiously taken in a liquid form, largely diluted; or in that of a bolus, which should be made up only as it is wanted. The dose is from a grain or two to ten or twelve. Ten drops of a well made spirit, or saturated solution, are reckoned to contain about a grain of the salt. In intermittents, fifteen or twenty drops of the spirit are given in a tea-cup full of cold spring-water, and repeated five or six times in each intermission.

656. The volatile salts and spirits prepared from different animal substances, have been supposed capable of producing different effects upon the human body, and to receive specific virtues from the subject. The salt of vipers has been esteemed particularly serviceable in the disorders occasioned by the bite of that animal; and a salt drawn from the human skull, in diseases of the head. But modern practice acknowledges no such different effects from these preparations, and chemical experiments have shewn their identity. There is indeed, when not sufficiently purified, a very perceptible difference in the smell, taste, degree of pungency, and volatility of these salts; and in this state their medicinal virtues vary considerably enough to deserve notice; but this difference they have in common, according as they are more or less loaded with oil, not as they are produced from this or that animal substance. As first distilled, they may be looked upon as a kind of volatile soap, in which the oil is the prevailing principle; in this state they have much less of the proper alkaline acrimony and pungency than when they have undergone repeated distillations, and such other operations as disengage the oil from the salt; for by these means they lose their saponaceous quality, and, acquiring greater degrees of acrimony, become medicines of a different class. These preparations, therefore, do not differ near so much from one another as they do from themselves in different states of purity. To which may be added, that when we consider them as loaded with oil, the virtues of a distilled animal-oil itself are likewise to be brought into the account.

These oils, as first distilled, are highly fetid and offensive, of an extremely heating quality, and of such activity, that, according to Hoffman's account, half a drop, dissolved in a dram of spirit of wine, is sufficient to raise a copious sweat. By repeated rectifications, they lose their offensiveness, and at the same time become mild in their medicinal operation: the rectified oils may be given to the quantity of twenty or thirty drops, and are said to be anodyne and antispasmodic, to procure a calm sleep and gentle sweat, without heating or agitating the body. It is obvious, therefore, that the salts and spirits must differ, not only according to the quantity of oil they contain, but according to the quality of the oil itself

in its different states.

The volatile salts and spirits, as first distilled, are of a brown colour, and a very offensive smell: by repeated rectification, as directed in the processes above set down, they lose great part of the oil on which these qualities depend, the salt becomes white, the spirit limpid as water, and of a grateful odour; and this is the mark of sufficient rectification.

It has been objected to the repeated rectification of these preparations, that by separating the oil, it renders them similar to the pure salt and spirit of sal ammoniac, which are procurable at an easier rate. But this is by no means the case. The intention is not to purify them wholly from the oil, but to separate the grosser part, and to subtilize the rest, so as to bring it towards the same state as when the oil is rectified by itself. Dr Lewis has repeated the rectification of spirit of hartshorn twenty times successively, and found it still to participate of oil, but of an oil very different from what it was in the first distillation.

The rectified oils, in long keeping, become again fetid. The salts and spirits also, however carefully rectified, suffer, in length of time, the same change; reluming their original brown colour and ill smell; a proof that the rectification is far from having divested them of oil.

#### 657. Spirit, salt, and oil of foot. L.

Distil foot after the same manner as directed above for hartshorn: but here more labour is required to render the spirit and salt pure.

The volatile salt and spirit of foot are, when sufficiently purified, not different in quality from those of animal substances; though some have preferred them in nervous complaints, particularly in epileptic cases.

#### 658. The volatile salt and spirit of sal ammoniac.

Take a pound and a half of any fixed alkaline salt, a pound of sal ammoniac, and four pints of water. Distil off, with a gentle heat, two pints of spirit. The volatile salt is made from a pound of sal ammoniac mixed with two pounds of pure chalk, and set to sublime in a retort with a strong fire. L. Take sal ammoniac, and purified potashes, each one pound; water, a pint and an half; distil to dryness. E.

The volatile salt and spirit of sal ammoniac are the purest of all the medicines of this kind. They are somewhat more acrimonious than those produced directly from animal-substances, which always contain a portion of the oil of the subject, and receive from thence some degree of a saponaceous quality. These salt may be reduced to the same degree of purity, by combining them with acids into ammoniacal salts; and afterwards recovering the volatile alkali from these compounds by the processes above directed.

659. The matter which remains in the retort, after the distillation of the spirit, and sublimation of the salt of sal ammoniac, is found to consist of marine acid united with the fixed alkali or chalk employed. When fixed alkaline salt has been used as the intermediate, the residuum, or *caput mortuum*, as it is called, yields, on solution and crystallization, a salt exactly similar to the *coagulated spirit of sea salt* hereafter described. And hence we may judge of the ex-  
tract-

traordinary virtues formerly attributed to this salt, under the names of *sal antihystericum*, *antihypocondriacum*, *fibrifugum*, *digestivum sylvii*, &c.

660. The caput mortuum of the volatile salt, where chalk is employed as an intermedium, exposed to a moist air, runs into a pungent liquor, which proves nearly the same with a solution of chalk made directly in the marine acid: it is called by some *oleum cretae*, "oil of chalk." If calcined shells, or other animal-limes, be mingled with sal ammoniac, a mass will be obtained, which likewise runs in the air, and forms a liquor of the same kind. This liquor seems to be the secret of some pretenders to a dissolvent of the calculus.

#### 661. Volatile caustic spirit.

Take of sal ammoniac, one pound; quicklime, a pound and a half; water, four pints. Quench the lime in the water; and having put this mixture into a retort, add to it the powdered salt. Immediately adapt a recipient, and with a very gentle heat draw off two pints.—The Edinburgh college order a pound of quicklime, with only eight ounces of sal ammoniac, and as much water. The lime is slaked with the water; then ground with the salt, and distilled.

This spirit is commonly called, from the intermedium, *spirit of sal ammoniac with quicklime*. The effect of the quicklime on the sal ammoniac, is very different from that of the chalk and fixed alkali in the foregoing process. Immediately on mixture, a very penetrating vapour exhales; and in distillation, the whole of the volatile salt arises in a liquid form; no part of it appearing in a concrete state, how gently soever the liquor be redistilled. This spirit is far more pungent than the other both in smell and taste; and, like fixed alkalies rendered caustic by the same intermedium, it raises no effervescence on the admixture of acids.

This spirit is held too acrimonious for internal use, and has therefore been chiefly employed for smelling to in faintings, &c. though, when properly diluted, it may be given inwardly with safety. It is an excellent menstruum for some vegetable substances, as Peruvian bark, which the other spirit extracts little from.

### § 3. COMBINATION OF ALKALIES WITH OILS AND INFLAMMABLE SPIRITS.

#### 662. Almond soap. L.

TAKE any quantity of fresh-drawn oil of almonds, and thrice its quantity by measure of the foregoing soap leys. Digest them together in such a heat, that they may but just boil or simmer, and in a few hours they will unite: after which, the liquor in boiling, will soon become ropy, and in good measure transparent; a little of it suffered to cool, will appear like jelly. When this happens, throw in by little and little some common salt, till the boiling liquor loses it rosinels; and continue the coction, till, on receiving some drops on a tile, the soap is found to coagulate, and the water freely separates from it. The fire being then removed, the soap will gradually arise to the surface of the liquor; take it off before it grow cold, and put it into a wooden mould or frame, which has a cloth for its bottom;

afterwards take out the soap, and set it by till sufficiently dried. After the same manner, a soap may likewise be made with oil-olive; but the purest oil must be used, that the soap may be as little ungrateful as possible either to the palate or stomach.

This process is so fully described, as to render any further directions unnecessary. The general virtues of soap have been already mentioned in the *Table of MATERIA MEDICA*; that prepared after this manner is not different in quality from the hard sort there mentioned.

#### 663. Purified soap.

Slice one pound of dry, hard, Genoa, Alicant, or any other oil-soap, into a clean pewter vessel, and pour upon it two gallons of rectified spirit of wine. Place the vessel in a water-bath, and apply such a degree of heat as may make the spirit boil, when it will soon dissolve the soap. Let the vessel stand close covered in a warm place, till the liquor has grown perfectly clear; if any oily matter swim upon the surface, carefully scum it off. Then decant the limpid liquor from the feces, and distil off from it all the spirit that will arise in the heat of a water-bath. Expose the remainder to a dry air for a few days, and it will become a white, opaque, and somewhat friable mass.

Soap thus purified has little or no smell; and proves, upon examination, not in any degree acrimonious, but quite mild and soft, and consequently well fitted for medicinal purposes.

#### 664, a. Saponaceous lotion. L.

Take of rose-water, three quarters of a pint; oil-olive, one quarter of a pint; ley of tartar, half an ounce by measure. Grind the ley of tartar and the oil together, until they unite; then gradually add the rose water.

This is designed for external use, as a detergent wash; and, like other soapy liquors, answers this purpose very effectually. Where it is required to be more deterfise, it may be occasionally rendered so by the addition of a small quantity of a solution of any fixed alkaline salt.

#### 664, b. Saponaceous liniment. L.

Take of spirit of rosemary, one pint; hard Spanish soap, three ounces; camphor, one ounce. Digest the soap in the spirit of rosemary, until it is dissolved; then add the camphor.

This composition also is employed chiefly for external purposes, against rheumatic pains, sprains, bruises, and other like complaints. Soap acts to much better advantage, when thus applied in a liquid form, than in the solid one of a plaster.

#### 665. Anodyne balsam, commonly called Bates's balsam. E.

Take of white soap, five ounces; crude opium, an ounce; camphor, two ounces; essential oil of rosemary, half an ounce; rectified spirit of wine, two pints. Digest the spirit with the soap and opium, in a gentle sand-heat, for three days; then strain the liquor, and add to it the camphor and essential oil.

This composition is greatly commended for allaying pains, and it is said to have been sometimes used with benefit even in the gout; a cloth dipt in it being laid on the part. It is sometimes likewise directed to be taken inwardly in the same disorder, as also in nervous colics, jaundice, &c. from twenty to fifty drops or more; though surely, in gouty cases, the use of opiate medicines requires great caution. One grain of opium is contained in about ninety drops of the balsam.

666. *Saponaceous balsam, commonly called opodeldoc.* This is exactly the same with the foregoing; omitting only the opium. *E.*

667. *Dulcified spirit of sal ammoniac.* *L.* Take half a pound of any fixed alkaline salt, four ounces of sal ammoniac, and three pints of proof-spirit of wine. Distil off, with a gentle heat, a pint and a half.

This spirit has lately come much into esteem, both as a medicine and a menstruum. It is a solution of volatile salt in rectified spirit of wine; for though proof-spirit is made use of, its phlegmatic parts does not arise in the distillation, and serves only to facilitate the action of the pure spirit upon the ammoniacal salt. Rectified spirit of wine does not dissolve volatile alkaline salts by simple mixture: on the contrary, it precipitates them, as has been already observed, when they are previously dissolved in water; but by the present process, a considerable proportion of the volatile alkali is combined with the spirit. It might perhaps, for some purposes, be more advisable, to use in this intention the volatile spirit made with quicklime; for this may be mixed at once with the rectified spirit of wine, in any proportions, without the least danger of any separation of the volatile alkali: And accordingly the Edinburgh college have now ordered this spirit to be made by mixing four ounces caustic spirit of sal ammoniac with eight of spirit of wine.

668. *The volatile fetid spirit.* *L.* Take of any fixed alkaline salt, a pound and a half; sal ammoniac, one pound; asafetida, four ounces; proof-spirit of wine, six pints. Draw off with a gentle heat, five pints.

669. *Fetid volatile spirit.* *E.* Take of vinous spirit of sal ammoniac, eight ounces; asafetida, half an ounce. Digest 12 hours in a close vessel; then distil eight ounces in a water-bath.

This spirit is designed as an antihysteric, and is undoubtedly a very elegant one.

670. *Volatile aromatic spirit.* *L.* Take of essential oil of nutmegs, essence of lemons, each two drams; essential oil of cloves, half a dram; dulcified spirit of sal ammoniac, one quart. Distil them with a very gentle fire.

671. *Volatile oily spirit, commonly called saline aromatic spirit.* *E.*

Take of vinous spirit of sal ammoniac, eight ounces; essential oil of rosemary, one dram and a half; essence of lemon-peel, a dram. Mix the whole together. Draw off by distillation, in the heat of a water-bath, near one gallon.

Volatile salts thus united with aromatics, are not only more agreeable in flavour, but likewise more acceptable to the stomach, and less acrimonious, than in their pure state. Both the foregoing compositions turn out excellent ones, provided the oils are good, and the distillation skilfully performed. The dose is from five or six drops to sixty or more.

#### §. 4. ACID SPIRITS.

672. *Weak spirit and the strong spirit (or oil,) of vitriol, and colcothar.* *L.*

Let calcined vitriol be distilled in earthen vessels, with reverberatory fire, for three days without intermission. What remains in the vessels is called *colcothar* of vitriol. Put the distilled liquor into a glass retort, and place it in a sand furnace: the weak spirit will come over, the strong (improperly called *oil* of vitriol) remaining behind.

This process, was never practicable to advantage without a very large apparatus, and is now entirely superseded by the much cheaper method of preparing the acid from sulphur.

The acid spirit, as it arises in the first distillation, appears of a dark or blackish colour, and contains a considerable portion of phlegm. In the second distillation, the phlegmatic parts arise first, together with the lighter acid, which are kept apart under the name of *weak spirit*: at the same time, the remaining strong spirit, or *oil* as it is called, loses its black colour, and becomes clear; and this is the usual mark for discontinuing the distillation.

673. The spirit of vitriol is the most ponderous of all the liquids we are acquainted with; and the most powerful of the acids. If any other acid be united with a fixed alkaline salt or earth; upon the addition of the vitriolic, such acid will be dislodged, and arise on applying a moderate heat, leaving the vitriolic in possession of the alkali; though without this addition it would not yield to the most vehement fire. In medicine it is employed chiefly as subservient to other preparations: it is likewise not unfrequently mixed with juleps and the like, in such quantity as will be sufficient to give the liquor an agreeable tartness in the intentions of a cooling antiseptic, restraining, and stomachic.

674. *Sulphurated water, commonly called gas sulphuris.* *L.*

Take a quart of water, and half a pound of sulphur. Let part of the sulphur be set on fire in an iron ladle, and suspended over the water in a close vessel: as soon as the fumes subside, some more of the sulphur is to be fired in the same manner; and this repeated till the whole quantity is burnt.

This preparation is said to give relief in fits of the convulsive asthma. It is taken to the quantity of a spoonful or half an ounce, two or three times a day, in any suitable vehicle.

675. *Glauber's spirit of nitre.*

Take three pounds of nitre, and one pound of the strong spirit or oil of vitriol. Mix them cautiously and gradually together under a chimney; and then distil at first with a gentle, and afterwards with a stronger heat. *L.*

Put two pounds of nitre into a glass retort; and add  
by

by degrees one pound of oil of vitriol diluted with an equal quantity of warm water. Distil in a sand-heat, gradually increased, till the matter remains dry.

—This spirit is rectified by a second distillation with the heat of a water-bath, in a glass cucurbit, with its head and receiver; the phlegm arises, leaving the spirit behind. *E.*

The acid of nitre is next in strength to the vitriolic, and dissolves all but that from alkaline salts or earths. It differs from all the other acids in desagrating with inflammable matters: if a solution of any inflammable substance, as hartshorn, &c. in this acid be set to evaporate; as soon as the matter approaches to dryness, a violent detonation ensues. The chief use of this acid is as a menstruum for certain minerals, and as the basis of some particular preparations, of which hereafter. It has been given likewise diluted, with any convenient vehicle, as a diuretic, from 10 to 50 drops.

#### 676. *Glauber's spirit of sea-salt.*

Two pounds of sea-salt, and the same quantity of strong spirit or oil of vitriol. Dilute the acid spirit with a pint of water, and pour this mixture, by little and little, on the salt under a chimney; then distil, at first with a gentle, and afterwards with a stronger fire. *L.*

The spirit of sea-salt is the weakest of the mineral acids, but stronger than any of the vegetable; it requires a greater fire to distil it than that of nitre, yet is more readily dissipated by the action of the air. It is used chiefly as a menstruum for the making of other preparations; sometimes likewise it is given, properly diluted, as an antiphlogistic, aperient, and diuretic, from 10 to 60 or 70 drops.

#### 677. *Aqua fortis. L.*

Take of nitre, green vitriol uncalcined, each three pounds; the same vitriol calcined, one pound and a half. Mix them well together, and distil with a very strong fire, as long as any red vapour arises. *L.*

Here the direction of thoroughly mixing the ingredients ought to be well attended to, for if this is neglected, or but slightly performed, the due quantity of acid will not be obtained. The produce of these processes is a spirit of nitre containing so much more phlegm, or watery moisture, than Glauber's spirit, as the vitriol employed in its preparation does more than an equivalent quantity of oil of vitriol.

The great demand which there is in sundry businesses for aquafortis has occasioned the preparation of it to become a trade by itself. Hence larger and less expensive instruments than those mentioned above, have been contrived. The common distilling vessel is a large iron pot, with an earthen, or stone-ware still-head, to which is adapted a large glass globe, or else a jar made of the same kind of clay as the head. The workmen are not at the trouble either of drying the vitriol, or pounding the nitre, but throw them both promiscuously into the pot, where the fire soon liquefies and mixes them together. The aquafortis prepared after this manner is extremely impure, and utterly unfit for many purposes, such in particular are the solutions of mercury and of silver; the violence of the fire, employed in the operation, never fails to elevate some of the metallic parts of the vitriol; the nitre is used rough or unrefined, which containing a portion of sea-

salt, sends over some of the marine along with the nitrous acid; nor are the ingredients free from bits of wood, or other vegetable matters, which burning in the process foul the spirit with an empyreumatic oil, giving it, at the same time, an high colour. If therefore common aquafortis be employed in any medicinal preparation, it ought to be previously purified: the most effectual method of doing which is the following.

#### 678. *Purified aquafortis.*

Drop into the aquafortis a drop or two of solution of silver. If it becomes milky or cloudy, drop in a little more of the solution, till a fresh addition occasions no further change; allowing proper intervals for the white matter to settle, that the effect of a new addition may be the better perceived. Then pour the liquor into a glass retort, and distil in a sand-heat to dryness.

The milkiness produced by the solution of silver is a certain mark of marine or vitriolic acid in the aquafortis; the silver absorbing those acids, and forming with them a concrete which the liquor is incapable of holding dissolved. If the aquafortis is not made at all cloudy by this solution, we may be certain of its having been previously free from the least admixture of those heterogeneous acids; and when it ceases to become milky from a fresh addition, we may be equally certain, that how much soever it might have contained of them at first, they are now perfectly separated.

The solution of silver is to be made in aquafortis already purified. Where this cannot be had, the little quantity generally sufficient for the present purpose, may be made in the common impure sort of aquafortis, which will be purified during the dissolution itself. Put a thin bit of silver into a little of the aquafortis, and set the vial in a sand-heat; if the aquafortis is pure, numerous minute bubbles will issue from the silver on all sides, and the metal will gradually dissolve without altering the transparency of the liquor; but if the aquafortis contains marine or vitriolic acid, it will quickly become milky, those acids uniting with the silver, as in the above process, as fast as the nitrous acid dissolves it. As the white matter precipitates upon, and adheres to, the surface of the silver, so as to impede the further action of the menstruum; the liquor must be filtered, and treated in the same manner with a bit of fresh silver: if any milkiness still ensues, the operation must be repeated with another piece of the metal, till all the foreign acids are separated, and the silver is found to dissolve clear. Good aquafortis takes up about half its own weight of silver.

Instead of all these operose preparations, however, the Edinburgh college now order only a weak nitrous acid, composed of equal parts of strong spirit of nitre and water.

#### 679. *Distilled vinegar, or spirit of vinegar.*

Let vinegar be distilled with a gentle heat as long as the drops fall free from an empyreuma. If some part of the spirit which comes over first be thrown away, the rest will be the stronger. *L.*

Distil a gallon of vinegar in glass vessels, throwing away the first two pounds of produce. The next four pounds are to be kept as spirit of vinegar; and the remainder, as being empyreumatic, kept for other purposes. *E.*

680. This process may be performed either in a common

mon still with its head, or in a retort. The better kinds of wine-vinegar should be made use of: those prepared from malt-liquors, however fine and clear they may seem to be, contain a large quantity of a viscons substance, as appears from the sliminess and ropiness to which they are very much subject; this not only hinders the acid parts from arising freely, but likewise is apt to make the vinegar boil over into the recipient, and at the same time disposes it to receive a disagreeable impression from the fire. And indeed, with the best kind of vinegar, if the distillation be carried on to any great length, it is extremely difficult to avoid an empyreuma. The best method of preventing this inconvenience is, if a retort be made use of, to place the sand but a little way up its sides; and, when somewhat more than half the liquor is come over, to pour on the remainder a quantity of fresh vinegar equal to that of the liquor drawn off: this may be repeated three or four times; the vinegar supplied at each time being previously made hot: the addition of cold liquor would not only prolong the operation, but also endanger breaking the retort. If the common still is employed, it should likewise be occasionally supplied with fresh vinegar, in proportion as the spirit runs off; and this continued, until the process can be conveniently carried no farther: the distilled spirit must be rectified by a second distillation in a retort; or glass alembic; for though the head and receiver be of glass or stone-ware, the acid will contract a metallic taint from the pewter worm.

The residuum of this process is commonly thrown away as useless, though, if skillfully managed, it might be made to turn to good account; the most acid parts of the vinegar still remaining in it. Mixed with about three times its weight of fine dry sand, and committed to distillation in a retort, with a well-regulated fire, it yields an exceeding strong acid spirit, together with an empyreumatic oil, which taints the spirit with a disagreeable odour. This acid is nevertheless, without any rectification, better for some purposes (as a little of it will go a great way) than the pure spirit; particularly for making the sal diureticus of the London dispensatory; for there the oily matter, on which its ill flavour depends, is burnt out by the calcination.

681. The spirit of vinegar is a purer and stronger acid than vinegar itself, with which it agrees in other respects. The medical virtues of these liquors may be seen in the *Table of MATERIA MEDICA*. Their principal difference from the mineral acids consists in their being milder, less stimulating, less disposed to affect the kidneys and promote the urinary secretions, or to coagulate the animal juices.

#### § 5. COMBINATION OF ACID with VINOUS SPIRIT.

682. All the mineral acids, on being mixed with spirit of wine, raise a great ebullition and heat. If the acid is in a small quantity, it unites intimately with the vinous spirit, so as to arise with it in distillation. The taste and all the characters of acidity are destroyed; and the mixture acquires a grateful flavour, which neither of the ingredients had before.

##### 683. *Vitriolic ether.* E.

Take of rectified spirit of wine, 32 ounces by weight; oil of vitriol, one pound. Put the spirit into a glass

retort capable of bearing a sudden heat, and pour in the acid in a continued stream. Mix the two together by agitating them gently, but frequently; distil immediately in a sand-bath previously made hot, into a receiver cooled with water or snow. The fire in the mean time must be regulated in such a manner that the liquor must begin to boil as soon as possible, and continue to do so till 16 ounces by weight have come over. To the distilled liquor add two drams of the sharpest common caustic; then distil again out of a very high retort, and with a very gentle heat, into a very cold receiver, till 10 ounces by weight have come over.

##### 684. *Dalciſed ſpirit of vitriol.*

Mix two parts by weight of rectified spirit of wine with one part of vitriolic ether. E.

Take of the strong spirit or oil of vitriol, one pound; of rectified spirit of wine, one pint. Cautiously mix them together by little and little at a time, and distil the mixture, with a very gentle heat, till a black froth begins to arise: then immediately remove the whole from the fire, lest this froth should pass over into the recipient, and frustrate the operation. L.

When the method of making this spirit recommended by the London pharmacopœia is adopted, a good deal of caution is requisite in mixing the two liquors. Some direct the spirit of wine to be put first into the retort, and the oil of vitriol to be poured upon it all at once; a method of procedure by no means advisable, as a violent heat and ebullition always ensue, which not only dissipate a part of the mixture, but hazard also the breaking of the vessel, to the great danger of the operator. Others put the oil of vitriol into the retort first; then by means of a funnel, with a long pipe that may reach down just to the surface of the acid, pour in the spirit of wine: if this is done with sufficient caution, the vinous spirit spreads itself on the surface of the oil of vitriol, and the two liquors appear distinct: on standing for a week or two, the vinous spirit is gradually imbibed without any commotion, and the vessel may then be safely shaken, to complete the mixture; but if the spirit is poured in too hastily at first, or if the vessel is moved before the two liquors have in some degree incorporated, the same effect ensues as in the foregoing case. The most secure way is, to add the oil of vitriol to the spirit of wine by a little quantity at a time, waiting till the first addition is incorporated before another quantity is put in: by this management, the heat that ensues is inconsiderable, and the mixture is effected without any inconvenience.

The distillation should be performed with an equable and very gentle heat, and not continued so long as till a black froth begins to appear; for before this time a liquor will arise of a very different nature from the spirit here intended. The several products are most commodiously kept apart by using a tubulated receiver, so placed, that its pipe may convey the matter which shall come over into a vial set underneath; the juncture of the retort and recipient is to be luted with a paste made of linseed meal, and further secured by a piece of wet bladder: the lower juncture may be closed only with some soft wax, that the vial may be occasionally removed with ease.

The true dulcified spirit arises in thin subtle vapours, which

which condense upon the sides of the recipient in straight stræ. It is colourless as water, very volatile, inflammable, of an extremely fragrant smell, in taste somewhat aromatic.

After the fire has been kept up for some time, white fumes arise, which either form irregular stræ, or are collected into large round drops like oil: on the first appearance of these, the vial (or the receiver, if a common one is made use of) must be taken away. If another be substituted, and the distillation continued, an acid liquor comes over of an exceeding pungent smell, like the fumes of burning brimstone. At length a black froth begins hastily to arise, and prevents our carrying the process further.

On the surface of the sulphureous spirit is found swimming a small quantity of oil, of a light yellow colour, a strong, penetrating, and very agreeable smell. This oil seems to be nearly of the same nature with the essential oils of vegetables. It readily and totally dissolves in rectified spirit of wine, and communicates to a large quantity of that menstruum the taste and smell of the aromatic or dulcified spirit.

The matter remaining after the distillation is of a dark blackish colour, and still highly acid. Treated with fresh spirit of wine, in the same manner as before, it yields the same productions; till at length, all the acid that remains unvolatilized being satiated with the inflammable oily matter of the spirit, the compound proves a bituminous, sulphureous mass: which, exposed to the fire in open vessels, readily burns, leaving a considerable quantity of fixed ashes; in close ones, explodes with violence; and with fixed alkaline salts, forms a compound scarcely similar to one composed of alkalies and sulphur.

Dulcified spirit of vitriol has been for some time greatly esteemed both as a menstruum and a medicine. It dissolves some resinous and bituminous substances more readily than spirit of wine alone, and extracts elegant tinctures from sundry vegetables; especially if rectified, from a little fixed alkaline salt, to separate any redundant acidity. As a medicine, it promotes perspiration and the urinary secretion, expels flatulencies, and in many cases abates spasmodic strictures, eases pains, and procures sleep: the dose is from 10 to 80 or 90 drops in any convenient vehicle. It is not essentially different from the celebrated anodyne liquor of Hoffman; to which it is, by the author himself, not unfrequently directed as a succedaneum.

The ether or ethereal spirit is the lightest, most volatile, and inflammable, of all known liquids. It is lighter than the most highly rectified spirit of wine, in the proportion of about seven to eight: a drop let fall on the hand evaporates almost in an instant, scarcely rendering the part moist. It does not mix, or only in a small quantity, with water, spirit of wine, alkaline lixivis, volatile alkaline spirits, or acids; but is a powerful dissolvent for oils, balsams, resins, and other analogous substances. Its medical effects are not as yet much known, though it is not to be doubted that a fluid of so much subtlety must have considerable ones. It has often been found to give ease in violent headaches, by being applied externally to the part; and to relieve the toothach, by being laid on the afflicted jaw. It has been given also internally, with benefit, in

VOL. VIII.

1

whooping coughs and hysterical cases, from two or three drops to five and twenty, in a glass of wine or water, which should be swallowed as quick as possible, as the ether so speedily exhales.

### 685. *Dulcified spirit of nitre.*

Take a quart of rectified spirit of wine, and half a pound of Glauber's spirit of nitre. Mix them, by pouring the nitrous spirit into the other; and distil with a gentle heat, as long as the liquor which comes over does not raise any effervescence with lixivial salts. *L.*

Put three parts of rectified spirit of wine into a large bolt-head, and gradually add thereto one part of spirit of nitre. Digest them together for seven days, and then distil in a water-bath as long as any spirit comes over. *E.*

Here the operator must take care not to invert the order of mixing the two liquors, by pouring the vinous spirit into the acid; for if he should, a violent effervescence and heat would ensue, and the matter be dispersed in highly noxious red fumes. The most convenient and safe method of performing the mixture seems to be, to put the inflammable spirit into a large glass body with a narrow mouth, placed under a chimney, and to pour upon it the acid by means of a glass funnel, in very small quantities at a time; shaking the vessel as soon as the effervescence ensuing upon each addition ceases, before a fresh quantity is put in: by this means the glass will heat equally, and be prevented from breaking. During the action of the two spirits upon one another, the vessel should be lightly covered; if close stopped, it will burst; and if left entirely open, some of the more valuable parts will exhale.

The liquors, mixed together, should be suffered to rest for at least twelve hours, that the fumes may entirely subside, and the union be in some measure completed. The distillation should be performed with a very slow and well regulated fire; otherwise the vapour will expand with so much force as to burst the vessels. Wilson seems to have experienced the justness of this observation; and hence directs the juncture of the retort and receiver not to be luted, or but slightly; if a tubulated recipient, with its upright long pipe, be made use of, and the distillation performed with the heat of a water-bath, the vessels may be luted without any danger. This method has likewise another advantage, as it ascertains the time when the operation is finished. Examining the distilled spirit every now and then with alkaline salts, as directed above, is sufficiently troublesome; whilst in a water-bath we may safely draw over all that will arise, for this heat will elevate no more of the acid than what is dulcified by the vinous spirit.

Dulcified spirit of nitre has been long held, and not undeservedly, in great esteem. It quenches thirst, promotes the natural secretions, expels flatulencies, and moderately strengthens the stomach: it may be given from twenty drops to a dram in any convenient vehicle. Mixed with a small quantity of spirit of hartshorn, the *spiritus volatilis aromaticus*, or any other alkaline spirit, it proves a mild yet efficacious diaphoretic, and often notably diuretic; especially in some febrile cases, where such a salutary evacuation is wanted.

ed. A small proportion of this spirit added to malt-spirits, gives them a flavour approaching to that of French brandy.

### § 6. NEUTRAL SALTS.

686. WHEN any acid and any alkaline salts are mixed together, in such proportion that neither of them may prevail, they form by their coalition a new compound, called *neutral*. In all the combinations of this kind, (except some of those with vegetable acids), the alkali and acid are so strongly retained by one another, that they are not to be disunited by any degree of fire. How volatile soever the acid was by itself, if combined with a fixed alkali, it proves almost as fixed as the pure alkali: if the alkali is of the volatile kind, the compound proves also volatile, subliming in its whole substance, without any separation of its parts. There are, however, means of procuring this disunion by the intervention of other bodies, as we have already seen in the separation of the volatile alkali of sal ammoniac, and of the acids of nitre and sea-salt: but in all cases of this kind, only one of the ingredients of the neutral salt can possibly be obtained by itself, the separation of this happening solely in virtue of the superadded body uniting with the other.

There is another kind of compound salts, formed by the coalition of acids with earthy and metallic bodies. These salts differ from the true neutral ones in several obvious properties; some of them change blue vegetable juices to a green like alkalies, and others to a red like acids, while neutral salts make no change in the colour: mixed with boiling milk, they coagulate it, while neutral salts rather prevent its coagulation: from most of them the acid is disunited by fire, without the intervention of any additional matter, of which we have seen an instance in the distillation of the acid of vitriol: but the most distinguishing and universal character of these salts is, that solutions of them, on the addition of any fixed alkali, grow turbid, and deposit their earth or metal. It were to be wished, that custom had appropriated some particular name to the salts of this class, to prevent their being confounded, which several of them have often been, with the perfect neutral salts.

The following table exhibits, at one view, the several compound salts resulting from the union of each of the pure acids with each of the common alkalies and soluble earths; the acids being placed on the top, the alkalies and earths on the left hand, and the compound salts in the respective intersections; and is thus to be understood. In the upright columns, under each of the acids, are seen the several compound salts resulting from the union of that acid with the respective alkalies and earths on the left side. In the transverse columns, opposite to each particular alkali and earth, are seen the compound salts resulting from the union of that alkali or earth with the respective acids on the top; and conversely of each of the compound salts expressed in the table, the component parts are found on the top of the upright column, and on the left side of the transverse column, in whose intersection that particular salt is placed.

Soluble earths of clay.	Magnesia.	Calcareous Earth.	Volatile alkali.	Acetic of sea salt.	Common fixed alkali.	Prepara- tions.		
						VITRIFIC ACID.	NITROUS ACID.	MARINE ACID.
Alum.	Sal carboni- cus amarus.	Selenites.	Phosphoric sal ammon.	Glauber's salt.	Unstated tartar.	Common nitre.	Repetrated sea-salt.	Sal diure- ticus.
		Calcareous nitre.	Volatile nitre.	Cubical nitre.		Sea-salt.	A salt similar to sal diuretic.	
		Calcareous marinate salt.	Sal ammo- niac.					
		A (barytes- gent salt).	Serpi- naceous Madder-salt.					
Astringent salts, not distinguished by any particular name.								

### 687. Crystallization of salts.

This is a general operation on neutral and most of the other compound salts. It depends upon these principles: that water, of a certain degree of heat, dissolves, of any particular salt, only a certain determinate quantity: that, on increasing the heat, it dissolves more and more (except only in one instance, common salt) till it comes to boil; at which time, both its heat and dissolving power are at their height: that, in returning to its first temperature, it throws off again all that the additional heat had enabled it to dissolve: that, independently of any increase or diminution of heat, a gradual evaporation of the fluid itself will occasion a proportional separation of the salt; and that the particles of the salt, in this separation from the water, unless too hastily forced together by sudden cooling or strong evaporation, or disturbed by external causes, generally concrete into transparent and regularly figured masses, called *crystals*. The several salts assume, in crystallization, figures peculiar to each: thus the crystals of nitre are hexagonal prisms; those of sea-salt, cubes; those of alum, octohedral masses; while sal ammoniac shoots into thin fibrous plates like feathers.

The use of preparing salts in a crystalline form, is not merely in regard to their elegance, but as a mark of, and the means of securing, their purity and perfection. From substances not dissoluble in water, they are purified by the previous solution and filtration; by crystallization, one salt is purified from an admixture of such other saline bodies as dissolve either more easily or more difficultly than itself. For if two or more salts be dissolved together in a certain quantity of hot water, the salt which requires the greatest heat for its solution in that quantity of water, will first begin to separate

separate in cooling; and if the water is kept evaporating in an uniform heat, the salt which requires most water in that heat will be the first in crystallizing. In all cases of this kind, if the process is duly managed, the first shootings are generally well figured and pure; the succeeding ones, sooner or later, according to the quantity of the other salts in the liquor, retain an admixture of those salts, which they betray by their smallness and by their figure.

In order to the crystallization of saline solutions, it is customary to boil down the liquor till so much of the fluid has exhaled, as that the salt begins to congregate from it even while hot, forming a pellicle upon the surface exposed to the air; when this mark appears, the whole is removed into a cold place. This method seldom affords perfect crystals; for when water is thus saturated with the salt in a boiling heat, and then suddenly cooled, the particles of the salt run hastily and irregularly together, and form only a confused semitransparent mass. It is by slow concretion that most salts assume their crystalline form in perfection. The evaporation should be gentle, and continued no longer than till some drops of the liquor, in a heat below boiling, being let fall upon a cold glass plate, discover crystalline filaments: the liquor is then immediately to be removed from the fire into a less warm, but not a cold place; and the vessel covered with a cloth, to prevent the access of cold air, and the formation of a pellicle, which, falling down thro' the fluid, would disturb the regularity of the crystallization. This is the most effectual method for most salts; though there are some whose crystallization is to be effected, not by an abatement of the heat, but by a continued equable evaporation of the fluid; such in particular is sea-salt.

Salts retain in crystallization a portion of the aqueous fluid, without betraying any marks of it to the eye: on this their crystalline form appears in great measure to depend. The quantity of phlegm or water varies in different salts: dry crystals of nitre were found, on several careful trials, to contain about one twentieth of their weight; those of alum, one sixth; sea-salt, one fourth; borax, green vitriol, and the purging-salts, no less than one half. The same salt appears always to retain nearly the same quantity.

Some salts dissolve in spirit of wine: and here also, as in water, the solution is limited, though the salt is not easily recovered in a crystalline form. Such in particular are combinations of the nitrous acid with volatile alkalies, and with calcareous earths; of the marine acid with all the soluble earths; of the acetic acid with fixed and volatile alkalies. Scarce any of the compound salts, whose acid is the vitriolic, are affected by vinous spirits.

Salts differ greatly in their disposition to assume and retain a crystalline form. Many, even of the compound kind, imbibe humidity like fixed alkalies, so as to crystallize with difficulty; and when crystallized, or exsiccated by heat, to deliquesce again in the air. Such are the combinations of the nitrous and marine acid with all the soluble earths, and of the acetic acid with earths and alkalies. The vitriolic acid, on the other hand, forms, with all the substances it dissolves, permanent crystals; as do likewise the other mineral acids with all alkalies.

The crystallization of those salts, which are not dissolvable in spirit of wine, is generally promoted by a small addition of that spirit; which, absorbing the water, or weakening its dissolving power on the salt, disposes the salt to part from it more freely. The operator must be careful, however, not to add too much of the spirit, especially where the salt is composed of an earthy or metallic body united with the acid; lest it absorb the acid as well as the water, and, instead of a gradual and regular crystallization, hastily precipitate the earth or metal in a powdery form.

Mr Rouelle, of the French Academy of Sciences, has examined with great attention the phenomena of the crystallization of salts, and published the result of his observations in different volumes of the *Memoirs of that academy*. Among other curious particulars, he has given a general distribution of salts, in regard to their crystallization, which will be of practical utility to the artist.

He divides evaporation into three degrees: *insensible evaporation*, or that effected by the natural warmth of the atmosphere, from freezing, up to the heat of the summer's sun; *mean evaporation*, commencing with the sun's heat, and extending to that in which the exhaling steam is visible to the eye, and the liquor too hot to be endured by the hand; and *strong evaporation*, reaching from this period to boiling. He divides salts into six classes; the distinctions of which are taken from the degree of evaporation in which they crystallize most perfectly, from the figure of their crystals, their disposition to remain single or unite into clusters, and their receiving an increase from a continuance of the crystallization.

I. The first class consists of salts which crystallize into small plates or very thin scales. The crystals are single. They are, of all salts, those which crystallize most frequently on the surface of their solutions, which retain least water in their crystals, and require most to dissolve in. They crystallize most perfectly by insensible evaporation.

II. Salts whose crystals are cubes, cubes with the angles truncated, or pyramids of four or six sides. They form single, and change their figure by new accretions. By insensible evaporation they crystallize at the bottom, by mean evaporation at the surface, and by both kinds they prove perfect and regular: by strong evaporation the liquor contracts a pellicle, and in cooling yields few crystals, and those ill figured.

III. Salts whose crystals are tetrahedral, pyramidal, parallelopipedes, rhomboidal, and rhomboidal parallelopipedes; with the angles variously truncated according to different circumstances. They form single (except that some few unite by the bases), and change their figure by new accretions. They crystallize at the bottom, most perfectly by insensible evaporation: by mean and strong evaporation the liquor contracts a pellicle, and in cooling the crystals adhere to the pellicle, and prove confused and ill formed. They retain a large quantity of water.

- IV. Salts whose crystals are flattened parallelepipeds, with the extremities terminating in two surfaces inclined to one another, so as to form a point and acute angles with the large sides. They cluster together, uniting by the bases into tufts. The crystals are largest and most regular by insensible evaporation: by mean and hasty evaporation, a pellicle is formed, and in cooling the crystals prove very small. They retain a large quantity of water in crystallization, and require little to dissolve in.
- V. Salts whose crystals are very long, in form of needles, prisms, or columns of different surfaces. They shoot at the bottom, and cluster together into tufts of regular figures. By insensible evaporation they scarce ever crystallize well. By mean and strong evaporation they give a pellicle; and in slow cooling, if the evaporation was not carried too far, they yield perfectly well formed crystals, which at first swim, but soon fall to the bottom. If the evaporation was too long continued, the crystals prove confused and ill formed.
- VI. Salts whose crystals are in very small needles, or of other indeterminate figures. None of them crystallize by insensible evaporation, and few of them by the mean degree. They require to be reduced by strong evaporation to a thick confidence: they then contract a pellicle, and crystallize with confusion. If the crystals are wanted regular, spirit of wine must be used, or some other medium if the salt is soluble in spirit. They readily dissolve in water, and liquefy in the air.

688. *Purified nitre.* L.  
Boil nitre in water till it is dissolved; filter the solution through paper; and then, after due evaporation, set it by in a cold place, that the nitre may shoot into crystals.

Common nitre contains usually a considerable proportion of sea-salt; which in this process is separated, the sea-salt remaining dissolved after greatest part of the nitre has crystallized. The crystals which shoot after the first evaporation, are large, regular, and pure; but when the remaining liquor is further evaporated, and this repeated a second or third time, the crystals prove at length small, imperfect, and tipped with little cubical globes of sea-salt.

When rough nitre, in the state wherein it is first extracted from the earths impregnated with it, is treated in this manner, there remains at last a liquor, called *mother-ley*, which will no longer afford any crystals. This appears to participate of the nitrous and marine acids, and to contain an earthy matter dissolved by those acids. On adding alkaline lixivium, the earth is precipitated; and when thoroughly washed with water, proves insipid. If the liquor may be evaporated to dryness, a bitterish saline matter is left; which being strongly calcined in a crucible, parts with the acids, and becomes, as in the other case, insipid.

This earth has been celebrated as an excellent purgative, in the dose of a dram or two; and, in smaller doses, as an alterant in hypochondriacal and other disorders. This medicine was for some time kept a great

secret, under the names of *magnesia alba*, *nitrous panacea*, *count Palmer's powder*, *il polvere albo Romano*, *podre de Sentinelli*, &c. till Lancioli made it public in his notes on the *Metallotheca Vaticana*. It has been supposed that this earth is no other than a portion of the lime commonly added in the elixation of nitre at the European nitre-works: but though the specimens of magnesia examined by Neumann, and some of that which has lately been brought hither from abroad, gave plain marks of a calcareous nature; yet the true magnesia must be an earth of a different kind, calcareous earths being rather astringent than purgative. The earthy basis of the *sal catharticus amarus*, is found to have the properties ascribed to the true magnesia of nitre, and appears to be the very same species of earth: from that fact therefore this medicine is now prepared, as will be seen hereafter.

#### 689. *Purified sal ammoniac.* L.

This salt is purified by solution in water, filtration, and crystallization, after the manner above directed for nitre.

The impurities of sal ammoniac are commonly such as will not dissolve in water; and hence the purification is effected by the solution and filtration. The very last crystals seldom betray an admixture of any other salt.

#### 690. *Purified white vitriol, commonly called gilla of vitriol.* E.

Take eight ounces of white vitriol, half an ounce of filings of zinc; water, one pound. Digest with a gentle heat for some hours; then filter the liquor, and set it to crystallize.

#### 691. *Salt of vitriol.* L.

Take of white vitriol, one pound; strong spirit (called *oil*) of vitriol, one ounce by weight; water, as much as is sufficient. Boil them together till the vitriol is dissolved; then filter the liquor; and after due evaporation, set it by in a cold place to crystallize.

Here the intention is not to separate the ochery matter of the vitriol, but to prevent its separating and colouring the crystals. This is effectually answered by the addition of the acid, by which it is kept dissolved.

#### 692. *Burnt alum.* L. E.

Let alum be calcined in an iron or earthen vessel, so long as it bubbles and swells up.

The bubbling or blistering proceeds from the phlegm retained in the crystals: after that is expelled, the salt cannot be made liquid by any degree of fire. Alum is composed of vitriolic acid and an earth; and it is remarkable, that combinations of that acid with all earths, with most metals, and even with vegetable fixed alkalies, are unfusible.

The alum, thus deprived of its phlegm, proves considerably stronger, and more acrid, inasmuch as it is sometimes employed for consuming fungous flesh: it is said to have an inconvenience of leaving a hardness upon the part.

#### 693. *Calcined vitriol.*

Let green vitriol be calcined in an earthen vessel, with an

**Preparations.** an open fire, till it becomes thoroughly dry; then breaking the vessel, take out the vitriol, and set it by for use, well closed from the air. The vitriol is sufficiently calcined, if it has acquired a red colour at the sides and bottom of the vessel. *Z.*

This process succeeds tolerably well for small quantities, but does not answer so perfectly for larger. As the action of the fire is exerted first on the external parts of the mass, these will be calcined first, and, where the quantity is large, exhibit the mark of sufficient calcination, whilst the internal part remains almost unchanged: and even if the process is still farther continued, the effect required will not be produced; for the outside growing first hard, prevents the evaporation of the aqueous parts from within.

Expose any quantity of powdered green vitriol, in an unglazed earthen vessel, to the action of a moderate fire, till it becomes white. *E.*

This method is sufficiently troublesome: for unless the heat be very gentle, and the matter spread very thin over the bottom of a broad shallow vessel, it is almost impossible to avoid melting it, which makes it adhere to the sides of the pan, and renders the previous pulverisation an useless labour.

The method usually practised by the chemists is, to place a deep earthen pan, with some vitriol in it, upon a gentle fire; the vitriol soon liquefies, boils up, and by degrees incrustates to the sides of the vessel: some more vitriol is then thrown in and suffered to incrustate in the same manner; and this procedure repeated till the pan is nearly full of the concreted matter, which proves of a whitish colour, except on the outside next the pan (which must be broken to take it out), where it appears yellowish or reddish, according to the continuance and degree of fire. If the vitriol be desired still farther dephlegmated, this may be commodiously effected, by reducing the mass into a gross powder (which will now no longer melt); and then calcining it over a strong fire, in a shallow iron pan, till it has gained the degree of dryness required, which may be known from its colour.

#### 694. *Vitriolated tartar.*

Dissolve eight ounces of green vitriol in four pints of boiling water: and whilst the liquor continues boiling, throw into it salt of tartar, or any other alkaline salt, till no farther effervescence arises upon a fresh addition; which generally happens when four ounces, or a little more, of the salt have been used. Filter the liquor thro' paper, and after due evaporation set it by to crystallize. *E.*

Here the acid of the vitriol forsakes the iron, which it was before in possession of, to unite with the alkaline salt: particular care ought to be had that the quantity of alkali be sufficient to fully saturate the acid, otherwise it will not deposit all the metal. It is convenient, even after the saturation seems, from the effervescence ceasing, to be completed, to throw in a little more of the alkali: for by this means the preparation is secured from containing any metallic matter; whilst the superfluous quantity of alkali can do no prejudice, as it remains uncrystallized.

It is remarkable, that although the vitriolic acid and fixed alkaline salt do each readily unite with wa-

ter, and strongly attract moisture even from the air; yet the neutral salt resulting from the combination of these two, vitriolated tartar, is one of the salts most difficult of solution, very little of it being taken up by cold water. Hence some have directed the liquor in this process to be filtered whilst very hot, suspecting, that if it was suffered to cool, great part of the salt would be thrown off and left upon the paper. The college, however, have avoided this inconvenience, by ordering a quantity of water which is found to be sufficient for keeping the salt dissolved in the cold or at least in a moderate warmth.

Take oil of vitriol diluted with equal its quantity of warm water; put it into a large glass vessel, and gradually drop into it a solution of purified potash in twice its quantity of water, till the effervescence ceases. Then filter the liquor, evaporate it till a pellicle appears upon the surface, and set it by in a cold place to crystallize. *E.*

This is an elegant, and one of the least troublesome ways of preparing this salt. The Edinburgh college, in former editions, ordered the acid liquor to be dropped into the alkaline: by the converse procedure, now received, it is obviously more easy to secure against a redundancy of acidity: for the greater certainty in this point, it may be expedient, as in the foregoing process, to drop in a little more of the alkaline ley than the cessation of the effervescence seems to require.

But though the manner of preparation, here directed, appears to be the most commodious, there is one imperfection in the process, a deficiency in the quantity of water. There is not near water enough to keep vitriolated tartar dissolved; and of consequence, as salt as the alkaline salt is neutralized by the acid, great part falls to the bottom in a powdery form. In the Leyden pharmacopoeia, this inconvenience is judiciously provided against: The oil of vitriol is diluted with four times its quantity of water; and the alkaline ley being gradually dropped into it till the point of saturation is obtained, four times the quantity of water is added, and the mixture boiled, that such part of the salt as had precipitated may be dissolved: the liquor is then filtered while hot, and set by to crystallize. In order to obtain perfect and well-formed crystals, the liquor should not be set in the cold, but continued in a moderate heat, such as the hand can scarcely bear, that the water may slowly evaporate.

Vitriolated tartar, in small doses, as a fruple or half a dram, is an useful aperient; in larger ones, as four or five drams, a mild cathartic, which does not pass off so hastily as the *sal catharticus anarus*, or *Glauber's salt*, and seems to extend its action further. The wholesale dealers in medicines have commonly substituted to it an article otherwise almost useless in their shops, the residuum of Glauber's spirit of nitre. The purchaser ought, therefore, to insist upon the salt being in a crystalline form. The crystals, when perfect, are oblong, with six flat sides, and terminated at each end by a six-sided pyramid: some appear composed of two pyramids joined together by the bases, and many are irregular.

#### 695. *Vitriolated nitre. L.*

Dissolve in warm water the mass which remains after the distillation of Glauber's spirit of nitre: filter  
the

**Preparations.**

Prepara-  
tions.

the solution through paper, and crystallize the salt.

This salt is not different from the *vitriolated tartar*, being composed of the vitriolic acid, and the alkaline basis of nitre; which alkali is no other than the common vegetable fixed alkaline salt, as salt of tartar or potash: it is, in effect, from the ashes of vegetables, that the nitre prepared in Europe receives its alkaline basis. If any unchanged nitre remains in the mass, it is left dissolved in the water while the vitriolated alkali crystallizes.

696. *Sal polychrestum, or salt of many virtues.*

Take of nitre in powder, flowers of sulphur, of each equal parts. Mingle them well together, and inject the mixture, by little and little at a time, into a red-hot crucible: after the deflagration ceases, keep the crucible in the fire for an hour. The salt may be purified by dissolving it in warm water, filtering the solution, and exhaling it to dryness; or by crystallization.

This is another method of uniting the vitriolic acid with the common vegetable fixed alkali. Both the nitre and the sulphur are decomposed in the operation: the acid of the nitre, and the inflammable principle of the sulphur, detonate together, and are dissipated; while the acid of the sulphur remains combined with the alkaline basis of the nitre. The shops accordingly have substituted to the *sal polychrest* the foregoing preparation.

697. *Sal prunelle. E.*

Take of pure nitre, reduced to powder, two pounds; flowers of sulphur, one ounce. Melt the nitre in a crucible, and sprinkle into it the sulphur by little at a time. When the deflagration is over, pour out the melted salt upon a clean, dry, and warm brass plate, so as to form it into cakes.

Those who prepare *sal prunell* in large quantities, make use of a clean iron pot instead of a crucible; and, when the nitre is melted, and the sulphur deflagrated, take out the salt with an iron ladle, and pour it into brass moulds kept for this purpose. The previous pounding of the nitre, directed above, may be as well omitted, as occasioning a needless trouble.

This preparation was formerly in great esteem, and is sometimes still ordered in prescription.

698. *The cathartic salt of Glauber, commonly called sal mirabile. L. E.*

Dissolve in warm water the mass which remains after the distillation of spirit of sea-salt: filter the solution, and crystallize the salt.

The title of this salt expresses its medical virtues. Taken from half an ounce to an ounce or more, it proves a mild and useful purgative; and in smaller doses, largely diluted, a serviceable aperient and diuretic. The shops frequently substitute to it the *sal catharticus amarus*, which is nearly of the same quality, but somewhat more unpleasant, and, as is said, less mild in operation: They are very easily distinguishable from one another, by the effect of alkaline salts upon solutions of them. The solution of Glauber's salt suffers no visible change from this addition, its own basis being a true fixed alkali: but the solution of

the *sal catharticus amarus* grows instantly white and turbid; its basis, which is an earth, being extricated copiously by the alkaline salt: as in the following process.

699, a. *Magnesia alba, or White magnesia. E.*

Dissolve *sal catharticus amarus* in a sufficient quantity of water. Filter the solution; and add to it a filtered ley of potash, so long as a fresh addition continues to occasion any milkiness. A white powder will precipitate; which, being separated from the liquor is to be boiled for some time in water, and afterwards dried.

This powder appears to be the same species of earth with that obtained from the mother ley of nitre (see n° 688.) which was for several years a celebrated secret in the hands of some particular persons abroad. Hoffman, who describes the preparation of the nitrous magnesia, gives it the character of an useful antacid, a safe and inoffensive laxative in doses of a dram or two, and diaphoretic and diuretic when given in smaller doses of fifteen or twenty grains. Since this time it has had a considerable place in the practice of foreign physicians, and now begins to come into esteem among us, particularly in heartburns, and for preventing or removing the many disorders which children are so frequently thrown into from a redundancy of acid humours in the first passages: it is preferred, on account of its laxative quality, to the common absorbents, which (unless gentle purgatives are given occasionally to carry them off) are apt to lodge in the body, and occasion a coliciveness very detrimental to infants.

Though the preparation of this medicine is now commonly known, its nature and properties are very little understood: whilst some suppose it to possess uncommon virtues, others affirm, that, when duly edulcorated, it is in no respect different from calcined hartshorn, or any other simple animal or vegetable earth. The following observations of its real properties will be sufficient to determine this point.

*Magnesia alba*, when prepared in perfection, is a white and very subtile earth, perfectly void of smell or taste, of the class of those which dissolve in acids. It dissolves freely, even in the vitriolic acid; which, in the common way of making solutions, takes up only an inconsiderable portion of other earths. Combined with this acid, it forms a bitter salt, very easily soluble in water; while the common absorbents form with the same acid almost insipid concretes, very difficult of solution. Solutions of magnesia in all acids are bitter and purgative; while those of the other earths are more or less astringent and altringent. A large dose of the magnesia, if the stomach contains no acid to dissolve it, does not purge or produce any sensible effect: a moderate one, if an acid is lodged there, or if acid liquors are taken after it, procures several stools; whereas the common absorbents, in the same circumstances, instead of loosening, bind the belly. It is obvious, therefore, that magnesia is specifically different from the other earths, and that it is applicable to useful purposes in medicine.

699, b. *Burnt magnesia. E.*

Let any quantity of magnesia be put into a crucible, and

Prepara-  
tions.

and heated hot, in which state keep it for two hours; then take it out, and preserve it in a glass bottle well stoppered.

#### 700. *Cubical nitre.*

Dissolve chalk or lime in purified aquafortis; and add the solution by degrees to a solution of Glauber's salt in water, so long as a fresh addition produces any milkiness: a white powder will precipitate; after which the liquor is to be filtered, and, after due evaporation, set to crystallize.

In this process, both the solutions are decomposed, and two new compounds produced. The vitriolic acid of the Glauber's salt unites with the chalk; and forms with it an indissoluble selenitic concrete, which of course precipitates; while the alkali of the Glauber's salt, and the nitrous acid, unite into a neutral salt, which is separated from the liquor by crystallization; the crystals are rhomboidal, of a cooling taste, greatly resembling that of common nitre. How far this salt differs from common nitre in its medical virtue, is not known. The process is here inserted, partly as being a very instructive one in regard to the transpositions which happen on the mixture of different saline bodies, and partly as affording the most convenient means of obtaining the pure alkaline basis of sea-salt. In the distillation of spirit of salt, that basis was disunited from its own acid, and combined with the vitriolic: it is here transferred from the vitriolic to the nitrous; and in n° 644, we have given a method of dissipating or destroying the nitrous acid, and leaving the alkali, that was combined with it, pure.

#### 701. *Spirit of sea-salt coagulated. L.*

Drop, into Glauber's spirit of sea-salt, a ley of fixed alkaline salt, till all effervescence ceases; then evaporate the mixture to dryness.

This preparation is inserted, under the same title, in the Württemberg pharmacopœia. It has been commonly called *regenerated sea-salt*, though with little propriety, as it differs from that salt in its basis; the common vegetable alkali being here substituted to the mineral alkali of sea-salt. How far it differs from sea-salt in its medicinal qualities, hath not yet been determined: it is manifestly sharper in taste, and somewhat more difficult both of solution in water and of fusion in the fire.

#### 702. *Regenerated tartar. E.*

Put any quantity of dry salt of tartar, powdered, into a large glass vessel; and pour thereon, by little and little, as much distilled vinegar as is necessary to saturate it. Filter the liquor; and exhale it, over a very gentle fire, to dryness, taking great care that the matter contract not an empyreuma. On the salt which remains, pour as much more spirit of vinegar as will saturate it; then dehydrate the liquor again, and carefully exsiccate it into a dry salt.

If the common alkalies are made use of for this process, they should be previously purified, by solution and crystallization, from the neutral salt which they generally contain. The distilled vinegar may be perfectly free from any empyreumatic taint: it is not necessary to dephlegmate it, or throw away the first

runnings in the distillation, since these contain a portion of the acid (the part here wanted) as well as the phlegm.

It is difficult to hit the point of saturation betwixt the acetous acid and the alkaline salt. After about fourteen parts of strong distilled vinegar have been gradually poured upon one of the fixed salt, the addition of a little more of the acid will not occasion any further effervescence in the cold; but if the mixture be now strongly stirred and well heated, the effervescence will appear afresh; upon which some more vinegar is to be added, till it again ceases. The saturation is not as yet complete; for upon exhaling the aqueous parts, the remaining salt still effervesces with fresh vinegar. When so much of the acid has now been added, that no marks of fermentation any longer appear, a little more of the vinegar may be poured in before you proceed to the last evaporation; by this means, the saturation of the alkali will be secured, whilst, if the acid prevails, the superfluous quantity of it will exhale.

The salt thus prepared, is of a dark-brown colour, a peculiar, not ungrateful odour, a penetrating, faponaceous, saline taste, in nowise alkaline or acid. Its brown colour and faponaceous quality proceed from the oily parts of the vinegar; the depuration of the salt from this oil, is not in the foregoing process insisted on. In the London pharmacopœia, the salt is ordered to be purified to perfect whiteness, under the title of

#### 703. *Diuretic salt. L.*

Take a pound of any fixed alkaline salt; and boil it, with a very gentle heat, in four or five times its weight of distilled vinegar. When the fermentation ceases, add more distilled vinegar; and proceed with fresh additions thereof, until, the vinegar being almost evaporated, fresh vinegar will no longer raise any fermentation; which generally happens by the time that twenty pounds of distilled vinegar have been used. Then slowly exhale to dryness.—Melt the remaining impure salt for a little time, but not too long, over a gentle fire; then dissolve it in water, and filter the solution through paper. If the melting has been duly performed, the filtered liquor will be limpid and colourless as water; but if otherwise, of a brown colour.—Evaporate the limpid solution, with an exceeding gentle heat, in a shallow glass vessel; occasionally stirring the salt as it dries, that its moisture may be the sooner exhaled. Afterwards keep it for use in a vessel very closely stopped; for it will liquefy by the air.

This salt ought to be of perfect whiteness; and should totally dissolve both in water and in spirit of wine, without leaving any faeces. If the salt, though ever so white, deposits any faeces in spirit of wine; the whole of it must be dissolved in that spirit, the solution filtered, and exsiccated again.

The purification of this salt is not a little troublesome. The operator must be particularly careful in melting it, not to use too great a heat, or to keep it liquefied too long: a little should be occasionally taken out, and put into water; and as soon as it begins to part freely with its black colour, the whole is to be removed from the fire. In the last drying,

drying, the heat must not be so great as to melt it; otherwise it will not prove totally soluble. If the solution in spirit of wine be exsiccated, and the remaining salt liquefied with a very soft fire, it gains the leafy appearance which has procured it the name of *terra foliata*.

These salts are medicines of great efficacy, and may be so dosed and managed as to prove either mildly cathartic, or powerfully diuretic: few of the saline deobstruents come up to them in virtue. The dose is from half a scruple to a dram or two. A bare mixture of alkaline salt and vinegar without exsiccation, is not perhaps much inferior as a medicine to the more elaborate salt.

#### 704. *Spirit of Mindererus.* E.

Take any quantity of the volatile alkaline salt of sal ammoniac, and gradually power upon it distilled vinegar, till the effervescence ceases; occasionally stirring the mixture, to promote the action of the vinegar on the salt.

This is an excellent aperient saline liquor. Taken warm in bed, it proves commonly a powerful diaphoretic or sudorific; and as it operates without heat, it has place in febrile and inflammatory disorders, where medicines of the warm kind, if they fail of procuring sweat, aggravate the distemper. Its action may likewise be determined to the kidneys, by walking about in a cool air. The common dose is half an ounce, either by itself, or along with other medicines adapted to the intention. Its strength is not a little precarious, depending in great measure on that of the vinegar; an inconvenience which cannot easily be obviated, for the saline matter is not reducible to the form of a concrete salt.

#### § 7. ANOMALOUS SALTS.

##### 705. *Crytals of tartar.*

Let powdered white tartar be boiled in twenty times its quantity of water, till perfectly dissolved; and the solution, whilst it continues hot, passed through filtering paper, or a woollen cloth, and received in a wooden vessel: then expose it for a night or longer to the cold air, that crytals may form themselves, and shoot to the sides of the vessel: the water being now poured off, the crytals are to be collected and dried for use.

The filtration of the solution of tartar through paper succeeds very slowly; and unless managed with a good deal of address, not at all: for as soon as the boiling liquor begins to grow sensibly less hot, it deposits much of the tartar all over the surface of the paper, which hinders the remainder from passing through. Zwelfer, in his animadversions on this process in the Augustan pharmacopœia, directs the solution to be clarified with whites of eggs, and strained only through a linen cloth. He likewise judiciously orders the vessel to be close covered, and the crystallization performed in a warm place: for if the solution be suffered to cool very fast, it is in vain to expect any appearance of crytals; the tartar will inevitably be precipitated to the bottom of the vessel in the form of sand. And indeed, the business of refining and crystallizing tartar is so very troublesome, and requires so large

an apparatus, that scarce any of the apothecaries, or even of the trading chemists, are at the trouble of it; but either import it ready refined from Holland, or purchase it from some people here who make it their sole business.

##### 706. *Cream of tartar.*

Take any quantity of solution of tartar, made as in the foregoing process, and passed through a filter. Boil it over the fire, till a thick cuticle appears on the surface, which is to be taken off with a wooden skimmer bored full of holes; continue the boiling till a fresh cuticle arises, which is to be taken off as the foregoing, and the operation repeated till the whole quantity of liquor is thus consumed. Afterwards dry all the cuticles together in the sun.

The preparation of this in no respect differs from crytals of tartar reduced to powder. Indeed the purchaser ought always to prefer the crytals; for the powder is often sophisticated with saline substances of another kind.

##### 707. *Soluble tartar.* L. E.

Dissolve a pound of any fixed alkaline salt in a gallon of boiling water; and gradually throw in crytals of tartar, as long as a fresh addition thereof raises any effervescence; which generally ceases before three pounds of the crytals have been used. Then filter the liquor; and, after due evaporation, set it by to crytallize, or evaporate it to dryness, and keep the remaining saline mass for use.

Common white tartar is perhaps preferable for this operation to the crytals usually met with. Its impurities can here be no objection; since it will be sufficiently depurated by the subsequent filtration.

Soluble tartar, in doses of a scruple, half a dram, or a dram, is a mild cooling aperient; two or three drams commonly loosen the belly; and an ounce proves pretty strongly purgative. Malouin says it is equal in purgative virtue to the cathartic salt of Glauber. It is an useful addition to the purgatives of the resinous kind, as it promotes their operation, and at the same time tends to correct their griping quality. But it must never be given in conjunction with any acid: for all acids decompose it; absorbing its alkaline salt, and precipitating the tartar.

##### 708. *Rochelle salt.* Ph. Par.

Let the salt extracted from the ashes of the kelp or kali of Alicante be calcined till it melts; then dissolve in water, the solution filtered, and after due evaporation set by, that the salt may shoot into pure white crytals. Dissolve crytals of tartar in boiling water, and saturate the solution with the crytals of kali: the proportions necessary for this purpose will be, about sixteen ounces of the latter to twenty of the former. Duly exhale the liquor in the heat of a water-bath; and after filtration, set it in the cold to crytallize.

This is a species of soluble tartar, made with the salt of kali or soda, with the mineral alkali or basis of sea-salt: It crytallizes far more easily than the preceding preparation, and does not, like it, grow moist in the air. It is also considerably less purgative, but is equally decomposed by acids. It appears to be

a very elegant salt, and begins now to come into esteem in this country, as it has long been in France.

709. *Essential salt of sorrel.*

Let the juice of sorrel, after settling and decantation from the feces, be evaporated, till only one-third remains; then strained through a flannel-bag, and exhaled again till a pellicle appears upon the surface. Put the liquor into a glass vessel; and, a little oil olive being poured upon the top, let it by in a cellar till plenty of crystals are formed: these are to be gently washed with water, and afterwards dried.

After the same manner, essential salts are obtained from all acid, austere, astringent, and bitterish plants that contain but a small quantity of oil.

Herbs of a dry nature are to be moistened, in the bruising, with a little water, that the juice may be the more easily pressed out.

The waters of these plants, which are in vain endeavoured to be drawn over by distillation, may be obtained by dissolving a suitable quantity of their essential salts in common water.

713. The process for obtaining these salts is very tedious, inasmuch as scarce to be completed in less than seven or eight months; and the quantity of salt which the juices afford, is extremely small: hence they are hardly ever made or expected in the shops.

714. The virtues of the essential salts have not been sufficiently determined from experience.

710. *Flowers of benzoine.*

Put some powdered benzoine into an earthen pot placed in sand; and with a gentle heat sublime the flowers into a conical paper-cap fitted to the pot.

—Or the sublimation may be performed in a retort; the flowers will arise with a soft heat into the neck.

—If the flowers have any yellow tinge, mix them with tobacco-pipe clay, and sublime again. *L.*

The sublimation is to be performed in a glazed earthen pot, and repeated in the same instruments with fresh parcels of benzoine, till the paper-cap becomes foul with oil. *E.*

Benzoine, exposed in a retort to a gentle fire, melts and sends up into the neck white shining crystalline flowers, which are followed by an oily substance. On raising the heat a little, (a recipient being applied to the neck of the retort), a thin yellowish oil comes over, intermingled with an acid liquor, and afterwards a thick butyraceous substance: this last, liquefied in boiling water, gives out to it a considerable quantity of saline matter, (separable by filtration and proper exhalation), which appears in all respects similar to the flowers.

It appears, therefore, that the whole quantity of flowers which benzoine is capable of yielding, cannot be obtained by the above processes, since a considerable portion arises after the time of their being discontinued: the greatest part of the flowers arises with a less degree of heat than what is necessary to elevate the oil; but that if the operation is hastily conducted, or if the fire is not exceeding gentle, the oil will arise along with the flowers, and render them foul. Hence in the way of trade, it is extremely difficult to prepare them of the requisite whiteness and purity: the heat which becomes necessary when large quantities of the

benzoine are employed, being so great as to force over some of the oil along with them.

In order therefore to obtain these flowers in perfection, only a small quantity of benzoine should be put into the vessel at a time: and that this may not be any impediment to the requisite dispatch, a number of shallow, flat-bottomed, earthen dishes may be employed, each fitted with another vessel inverted over it. With these you may fill a sand-furnace, having fresh dishes charged in readiness to replace those in the furnace as soon as the process shall appear finished in them: the residuum of the benzoine should be scraped out of each of these vessels before a fresh parcel is put in.

These flowers, when made in perfection, have an agreeable taste and fragrant smell. They totally dissolve in spirit of wine, and likewise by the assistance of the heat in water; but separate again from the latter upon the liquor's growing cold, shooting into fine spicula, which unite together into irregular masses. By the mediation of sugar, they remain suspended in cold water, and thus form an elegant balsamic syrup. Some have held them in great esteem, as pectoral and sudorific, in the dose of half a scruple or more: but the present practice rarely makes use of them, on account of the offensive oil which, as usually prepared, they are tainted with, and from which a fresh sublimation from tobacco-pipe clay does not free them so effectually as might be wished. The observations above related point out a method of depurating them more perfectly, viz. by solution, filtration, and crystallization.

711. *Salt of borax, called sedative salt.*

Put eight ounces of powdered borax into a wide-necked retort; pour thereon three ounces of water, and then add three ounces of oil of vitriol. Place the retort in a proper furnace, adapt to it a receiver, and increase the fire till the vessel becomes red-hot. The sedative salt will arise into the neck in form of thin shining plates, which are to be swept out with a feather; and a little liquor will pass into the receiver. When the matter in the retort is grown cool, pour back upon it the distilled liquor, and sublime again. Repeat this process so long as the borax continues to yield any considerable quantity of saline flowers. *Or,*

Dissolve the borax in a sufficient quantity of warm water, and add thereto the oil of vitriol. Evaporate this mixture till thin plates begin to appear upon the surface; then suffer the fire to decay, and let the vessel stand unmoved till plenty of crystals are formed, which are to be well rinsed with cold water, and then dried for use.

In the preparation of this salt by sublimation, the fire must be expeditiously raised when the matter begins to grow dry; for it is only at this period that the salt sublimes. The sublimed salt itself, in a perfectly dry state, proves fixed in the fire; if moistened with water, and then exposed to a smart heat, part of it continues to rise till the moisture is wholly exhaled; after which, nothing more can be forced up by heat till the salt is again moistened. Hence the use of returning the distilled liquor, and repeating the sublimations. Lemery says, he found flowers continue to rise till the thirty-sixth sublimation; and that the

quantity obtained by all these sublimate's amounted to half an ounce and thirty-five grains from two ounces of borax.

The process of crystallization is less troublesome than that by sublimation; but the salt proves generally less white, and is apt likewise to retain a part of the Glauber's salt, especially if the evaporation is too long protracted.

The fedative salt appears to the taste a neutral salt; but, examined with alkalies, has the properties of an acid, effervesces, uniting, and crystallizing with them, and destroying their alkaline quality. It dissolves both in water and in spirit of wine, though not very readily in either. As to its virtue, it is supposed to be a mild anodyne (whence its name) to calm the heat of the blood in burning fevers, to prevent or remove delicious symptoms, and allay spasmodic affections, whether hypochondriacal or hysterical, at least for a time. The dose is from two to eighteen grains in any proper liquor.

712. *Spirit, salt, and oil, of amber. E.*

Mix powdered white amber with thrice its weight of clean sand, and put them into a glass retort, of which the mixture may fill one half: then adapt a large receiver, and distil in a sand-furnace, with a fire gradually increased. At first a spirit will come over with some yellow oil; then more yellow oil along with a little salt; and upon raising the heat, more of the salt, with a reddish coloured oil.—When the distillation is finished, empty the liquor out of the receiver; and having collected together the salt which adheres to the sides, dry it by gentle pressure between the folds of some spongy paper.—The oil may be separated from the spirit by filtration, and afterwards rectified by four distillations, using very clean retorts, and leaving an eighth part of the oil each time, which is to be thrown away as useless.—The salt is to be purified by solution in water and crystallization.

In the distillation of amber, the fire must for some time be continued gentle, scarce exceeding the degree at which water boils, till the aqueous phlegm and thin oil have arisen; after which it is to be slowly increased. If the fire was urged hastily, the amber would swell up, and rise in its whole substance into the receiver, without undergoing the required decomposition or separation of its parts. When sand or other like intermedia are mixed with it, it is less subject to this rarefaction, and the fire may be raised somewhat more expeditiously; though this little advantage is perhaps more than counterbalanced by the room which the sand takes up in the retort.

Our chemists generally leave the receiver unluted, that it may be occasionally removed as the salt rises and concretes in the neck of the retort; from whence it is every now and then scraped out, to prevent the oil from carrying it down into the receiver. When a gross thick oil begins to arise, and no more salt appears, the distillation is stopped, though it might perhaps be continued longer to advantage.

713. *The spirit of amber*, so called, is no more than a solution of a small portion of the salt in phlegm or water; and therefore is very properly employed for dissolving the salt in order to its crystallization.

721. Pure salt of amber has a penetrating, sub-stringent acid taste. It dissolves both in water and in rectified spirit, though not readily in either, and scarcely at all in the latter without the assistance of heat: of cold water in summer, it requires for its solution about twenty times its own weight; of boiling water, only about twice its weight. Expofed in a glass vessel, to a heat a little greater than that of boiling water, it first melts, then rises in a white fume, and concretes again in the upper part of the glass into fine white flakes, leaving, unless it was perfectly pure, a little coaly matter behind. It effervesces with alkalies both fixed and volatile, and forms with them neutral compounds, greatly resembling those composed of the same alkalies and vegetable acids. Mixed with acid liquors, it makes no sensible commotion. Ground with fixed alkaline salts, it does not exhale any urinous odour. By these characters, it is conceived this salt may be readily distinguished from all the other matters that have been mixed with or vended for it. With regard to its virtue, it is accounted aperient, diuretic, and, on account of its retaining some portion of the oil, antihysterical. Boerhaave gives it the character of *diureticorum et antihystericorum princeps*. Its great price, however, has prevented its coming much into use; and perhaps its real virtues are not equal to the opinion generally entertained of them.

714. The rectified oil has a strong bituminous smell, and a pungent acid taste. Given in a dose of ten or twelve drops, it heats, stimulates, and promotes the fluid secretions: it is chiefly celebrated in hysterical disorders, and in deficiencies of the uterine purgations. Sometimes it is used externally in liniments for weak or paralytic limbs, and rheumatic pains. This oil differs from all those of the vegetable kingdom, and agrees with the mineral petroles, in not being soluble, either in its rectified or unrectified state, by spirit of wine, fixed alkaline lixivium, or volatile alkaline spirits; the oil, after long digestion or agitation, separating as freely as common oil does from water.

## SECT. IX. Preparations of sulphur.

715. *Flowers of Sulphur. L.*

SUBLIME sulphur in proper vessels; and reduce the flowers that concrete into powder, either in a wooden mill, or in a marble-mortar with a wooden pestle.

This process is rarely attempted by the apothecaries, a large apparatus being necessary for performing it to advantage. Those who prepare the flowers of brimstone in quantity, use for the subliming vessel a large iron pot, capable of holding two or three hundred weight; this communicates with an arched chamber, lined with glazed tiles, which serves for the recipient.

This preparation of sulphur makes no change in its qualities; only separating its impurities, and at the same time reducing it into a finer powder than it can easily be brought to by other means. At the bottom of the subliming vessel there remains a ponderous grey-coloured mass, composed of sand, earth, stony and sometimes metallic matters, with a small portion of sulphur that has escaped the subliming heat. This is usually broken in pieces, and vended in the shops un-

der the name of *sulphur vivum*.

716. *Washed flowers of sulphur. L.*

Pour upon the flowers as much water as will arise to the height of four fingers above them, and boil them for some time; then pouring off this water, let some cold water be added, and thoroughly wash the flowers; after which they are to be dried for use.

As the flowers of sulphur are generally sublimed into very capacious rooms, which contain a large quantity of air, or in vessels not perfectly close; some of those that arise at first are apt to take fire, and thus are changed into a volatile acid vapour, which mingling with the flowers that sublime afterwards, communicates to them a notable degree of acidity. In such case the ablation here directed is for the general use of the medicine absolutely necessary; for the flowers, thus tainted with acid, sometimes occasion gripes, and may in other respects be productive of effects different from those of pure sulphur.

717. *Thick balsam of sulphur. E.*

Take eight ounces of olive-oil, and one ounce of flowers of sulphur. Boil them together over a gentle fire, keeping them continually stirring, till they come to the consistence of a balsam.

Linseed oil more readily dissolves sulphur than olive, and a preparation made with it is reckoned somewhat less disagreeable. The vessel they are boiled in ought to be capable of holding at least three times the quantity of the ingredients. As soon as the oil begins to act upon the sulphur, which happens nearly at the point of ebullition, the mixture rarifies very much, so as, if not prudently removed from the fire, to run over into the furnace; and as the matter is very susceptible of flame, dangerous consequences may ensue, especially if the quantity is large. The operator ought therefore to be upon his guard in the management of this process.

718. *Balsam of sulphur with Barbadoes tar. L.*

This is made after the same manner as the foregoing, by using Barbadoes tar instead of the oil.

719. *Balsam of sulphur with oil of turpentine.*

Take two ounces of washed flowers of sulphur, and six ounces of oil of turpentine. Digest them together in a sand-heat, till the oil is saturated with the sulphur.

720. *Balsam of sulphur with oil of aniseed.*

Take two ounces of washed flowers of sulphur; six ounces of oil of turpentine; and four ounces of essential oil of aniseeds. Digest them together as in the preceding process.

These preparations are more conveniently and safely made in a tall glass body, with the mouth at least an inch in diameter, than in the circulatory or close vessels in which they have commonly been directed to be prepared; for when the sulphur and oil begin to act vehemently upon each other, they not only rarify into a large volume, but likewise throw out impetuously great quantities of an elastic vapour, which, if the vessels are closed, or the orifices not sufficient to allow it a free exit, infallibly burst them: Hoffman relates a very remarkable history of the effects of an ac-

cident of this kind. In the vessel above recommended, the process may be completed, without danger, in four or five hours, by duly managing the fire; which should be very gentle for some time, and afterwards increased so as to make the oil just bubble or boil, in which state it should be kept till all the sulphur appears to be taken up.

Essential oils, employed as menstrua for sulphur, undergo a great alteration from the degree of heat necessary for enabling them to dissolve the sulphur; and hence the balsams have not near so much of their flavour as might be expected. It should therefore seem more eligible to add a proper quantity of the essential oil to the simple balsam: these readily incorporate by a gentle warmth, if the vessel be now and then shaken. Sixteen parts of essential oil, and six of the *thick balsam*, compose a balsam more elegant than those made in the foregoing manner, and which retains so much of the flavour of the oil as is in some measure sufficient to cover the taste of the sulphur and render it supportable.

Balsams of sulphur have been strongly recommended in coughs, consumptions, and other disorders of the breast and lungs. But the reputation which they have had in these cases does not appear to have been built upon any fair trial or experience of their virtues. They are manifestly hot, acrimonious, and irritating; and therefore should be used with the utmost caution. They have frequently been found to injure the appetite, offend the stomach and viscera, parch the body, and occasion thirst and febrile heats. The dose is from 5 to 20 drops. Externally, they are employed for cleansing and healing foul running ulcers: Boerhaave conjectures, that their use in these cases gave occasion to the virtues ascribed to them when taken internally.

721. *Precipitated sulphur. L.*

Boil flowers of sulphur in water, with thrice their weight of quicklime, till the sulphur is dissolved. Filter the solution, and drop into it some of the weak spirit of vitriol: this will throw down a precipitate, which is to be washed in fresh portions of water, till it becomes insipid.

722. *Lac sulphuris.*

Boil the hepar sulphuris, reduced to powder, in four times its quantity of water for three hours; adding more water if there is occasion. Then filter the solution whilst hot; and drop it into spirit of vitriol, till the effervescence ceases; a powder will be precipitated to the bottom, which is to be washed with hot water, and afterwards dried for use.

The method of preparing this lac, as it is called, with hepar sulphuris, is the most expeditious, and least troublesome, provided the hepar † be well made; and, on the other hand, quicklime gives the preparation a † See Chem. more saleable whiteness. Some have been accustomed to add to the quicklime a portion of alkaline salt, with a view to promote its dissolving power.

The medicine is nearly the same in both cases. It would be exactly the same, if the precipitation was performed with any other acid than the vitriolic: for this acid forms with the dissolved lime a selenitic concrete, which precipitates along with the sulphur, and is not afterwards separable by any ablation; whilst the

neutral salt, which that acid forms with the fixed alkali of the hepar, may be totally dissolved and washed off by repeated ablution with hot water, and the combinations of all the other acids, both with the lime and alkali, are separated by cold water. It is probably to the admixture of the white felenitic matter, resulting from the vitriolic acid and lime, that the finer colour of the preparation made with lime is owing.

Pure lac sulphuris is not different in quality from pure sulphur itself; to which it is preferred in unguents, &c. only on account of its colour. The whiteness does not proceed from the sulphur having lost any of its parts in the operation, or from any new matter superadded: for if common sulphur be ground with alkaline salts, and set to sublime, it arises of a like white colour, the whole quantity of the alkali remaining unchanged; and if the lac be melted with a gentle fire, it returns into yellow sulphur again.

It may be observed, that the name *lac sulphuris*, or "milk of sulphur," applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it.

#### 723. Volatile tincture of sulphur.

Take of flowers of sulphur, six ounces; sal ammoniac, one pound; quicklime, a pound and a half. Sprinkle some water on the lime; and, when flaked and fallen into powder, grind it first with the sulphur, and afterwards with the sal ammoniac, in small quantities at a time: then distil the mixture in a retort, with a fire gradually increased. The distilled liquor is to be kept, in a bottle close stopped, for use.

This liquor has a strong offensive smell: the vapour spreads to a considerable distance, changes silver or copper utensils to a brown or blackish colour, and produces disagreeable alterations in many medical preparations: to this circumstance, therefore, due regard ought to be had in the performance of that process, and in the keeping of this tincture. If a piece of paper, written upon with a saturated solution of lead in vegetable acids, and gently dried, be placed in the middle of a quire of paper, or of a pretty thick book, and brought near the unstoppered orifice of the bottle containing this tincture, the vapour will quickly reach it, and change the colourless writing to a legible black.

Hoffman has a great opinion of the virtues of this preparation. He says, a mixture of one part of the tincture with three of spirit of wine, in a dose of 30 or 40 drops, proves a most powerful diaphoretic; and that a liquor composed of this and camphor, takes off the pain of the gout, by bathing the feet with it. This tincture may be a powerful medicine, but it is certainly a very unpleasant one.

### SECT. X. Metallic Preparations.

#### § 1. PREPARATIONS OF GOLD.

724. GOLD is the most ponderous and perfect of the metals: it abides fixed and unaltered in the strongest fire; and is not acted upon by alkaline, or any simple acid menstruum. It dissolves in aqua regia alone, into a yellowish transparent fluid: this solution stains the skin, &c. purple; the ethereal spirit of wine, and some essential oils, take up the gold from it: alkalies

precipitate the metal in form of a yellowish mud, which exiccated, and exposed to a small heat, violently explodes.

As to the medicinal virtues of this metal, experience has sufficiently shown, that it is not possessed of any valuable ones. In its metallic form, however finely comminuted, it proves inactive; when satiated with acid, corrosive; and in the intermediate states, either insignificant or unsafe.

#### 725. Potable gold.

Dissolve with a moderate heat, half a dram of fine gold, in two ounces of aqua regia; and add to the solution one ounce of the essential oil of rosemary. Shake them together, and then suffer them to rest: the acid loses its gold yellow colour; and the oil, which arises to the surface, becomes richly impregnated therewith. Separate the oil by decantation, and add to it four or five ounces of rectified spirit of wine: digest this mixture for a month, and it will acquire a purplish colour.

There have been many preparations of this kind contrived by the designing pretenders to alchemy, and imposed upon the credulous and unwary, as cordials and diaphoretics of inestimable value. The above seems to be one of the best and safest of them; though it would be equally serviceable as a medicine, if made without the ingredient which it receives its name from. The gold is indeed taken up from the acid, and kept for a time dissolved by the oil; but on standing, it totally separates, in form of fine yellow films, like leaf-gold. The effect is the same, whether the oil or the vinous spirit be mixed with the solution of the gold in aqua regia: the only difference is, that the gold is thrown off from the oil to the sides of the glass; whilst the spirit revives it into such subtle films, as to float upon the surface of the liquor. No means have yet been found of permanently combining gold with either oils or vinous spirits.

#### § 2. PREPARATIONS OF SILVER.

726. SILVER is the most permanent in the fire of all the metals after gold. It dissolves in the pure nitrous acid, into a colourless transparent liquor, intensely bitter and corrosive. This solution exiccated, furnishes the shops with an useful caustic; which has likewise been taken internally, in small doses, and mixed with other substances, as an hydragogue: it stains the skin black.

#### 727. a. The lunar caustic. L.

Let pure silver be dissolved in about twice its weight of aquafortis, upon warm sand; then gently increase the heat, until a dry mass is left. Melt this in a crucible, that it may be poured into proper moulds, carefully avoiding overmuch heat, lest the matter should grow too thick.

#### 727. b. The lunar caustic, or infernal stone. E.

Take four ounces of well-cupelled silver, flattened into plates, and cut in pieces. Dissolve it, by the heat of a sand-bath, in a mixture of eight ounces of weak spirit of nitre, and four ounces of water. Evaporate the solution to dryness, and put the remaining calx into a large crucible. Let the fire at first be gentle, and augment it by degrees, until the mass flows like oil, and ceases to fume: then pour it into

to iron pipes made for this purpose, previously heated and greased: lastly, let it be dried and kept for use in a glass vessel closely stopp'd.

The crucible ought to be large enough to hold five or six times the quantity of the dry matter; for it bubbles and swells up greatly, so as otherwise to be apt to run over: during this time, also, little drops are now and then spirted up, whose causticity is increased by their heat, and which the operator ought therefore to be on his guard against. The fire must be kept moderate till this ebullition ceases, and till the matter becomes consistent in the heat that made it boil before: then quickly increase the fire till the matter flows thin at the bottom, like oil; on which it is to be immediately poured into the mould, without waiting till the fumes cease to appear; for when this happens, the preparation proves not only too thick to run freely into the mould, but likewise less corrosive than it is expected to be.

In want of a proper iron mould, one may be formed of tempered tobacco-pipe-clay, not too moist, by making in a lump of it, with a smooth stick first greased, as many holes as there is occasion for; pour the liquid matter into these cavities, and when congealed, take it out by breaking the mould. Each piece is to be wiped clean from the grease, and wrapt up in dry soft paper, not only to keep the air from acting upon them, but likewise to prevent their corroding or discolouring the fingers in handling.

This preparation is a strong caustic, and frequently employed as such for consuming warts and other fleshy excrescences, keeping down fungous flesh in wounds or ulcers, and other like uses. It is rarely applied where a deep eschar is required, as in the laying open of imposthumes and tumours; for the quantity necessary for these purposes, liquefying by the moisture of the skin, spreads beyond the limits in which it is intended to operate.

#### 728. *The lunar pills.*

Dissolve pure silver in aquafortis; and after due evaporation, set the liquor to crystallize. Let the crystals be again dissolved in common water, and mingled with a solution of equal their weight of nitre. Evaporate this mixture to dryness, and continue the evaporation with a gentle heat, keeping the matter constantly stirring till no more fumes arise.

Here it is necessary to continue the fire till the fumes entirely cease, as more of the acid is required to be dissipated than in the preceding process. The preparation is, nevertheless, in taste very sharp, intensely bitter, and nauseous; applied to ulcers, it acts as a caustic, but much milder than the foregoing. Boerhaave, Boyle, and others, greatly commend it in hydropic cases. The former assures us, that two grains of it made into a pill, with a crumb of bread and a little sugar, and taken on an empty stomach, (some warm water, sweetened with honey, being drank immediately after), purge gently without griping, and bring away a large quantity of water, almost without the patient's perceiving it: that it kills worms, and cures many inveterate ulcerous disorders. He nevertheless cautions against using it too freely, or in too large a dose; and observes, that it always proves corrosive and weakening, especially to the stomach.

#### §. 3. PREPARATIONS OF IRON.

729. Iron calcines by fire the most easily, and melts the most difficultly of all the metals. Sulphur promotes its fusion, and changes it into a substance not greatly dissimilar to a combination of the metal with acid. All acids dissolve this metal; even the air corrodes it into a rust or calx.

Iron, in its metallic form, or lightly calcined, or combined with vegetable or with mineral acids, acts in the human body in the same manner (but with different degrees of power) by constringing the fibres. In all these states, it promotes or restrains secretions, where the deficiency or excess proceed from a laxity and debility of the vessels; and, in general, raises the pulse, and quickens the circulation. The calces seem to be the least active preparations; the crude metal duly comminuted, is more easily soluble in the animal fluids, and, if aescient juices are lodged in the primæ viæ, soon manifests its operation by noxious eruptions, and the black colour of the alvine fæces; if previously combined with saline bodies, it scarce ever fails of taking effect.

735. As the calces of iron are scarcely dissoluble in acids, it has been concluded that they are not soluble in the human body, and that therefore they are to be looked upon no otherwise than as a mere inactive earth. But admitting the absolute indissolubility of iron while it continues a calx, it must be observed, that the calces of this metal are remarkably easy of revival into their metallic state. Mr Beaume relates, that calx of iron, digested for an hour or two in oil-olive, resumes its perfect metallic nature, so as to be attracted by the magnet, and totally soluble in acids; from whence he infers, that a like revival of the metal happens in the human body. It is matter of common observation, that calces of iron tinge the excrements black, a sure mark of their taking effect: though their effect appears to be neither so speedy nor so great as that of iron in some other forms.

#### 730. *Rust of steel prepared. L.*

Expose filings of steel to the air, frequently moistening them with vinegar or water, until they change into rust: then grind them in a mortar; and, pouring on water, wash over the more subtle powder. The remainder is to be exposed afresh to the air, and moistened as at first; then triturated and washed again; and the powders that have been washed over, dried and kept for use.

The rust of iron is preferable as a medicine to the calces, or croci, made by a strong fire. Hoffman relates, that he has frequently given it with remarkable success in obstinate chlorotic cases, accompanied with excessive headaches and other violent symptoms; and that he usually joined it with pimperella, arum root, and salt of tartar, with a little cinnamon and sugar. The dose is from four or five grains to 20 or 30: some have gone as far as a dram; but all the preparations of this metal answer best in small doses, which should rather be often repeated than enlarged.

#### 731. *Scales of iron prepared. E.*

The scales beat off from pieces of iron when hammered on the anvil are to be cleaned by a magnet; those which the magnet attracts being kept for use.

732. *Martial ethiops.*

Put filings of steel into an unglazed earthen vessel, with so much water as will stand above them about four inches; the whole is to be well stirred every day, and more water supplied as that in the vessel exhales, so that the filings may remain always covered: continue this procedure for several months, till they lose their metallic aspect, and are reduced to a fine powder of an inky blackness.

This preparation is described by Lemery in the memoirs of the French academy. But the tediousness of the process has prevented its coming into use; especially as it does not promise any advantage above the common chalybeate preparations, to counterbalance that inconvenience.

733. *Steel prepared with sulphur.* L.

Heat the steel with a very fierce fire to a strong white heat, and in this state apply it to a roll of sulphur held over a vessel of water: the steel will melt, and fall down in drops, which are to be picked out from the sulphur that runs down with them, and ground into an impalpable powder.

The shops have been generally supplied with a preparation of steel with sulphur made at an easier rate in the following manner.

734. *Sulphurated iron.*

Mix filings of iron with twice their weight of powdered sulphur, and as much water as is sufficient to make them into a paste; which on standing at rest for six hours, will swell up. The matter is then to be pulverized, put by degrees into a hot crucible to deflagrate, and kept continually stirring with an iron spatula till it falls into a deep black powder.

If the quantity of this mixture is considerable, and strongly pressed down, it will not only swell on standing for some hours, but will heave up very weighty obstacles, and burst out into flame.

735. *Opening crocus of iron.*

This is made by keeping the foregoing preparation longer over the fire, till it assumes a red colour.

736. *Astringent crocus of iron.*

This is made from the opening crocus of iron, by reverberating it for a long time in the most extreme degree of heat.

These preparations differ from one another in virtue; though the difference is not of such a kind as the titles they have been usually distinguished by import. All the preparations of steel act by an astringent quality; that above, denominated *astringent*, seems to have the least effect. They may be given in form of bolus, electuary, or pill, from six grains to a scruple.

In some foreign pharmacopœias, the croci of iron are prepared from pure green vitriol. This strongly calcined (or the colcothar remaining after the distillation of oil of vitriol), is the *astringent crocus*; when less calcined, it is called *aperient*. These preparations differ little, if at all, from those above distinguished by the same appellations: and accordingly the Edinburgh college has now allowed the substitution of colcothar of vitriol to both the croci.

737. *Soluble or tartarized steel.* E.

Mix equal parts of iron filings and crystals of tartar,

with as much water as is sufficient to reduce them into a mass: this mass is to be dried in a sand-heat; then powdered, moistened, and dried again; and this process repeated, till such time as the matter will easily grind into an impalpable powder.

This is a very elegant and useful preparation of steel. It may be given either in a liquid form, or in that of a bolus, &c. in doses of four five grains, or half a scruple. Dr Willis is said to have been the inventor of this preparation, and by his name it has been usually distinguished in the shops.

738. *Martial flowers.* L.

Take of colcothar of green vitriol washed, or filings of iron, one pound; sal ammoniac, two pounds. Mix and sublime in a retort. Grind the flowers with the matter which remains in the bottom of the retort, and repeat the sublimation until the flowers arise of a beautiful yellowish colour. To the residuum you may add half a pound of fresh sal ammoniac, and sublime as before; repeating this as long as the flowers arise well coloured.

This preparation is supposed to be highly aperient and attenuating; though no otherwise so than the rest of the chalybeates, or at most only by virtue of the saline matter joined to the iron. It has been found of good service in hysterical and hypochondriacal cases, and in distempers proceeding from a laxity and weakness of the solids, as the rickets. It may be conveniently taken in the form of a bolus, from two or three grains to ten: it is nauseous in a liquid form (unless in spirituous tincture), and occasions pills to swell and crumble except such as are made of the gums.

739. *Salt of steel.* L.

Take of strong spirit or oil of vitriol, eight ounces; iron filings, four ounces; water, two pints. Mix them together; and after the ebullition ceases, let the mixture stand for some time upon a warm sand; then pour off and filter the liquor; and after proper exhalation set it by to crystallize.

The salt of steel is one of the most efficacious preparations of this metal; and not unfrequently made use of in cachectic and chlorotic cases, for exciting the uterine purgations, strengthening the tone of the viscera, and destroying worms. It may be conveniently taken in a liquid form, largely diluted with aqueous fluids. Boerhaave directs it to be dissolved in an hundred times its quantity of water, and the solution to be taken in the dose of 12 ounces, on an empty stomach, walking gently after it; thus managed, he says, it opens the body, purges, proves diuretic, kills and expels worms, tinges the excrements black, or forms them into a matter like clay, strengthens the fibres, and thus cures many different distempers. The quantity of vitriol in the above dose of the solution is 57 grains and a half: but in common practice, such large doses of this strong chalybeate are never ventured on. Four or five grains, and in many cases half a grain, are sufficient for the intentions in which chalybeate medicines are given. Very dilute solutions, as that of a grain of the salt in a pint of water, may be used as succedanea to the natural chalybeate waters, and will in many cases produce similar effects.

## § 4. PREPARATIONS OF COPPER.

740. COPPER is less easy of solution than iron; and in its metallic state, does not appear to be acted on by the animal fluids, or to have any considerable effect in the body. Dissolved, it proves externally an escharotic; internally, a violent purgative and emetic. Acids of every kind dissolve it, and likewise volatile alkalies. With the vegetable and marine acids, it forms a green solution; with the vitriolic acid and volatile alkalies, a blue.

741. *Volatile tincture of copper.*

Take of copper filings, one dram; spirit of sal ammoniac, 12 drams. Let them stand together in a close vessel, frequently shaking it, until the liquor is tinged of a beautiful violet colour.

This tincture, or solution, of copper has been given internally, in the dose of a few drops, as a diuretic. Boerhaave directs at first three drops to be taken in a morning fasting, with a glass of mead; and this dose to be daily doubled till it comes to 24 drops; which last quantity is to be continued for some days: he says, that by this means he cured an hydropic person labouring under a confirmed ascites, and that the medicine procured surprising discharges of urine; that nevertheless, on trying it in another case of the same kind, it did not answer.

742. *Ammoniacal copper. E.*

Take of blue vitriol, two ounces; dissolve it in six ounces of boiling water, gradually drop in as much spirit of sal ammoniac as will first precipitate, and then entirely dissolve the metal. Evaporate the liquor with a very gentle heat, and keep the blue saline mass in bottles well stoppered.

## § 5. PREPARATIONS OF LEAD.

743. LEAD readily melts in the fire, and calcines into a dusky powder; which, if the flame is reverberated on it, becomes at first yellow, then red, and at length melts into a vitreous mass. This metal dissolves easily in the nitrous acid, difficultly in the vitriolic, and in small quantity in the vegetable acids; it is also soluble in expressed oils, especially when calcined.

Lead and its calces, whilst undissolved, have no considerable effects as medicines. Dissolved in oils, they are supposed to be (when externally applied) anti-inflammatory and desiccative. Combined with vegetable acids, they are notably so; and taken internally, prove a powerful but dangerous styptic.

744. *Minium, or red lead.*

Let any quantity of lead be melted in an unglazed earthen vessel, and kept stirring with an iron spatula, till it falls into a powder, at first blackish, afterwards yellow, and at length of a deep red colour, in which last state it is called *minium*; taking care not to raise the fire so high as to run the calx into a vitreous mass.

These calces are employed in external applications, for abating inflammations, cleansing and healing ulcers, and the like. Their effects, however, are not very considerable; nor are they perhaps of much farther

real use, than as they give consistence to the plaster, unguent, &c.

745. *Cerusse, or white lead. E.*

Put some vinegar into the bottom of an earthen vessel, and suspend over the vinegar very thin plates of lead, in such a manner that the vapour which arises from the acid may circulate about the plates. Set the containing vessel in the heat of horse-dung, for three weeks: if at the end of this time the plates are not totally calcined, scrape off the white powder, and expose them again to the steam of vinegar, till all the lead is thus corroded into powder.

In this operation the lead is so far opened by the acid, as to discover, when taken internally, the malignant quality of the metal; and to prove externally, when sprinkled on running sores, or ulcers, moderately cooling, drying, and astringent.

746. *Sugar of lead.*

Boil cerusse with distilled vinegar in a leaden vessel, until the vinegar becomes sufficiently sweet; then filter the vinegar through paper, and after due evaporation set it to crystallize. L.

Put any quantity of cerusse into a cucurbit, and pour thereon distilled vinegar to the height of four inches. Digest them together for some days in a sand-heat, till the vinegar has acquired a sweetish taste; when it is to be suffered to settle, and then poured off. Add fresh vinegar to the remainder, and repeat this process till the menstruum no longer extracts any sweet taste. Let all the impregnated liquors rest for some time; and after they have been poured from the feces, evaporate them in a glass vessel, to the consistence of thin honey; so that upon being set in a cool place, the sugar may shoot into crystals, which are afterwards to be dried in the shade. Exhale the remaining liquor to a pellicle, set it again in the cold, and more crystals will shoot; repeat this operation till no crystals can any longer be obtained. E.

The sugar of lead is much more efficacious than the foregoing preparations, in the several intentions which they are applied to. Some have ventured upon it internally, in doses of a few grains, as a styptic, in hæmorrhages, profuse colligative sweats, seminal fluxes, the fluor albus, &c. nor has it failed their expectations. It very powerfully restrains the discharge; but almost as certainly as it does this, it occasions symptoms of another kind, often more dangerous than those removed by it, and sometimes fatal. Violent pains in the bowels or through the whole body, and obstinate constipations, sometimes immediately follow, especially if the dose has been considerable; cramps, tremors, and weakness of the nerves, generally, sooner or later ensue.

## § 6. PREPARATIONS OF TIN.

747. TIN easily melts in the fire, and calcines into a dusky powder, which by a farther continuance of the heat becomes white. A mass of tin heated till it is just ready to melt proves extremely brittle, so as to fall in pieces from a blow, and by dextrous agitation into powder. Its proper menstruum is aqua regia; though the other mineral acids also may be made to dissolve it, and the vegetable ones, in small quantity. It crystal-

lizes with the vegetable and vitriolic acids; but with the others, deliquesces.

The virtues of this metal are little known. It has been recommended as an antihysteric, antiseptic, &c. At present it is chiefly used as an anthelmintic.

#### 748. Powdered tin. L.

Melt the tin, and pour it into a wooden box rubbed in the inside with chalk: then immediately let the box be nimbly shaken, and a part of the tin will fall into powder. The remainder is to be melted a second time, and treated in the same manner, till the whole of the metal is thus reduced into powder.

This preparation has been used for some time as a remedy against worms, particularly the flat kinds, which too often elude the force of other medicines. The general dose is from a scruple to a dram; some confine it to a few grains. But Dr Alston assures us, in the Edinburgh Essays, that its success chiefly depends upon its being given in much larger quantities: he gives an ounce of the powder on an empty stomach, mixed with four ounces of melleas; next day, half an ounce; and the day following, half an ounce more; after which, a cathartic is administered: he says the worms are usually voided during the operation of the purge, but that pains of the stomach occasioned by them are removed almost immediately upon taking the first dose of the tin.

#### § 7. PREPARATIONS OF MERCURY.

749. MERCURY, or quicksilver, is a ponderous metallic fluid, totally volatile in a strong fire, and calculable by a weaker one (tho' very difficultly) into a red powdery substance. It dissolves in the nitrous acid, is corroded by the vitriolic, but not acted on by the marine in its liquid state: it nevertheless may be combined with this last, if skillfully applied in the form of fume. Quicksilver unites, by trituration, with earthy, unctuous, resinous, and other like substances, so as to lose its fluidity: triturated with sulphur, it forms a black mass, which by sublimation changes to a beautiful red one.

The general virtues of the mercurial preparations are, to fufe the juices, however viscid, in the minutest and remotest vessels; by this means they prove eminently serviceable in inveterate chronic disorders, proceeding from a thickness and sluggishness of the humours, and obstinate obstructions of the glands. Crude mercury has no effect this way. Resolved into fume, or divided into minute particles, and prevented from re-uniting by the interposition of other substances, it operates very powerfully; unless the dividing body be sulphur, which restrains its action. Combined with a small quantity of the mineral acids, it acts effectually, though in general mildly; with a larger, it proves violently corrosive.

#### 750. Purification of quicksilver. L.

Distil quicksilver in a retort; and afterwards wash it with water and common salt, or with vinegar.

If a glass retort is made use of for this operation, it ought to have a low body, and a long neck; and the neck should be considerably inclined downwards, so as to allow the elevated mercury a quick descent: the receiver should be filled almost to the neck of the retort with water; the use of this is not to condense,

but to cool, the distilling quicksilver, lest falling hot upon the bottom it should crack the glass. The distillation may be more conveniently performed in an iron retort, or an iron pot fitted with a head.

The fire should be raised no higher than is sufficient to elevate the mercury; for certain mineral substances, which are said to be sometimes mixed with it, prove in part volatile in a degree of heat not much greater than that in which mercury distils. Mr Boyle relates, that he has known quicksilver carry up with it a portion even of lead, so as to have its weight very sensibly increased thereby; and this happened tho' only a moderate fire was used.

#### 751. Sugared mercury.

Take pure quicksilver, brown sugar-candy, of each half an ounce. Essential oil of juniper-berries, 16 drops. Grind them together in a glass mortar, until the mercury ceases to appear.

The essential oil, here added, is said to be a very useful ingredient; not only promoting the extinction of the quicksilver (which, however, is still not a little difficult and tedious), but likewise improving the medicine. The intention is only to divide the mercury by the interposition of other bodies; for when thus managed, it has very powerful effects; tho' whilst undivided, it seems to be altogether inactive. Sugar alone apparently answers this intention; but on the commixture of aqueous fluids, the sugar dissolves by itself, leaving the mercury to run together again in its original form: the addition of the oil is said in great measure to prevent this inconvenience. The dose of this medicine, as an alterative, is from two or three grains to a scruple.

#### 752. Ethiops mineral.

Take purified quicksilver, flowers of sulphur, unwashed, of each equal weights. Grind them together in a glass or stone mortar, until they are united. L. Take of purified quicksilver, flowers of sulphur, each equal weights. Grind them together in a glass mortar, with a glass pestle, till the mercurial globules totally disappear. E.

An ethiops is made also with a double quantity of mercury.

The union of the mercury and sulphur might be greatly facilitated by the assistance of a little warmth. Some are accustomed to make this preparation in a very expeditious manner, by melting the sulphur in an iron ladle, then adding the quicksilver, and stirring them together till the mixture is completed. The small degree of heat here sufficient, cannot reasonably be supposed to do any injury to substances which have already undergone much greater fires, not only in the extraction from their ores, but likewise in the purifications of them directed in the pharmacopœia. In the following process, they are exposed in conjunction to a strong fire, without suspicion of the compound receiving any ill quality from it. Thus much is certain, that the ingredients are more perfectly united by heat, than by the degree of triture usually bestowed upon them. From the ethiops prepared by triture, part of the mercury is apt to be spued out on making it into an electuary or pills: from that made by fire, no separation is observed to happen.

Ethiops

Ethiops mineral is one of the most inactive of the mercurial preparations. Some practitioners have boldly asserted its possessing extraordinary virtues; and most people imagine it a medicine of some efficacy. But what benefit is to be expected from it in the common doses of eight or ten grains, or a scruple, may be judged from hence, that it has been taken in doses of several drams, and continued for a considerable time, without producing any remarkable effect. Sulphur eminently abates the power of all the more active minerals, and seems to be at the same time restrained by them from operating in the body itself. Boerhaave, who is in general sufficiently liberal in the commendation of medicines, disapproves the ethiops in very strong terms. "It cannot enter the absorbent vessels, the lacteals, or lymphatics; but passes directly through the intestinal tube, where it may happen to destroy worms, if it operates lockily. They are deceived who expect any other effects from it; at least I myself could never find them. I am afraid, it is unwarily given, in such large quantities, to children and persons of tender constitutions; as being a foreign mass, unconquerable by the body, the more to be suspected, as it continues long, sluggish, and inactive. It does not raise a salivation, because it cannot come into the blood. Who knows the effects of a substance, which, so long as it remains compounded, seems no more active than any insipid ponderous earth!" The ethiops with a double proportion of mercury, received into the former edition of the Edinburgh pharmacopoeia, has a greater chance for operating as a mercurial; and probably the quantity of mercury might be still further increased to advantage.

#### 753. Artificial cinnabar. E.

Take of purified quicksilver, three pounds and a half; flowers of sulphur, washed, one pound. Melt the sulphur in a large iron vessel, over a gentle fire; and add to it by degrees the quicksilver previously heated, stirring them constantly together with an iron spatula that they may be perfectly mixed. Immediately fit upon the vessel a wooden cover, to prevent the mixture from taking fire: before the matter is grown cold, grind it into powder, and sublime according to art.

It has been customary to order a larger quantity of sulphur than here directed: but this smaller proportion answers better; for the less sulphur, the finer coloured is cinnabar.

The principal use of cinnabar is as a pigment. It was formerly held in great esteem as a medicine, in cutaneous foulnesses, gouty and rheumatic pains, epileptic cases, &c. but of late it has lost much of its reputation. It appears to be nearly similar to the *ethiops*, already spoken of. Cartheuser relates, that having given cinnabar in large quantities to a dog, it produced no sensible effect; but was partly voided along with the feces unaltered, and partly found entire in the stomach and intestines, upon opening the animal. The celebrated Frederick Hoffman, after bestowing high encomiums on this preparation, as having in many instances within his own knowledge perfectly cured epilepsies and vertiges from contusions of the head (where it is probable, however, that the cure did not so much depend upon the cinnabar, as on the spon-

aneous recovery of the parts from the external injury) observes, that the large repeated doses, necessary for having any effect, can be borne only where the first passages are strong; and that if the fibres of the stomach and intestines are lax and flaccid, the cinnabar, accumulated and concreting with the mucous matter of the parts, occasions great oppression: Which seems to be an acknowledgment that the cinnabar is not subdued by the powers of digestion, and has no proper medicinal activity. There are indeed some instances of the daily use of cinnabar having brought on a salivation; perhaps from the cinnabar, made use of in those cases, having contained a less proportion of sulphur than the sorts commonly met with. The regulus of antimony, and even white arsenic, when combined with a certain quantity of common sulphur, seem to have their deleterious power destroyed: on separating more and more of the sulphur, they exert more and more of their proper virulence. It does not seem unreasonable to presume, that mercury may have its activity varied in like manner; that when perfectly fatiated with sulphur, it may be inert; and that when the quantity of sulphur is more and more lessened, the compound may have greater and greater degrees of the proper efficacy of mercurials.

Cinnabar is sometimes used in fumigations against venereal ulcers in the nose, mouth, and throat. Half a dram of it burnt, the fume being imbibed with the breath, has occasioned a violent salivation. This effect is by no means owing to the medicine as cinnabar: when set on fire, it is no longer a mixture of mercury and sulphur; but mercury resolved into fume, and blended in part with the volatile vitriolic acid; in either of which circumstances, this mineral, as already observed, has very powerful effects.

#### 754. Calcined mercury. L.

Put purified quicksilver into a broad-bottomed glass vessel, having a small hole open to the air, and keep it in a constant heat, in a sand-furnace, for several months, until it is calcined into a red powder,

This tedious process might, in all probability, be greatly expedited, by employing, instead of a vessel with a small aperture, a very wide-mouthed, flat-bottomed glass body, of such a height that the mercury may not escape: by this means, the air, which is essentially necessary to the calcination of all metallic substances, will be more freely admitted. A vessel might be so contrived, as to occasion a continual flux of air over the surface of the mercury.

This preparation is by some highly esteemed in venereal cases, and supposed to be the most efficacious and certain of all the mercurials. It may be advantageously given in conjunction with opiates; a bolus or pill, containing from half a grain to two grains of this calx, and a quarter or half a grain or more of opium, with the addition of some warm aromatic ingredient, may be taken every night. Thus managed, it acts mildly, though powerfully, as an alterative and diaphoretic: given by itself in larger doses, as four or five grains, it proves a rough emetic and cathartic.

#### 755. Solution of mercury.

Take equal quantities of pure quicksilver, and good aqua-

aquafortis. Digest them together in a phial placed in a sand-furnace, that a limpid solution may be made.

Aquafortis dissolves mercury more easily, and in larger quantity, than any other acid: 16 ounces, if the menstruum is very strong and pure, will take up 11 or 12. As the liquor grows cold, a considerable part concretes, at the bottom of the vessel, into a crystalline form. If the whole is wanted to remain suspended, a proper quantity of water should be added after the solution is completed.

This process is given only as preparatory to some of the following ones. The solution is highly caustic, so as scarce to be safely touched. It stains the skin purple or black.

#### 756. Calx of mercury.

Take any quantity of the solution of mercury, and evaporate it over a gentle fire, till a white dry mass remains.

This calx, or rather salt, of mercury, is violently corrosive. It is rarely made use of any otherwise than for making the following preparation and the corrosive sublimate.

#### 757. Red calx of mercury, commonly called red precipitate. E.

Take any quantity of the calx of mercury, and reverbate it in a crucible with successive degrees of heat. Its white colour will change first into a brown, and afterwards a yellow; at length, upon increasing the fire, it passes into a deep red.

#### 758. The red mercurial corrosive. L.

Take of purified quicksilver, compound aquafortis (A), of each equal weights. Mix, and set them in a broad-bottomed vessel, in a sand-heat, till all the humidity is exhale, and the mass has acquired a red colour.

The marine acid in the compound menstruum ordered in this last process, disposes the mercurial calx to assume the bright sparkling look admired in it; which, though perhaps no advantage to it as a medicine, ought nevertheless to be insisted on by the buyer as a mark of its goodness and strength. As soon as the matter has gained this appearance, it should be immediately removed from the fire, otherwise it will soon lose it again. The preparation of this *red precipitate*, as it is called, in perfection, is supposed by some to be a secret not known to our chemists; inasmuch that we are under a necessity of importing it from abroad. This reflection seems to be founded on misinformation: we sometimes indeed receive considerable quantities from Holland; but this depends upon the ingredients being commonly cheaper there than with us, and not upon any secret in the manner of the preparation.

This precipitate is, as its title imports, an escharotic; and in this intention is frequently employed by the surgeons, with balsicum, and other dressings, for consuming fungous flesh in ulcers, and the like purposes. It is subject to great uncertainty in point of strength; more or less of the acid exhaling, according to the degree and continuance of the fire. The best criterion of its strength, as already observed, is its

brilliant appearance; which is also the mark of its genuineness: if mixed with minium, which it is sometimes said to be, the duller hue will discover the abuse. This admixture may be more certainly detected by means of fire: the mercurial part will totally evaporate, leaving the minium behind.

Some have ventured to give this medicine internally, in venereal, scrophulous, and other obstinate chronic disorders, in doses of two or three grains and more. But certainly, the milder mercurials, properly managed, are capable of answering all that can be expected from this; without occasioning violent anxieties, tormina of the bowels, and other ill consequences, which the best management can scarcely prevent this corrosive preparation from sometimes doing.

#### 759. The white mercurial corrosive, or corrosive mercury sublimate.

Take of purified quicksilver, forty ounces; sea-salt, thirty-three ounces; nitre, twenty-eight ounces; calcined green vitriol, sixty-six ounces. Grind the quicksilver, in a wooden or stone mortar, with an ounce or more of corrosive mercury sublimate already made, until the quicksilver is divided into small grains: this mixture is to be ground with the nitre, and afterwards with the sea-salt; then add the calcined vitriol, continuing the triture only for a little time longer, lest the quicksilver should run together again. Lastly, proceed to sublimation, in a glass matrass; to which you may adapt a head, in order to save a little spirit that will come over. L.

Take of quicksilver, and weak spirit of nitre, of each four ounces; calcined sea-salt and calcined vitriol, of each five ounces; dissolve the quicksilver in the acid, and let the mixture be evaporated almost to dryness; then add the vitriol and sea-salt, and sublime the mixture in a proper vessel. E.

The sublimate made by this method is the same with the foregoing; but as the quantity of fixed matter is small, it difficultly assumes the form of a cake. It requires indeed some skill in the operator, to give it this appearance when either process is followed. When large quantities are made, this form may be easily obtained, by placing the matrass no deeper in the sand than the surface of the matter contained in it; and removing a little of the sand from the sides of the glass, as soon as the flowers begin to appear in the neck; when the heat should likewise be somewhat lowered, and not at all raised during the whole process. The sublimation is known to be completed by the edges of the crystalline cake, which will form upon the surface of the caput mortuum, appearing smooth and even, and a little removed from it.

Sublimate is a most violent corrosive, presently corrupting and destroying all the parts of the body it touches. A solution of it in water, in the proportion of about a dram to a quart, is made use of for keeping down proud flesh, and cleansing foul ulcers; and a more dilute solution, as a cosmetic and for destroying cutaneous insects. But a great deal of caution is requisite even in these external uses of it.

Some have nevertheless ventured to give it internally, in the dose of one-tenth or one-eighth of a grain. Boerhaave relates, that if a grain of it be dissolved

(A) Compound aquafortis is made by distilling a pound of the common sort from a dram of sea-salt.

Preparations.

Preparations.

solved in an ounce or more of water, and a dram of this solution, softened with syrup of violets, taken twice or thrice a day, it will perform wonders in many reputed incurable distempers; but he particularly cautions us not to venture upon it, unless the method of managing it is well known.

Sublimate dissolved in vinous spirits has of late been given internally in larger doses; from a quarter of a grain to half a grain. This method of using it was brought into vogue by baron Van Swieten at Vienna, particularly for venereal maladies; and several trials of it have been made in this kingdom also with success. Eight grains of the sublimate are dissolved in sixteen ounces of rectified spirit of wine or proof-spirit; the rectified spirit dissolves it more perfectly, and seems to make the medicine milder in its operation than the proof-spirit of the original prescription of Van Swieten. Of this solution, from one to two spoonfuls, that is, from half an ounce to an ounce, are given twice a day, and continued till all the symptoms are removed; observing to use a low diet, with plentiful dilution, otherwise the sublimate is apt to purge and gripe severely. It generally purges more or less at the beginning, but afterwards seems to operate chiefly by urine and perspiration.

Sublimate consists of mercury united with a large quantity of marine acid. There are two general methods of destroying its corrosive quality, and rendering it mild; combining with it so much fresh mercury as the acid is capable of taking up, and separating a part of the acid by means of alkaline salts, and the like. On the first principle, *dulcified mercury sublimate* is formed; on the latter, *rubite precipitate*.

#### 760. *Dulcified mercury sublimate.*

Take of corrosive mercury sublimate, one pound; purified quicksilver, nine ounces. Having powdered the sublimate, add to it the quicksilver, and digest them together in a matras, with a gentle heat of sand, until they unite; then, increasing the heat, let the mixture be sublimed. The sublimed matter, freed from the acrimonious part at top and such mercurial globules as happen to appear distinct in it, is to be reduced into powder, and sublimed again; and this sublimation repeated six times. *L.*

Take of corrosive mercury sublimate, reduced to powder in a glass mortar, four ounces and a half; pure quicksilver, three ounces. Mix them well together, by long trituration in a glass or marble mortar, until the quicksilver ceases to appear; taking care to avoid the finer powder that flies off. Put the powder into an oblong phial, of such a size, that only one-third of it may be filled; and set the glass in a sand-furnace, so as that the sand may reach up to one half of its height. By degrees of fire successively applied, almost all the mercury will sublime, and adhere to the upper part of the vessel. The glass being then broken, and the red powder which is found in its bottom, with the whitish one that sticks about the neck, being thrown away, let the white mercury be sublimed again three or four times. *E.*

The trituration of corrosive sublimate with quicksilver is a very noxious operation: for it is almost im-

possible, by any care, to prevent the lighter particles of the former from arising, so as to affect the operator's eyes and mouth. It is nevertheless of the utmost consequence, that the ingredients be perfectly united before the sublimation is begun; and this may be most commodiously effected by the digestion ordered by the first of the above processes. It is indeed still necessary to pulverize the sublimate, before the mercury is added to it: but this may be safely performed, with a little caution; especially if, during the pulverization, the matter be now and then sprinkled with a little spirit of wine; this addition does not at all impede the union of the ingredients, or prejudice the sublimation: it will be convenient not to close the top of the subliming vessel with a cap of paper at first (as is usually practised) but to defer this till the mixture begins to sublime, that the spirit may escape.

The rationale of this process deserves particular attention; and the more so, as a mistaken theory herein has been productive of several errors with regard to the operation of mercurials in general. It is supposed, that the *dulcification*, as it is called, of the *mercurius corrosivus*, is owing to the spicula or sharp points, on which its corrosiveness depends, being broken and worn off by the frequent sublimations. If this opinion was just, the corrosive would become mild, without any addition, barely by repeating the sublimation; but this is contrary to all experience. The abatement of the corrosive quality of the sublimate is entirely owing to the combination of so much fresh mercury with it as is capable of being united; and by whatever means this combination is effected, the preparation will be sufficiently dulcified. Triture and digestion promote the union of the two, whilst sublimation tends rather to disunite them. The prudent operator, therefore, will not be solicitous about separating such mercurial globules as appear distinct after the first sublimation; he will endeavour rather to combine them with the rest, by repeating the triture and digestion.

The college of Wirtemberg require their *mercurius dulcis* to be only twice sublimed, and the Augustan but once; and Neumann proposes making it directly by a single sublimation, from the ingredients which the corrosive sublimate is prepared from, by only taking the quicksilver in a larger proportion. If the medicine, made after either of these methods, should prove in any degree acrid, water, boiled on it for some time, will dissolve and separate that part in which its acrimony consists. The marks of the preparation being sufficiently dulcified, are, its being perfectly insipid to the taste, and indissoluble by long boiling in water. Whether the water, in which it has been boiled, has taken up any part of it, may be known by dropping into the liquor a ley of any fixed alkaline salt, or any volatile alkaline spirit: if the decoction has any mercurial impregnation, it will grow turbid on this addition; if otherwise, it will continue limpid. But here care must be taken not to be deceived by an extraneous saline matter in the water itself: most of the common spring waters turn milky on the addition of alkalies; and therefore, for experiments of this kind, distilled water, or rain water, ought to be used.

*Mercurius dulcis*, seven times sublimed, has been commonly called *calomelas*, and *aquila alba*; names which are now dropped both by the London and Edinburgh colleges. *Calomelas* is indeed a very improper appellation, the word implying a black colour: by grinding *mercurius dulcis* with volatile spirits, it becomes blackish; and this perhaps is the true *calomel*.

*Mercurius dulcis* appears to be one of the best and safest preparations of this mineral for general use, whether intended to act as a salagogue, diaphoretic, or alterant. Many of the more elaborate processes are no other than attempts to produce from mercury such a medicine as this really is. The dose, for raising a salivation, is ten or fifteen grains, taken in the form of a bolus or pills, every night or oftener, till the ptyalism begins. As an alterant and diaphoretic, it is given in doses of five or six grains; a purgative being occasionally interposed, to prevent its affecting the mouth. It answers, however, much better when given in smaller quantities, as one, two, or three grains every morning and evening, in conjunction with such substances as determine its action to the skin, as the extract or resin of guaiacum; the patient at the same time keeping warm, and drinking liberally of warm diluent liquors. By this method of managing it, obstinate cutaneous and venereal distempers have been successfully cured, without any remarkable increase of the sensible evacuations.

#### 761. *White precipitate of mercury.*

Dissolve sublimate corrosive mercury in a sufficient quantity of hot water, and gradually drop into the solution some spirit of sal ammoniac, as long as any precipitation ensues. Wash the precipitated powder upon a filter, with several fresh quantities of warm water. *E.*

This preparation is used chiefly in ointments, in which intention its fine white colour is no small recommendation to it.

Take sublimate corrosive mercury, sal ammoniac, of each equal weights. Dissolve them both together in water; filter the solution, and precipitate it with a solution of any fixed alkaline salt. Wash the precipitated powder till it is perfectly sweet, (that is, insipid or void of acrimony.) *L.*

Here the sal ammoniac, besides its use in the capital intention, that of furnishing a volatile alkali to make a white precipitation, promotes the solution of the sublimate; which of itself is difficultly and scarce at all totally soluble by repeated boiling in water; for however skillfully it is prepared, some part of it will have an under proportion of acid, and consequently approach to the state of *mercurius dulcis*. A good deal of care is requisite in the precipitation; for, if too large a quantity of the fixed alkaline solution be imprudently added, the precipitate will lose the elegant white colour for which it is valued.

A precipitate of a different nature from the preceding has been commonly distinguished by the same name *mercurius precipitatus albus*. But it is a preparation very rarely made use of among us; notwithstanding the character given of it by Boerhaave, of being “perhaps the best remedy hitherto afforded by mer-

cury.” *Mercury dulcis* produces the good effects which this is supposed to do with a greater degree of certainty, and without disordering the constitution, occasioning vomiting, &c. which this precipitate, in a dose of two or three grains, frequently does.

#### 762. *The yellow mercurial emetic. L.*

Upon purified quicksilver, contained in a glass vessel, pour double its weight of the strong spirit or oil of vitriol. Heat the liquor by degrees, so as at length to make it boil, till a white mass remains, which is to be thoroughly dried with a strong fire. This mass on the addition of warm water grows yellowish, and falls into powder, which is to be diligently ground with the water in a glass mortar: then suffer it to settle, pour off the water, and wash the powder in several parcels of fresh water, until it is sufficiently dulcified.

#### 763. *Yellow precipitate of mercury, or turbith mineral. E.*

Take four ounces of pure quicksilver, and eight ounces of oil of vitriol. Cautiously mix them together; and distil, in a retort placed in a sand-furnace, to dryness; the white calx which is left at the bottom being ground to powder, and thrown into warm water, immediately grows of a yellow colour: wash this in fresh waters renewed several times, until it has lost all its acrimony; then dry it for use.

Boerhaave directs this preparation to be made in an open glass slowly heated, and then placed immediately upon burning coals; care being taken to avoid the fumes, which are extremely noxious. This method will succeed very well with a little address, when the ingredients are in small quantity: but where the mixture is large, it is better to use a retort, placed in a sand-furnace, with a recipient, containing a small quantity of water, luted to it. Great care should be taken, when the oil of vitriol begins to bubble, to steadily keep up the heat, without at all increasing it, till the ebullition ceases, when the fire should be augmented to the utmost degree, that as much as possible of the redundant acid may be expelled.

If the matter be but barely exsiccated, it proves a caustic salt, which in the ablution with water will almost dissolve, leaving only a little quantity of turbith: the more of the acid has been dissipated, the less of the remaining mercury will dissolve, and consequently the yield of turbith will be the greater; fire expelling only the acid, (*viz.* such parts of the acid as are not completely satiated with mercury), while water takes up always along with the acid, a proportionable quantity of the mercury itself. Even when the matter has been strongly calcined, a part will still be soluble: this evidently appears upon pouring into the washings a little solution of fixed alkaline salt, which will throw down a considerable quantity of yellow precipitate, greatly resembling the turbith, except that it is less violent in operation.

From this experiment it appears, that the best method of edulcorating this powder is, by impregnating the water intended to be used in its ablation, with a determined proportion of fixed alkaline salt; for by this means the washed turbith will not only turn out greater in quantity, but, what is of more consequence,

always

always have an equal degree of strength; a circumstance which deserves particularly to be considered, especially in making such preparations as, from an error in the process, may prove too violently corrosive to be used with any degree of safety.

Turbith mineral is a strong emetic, and in this intention operates the most powerfully of all the mercurials that can be safely given internally. Its action however is not confined to the primæ viæ; it will sometimes excite a pyralism, if a purgative is not taken soon after it. This medicine is used chiefly in virulent gonorrhæas, and other venereal cases where there is a great flux of humours to the parts: it is said likewise to have been employed with good success in robust constitutions, against leprous disorders, and obstinate glandular obstructions: the dose is from two grains to six or eight. It may be given in doses of a grain or two as an alterative and diaphoretic, after the same manner as the red precipitate.

This medicine has been of late recommended as the most effectual preservative against the hydrophobia. There are several examples of its preventing madness in dogs that had been bitten; and some, of its performing a cure after the madness was begun: from six or seven grains to a scruple may be given every day, or every other day, for a little time, and repeated at the two or three succeeding fulls and changes of the moon. Some few trials have likewise been made on human subjects bitten by mad dogs; and in these also the turbith, used either as an emetic or alterative, seemed in some cases to have good effects. See MEDICINE, n° 425.

#### § 8. PREPARATIONS OF ANTIMONY.

764. ANTIMONY is composed of a metal united with sulphur or common brimstone.

If powdered antimony be exposed to a gentle fire, the sulphur exhales; the metallic part remaining in form of a white calx, reducible by proper fluxes into a whitish brittle metal, called *regulus*. This is readily distinguished from the other bodies of that class, by its not being soluble in aquafortis; its proper menstruum is aqua regis.

If aqua regis be poured upon crude antimony, the metallic part will be dissolved, and the sulphur thrown out, partly to the sides of the vessel, and partly to the surface of the liquor, in form of a greyish yellow substance. This, separated and purified by sublimation, appears on all trials the same with pure common brimstone.

The metal, freed from the sulphur naturally blended with it, and afterwards fused with common brimstone, resumes the appearance and qualities of crude antimony.

765. The antimonial metal is a medicine of the greatest power of any known substance: a quantity too minute to be sensible on the tenderest balance, is capable of producing virulent effects, if taken dissolved or in a soluble state. If given in such a form as to be immediately miscible with the animal fluids, it proves violently emetic; if so managed as to be more slowly acted on, cathartic; and in either case, if the dose is extremely small, diaphoretic. Thus, though vegetable acids extract so little from this metal, that the remainder seems to have lost nothing of its weight, the tinctures

prove in no large doses strongly emetic, and in smaller ones powerfully diaphoretic. The regulus has been cast into the form of pills, which acted as virulent cathartics, though without suffering any sensible diminution of weight in their passage through the body; and this repeatedly, for a great number of times.

This metal, divested of the inflammable principle which it has in common with other metallic bodies, that is, reduced to a calx, becomes indissoluble and inactive. The calx nevertheless, urged with a strong fire, melts into a glass, as easy of solution (partially), and as virulent in operation, as the regulus itself: the glass thoroughly mingled with such substances as prevent its solubility, as wax, resins, and the like, is again rendered mild.

766. Vegetable acids, as already observed, dissolve but an extremely minute portion of this metal; the solution nevertheless proves powerfully emetic and cathartic. The nitrous and vitriolic acids only corrode it into a powder, to which they adhere so slightly as to be separable in good measure by water, and totally by fire, leaving the regulus in form of a calx similar to that prepared by fire alone. The marine acid has a very different effect: this reduces the regulus into a violent corrosive, and tho' it difficultly unites, yet very closely adheres to it, inasmuch as not to be separable by any ablation, nor by fire, the regulus arising along with it. The nitrous or vitriolic acids expel the marine, and thus reduce the corrosive into a calx similar to the foregoing.

767. Sulphur remarkably abates the power of this metal: and hence crude antimony (in which the regulus appears to be combined with from one-fourth to one half its weight of sulphur) proves altogether mild. If a part of the sulphur be taken away by such operations as do not destroy or calcine the metal, the remaining mass becomes proportionably more active.

The sulphur of antimony may be expelled by deflagration with nitre: the larger the quantity of nitre, to a certain point, the more of the sulphur will be diffused, and the preparation will be the more active. If the quantity of nitre is more than sufficient to consume the sulphur, the rest of it deflagrating with the inflammable principle of the regulus itself, renders it again mild.

The sulphur of antimony is likewise absorbed, in fusion, by certain metals, and by alkaline salts. These last, when united with sulphur, prove a menstruum for all the metals, (zinc excepted), and hence, if the fusion is long continued, the regulus is taken up and rendered soluble in water.

768. *Crocus of antimony, commonly called Crocus metal-lorum, and by foreign writers Hepar antimonii or liver of antimony.*

Take antimony, nitre, of each equal weights. Reduce them separately into powder; then mix, and inject them into a crucible heated to a white heat, that the mixture (after deflagration) may melt. Then pour it out, separate the scoria, and reserve the matter underneath them for use: it proves different in colour, according to the continuance of the heat: the longer it has been kept in fusion, the yellower it will be. *L.*

The mixture of antimony and nitre, made as above,

Prepara-  
tions.

is to be injected into a red-hot crucible; when the detonation is over, separate the reddish metallic matter from the whitish crust, and edulcorate it by repeated washings with hot water. *E.*

Here the antimonial sulphur is almost totally consumed, and the metallic part left divested of its corroder. These preparations, given from two to six grains, act as violent emetics, greatly disordering the constitution. Their principal use is in maniacal cases, as the basis of some other preparations; and among the farriers, who frequently give to horses an ounce or two a-day, divided into different doses, as an alterative: in these and other quadrupeds, this medicine acts chiefly as a diaphoretic.

#### 769. *Washed crocus of antimony. L.*

Reduce the crocus into a very subtile powder, and boil it in the water: then, throwing away this water, wash the powder several times in fresh warm water, until it becomes perfectly insipid.

This process is designed chiefly to fit the crocus for the preparation of emetic tartar, of which hereafter, and of the antimonial emetic wine. If the crocus was employed for those purposes without washing, the alkaline sale, which it is in some degree impregnated with from the deslagration of the nitre, would in part satiate the acids of the tartar and of the wine, and thus, impeding their action on the metallic part of the antimony, render the medicines very precarious in strength: that uncertainties of this kind may be the more effectually guarded against, the glass, or rather the pure regulus, of antimony, is by some preferred to the crocus, both for the emetic tartar and wine.

#### 770. *Medicinal regulus of antimony. E.*

Take of antimony, five ounces; sea-salt, four ounces; salt of tartar, one ounce. Grind them into powder; and throw the mixture, by little at a time, into a red-hot crucible; occasionally breaking, with an iron rod, the crust that forms on the surface. When the fusion is completed, pour out the matter into a heated cone, gently shaking it now and then, or striking it on the sides, that the regulus may settle to the bottom: when grown cold, beat off the scorice, and grind the regulus into a powder, which is to be kept in a close-stopped vial.

This preparation is greatly celebrated by Hoffman, and other German physicians, in sundry obstinate chronic disorders, and esteemed one of the best antimonials that can be given with safety as alterants: it operates chiefly as a diaphoretic, and sometimes, tho' rarely, emetic. The dose is from three or four grains to 20.

This regulus, reduced into a subtile powder, is the genuine *sebrifuge powder* of Craanius (*Pharm. Boruss. Brandenburg.* edit. 1734. p. 107.), and has been greatly commended in all kinds of fevers both of the intermittent and continual kind (*Pharm. Argent.* 1725. p. 252.) It is said that a dose or two have frequently removed these disorders, by occasioning either a salutary diaphoresis, or acting mildly by stool or vomit.

#### 771. *Simple regulus of antimony.*

The most advantageous process for obtaining this regulus appears to be the following.

Prepara-  
tions.

Let powdered antimony be calcined or roasted over a gentle fire, as directed hereafter for making the glass. Mix the calx with about equal its weight of some reducing flux, such as the black flux. Melt the mixture in a crucible, with a quick fire, and when in thin fusion pour it into a cone heated over a smoky flame: the pure regulus will fall to the bottom, the scorice floating on the top.

#### 772. *Precipitated sulphur of antimony. L.*

Take of antimony, 16 ounces; tartar, a pound; nitre, half a pound. Let these be reduced separately into powder; then mixed, thrown by degrees into a red-hot crucible, and melted with a strong fire. Pour out the matter into a conical mould; the metallic part, commonly called *regulus of antimony*, will sink to the bottom, the scorice swimming about it. Dissolve these scorice in water, filter the solution through paper, and precipitate the sulphur by dropping in some spirit of sea-salt: lastly, wash the sulphur from the salts, and dry it for use.

#### 773. *Golden sulphur of antimony. E.*

Boil in an iron pot, four pints of soap-leys diluted with three pints of water, and throw in by degrees two pounds of powdered antimony; keeping them continually stirring, with an iron spatula, for three hours, over a gentle fire; and occasionally supplying more water. The liquor, loaded with the sulphur of antimony, being then strained through a double linen cloth, drop into it gradually, whilst it continues hot, so much spirit of nitre, diluted with an equal quantity of water, as shall be sufficient to precipitate the sulphur, which is afterwards to be carefully washed with hot water.

The foregoing preparations prove emetic when taken on an empty stomach, in a dose of four, five, or six grains: but in the present practice, they are scarce ever prescribed in this intention; being chiefly used as alterative deobstruents, particularly in cutaneous disorders. Their emetic quality is easily blunted, by making them up into pills with resins or extracts, and giving them on a full stomach: with these cautions, they have been increased to the rate of 16 grains a-day, and continued for a considerable time, without occasioning any disturbance upwards or downwards. As their strength is precarious, they should be taken at first in very small doses, and increased by degrees according to their effect.

A composition of the golden sulphur with *mercurius dulcis*, has been a powerful, yet safe, alterative in cutaneous disorders; and has completed a cure after salivation had failed; in venereal cases likewise, this medicine has produced excellent effects. A mixture of equal parts of the sulphur and calomel (well triturated together, and made into pills with extracts, &c.) may be taken from four to eight or ten grains, morning and night; the patient keeping moderately warm, and drinking after each dose a draught of a decoction of the woods or other like liquors. This medicine generally promotes perspiration, scarce occasioning any tendency to vomit or purge, or affecting the mouth. See the *Edinburgh essays*, vol. i. and the *Acta natur. curios.* vol. v.

773—789. *Kermes mineral.* See *KERMES (Mineral)*, in the order of the alphabet.

790. *Panacea of antimony.*

Take of antimony, six ounces; nitre, two ounces; common salt, an ounce and a half; charcoal, an ounce. Reduce them into a fine powder, and put the mixture into a red-hot crucible, by half a spoonful at a time, continuing the fire a quarter of an hour after the last injection: then either pour the matter into a cone, or let it cool in the crucible, which when cold must be broken to get it out. In the bottom will be found a quantity of regulus; and above this a compact liver-coloured substance; and on the top, a more spongy mass: this last is to be reduced into powder, edulcorated with water, and dried, when it appears of a fine golden colour.

This preparation is supposed to have been the basis of *Lockyer's pills*, which were formerly a celebrated purge. Ten grains of the powder mixed with an ounce of white sugar-candy, and made up into a mass with mucilage of gum tragacanth, may be divided into an hundred small pills; of which one, two, or three, taken at a time, are said to work gently by stool and vomit.

791. *Glass of antimony. E.*

Take of antimony reduced to powder, one pound. Calcine it over a gentle fire, in an unglazed earthen vessel, keeping it continually stirring with an iron spatula, until the fumes cease, even when the matter is red-hot. Melt the calx in a crucible, with an intense fire, and pour out the liquid matter into a heated brass dish.

The calcination of antimony, to fit it for making a transparent glass, succeeds very slowly, unless the operator be very wary and circumspect in the management of it. The most convenient vessel is a broad shallow dish, or a smooth flat tile, placed under a chimney. The antimony should be of the purest sort, such as is usually found at the apex of the cones: this, grossly powdered, is to be evenly spread over the bottom of the pan, so as not to lie above a quarter of an inch thick on any part. The fire should be at first no greater than is just sufficient to raise a fume from the antimony, which is to be now and then stirred: when the fumes begin to decay, increase the heat, taking care not to raise it so high as to melt the antimony, or run the powder into lumps: after some time the vessel may be made red-hot, and kept in this state until the matter will not, upon being stirred, any longer fume. If this part of the process be duly conducted, the antimony will appear in an uniform powder, without any lumps, and of a grey colour.

With this powder, fill two-thirds of a crucible, which is to be covered with a tile, and placed in a wind-furnace. Gradually increase the fire, till the calx is in perfect fusion, when it is to be now and then examined by dipping a clean iron wire into it: if the matter, which adheres to the end of the wire, appears smooth and equally transparent, the vitrification is completed, and the glass may be poured out upon a hot smooth stone or copper plate, and suffered to cool by slow degrees to prevent its cracking and flying in pieces. It is of a transparent yellowish-red colour.

The calcined antimony is said by Boerhaave to be

violently emetic. Experience has shown that the glass is so, inasmuch as to be unsafe for internal use. It is employed chiefly, in the present practice, as being subservient to some other preparations, particularly the emetic tartar and antimonial wine; and in combination with wax, and some other substances, by which its power is obtunded.

792. *Cerated glass of antimony. E.*

Take of yellow wax, a dram; glass of antimony, reduced into powder, an ounce. Melt the wax in an iron vessel, and throw into it the powdered glass: keep the mixture over a gentle fire for half an hour, continually stirring it; then pour it out upon a paper, and when cold grind it into powder.

The glass melts in the wax, with a very soft heat: after it has been about 20 minutes on the fire, it begins to change its colour, and in 10 more comes near to that of Scotch snuff, which is a mark of its being sufficiently prepared: the quantity set down above, loses about one dram of its weight in the process.

This medicine has for some time been greatly esteemed in dysenteries: several instances of its good effects in these cases may be seen in the fifth volume of the *Edinburgh essays*, from which the above remarks on the preparation are taken. The dose is from two or three grains to twenty, according to the age and strength of the patient. In its operation, it makes some persons sick and vomit; it purges almost every one; though it has sometimes effected a cure without occasioning any evacuation or sickness.

793. *The antimonial caustic. L. E.*

Take of crude antimony, one pound; corrosive mercury sublimate, two pounds. Reduce them separately into powder; then mix, and distil them in a wide-necked retort, with a gentle sand-heat. The matter which arises into the neck of the retort is to be exposed to the air, that it may run into a liquor.

This is intended for consuming fungous flesh and the callous lips of ulcers.

794. *Cinnabar of antimony.*

Is composed of the sulphur of the antimony, and the mercury of the sublimate, which are perfectly the same with the common brimstone and quicksilver, of which the artificial cinnabar is made. The antimonial cinnabar therefore, whose ingredients are laboriously extracted from other substances, is not different from the common cinnabar made with the same materials procured at a much cheaper rate.

795. *Emetic tartar.*

Take of washed crocus of antimony, crystals of tartar, each half a pound; water, three pints. Boil them together for half an hour; then filter the liquor, and after due evaporation set it by to crystallise. *L.*

Take of powdered cream of tartar, four ounces; levigated glass of antimony, six ounces. Mix, and throw them by little and little into a gallon of water boiling in a glass vessel set in a sand-heat. Let the whole boil gently for six hours; constantly supplying the water consumed by evaporation; then let the liquor be strained when cold, and evaporated  
to

to a proper pitch that crystals may be formed. Tartar emetic may be made after the same manner from crocus metallorum, provided this has been properly prepared, which is known by its being of a yellow colour when powdered. *E.*

The title of this medicine expresses its principal operation. It is one of the best of the antimonial emetics, acting more powerfully than the quantity of crocus contained in it would do by itself, though it does not so much ruffle the constitution.

The dose of emetic tartar, when designed to produce the full effect of an emetic, is from four to six or eight grains. It may likewise be advantageously given in smaller doses, half a grain, for instance, as a diaphoretic and alterative in cutaneous disorders; and added in the quantity of a grain as a stimulus to ipécacuanha, &c.

#### § 9. PREPARATIONS OF BISMUTH.

796. This metal resembles in appearance the regulus of antimony, but differs greatly from it in its pharmaceutical properties and medical qualities. It melts in a very small heat long before ignition; and totally dissolves, with great effervescence, in aquafortis, which only corrodes the antimonial metal. As a medicine, it seems, when pure, to have little or no effect; though some preparations of it were formerly accounted diaphoretic. At present only one preparation comes under the notice of the apothecary or chemist, and that designed for external use.

##### 797. *Magistery of bismuth.*

Dissolve bismuth in a proper quantity of aquafortis, without heat, adding the bismuth by little and little at a time. Pour the solution into sixteen times its quantity of fair water: it will grow milky, and on standing for some time, deposit a bright white precipitate: the addition of spirit of wine will expedite the precipitation. Wash the powder in fresh parcels of water, and dry it in a shady place between two papers.

This preparation is of some esteem as a cosmetic, which is the only use it is now applied to.

#### § 10. PREPARATIONS OF ZINC.

798. This metal melts in a red heat; and, if the air is admitted, flames, and sublimates into light, white, downy flowers: if the air is excluded, it arises by a strong fire in its metallic form. Sulphur, which unites with or scorifies all the other metals except gold, does not act on zinc. Acids of every kind dissolve it.

Zinc, its flowers or calces, and solutions, taken internally, prove strong and quick emetics; in small doses, they are said to be diaphoretic. Externally, they are cooling, astringent, and desiccative.

##### 799. *Purification of zinc.*

Melt zinc with a heat no greater than is just sufficient to keep it fluid. Stir it strongly with an iron rod; and throw in alternately pieces of sulphur and of tallow, the first in largest quantity. If any consistent matter or scoria forms on the top, take it off, and continue the process until the sulphur is found to burn freely and totally away on the surface of the fluid zinc.

Zinc usually contains a portion of lead, which this process effectually separates. Sulphur united with lead forms a mass, which does not melt in any degree of fire that zinc is capable of sustaining.

##### 800. *Flowers of zinc.*

Let a large and very deep crucible, or other deep earthen vessel, be placed in a furnace, in an inclined situation, only half upright. Put a small quantity of zinc into the bottom of the vessel, and apply a moderate fire, no greater than is necessary to make the zinc flame; white flowers will arise, and adhere about the sides of the vessel like wool. When the zinc ceases to flame, stir it with an iron rod, and continue this operation till the whole is sublimed.

These flowers should seem preferable for medicinal purposes, to tutty, and the more impure sublimate of zinc which are obtained in the brass-works; and likewise to calamine, the natural ore of this metal, which contains a large quantity of earth, and frequently a portion of heterogeneous metallic matter.

##### 801. *Salt or vitriol of zinc.*

Dissolve purified zinc by a gentle heat of sand in a mixture of one part of oil of vitriol and four of water. Filter the solution; and after due evaporation, set it to crystallize.

This salt is an elegant white vitriol. It differs from the common white vitriol and the *sal vitrioli* of the shops, only in being purer, and perfectly free from any admixture of copper, or such other foreign metallic bodies as the others generally contain.

#### § 11. COMPOUND METALLIC PREPARATIONS.

##### 802. *The medicinal stone.*

Take of litharge, bole armenic, or French bole, alum, each half a pound; colcothar of green vitriol, three ounces; vinegar, a quarter of a pint. Mix and dry them till they grow hard.

This preparation is employed externally as an astringent for loosening loose teeth, preserving the gums, healing and drying up ulcers and wounds, and refreshing desfluxions of thin acrid humours upon the eyes. It is sometimes used in injections for checking a gonorrhœa, after the virulence is expelled.

803. *An astringent preparation taken from Maetz, which has been sold under the name of Colbatch's styptic powder.*

Take any quantity of iron filings, and as much spirit of salt as will rise above them three or four inches. Digest them together with a gentle heat till the spirit ceases to act on the metal; then pour off the liquor, evaporate it to one half, and add thereto an equal weight of sugar of lead. Continue the evaporation with a small heat, until the matter remains dry, and assumes a red colour. If the process is stopped as soon as it becomes dry, it has exactly the appearance of Colbatch's powder. It must be kept close from the air, otherwise it deliquesces.

This is said to be the styptic with which so much noise was made some time ago, by the author of the *Novum lumen chirurgiæ*, and for the sale of which a patent was procured: only in that was used oil of vitriol, instead of the spirit of salt in this; a difference

not very material. The preparation stands recommended in all kinds of hæmorrhages and immoderate fluxes, both internally and externally: the dose is from four grains to twelve. It is undoubtedly an efficacious styptic, but for internal use a dangerous one.

#### 804. *Antimonial ethiops.*

Let equal quantities of antimony and sea-salt be melted together in a crucible for an hour: when grown cold, a regulus (improperly so called) will be found in the bottom; which is to be separated from the scoræ that lie above it, and ground with an equal weight of purified quicksilver until they are united.

This medicine is said to be of remarkable efficacy in venereal cases of long standing, in cancerous tumours, scorbutic and scrophulous disorders, obstinate glandular obstructions, and sundry other chronic dilemperers which elude the force of the common medicines. A few grains may be given at first, and the dose gradually increased, according to its operation, to a scruple or more. It acts chiefly by promoting perspiration: in some constitutions it proves purgative; and in others, if the dose is considerable, emetic.

### C H A P. II.

#### Medicinal COMPOSITIONS.

##### SECT. I. *Powders.*

805. THIS form receives such materials only as are capable of being sufficiently dried to become pulverable, without the loss of their virtue. There are many substances, however, of this kind, which cannot be conveniently taken in powder: bitter, acrid, fetid drugs, are too disagreeable: emollient and mucilaginous herbs and roots are too bulky; pure gums cohere, and become tenacious in the mouth; fixed alkaline salts liquefy upon exposing the composition to the air; and volatile alkalies exhale.

The dose of powders, in extemporaneous prescription, is generally about half a dram; it rarely exceeds a whole dram, and is not often less than a scruple. Substances which produce powerful effects in smaller doses are not trusted to this form, unless their bulk is increased by additions of less efficacy: those which require to be given in larger ones, are better fitted for other forms.

The usual vehicle for taking the lighter powders in, is any agreeable thin liquid. The ponderous powders, particularly those prepared from metallic substances, require a more consistent vehicle, as syrups; for from thin ones they soon subside. Resinous substances likewise are most commodiously taken in thick liquors: in thin ones, they are apt to run into lumps, which are not easily again dissoluble.

#### 806. *General rules for making powders.*

I. Particular care ought to be taken that nothing carious, decayed, or impure, be mixed in the composition of powders: the stalks and corrupted parts of plants are to be separated.

II. The dry aromatics ought to be sprinkled, during

their pulverization, with a few drops of any proper water.

III. The moister aromatics may be dried with a very gentle heat before they are committed to the mortar.

IV. Gums, and such other substances as are difficultly pulverable, should be pounded along with the drier ones, that they may pass the sieve together.

V. No part should be separated for use until the whole quantity put into the mortar has passed the sieve, and the several siftings been mixed together; for those parts of one and the same subject which powder first, may prove different, at least in degree of efficacy, from the rest.

VI. Powders of aromatics are to be prepared only in small quantities at a time, and kept in glass vessels very closely stoppered.

If powders are long kept, and not carefully secured from the air, their virtue is in great measure destroyed, although the parts in which it consists should not in other circumstances prove volatile. Thus, though the virtues of ipecacoanha are so fixed as to remain entire even in extracts made with proper menstrua, yet if the powdered root be exposed for a length of time to the air, it loses its emetic quality.

807. *Pulvis Antilyssus, or Powder against the bite of a mad dog.* L. E.

Take of ash-coloured ground-liverwort, two ounces; black pepper, one ounce. Beat them together into a powder.

The virtue which this medicine has been celebrated for, is expressed in its title: the dose is a dram and a half, to be taken in the morning fasting in half a pint of cows milk warm, for four mornings together.

#### 808. *Compound powder of arum.* L.

Take of arum-root, fresh dried, two ounces; yellow water-flag roots, burnet faxifrage-roots, each one ounce; crabs-eyes prepared, cinnamon, each half an ounce; salt of wormwood, two drams. Beat them into a powder, which is to be kept in a close vessel.

The compound powder of arum was originally intended as a stomachic; and in weaknesses and relaxations of the stomach, accompanied with a surcharge of viscid humours, it is doubtless a very useful medicine. It frequently also has good effects in rheumatic cases. The dose may be from a scruple to a dram, two or three times a-day, in any convenient liquor. It should be used as fresh as possible, for its virtue suffers greatly in keeping.

#### 809. *Compound powder of bole without opium.*

Take of bole armenic, or French bole, half a pound; cinnamon, four ounces; tormentil root, gum arabic, each three ounces; long pepper, half an ounce. Reduce these ingredients into powder.

#### 810. *Compound powder of bole with opium.* L.

Take of opium strained, three drams. Dry it a little, so as to render it easily pulverable; and add it to the foregoing species, that they may all beat into a powder together.

This powder with opium is an elegant reform of the

species of *Fracaforius's* confection, commonly called *diafordium*; consisting only of such of the ingredients of that composition as are most conducive to the intention for which it is at present prescribed. Forty-five grains of the powder contain one of opium.

The powder is directed to be kept in the shops without opium, for cases where the assistance of that drug is not wanted. It is a warm glutinous astringent; and is given in fluxes, or other disorders where medicines of this class are proper, in doses of a scruple or half a dram.

#### 811. *Compound powder of cerusse. L.*

Take of cerusse, five ounces; sarcocolla, an ounce and a half; gum tragacanth, half an ounce. Beat them together into a powder.

This composition is the *trochisci albi* of Razi, brought back to its original simplicity with regard to the ingredients, and without the needless trouble of making it into troches. It is employed for external purposes, as in collyria, lotions, and injections, for repelling acrimonious humours, and in inflammations.

#### 812. *Compound powder of crabs-claws. L.*

Take of the tips of crabs-claws prepared, one pound; pearls prepared, red coral prepared, each three ounces. Mix them together.

#### 813. *Compound testaceous powder.*

Take of oyster-shells prepared, one pound; white chalk, half a pound. Mix them together.

This cheap absorbent powder is at least equally valuable as a medicine with the more costly and compounded crabs-claw and bezoardic powders of the shops. These kinds of preparations are given from half a scruple to half a dram, for absorbing or destroying acidities in the first passages; which seems to be the only good effect that can be reasonably expected from these simple antacid earths. If they meet with no acid to dissolve them, they promise to be injurious rather than beneficial.

It may here be proper to take notice of a quality hitherto little expected from these kind of substances, that of strongly promoting putrefaction. Flesh mixed with a small proportion of chalk, and exposed to a heat equal to that of the human body, not only corrupts sooner than without this addition, but likewise in a far greater degree, resolving in a few days into a perfect mucus. This quality of the absorbent powders (for the discovery of which, with many other curious experiments on the same subject, the public are obliged to Dr Pringle) seems to forbid their use in all those kinds of fevers where the animal-juices are already too much disposed to a putrefactive state. Indeed, in fevers of any kind, though frequently employed, they are at best unserviceable; and perhaps their ill effects would be oftener seen, if it was not for the quantity of acids usually given in acute diseases.

#### 814. *Bezoardic powder. L.*

Take of compound powder of crabs-claws, one pound; Oriental bezoar prepared, one ounce. Mix them together.

Bezoar has hitherto been an ingredient in the foregoing composition, which was then called *Gascoign's*

powder; though, notwithstanding the addition which this article made to the price, it added nothing to the virtue of the medicine. The college of London have therefore very prudently directed an absorbent powder without this costly article; and composed another, distinguished by its name, for the use of those who expect any particular virtues from it.

#### 815. a. *Compound powder of contrayerva.*

Take of compound powder of crabs-claws, a pound and a half; contrayerva root, five ounces. Make them into a powder. *L.*

Take of contrayerva root, six drams; Virginian snake-root, two drams; English saffron, one dram; compound powder of crabs-claws, two ounces. Make them into a powder. *E.*

These medicines have a much better claim to the title of an alexipharmic and sudorific than the two foregoing compositions. The contrayerva, snake-root, and saffron, by themselves are such, and prove very serviceable in low fevers, where the vis vitæ is weak, and a diaphoresis to be promoted. It is possible that the crabs-claw powders are of no farther service than as they divide those powerful ingredients, and render them supportable to the stomach.

#### 815. b. *Powder of chalk. E.*

Take of white chalk prepared, four ounces; nutmegs and cloves, of each half a dram. Mix them together into a powder, which supplies the place of the troches against the heartburn.

#### 816. *Epileptic powder.*

Take wild valerian root, peony root, of each equal parts. Make them into a powder.

This powder may be looked on as a medicine of some importance for the purposes expressed in its title, far superior to those of similar intention in other pharmacopœias. The dose is from ten grains to half a dram for children, and from half a dram to two drams for adults.

#### 817. *Compound powder of myrrh. L.*

Take of rue leaves dried, dittany of Crete, myrrh, each an ounce and a half; alosetida, sagapenum, Ruffia castor, opopanax, each one ounce. Beat them together into a powder.

This is a reformation of the troches of myrrh, a composition contrived by Razi against uterine obstructions. It may be taken in any convenient vehicle, or made into boluses, from a scruple to a dram or more two or three times a day.

#### 818. *Powder to promote delivery.*

Take of borax, half an ounce; castor, saffron, each a dram and a half; oil of cinnamon, eight drops; oil of amber, six drops. Beat the species together into a powder, to which add the oils, and mix the whole well together.

This medicine has long been held in esteem for the purpose expressed in its title; nevertheless, its real efficacy, and what share thereof is owing to each of the ingredients, has not been sufficiently determined: the borax, though by some thought to be of little importance, does not perhaps contribute least to its virtue.

ture. The dose is from a scruple to a dram, or so much as can be conveniently taken up at once on the point of a knife. It should be kept in a very close vessel, otherwise it will soon lose a considerable deal of its more valuable parts.

819. *Compound powder of scammony.*

Take of scammony, four ounces; calcined hartshorn prepared, three ounces. Grind them diligently together into a powder. *L.*

Take of scammony, crystals of tartar, of each two ounces; mix and rub them together into a very fine powder. *E.*

Here the scammony is divided by the earthy calx and salt, and thus rendered somewhat more soluble, and less adhesive; hence its purgative quality is promoted, at the same time that it becomes less griping. The dose of the compound is from fifteen grains to half a dram.

820. *Compound powder of senna.* *L.*

Take of crystals of tartar, senna, each two ounces; scammony, half an ounce; cloves, cinnamon, ginger, each two drams. Powder the scammony by itself, and all the other ingredients together; then mix them.

This powder is given as a cathartic, in the dose of two scruples or a dram. The spices are added, not only to divide, but to warm the medicine, and make it sit easier on the stomach. The scammony is used as a stimulus to the senna; the quantity of the latter necessary for a dose, when not assisted by some more powerful material, being too bulky to be conveniently taken in this form.

821. *Sternutatory powder.* *L.*

Take of asarum, marjoram, marum-lyriacum leaves dried, lavender flowers dried, each equal weights. Rub them together into a powder.

822. *Cephalic powder.* *E.*

Take of the leaves of asarum, three parts; of marjoram, one part. Beat them together into a powder.

The titles of these powders sufficiently express their intention. They are both agreeable and efficacious emetics, and superior to most of those usually sold under the name of *herb-snuff*.

823. *Styptic powder.* *E.*

Take of alum, an ounce and a half; gum kino, three drams. Make them into a powder.

This powder is a very powerful astringent.

824. *Compound powder of amber.* *L.*

Take of amber prepared, gum arabic, each ten drams; juice of hypocistis, balsamites, Japan earth, each five drams; oilibanum, half an ounce; strained opium, one dram. Beat them together into a powder.

This medicine may be looked upon as an useful, and tolerably elegant astringent; though possibly the ingredient which it receives its name from, contributes little to its virtue. Two scruples of the composition contain one grain of opium.

825. *Compound powder of gum tragacanth.* *L.*

Take of gum tragacanth, gum arabic, marshmallow root, each an ounce and a half; starch, liquorice, each half an ounce; double-refined sugar, three ounces. Grind them into a powder.

This powder is a mild emollient; and hence becomes serviceable in hectic cases, tickling coughs, strangury, some kinds of alvine fluxes, and other disorders proceeding from a thin acrimonious state of the humours, or an abrasion of the mucus of the intestines: it softens and gives a greater degree of consistency to the former, and defends the latter from being irritated or excoriated by them. The dose is from half a dram to two or three drams, which may be frequently repeated.

826. *Hiera picra.*

Take of gum extracted from socotorine aloes, one pound; canella alba, three ounces. Beat them separately into powder, and then mix them together. *L.*

Take socotorine aloes, four ounces; Virginian snake-root, ginger, each half an ounce. Mix, and beat them into a powder. *E.*

These compositions were originally directed to be made into an electuary: with us, they have been rarely used in that form, and not often in this of a powder, on account of their great nauseousness. They are chiefly employed as the basis of a tincture called *tinctura sacra*. See n° 376.

827. a. *Aromatic species.* *L.*

Take of cinnamon, two ounces; lesser cardamom seed hulked, ginger, long pepper, each one ounce. Beat them together into a powder.

827. b. *Aromatic powder.* *E.*

Take of nutmegs, lesser cardamom seeds, ginger, each two ounces. Beat them together into a powder, to be kept in glass vessels well stoppered.

Both these compositions are agreeable, hot, spicy medicines; and as such may be usefully taken in cold phlegmatic habits and decayed constitutions, for warming the stomach, promoting digestion, and strengthening the tone of the viscera. The dose is from ten grains to a scruple and upwards. The first is considerably the warmest.

828. *Species of scordium without opium.* *L.*

Take of bole armenic, or French bole, four ounces; scordium, two ounces; cinnamon, an ounce and a half; storax strained, tormentil root, bistort root, gentian, dittany of Crete, galbanum strained, gum arabic, red roses, each one ounce; long pepper, ginger, each half an ounce. Reduce them into powder.

829. *Species of scordium with opium.* *L.*

Take of strained opium, three drams. Dry it a little, that it may easily pulverize; and add it to the foregoing species in the beating; that they may be all reduced into a powder together.

This is the species of *Fracassorius's confectio*, or *diascordium*, which has been hitherto kept in the shops in the form of an electuary only, but is now ju-

diciously directed in that of a powder also, both with and without the opium: when made into an electuary, the medicine, in keeping, loses of its astringency, in which consists great part of its virtue. As this composition has in common practice been looked upon as a medicine of great consequence, and its effects determined by long experience; the college have made no farther alteration in its ingredients, than substituting red roses themselves to the sugar of roses, omitting sorrel seeds, which are certainly insignificant, and supplying the Lemnian earth, which with us is scarce ever met with genuine, by a proper increase of the bole.

#### 830. *Salina cathartica powder.*

Take of vitriolated tartar, crystals of tartar, each one dram; sal prunel, or purified nitre, one scruple. Make them into a powder.

This is an useful cathartic in inflammatory disorders and a viscid impure state of the juices. The quantity above directed is intended for one dose, which should be accompanied with plentiful dilution.

#### 831. *Carminative powder.*

Take of aniseed, sweet-fennel seed, each two scruples; ginger, one scruple; nutmegs, half a scruple; fine sugar, half a dram. Reduce them into a powder, for four doses.

This powder is employed for expelling flatulencies arising from indigestion, particularly those to which hypochondriacal and hysterical persons are subject. It is likewise usefully given in the gripes of young children, either mixed with their food or otherwise.

#### 832. *Diuretic powder.*

Take of sal prunel, ten grains; salt of amber, four grains; oil of turpentine, three drops; fine sugar, one scruple. Drop the oil upon the sugar, then add the salts, and grind the whole together.

This powder is a very efficacious diuretic, and may be given to advantage in cases where the assistance of such forcing medicines is required. The salts somewhat abate the heating quality of the oil, and at the same time cool and relax the passages.

#### 833. *Strengthening powder.*

Take of extract of Peruvian bark, 12 grains; salt of steel, two grains; oil of cinnamon, one drop; fine sugar, half a dram. Having mixed the oil with the sugar, add the other ingredients, and grind the whole well together for two doses.

This medicine has a much better title to the appellation of a *strengthenener*, than those usually met with under that name in dispensaries. In lax habits, debilities of the nervous system, the weaknesses peculiar to either sex, it has generally good effects.

#### 834. *Powder against the king's evil.*

Take of burnt sponge, one scruple; nitre, coralline, fine sugar, each half a scruple. Reduce them into powder.

This powder is recommended in scrophulous disorders and obstructions of the glands: it is supposed to open and deterge the minute vessels, and carry off the offending matter by urine. Dr Mead informs us, in

his *Maxima Medica*, that he very frequently experienced its good effects; he used to give the quantity above prescribed, twice a day, with three or four glassfuls of the less compounded lime-water along with each dose: if the patient was much emaciated, the lime-water was mixed with about an equal quantity of milk.

#### 835. *Vermifuge powder.*

1. Take of tanfy flowers, worm-seed, each three drams; salt of steel, one dram. Make them into a powder.
2. Take of tin reduced into fine powder, two drams; ethiops mineral, half a dram; fine sugar, one scruple. Mix them well together.
3. Take of choice rhubarb, three drams; scammony, calomel, each one dram. Mix, and make them into a powder.

All these compositions are well calculated for the purpose expressed in the title. The first is given in hospitals, in doses of half a dram twice a day; which quantity contains about four grains and a half of the salt of steel. The second is divided into three or four doses, one of which is taken every morning, and a cathartic on the day following. The third, which is a brisk purgative, is used in the quantity of half a dram, after the others have been premixed; or it is taken once or twice a week without their assistance.

#### 836. *Compound powder of jalap.* E.

Take of jalap root, one ounce; crystals of tartar, two ounces. Mix, and rub them together into a very fine powder. E.

#### 837. *Dover's sweating powder.*

Take of vitriolated tartar, four ounces and an half; opium, powdered ipecacuanha root, of each half an ounce. Mix, and rub them well together into a fine powder.

### SECT. II. *Troches and Lozenges.*

836. *Troches and lozenges* are composed of powders made up with glutinous substances into little cakes, and afterwards dried. This form is principally made use of for the more commodious exhibition of certain medicines, by fitting them to dissolve slowly in the mouth, so as to pass by degrees into the stomach; and hence these preparations have generally a considerable proportion of sugar or other materials grateful to the palate. Some powders have likewise been reduced into troches, with a view to their preservation; though possibly for no very good reasons: for the moistening, and afterwards drying them in the air, must in this light be of greater injury than any advantage accruing from this form can counterbalance.

#### *General rules for making troches.*

- I. The three first rules laid down for making powders, are also to be observed in the powders for troches.
- II. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any convenient sweet or aromatic oil; or else sprinkled with powder of starch, or with that of liquorice.
- III. In order to thoroughly dry the troches, put them on an inverted sieve, in a shady, airy place, and frequently turn them.
- IV. Troches are to be kept in glass vessels, or in earthen ones well glazed.

#### 838. *White*

838, a. *White pectoral troches.*

Take of double-refined sugar, a pound and a half; starch, an ounce and a half; liquorice, six drams; Florence orris root, half an ounce. Reduce these ingredients into powder, which is to be made up into troches with a proper quantity of mucilage of gum tragacanth. *L.*

Take of white sugar, one pound; gum arabic, two ounces; starch, one ounce; Florentine orris root, one ounce. Make them into troches with rose-water. *E.*

These compositions are very agreeable pectorals, and may be used at pleasure. They are calculated for softening acrimonious humours, and allaying the tickling in the throat which provokes coughing.

838, b. *Black pectoral troches.*

Take of extract of liquorice, gum arabic, each four ounces; white sugar, eight ounces. Boil the extract and gum in a sufficient quantity of water till they are dissolved: then having strained the liquor, add to it the sugar, and evaporate the mixture over a gentle fire, till it is of a proper consistence for being formed into troches. *E.*

This composition is designed for the same purposes as the white pectoral troches above described.

838, c. *Pectoral troches with opium.* *E.*

Take of opium, balsam of Peru, of each one dram; fine sugar, two drams; of the mafs for black pectoral troches, seven ounces. Rub the opium very well with the balsam and sugar; then gradually add the mafs of troches well softened with warm water. When all is very accurately mixed, form it into troches, each weighing 15 grains.

839. *Red-lead troches.*

Take of red-lead, half an ounce; corrosive mercury sublimate, one ounce; crumb of the finest bread, four ounces. Make them up with rose-water into oblong troches.

Red-lead troches are employed only for external purposes as escharotics: they are powerfully such, and require a good deal of caution in their use.

840. *Troches of nitre.*

Take of nitre purified, four ounces; double-refined sugar, one pound. Make them into troches with mucilage of gum tragacanth. *L.*

Take of nitre, three ounces; fine sugar, nine ounces. Powder them together, and make them into troches with mucilage of gum tragacanth. *E.*

This is a very agreeable form for the exhibition of nitre; though, when the salt is thus taken without any liquid (if the quantity is considerable) it is apt to occasion uneasiness about the stomach, which can only be prevented by large dilution with aqueous liquors.

841. *Troches of squills.* *L.*

Take of baked squills, half a pound; wheat flour, four ounces. Beat them together, and form the mafs into troches, which are to be dried with a gentle heat.

This preparation is used only as an ingredient in the *theriac*.

842. *Troches of sulphur.*

Take of flowers of sulphur, washed, two ounces; double-refined sugar, four ounces. Beat them together; and, adding some mucilage of quince seeds, form them into troches. *L.*

Take of flowers of sulphur, two ounces; flowers of benzoin, one scruple; white sugar, four ounces; factitious cinabar, half a dram. Mucilage of gum tragacanth, as much as is sufficient. Mix, and make them into troches, according to art.

These compositions are to be considered only as agreeable forms for the exhibition of sulphur, no alteration or addition being here made to its virtue; unless that by the flowers of the benzoin in the second prescription, the medicine is supposed to be rendered more efficacious as a pectoral.

843. *Troches of Japan earth.* *L.*

Take of Japan earth, gum arabic, each two ounces; sugar of roses, 16 ounces. Beat them together; and dropping in some water, make them into troches.

A preparation of this kind, with the addition of ambergris and musk, which are here more prudently omitted, has long been in some esteem as a mild restringent, &c. under the title of *catechu*. These troches are sufficiently palatable, and of considerable service in some kinds of coughs, thin acrid desfluxions, diarrhæas, &c.

844. *Cardialgic lozenges.* *L.*

Take of chalk prepared, four ounces; crabs-claws prepared, two ounces; bole armenic, or French bole, half an ounce; nutmegs, one scruple; double-refined sugar, three ounces. Reduce these ingredients into powder, and make them into troches with water.

This composition is calculated against that uneasy sensation at the stomach, improperly called the *heart-burn*; in which it oftentimes gives immediate relief, by absorbing and neutralizing the acid juices that occasion this disorder. The absorbent powders here made use of are of the most powerful kind, though there does not seem to be any occasion for using more than one of them.

It is, however, to be observed, that absorbent compositions, though very effectual for the intention, are accompanied with an inconvenience, which is frequently complained of in their use; their binding the belly. The following is free from this inconvenience.

845. *Laxative antacid lozenges.*

Take of magnesia alba, six ounces; double-refined sugar, three ounces; nutmegs, one scruple. Mix them well together, and form them into troches with mucilage of gum tragacanth.

846. *Sugar of roses.* *L.*

Take of red-rose buds, freed from the heels, and hastily dried, one ounce; double-refined sugar, one pound. Reduce them separately into powder; then mix, and moisten them with water, that they may be formed into troches, which are to be dried by a gentle heat.

This preparation is chiefly valued for its agreeableness to the eye and palate. Some likewise esteem it  
medi-

medicinally, as a light refringent; and look upon it, not undeservedly, as an excellent addition to milk in phthical and hectic cases.

#### 847. *Anthelmintic sugar cakes.*

1. Take of powdered tin, half a dram; fine sugar, half an ounce; rose-water, a sufficient quantity to make them into a mass for tablets.
2. Take of scammony, mercurius dulcis, each four grains; fine sugar, half an ounce; rose-water, a sufficient quantity to make them into tablets.

These compositions are calculated for children, who are not easily prevailed upon to take anthelmintic medicines in less agreeable forms. If the first is made use of, it must be repeated three or four mornings successively, after which a purge is to be taken; the second, if it requires a repetition, is to be given only every other morning. The proportions of the ingredients are to be varied, according to the age and strength of the patient.

#### 848. *Nerve troches.*

Take of compound spirit of lavender, 60 drops; oil of cinnamon, oil of rosemary, each four drops; Florence orrice root, two drams; fine sugar, one ounce; mucilage of gum tragacanth, as much as will reduce them into a mass, which is to be formed into troches of about half a scruple each.

One or two of these troches taken occasionally, and suffered to dissolve in the mouth, prove serviceable to those who are subject to paralytic and other nervous disorders. Warm aromatic medicines, given in this form and manner, are supposed, from their slow dissolution in the mouth, to affect the nervous system more immediately than if received at once into the stomach.

#### 849. *Purgive tablets.*

Take of crystals of tartar, half an ounce; scammony, three drams; oil of cinnamon, four drops; double-refined sugar, eight ounces. Make them up with rose-water into troches, weighing each about a dram.

This is a sufficiently elegant form for purgative troches. Each of the tablets contains two grains and a half of scammony.

#### 850. *Rhubarb troches.*

Take of creme of tartar, rhubarb, each two drams; fresh lemon-peel, half a dram; fine sugar, four ounces. Make them into troches with rose-water.

Two drams of these troches contain about seven grains of rhubarb, and as much creme of tartar.

#### 851. *Kunkel's antimonial tablets.*

Take of the best Hungarian antimony, levigated into an impalpable powder, three drams and a half; sweet almonds peeled, fresh pine-nuts, each half an ounce; cinnamon, one dram; lesser cardamom seeds husked, half a dram; double-refined sugar, four ounces. Dissolve the sugar in equal quantities of cinnamon-water and rose water; then mix therewith the other ingredients, and form the whole into tablets weighing one dram each.

These tablets were brought into esteem by Kunkel, at a time when the internal use of crude antimony was almost universally reckoned poisonous. He had re-

course to them as a desperate medicine, in violent pains and contractions of the arms, after all the common methods of cure had been used without any relief; and being happily, in a short time, perfectly freed from his complaints, he made trial of them in several other cases with remarkable success. He seems to have begun with doses of four or five grains, (that is, one of the tablets above prescribed); which were repeated thrice a day, and gradually increased to a dram or more of the antimony every day.

#### 852. *Stialogogue troches.*

Take of pellitory of Spain, half an ounce; mastich, two drams; oil of cloves and marjoram, each one dram; yellow wax, a sufficient quantity. Make them into troches or pellets.

One of these troches is to be occasionally held in the mouth, and chewed, to promote a discharge of saliva; which they effect by warming and stimulating the salivary glands.

#### 853. *Stomachic troches.*

Take of hard extract of Peruvian bark, one dram; oil of cinnamon, oil of mint, each ten drops; fine sugar, four ounces. Make them into troches, with mucilage of gum tragacanth.

These troches are of service for warming and strengthening the stomach, expelling flatulencies, and promoting digestion; for these purposes they are as effectual as any thing that can well be contrived in this form.

### SECT. III. *Pills.*

854. To this form are peculiarly adapted those drugs which operate in a small dose; and whose nauseous and offensive taste or smell require them to be concealed from the palate.

Pills dissolve the most difficultly in the stomach, and produce the most gradual and lasting effects, of all the internal forms. This is, in some cases, of great advantage; in others, it is a quality not at all desirable; and sometimes it may even be of dangerous consequence, particularly with regard to emetics, which if they pass the stomach undissolved, and afterwards exert themselves in the intestines, operate there as violent cathartics.

Hence emetics are, among us, scarce ever given in pills. And hence to the refinous and difficultly soluble substances, saponaceous ones ought to be added, in order to promote their solution.

Gummy resins and inspissated juices, are sometimes soft enough to be made into pills, without addition: where any moisture is requisite, spirit of wine is more proper than syrups or conserves, as it unites more readily with them, and does not sensibly increase their bulk. Light, dry powders, require syrup or mucilages; and the more ponderous, as the mercurial and other metallic preparations, thick honey, conserve, or extracts.

Light powders require about half their weight of syrup; of honey, about three-fourths their weight; to reduce them into a due consistence for forming pills. Half a dram of the mass will make five or six pills of a moderate size.

#### *General rules for making pills.*

- I. The three first rules, formerly laid down for making

king powders, are here also to be carefully observed.

II. Gums and inspissated juices are to be first softened with the liquid prescribed: then add the powders, and continue beating them all together till they are perfectly mixed.

III. The masses for pills are best kept in bladders, which should be moistened now and then with some kind of liquid that the mass was made up with, or with some proper aromatic oil.

#### 855. *Ethiopic pills.* E.

Take of quicksilver, six drams; honey, half an ounce; golden sulphur of antimony, gum guaiacum in powder, of each half an ounce. Having rubbed the quicksilver with the honey in a glass mortar, till the globules cease to appear, add the sulphur of antimony: then with mucilage of gum arabic make them into a mass of a proper consistence for pills.

These pills resemble Dr Plummer's, described in the Edin. Essays, (see n<sup>o</sup> 773. *supra*;) to which they are preferable in one respect, that they are less apt to run off by stool. They are an useful alternative both in cutaneous and venereal disorders. One-fourth part of the quantity above prescribed may be made into 60 pills; of which from one to four may be taken every night and morning, the patient keeping moderately warm during the whole time that this course is continued.

#### 856. *Aromatic pills.* L.

Take of focolatine aloes, an ounce and a half; gum guaiacum, one ounce; aromatic species, balsam of Peru, each half an ounce. Reduce the aloes and gum guaiacum separately into powder; then mix them with the rest, and make the whole into a mass with a sufficient quantity of syrup of orange-peel.

These pills, taken in small doses, as half a scruple or little more, and occasionally repeated, warm the stomach, and by degrees the whole habit, and promote perspiration and all the natural secretions. If the dose is considerable, they operate gently by stool: and if continued for some time in smaller doses, they prove at length purgative, or introduce a salutary looseness.

#### 857. *Alethic pills.*

Take of focolatine aloes in powder, extract of gentian, of each two ounces; sal polychrest in powder, half an ounce. Mix, and make them into a mass of pills with simple syrup.

#### 858. *Jalap pills.* E.

Take of extract of jalap, two ounces; aromatic species, half an ounce; simple syrup, a sufficient quantity. Beat them into a mass.

This composition was first received into the former edition of the pharmacopoeia. One of the same kind, with powdered jalap in substance instead of the extract, is used in some of the London hospitals, as a cheap and effectual purge.

#### 859. *Pills of scammony with aloes.*

Take of focolatine aloes, one dram; aromatic species, half a dram; scammony, one scruple; soft extract of liquorice, as much as is sufficient to reduce them

into a mass of a due consistence for being formed into pills.

This warm purgative is recommended for removing the crudities, &c. after a surfeit or debauch, and for preventing arthritic and other complaints incident to those who live high. The quantity above prescribed may be made into 30 pills, of which five or six are to be taken for a dose.

#### 860. *The more simple colocynth pills.* L.

Take of pith of colocynth, scammony, each two ounces; oil of cloves, two drams. Pulverize the colocynth and scammony by themselves, then mix in the oil, and make the whole into a mass with syrup of buckthorn.

The operator should be careful, in pulverising the colocynth, to avoid the finer particles that fly off from it; which, though they do not considerably affect the mouth or fauces, have sometimes been observed to occasion violent purging. The drug should first be well dried, cut with sheers into small pieces, and freed from the seeds; then rub it in an oiled mortar, adding a few drops of sweet oil occasionally during the trituration: afterwards mix this powder with the powdered scammony, add the essential oil prescribed, and make the mixture into a mass, as above directed. The composition is apt to grow stiff and dry in keeping, and therefore ought to be made pretty soft at first: the pills should be formed as they are wanted; for when long kept, they become so hard, as to have sometimes passed through the intestines undissolved.

These pills (formerly called *pilule de duobus*, or pills of two ingredients) are very strong cathartics, and ought not to be ventured upon in cases where less violent medicines will take effect. They have been often made use of in large doses, along with large doses also of mercurials, in venereal complaints, both in recent gonorrhœas, and in the swellings and inflammations which sometimes follow from the suppression of the discharge; but in both these cases they are apparently improper, as they generally injure the constitution, and as the latter complaint is for the most part aggravated by them. The dose is from 15 grains to half a dram: some have imprudently gone as far as two scruples.

#### 861. *The pills called cochiz.* E.

Take of colocynthida, one ounce; scammony, focolatine aloes, each two ounces; vitriolated tartar, two drams; oil of cloves, two drams; mucilage of gum arabic, a sufficient quantity. Powder the aloes, scammony, and salt, together; then add the colocynth in very fine powder, and the oil; lastly, with the mucilage make the whole into a mass of pills.

This composition, like the foregoing, is strongly cathartic; not less effectual, though somewhat less irritating.

#### 862. *Colocynth pills with aloes.* L.

Take of focolatine aloes, scammony, each two ounces; pith of colocynth, one ounce; oil of cloves, two drams. Let the dry species be separately reduced to powder; then mix in the oil, and make the whole into a mass with syrup of buckthorn.

Preparations.

By the diminution of coloquintida in this prescription, the ingredients are reduced to the proportions wherein they are set down in the original of Galen; and what is of greater consequence, the medicine becomes less ungrateful to the stomach, and less virulent in its operation.

863. *Deobstruent pills.* L.

Take of the aromatic pills, three ounces; rhubarb, extract of gentian, salt of steel, each one ounce; salt of wormwood, half an ounce. Beat them together into a mass, with solutive syrup of roses.

It is difficult to bring this mass into the due consistence, the two salts acting upon one another so as to make it swell and crumble. Notwithstanding the alkaline salt employed, the pill does not prove at all alkaline; for the acid of the salt of steel forsakes its metal, and unites with the alkali into a vitriolated tartar: whence some have proposed using, instead of the two salts here directed, an ounce of vitriolated tartar already made, and half an ounce of any of the calces of iron: this, they observe, prevents the inconvenience abovementioned, without making any apparent alteration in the quality of the medicine.

864. *Chalybeate cephratic pills.*

Take of the mass of common pills, called *Rufus's pills* described hereafter, one ounce and a half; gum ammoniacum, resin of guaiacum, each half an ounce; salt of steel, five drams; syrup of orange-peel, as much as is sufficient to reduce the whole into a mass.

Both these and the foregoing pills are very well calculated for answering the intention expressed in the title. A dram of the mass may be made into 12 pills, and two or three of these taken every night, or oftener, in chlorotic, or other cases, where warm, aperient, or deobstruent medicines are proper.

865. *Purging deobstruent pills.*

Take of focolorine aloes, extract of black hellebore, scammony, each one ounce; gum ammoniacum, resin of guaiacum, each half an ounce; vitriolated tartar, two drams; essential oil of juniper-berries, one dram. Beat them into a mass, with a sufficient quantity of syrup of buckthorn.

This composition may be given from eight or ten grains to a scruple or half a dram, according as it is intended to keep the belly open or to purge. Half a dram of the mass contains about six grains of each of the capital purgative ingredients; aloes, scammony, and extract of hellebore.

866. *Fetid pills.*

Take of asafetida, Russia castor, each one dram and a half; camphor half a dram; oil of hartshorn, 24 drops. Beat the camphor with the asafetida, then add the castor and oil of hartshorn, and make the whole into a mass.

867. *Gum pills.*

Take of galbanum, opopanax, myrrh, sagapenum, each one ounce; asafetida, half an ounce. Make them into a mass with syrup of saffron. L.

Take of asafetida, galbanum, myrrh, of each two ounces; rectified oil of amber, one dram. Mix

and make them into a mass with common syrup. E. Preparations.

All these pills are designed for antihysterics and emmenagogues, and very well calculated for answering those intentions: half a scruple, a scruple, or more, may be taken every night or oftener.

The following compositions are calculated for the same intentions as the foregoing deobstruent, fetid, and gum pills.

1. Take of asafetida, wood-foot, myrrh, each two ounces; oil of amber, one dram and a half; syrup of sugar, a sufficient quantity. Mix, and make them into a mass, according to art.

2. Take of asafetida, one dram; martial flowers, half a dram; oil of amber, eight drops; balsam of Peru, a sufficient quantity to reduce them into a mass.

3. Take of asafetida, gum ammoniacum, myrrh, aloes, rust of steel prepared, extract of gentian, each one scruple; syrup of ginger, as much as will make the other ingredients into a mass.

4. Take of galbanum, one dram; salt of steel, half a dram; asafetida, aromatic species, each one scruple; tincture of myrrh, as much as will make them into a mass.

A dram of either of the masses is to be made into 12 pills, one or two of which may be taken for a dose twice or thrice a-day.

868. *Mercurial pills.*

Take of purified quicksilver, honey, each one ounce; crumb of bread, two ounces. Grind them together in a glass-mortar till the mercurial globules cease to appear; then add a sufficient quantity of common syrup, and make the whole into a mass according to art. E.

Take of quicksilver, five drams; Strasburgh turpentine, two drams; cathartic extract, four scruples; rhubarb powdered, one dram. Grind the quicksilver with the turpentine until they are perfectly incorporated; then let the other ingredients be beat up with this mixture into a mass. If the turpentine happens to be too thick, soften it with a little oil-olive. L.

869. *Laxative mercurial pills.*

Take of pure quicksilver, one ounce; resin of guaiacum, extract of hellebore, powdered rhubarb, each half an ounce; common syrup, a sufficient quantity. Grind the quicksilver with the resin of guaiacum until they are perfectly incorporated; then add the other ingredients, and beat the whole into a mass according to art.

The three foregoing compositions are useful mercurial pills; the first as an alternative, the other two as purgative mercurials. They are all, however, liable to an inconvenience, uncertainty in regard to their strength: for the mercury is but loosely united with the other ingredients, and very apt to separate and run together in its original form; in which state it never exerts its proper virtue: though it appears perfectly extinguished by the matters it is ground with at first, part of it is apt to be spued out on beating up the mixture with the other ingredients into a mass.

870. *Gamboge pills.*

Take of focolorine aloes, extract of black hellebore, gamboge,

gamboge, mercurius dulcis, each two drams; essential oil of juniper-berries, half a dram; syrup of buckthorn, a sufficient quantity. Beat them into a mass.

This is a strong mercurial purgative, in which the mercurial preparation is not liable to the uncertainty which the crude quicksilver is accompanied with in the foregoing compositions. The dose is from 10 or 15 grains to half a dram.

871, a. *Thebaic, commonly called the pacific pills.* E. Take of opium, half an ounce; extract of liquorice, two ounces; Castile soap, an ounce and a half; Jamaica pepper, one ounce. Soften the opium and extract separately with water; then mix them together, and add the soap and pepper in powder; after which beat all well together into a mass.

871, b. *Saponaceous pills.* L. Take of almond-soap, four ounces; strained opium, half an ounce; essence of lemons, one dram. Soften the opium with a little wine; and then beat it with the rest, until they are perfectly mixed.

These are introduced in the room of those formerly so much celebrated under the name of *Starkey's* or *Matthew's* pills. The soap promotes the solution of the opium in the stomach, and thus occasions it to act the more quickly. The essence of lemons, in the last of these prescriptions, gives an agreeable flavour, makes the medicine sit easier on the stomach, and prevents a nausea, which it would otherwise be apt to occasion. Ten grains of the pill contain nearly one grain of opium.

871, c. *Storax pills.* L. Take of strained storax, two ounces; saffron, one ounce; strained opium, five drams. Beat them together till perfectly united.

These are contrived for dissolving more slowly in the stomach than the saponaceous pills, and consequently producing more gradual and lasting effects.

871, d. *Olibanum pills.* E. Take of olibanum, two ounces; myrrh, one ounce; opium, five drams; balsam of Peru, two drams; common syrup, a sufficient quantity. Make them into a mass; which supplies the place of the storax pills.

872. *Pectoral pills.* Take of gum ammoniacum, half an ounce; balsam of Tolu, two drams; flowers of benzoin, English saffron, each one dram; common syrup, a sufficient quantity. Make them into a mass according to art.

This composition is very well contrived for promoting expectoration; and may be usefully given in common colds, and in difficulty of breathing proceeding from viscid phlegm: the dose is from six or eight grains to a scruple or more.

873. *Rufus's pills.* L. Take of fœcotrine aloes, two ounces; myrrh, saffron, each one ounce. Make them into a mass with syrup of saffron. L.

Take of fœcotrine aloes, two ounces; myrrh, one ounce; saffron, half an ounce. Beat them into a

Vol. VIII.

2

mass with a proper quantity of syrup of orange-peel. E.

The pills, given to the quantity of half a dram or two scruples, prove considerably cathartic; but they answer much better purposes in smaller doses as laxatives or alteratives.

#### 874. *Squill pills.*

Take of Spanish soap, one ounce; gum ammoniacum, millepedes prepared, fresh squills, each half an ounce; balsam of Copaiba, as much as is sufficient. Reduce them into a mass according to art.

\* This is an elegant and commodious form for the exhibition of squills, whether for promoting expectoration, or in the other intentions to which that medicine is applied.

#### 875. *Pills against the dysentery.*

Take of yellow wax, half an ounce; spermaceti, Japan earth, each one dram; oil of cinnamon, twelve drops. Make them into a mass.

This medicine has often been of great benefit for the purpose expressed in its title; at the same time strengthening the intestines, and covering them with a soft mucus, which defends them from being irritated by the acrimony of the humours. Each half dram of the mass may be formed into five or six pills for one or two doses.

#### 876. *Spermaceti pills.*

Take of spermaceti, one dram; white sugar-candy in powder, two drams; balsamic syrup, as much as is sufficient. Grind the spermaceti with the sugar till they are perfectly mixed; then adding the syrup, rub them with a warm pælle into an uniform mass.

Where spermaceti cannot be commodiously exhibited in any other form, three or four moderate-sized pills, made from this mass, may be taken two or three times a-day, in erosions of the viscera by acrimonious humours, tickling coughs, and other like disorders.

#### 877. *Plummer's pills.* E.

Take of sweet mercury, golden sulphur of antimony, of each six drams; extract of liquorice, half an ounce; rub the mercury with the sulphur till they are thoroughly incorporated; then add the extract, and with mucilage of gum arabic make the whole into a mass.

#### SECT. IV. *Boluses.*

878. *BOLUSES* differ little in consistence from electuaries, being only somewhat stiffer, so as to retain their figure without spreading or falling flat.

This form is very convenient for the exhibition of the more powerful medicines, which require their doses to be exactly adjusted, as the stronger alexipharmacs, cathartics, and opiates. As boluses are chiefly intended for immediate use, volatile salts, and other materials, which, if the mass was to be kept, would exhale or swell it, are frequently admitted into them.

The quantity of a bolus very seldom exceeds a dram: if the ingredients are of the lighter kind, even this will be too bulky to be commodiously swallowed down.

The lighter powders are made up with syrup; a scruple or 26 grains of the powder, with as much sy-

34 L

rup

Composi-  
tions.

rup as will bring it to a due consistence, makes a bolus sufficiently large.

The more ponderous powders, as the mercurial ones, are commonly made up with conserve, syrups scarce holding them together. For the testaceous powders also an addition of conserve is used; though, if made up with this alone, they would be too bulky.

Both the light and ponderous powders may be conveniently made up with mucilage, which increases the bulk less than the other additions, and occasions them to pass down more freely.

The official pharmacopœias have no formula of this kind: most of the following compositions are taken from our hospitals.

#### 879. *Alexipharmae bolus.*

1. Take of compound powder of contrayerva, half a scruple; syrup of wild poppies, a sufficient quantity to make it into a bolus.
2. Take of contrayerva root, half a scruple; syrup of saffron, as much as is sufficient. Make them into a bolus.
3. Take of Virginian snakeweed, half a scruple; confection of kermes, as much as is sufficient. Mix and make them into a bolus.
4. Take of Virginian snakeweed, contrayerva root, each eight grains; saffron, three grains; syrup of meconium, a sufficient quantity to reduce them into a bolus.
5. Take of camphor, two grains; saffron, five grains; cordial confection, one scruple. Mix and make them into a bolus.
6. Take of camphor, two grains; nitre, contrayerva root, each ten grains; syrup of clove-julyflowers, as much as will make them into a bolus.
7. Take of musk, ten grains; salt of hartshorn, or of sal ammoniac, five grains; Thebaic extract, half a grain; syrup of saffron, a sufficient quantity. Make them into a bolus.

These boluses are designed for low depressed fevers, in which medicines of this kind are generally preferred, for keeping up the vis vitæ, raising the pulse, and promoting a diaphoresis. The compositions differ in strength, nearly according to the order in which they stand. The last is of great power, and designed chiefly for cases accompanied with convulsive symptoms, which are often abated by it.

#### 880. *Cassa bolus.*

Take of castor, one scruple; salt of hartshorn, five grains; or oil of hartshorn, five drops; simple syrup, a sufficient quantity. Make them into a bolus.

This medicine is given in hysterical and hypochondriacal disorders, and likewise as an alexipharma in fevers. Its virtues, which are great and unquestionable, seem to depend more on the fetid animal-oil, or volatile salt, than on the drug from whence it takes its name.

#### 881. *Diaphoretic bolus.*

Take of compound powder of contrayerva, crude sal ammoniac, each one scruple; simple syrup, a sufficient quantity to form them into a bolus.

This bolus is given in fevers, and other cases where a diaphoresis is to be promoted. Sal ammoniac is for this purpose one of the most efficacious of the neutral

Composi-  
tions.

salts. It requires, however, when thus given in a solid form, to be assisted by warm diluents, frequently repeated; which not only promote its action, but likewise prevent its sitting uneasy on the stomach.

#### 882. *Diuretic bolus.*

Take of fresh squills, six grains; compound powder of arum, ten grains; ginger, five grains; syrup of orange-peel, a sufficient quantity. Make them into a bolus.

This composition is recommended by Dr Mead, to be taken every morning in hydropic cases, for promoting urine. He observes, that in these disorders, diuretic medicines vary greatly in their effects, those which answer sufficiently in one person failing in another; and that the squill and its preparations are of all others those which most generally succeed.

#### 883. *Bolus against the dysentery.*

Take of the cordial confection, French bole, each one scruple; thebaic extract, one grain. Make them into a bolus.

This composition is excellently well calculated for the purpose expressed in its title. Dr Mead assures us, that he has never found any one medicine more effectual, either for restraining the flux, or healing the ulcerated membranes. Previous to the use of this or other like medicines, the first passages must be cleaned by mild emetics and cathartics, as ipecacacantha and rhubarb.

#### 884. *Emmenagogue bolus.*

Take of socotrine aloes, eight grains; saffron, four grains; Guinea pepper, two grains; oil of fennel, two drops; conserve of rue, as much as is sufficient to reduce them into a due consistence.

Take of black hellebore root, eight grains; fresh squills, four grains; essential oil of pepper-mint, two drops; conserve of orange-peel, as much as is sufficient to make them into a bolus.

These are medicines of great power for promoting or exciting the menstrual flux. The first is calculated for lax phlegmatic habits; the other for persons of a sanguine temperament, where chalybeate medicines cannot be borne.

#### 885. *Febrifuge bolus.*

Take of Peruvian bark, one scruple; cascarrilla, half a scruple; mucilage of quince seeds, a sufficient quantity to make them into a bolus.

This elegant composition is excellently well adapted to the cure of intermittent fevers, and may be given in cases where the Peruvian bark by itself would be less proper. Where aromatics, chalybeates, bitters, &c. are also requisite, they are either to be premixed, or occasionally interposed.

#### 886. *Hysteric bolus.*

Take of musk, asafoetida, each six grains; castor, half a scruple; syrup of saffron, as much as is sufficient to make them into a bolus.

This medicine is a very well contrived one for the purpose expressed in its title. It is of great service both in hysterical and hypochondriacal disorders; and often gives relief in the depressions, faintings, statu-

lent

Composi-  
tions.

lent colics, headachs, and other symptoms attending them. It may be taken twice a-day along with any suitable liquor.

887. *Iliac bolus.*

Take of cathartic extract, one scruple; thebaic extract, one grain. Make them into a bolus.

This bolus is prescribed by Dr Mead for easing the pain and procuring stools in the iliac-passion and dry belly-ach; where the irritating cathartics, exhibited by themselves, are thrown up by vomit. The use of this medicine is to be preceded by plentiful bleeding, and accompanied with purgative glysters of the more acrid kind; and its operation promoted by infusion of senna mixed with a little of the elixir of health, or tincture of senna.

888. *Mercurial bolus.*

Take of calomel, from five to fifteen grains; conserve of roses, half a dram. Mix, and make them into a bolus.

This bolus is given every night, or oftener, for raising a salivation in venereal and other disorders, which require that Herculean operation. It is likewise taken at night as an alternative, to be carried off next morning by a cathartic: mercurials exhibited in this manner, have generally better effects than when joined with purgatives directly.

889. *Pectoral bolus.*

Take of spermaceti, fifteen grains; gum ammoniacum, ten grains; salt of hartshorn, five grains; simple syrup, as much as is sufficient. Mix, and make them into a bolus.

In colds of long standing, old coughs, asthma, and beginning consumptions, this bolus generally gives relief; especially if bleeding is premised, and repeated, if necessary, at proper intervals.

890. *Bolus of rhubarb with mercury.*

Take of choice rhubarb, twenty-five grains; calomel, five grains; simple syrup, as much as will form them into a bolus.

This is a very mild mercurial purgative. It is given to destroy worms, and in cachectic, chlorotic, and other like disorders.

891. *Rheumatic bolus.*

Take of extract of guaiacum, half a dram; salt of hartshorn, seven grains; simple syrup, a sufficient quantity. Make them into a bolus.

In chronic rheumatisms, whether the remains of a rheumatic fever, or a continuation of pains that proceeded at first from neglected colds, this bolus has been given with good effects once a-week, or oftener, the patient keeping warm, and drinking warm liquors to promote its operation as a cathartic and diaphoretic. Its use ought to be accompanied by venesection, which is to be repeated every eight or ten days as long as the blood is fizy.

892. *Sudorific bolus.*

Take of camphor, five grains; thebaic extract, one grain; syrup of orange-peel, a sufficient quantity to reduce them into a bolus.

3

This medicine is one of the most effectual sudorifics, generally exciting a copious sweat.

Composi-  
tions.SECT. V. *Electuaries.*

893. ELECTUARIES are composed chiefly of powders mixed up with syrups, &c. into such a consistence that the powders may not separate in keeping, that a dose may be easily taken up on the point of a knife, and not prove too stiff to swallow.

Electuaries receive chiefly the milder alternative medicines, and such as are not ungrateful to the palate. The more powerful drugs, as cathartics, emetics, opiates, and the like, (except in official electuaries to be dispensed by weight), are seldom trusted in this form, on account of the uncertainty of the dose; disgustful ones, acrids, bitters, fetids, cannot be conveniently taken in it; nor is the form of an electuary well fitted for the more ponderous substances, as mercurials, these being apt to subside in keeping, unless the composition is made too stiff.

The lighter powders require thrice their weight of honey, or syrup boiled to the thickness of honey, to make them into the consistence of an electuary; of syrups of the common consistence, twice the weight of the powders is sufficient.

Where the common syrups are employed, it is necessary to add likewise a little conserve, to prevent the compound from drying too soon. Electuaries of Peruvian bark, for instance, made up with syrup alone, will often in a day or two grow too dry for taking.

Some powders, especially those of the less grateful kind, are more conveniently made up with mucilages than with syrups, honey, or conserve. The three latter stick about the mouth and fauces, and thus occasion the taste of the medicine to remain for a considerable time; whilst mucilages pass freely, without leaving any taste in the mouth. A little soft extract of liquorice, joined to the mucilage, renders the composition sufficiently grateful, without the inconveniences of the more adhesive sweets.

The quantity of an electuary directed at a time, in extemporaneous prescription, is rarely less than an ounce, or more than three ounces.

## General rules for making electuaries.

- I. The rules already laid down for decoctions and powders in general, are likewise to be observed in making decoctions and powders for electuaries.
- II. Gums, inspissated juices, and such other substances as are not pulverable, should be dissolved in the liquor prescribed: then add the powders by little and little, and keep the whole briskly stirring, so as to make an equable and uniform mixture.
- III. Astringent electuaries, and such as have pulps of fruits in their composition, should be prepared only in small quantities at a time: for astringent medicines lose greatly of their virtues on being kept in this form, and the pulps of fruits are apt to become sour.
- IV. The superfluous moisture of the pulps should be exhaled over a gentle fire before the other ingredients are added to them.
- V. Electuaries, if they grow dry in keeping, are to be reduced to the due consistence, with the addition of a little Canary wine, and not with syrup or honey;

ney : by this means the dose will be the least uncertain ; a circumstance deserving particular regard, in those especially which are made up with syrup, and contain a large quantity of opium, as the confection called *paulina* and *philonium*, n° 902. & 904.

#### 894. *Electuary of cassia.* L.

Take of solutive syrup of roses, pulp of cassia, fresh extracted, each half a pound ; manna, two ounces ; pulp of tamarinds, one ounce. Grind the manna in a mortar, and with a gentle heat dissolve it in the syrup : then add the pulps, and continue the heat until the whole is reduced to a due consistence.

#### 895. *Diacaasia.* E.

Take of pulp of cassia, six ounces ; pulp of tamarinds, Calabrian manna, of each an ounce and a half ; syrup of pale roses, six ounces. Dissolve the manna, beat in a mortar, in the syrup with a gentle heat ; then mix in the pulps, so as to make the whole into an uniform electuary, according to art.

These compositions are very convenient officials to serve as a basis for purgative electuaries, and other like purposes ; as the pulping a small quantity of the fruits, for extemporaneous prescription, is sufficiently troublesome. The tamarinds give them an agreeable taste, and do not subject them, as might be expected, to turn sour : after standing for four months, the composition was found no sourer than when first made up. They are likewise usually taken by themselves, in the quantity of two or three drams occasionally, for gently loosening the belly in costive habits.

#### 896. *Lentitive electuary.*

Take of figs, one pound ; fena, eight ounces ; pulp of tamarinds, pulp of cassia, pulp of French prunes, each half a pound ; coriander seeds, four ounces ; liquorice, three ounces ; double-refined sugar, two pounds and a half. Pulverise the fena along with the coriander-seeds, and sift out ten ounces of the powder ; the remainder is to be boiled with the figs and liquorice, in four pints of water to one half ; then strain and press out the liquor, and evaporate it to the weight of a pound and a half, or somewhat less : in this dissolve the sugar, so as to make it into a syrup ; and add this syrup, by little and little, to the pulps : lastly, mix in the powder before separated by the sieve. L.

This electuary may be occasionally taken to the quantity of a nutmeg or more, for loosening the belly in costive habits. It is frequently employed in glysters, though for that use the following is rather more convenient.

Take of fena, eight ounces ; coriander-seeds, four ounces ; pulp of prunes, two pounds. Powder the leaves and seeds ; then add the pulps, and mix the whole well together, so as to make them into an electuary. E.

#### 897. *Pectoral electuary.*

Take of rob of elder-berries, two ounces ; spermaceti dissolved in a sufficient quantity of yolk of eggs, half an ounce ; flowers of benzoine, one dram ; balsamic syrup, as much as is sufficient to make the other ingredients into an electuary.

This is a very useful medicine in tickling coughs

and common colds, calculated both to obtund acrimony and promote expectoration. It may be used two or three times a-day, in doses of about the quantity of a small nutmeg. Taken to the bulk of a large nutmeg, at bed-time, it generally not only relieves the breast, but tends to procure a salutary diaphoresis or sweat in the night.

#### 898. *Electuary of scammony.* L.

Take of scammony, an ounce and a half ; cloves, ginger, each six drams ; essential oil of caraway-seeds, half a dram ; honey, half a pound. Let the spices be ground together, and mixed with the honey ; then add the powdered scammony, and afterwards the oil.

This electuary is a warm brisk purgative. It is a reform of the *electuarium caryococcinum* of our preceding dispensaries ; a composition which was greatly complained of, as being inconvenient to take on account of the largeness of its dose. A dram and a half of this, which contains fifteen grains of scammony, is equivalent to half an ounce of the other.

#### 899. *Japonic confection.* E.

Take of Japan earth, four ounces ; gum kino, three ounces ; nutmeg, and cinnamon, each one ounce ; opium dissolved in a sufficient quantity of white-wine, half a dram ; syrup of dry roses, boiled to the thickness of honey, thrice the weight of the powders. Mix and make them into an electuary, which supplies the place of *diacodium*.—It is a moderately warm astringent and opiate.

#### 900. *Locatelli's balsam.*

Take of oil-olive, one pint ; Straßburg turpentine, yellow wax, each half a pound ; red sanders, six drams. Melt the wax over a gentle fire, with some part of the oil ; then add the rest of the oil, and the turpentine ; afterwards mix in the sanders, and keep them stirring together, until the mixture is grown cold. L.

Take of yellow wax, one pound ; oil of olive, a pint and a half ; Chio or Straßburg turpentine, a pound and a half ; balsam of Peru, two ounces ; dragons blood, in powder, one ounce. Melt the wax in the oil over a gentle fire, then add the turpentine ; and having taken them from the fire, mix in the balsam of Peru and dragons blood, keeping them continually stirring till grown cold.

Dragons blood gives a more elegant colour to this composition than red sanders ; though on another account it is somewhat less proper, having been found, when dissolved in oil, to communicate some degree of heat and pungency, qualities quite foreign to the intention of the medicine. This balsam is used in internal bruises and hæmorrhages, erosions of the intestines, dysenteries, and in some kinds of coughs and asthma : the dose is from two scruples to two drams : it may be commodiously taken with about double its weight of conserve of roses, as directed hereafter. Some have likewise applied it externally, for deterring and incrusting recent wounds and ulcers.

#### 901. *Cordial confection.* E.

Take of conserve of rosemary flowers, three ounces ; candied

candied nutmegs, one ounce and a half; candied ginger, six drams; cinnamon in fine powder, half an ounce; syrup of orange-peel, as much as is sufficient. Mix them into an electuary, according to art.

Particular care ought to be had in the choice of the essential oil; for on its goodness, that of the medicine in great measure depends.

902. *The confectio called paulina.* L.

Take of costus, or (in its stead) zedoary; cinnamon, long pepper, black pepper; storax, galbanum, opium, strained; each two ounces: Russia castor, two ounces; simple syrup, boiled to the consistence of honey, thrice the weight of the other ingredients. Warm the syrup, and carefully mix with it the opium first dissolved in wine: gradually add this mixture, whilst it continues warm, to the storax and galbanum previously melted together; and afterwards sprinkle in the other species reduced into powder.

This is a warm opiate medicine, and as such is sometimes made use of in practice: thirty-two grains contain one grain of opium.

903, a. *Mithridate, or the confectio of Damocrates.* L.

Take of cinnamon, fourteen drams; myrrh, eleven drams; agaric, Indian nard, ginger, saffron, seeds of Mithridate-mustard, frankincense, Chio turpentine, each ten drams; camels hay, costus or (in its stead) zedoary, Indian leaf or (in its stead) mace, stœchas, long pepper, hartwort seeds, hypocistis, storax strained, opopanax, galbanum strained, opobalsam or (in its stead) expressed oil of nutmegs, Russia castor, each one ounce; mountain poley, scordium, carpopalsam or (in its stead) cubebs, white pepper, Candy carrot seed, bdellium strained, each seven drams; Celtic nard, gentian root, dittany of Crete, red roses, Macedonian parsley seed, lesser-cardamom seeds hulked, sweet-fennel seed, gum arabic, opium strained, each five drams; calamus aromaticus, wild valerian root, aniseed, fagapenum strained, each three drams; meum athamanticum, St John's wort, acacia or (in its stead) terra Japonica, bellies of skinks, each two drams and a half; clarified honey, thrice the weight of all the other ingredients. Warm the honey, and mix with it the opium dissolved with wine; melt the storax, galbanum, turpentine, and opobalsam (or expressed oil of nutmegs) together in another vessel, continually stirring them about to prevent their burning; with these so melted, mix the hot honey, at first by spoonfuls, and afterwards in larger quantities at a time; when the whole is grown almost cold, add by degrees the other species reduced into powder.

903, b. *Theriaca Andromachi, or Venice treacle.* L.

Take of troches of squills, half a pound:—long pepper, opium strained, vipers dried, each three ounces:—cinnamon, opobalsam, or (in its stead) expressed oil of nutmegs, each two ounces:—agaric, Florence orris root, scordium, red roses, nawew seeds, extract of liquorice, each an ounce and a half:—Indian nard, saffron, amomum, myrrh, costus or (in its stead) zedoary, camels hay, each one

ounce:—cinquefoil root, rhubarb, ginger, Indian leaf or (in its stead) mace, dittany of Crete, horehound leaves, calamint leaves, stœchas, black pepper, Macedonian parsley seed, olibanum, Chio turpentine, wild valerian root, each six drams:—gentian root; celtic nard; spiguel; leaves of polcy mountain, St John's wort, groundpine; germander tops, with the seed; carpopalsam, or (in its stead) cubebs; aniseed; sweet-fennel seed; lesser-cardamom seeds, hulked; seeds of bishops-weed, hartwort-treacle, mustard; hypocistis; acacia, or (in its stead) Japan earth; gum arabic; storax strained; fagapenum strained; terra Lemnia, or (in its stead) bole armenic or French bole; green vitriol calcined; each half an ounce:—small or (in its stead) the long birthwort root; lesser centaury tops; Candy carrot seed; opopanax; galbanum strained; Russia castor; Jews pitch, or (in its stead) white amber prepared; calamus aromaticus; each two drams:—clarified honey, thrice the weight of all the other ingredients. Let these ingredients be mixed together, after the same manner as directed in making the mithridate.

These celebrated electuaries are almost the only remains, which the late reformation has left in the shops, of the wild exuberance of composition, which the superstition of former ages brought into vogue. The theriaca is a reformation of mithridate, made by Andromachus, physician to Nero: the mithridate itself is said to have been found in the cabinet of Mithridates king of Pontus. The first publishers of this pompous arcanum were very extravagant in their commendations of its virtues; the principal of which was made to consist in its being a most powerful preservative against all kinds of venom; whoever took a proper quantity in a morning, was insured from being poisoned during that whole day: this was confirmed by the example of its supposed inventor; who, as Celsus informs us, was, by its constant use, so fortified against the commonly-reputed poisons, that none of them would have any effect upon him when he wanted their assistance. But the notions of poisons which prevailed in those rude ages, were manifestly erroneous. Before experience had furnished mankind with a competent knowledge of the powers of simples they were under perpetual alarms from an apprehension of poisons, and busied themselves in contriving compositions which should counteract their effects, accumulating together all those substances which they imagined to be possessed of any degree of alexipharmic power. Hence proceed the voluminous antidotes which we meet with in the writings of the ancient physicians: yet it does not appear that they were acquainted with any real poison, except the cicuta, acornitum, and bites of venomous beasts; and to these they knew of no antidote whatever. Even admitting the reality of the poisons, and the efficacy of the several antidotes separately, the compositions could no more answer the purposes expected from them, than the accumulating of all the medicinal simples into one form could make a remedy against all diseases.

Yet notwithstanding the absurdity in the original intention of these medicines, and their enormity in point of composition, as they contain several powerful materials, whose virtues, though greatly prejudiced,

Composi- yet are not destroyed, by their multiplicity and contrariety; the compounds have been found, from repeated experience, to produce very considerable effects, as warm opiate diaphoretics.

The college of Edinburgh, paying very little deference to antiquity or common prejudice, ventured at length to discard these venerable reliques; and substituted in their room an elegant and simple form, equivalent to them both in efficacy, under the title of

#### 903. c. *Edinburgh theriaca.*

Take of Virginian snake-root, ten ounces; contrayerva root, six ounces; resin of guaiacum, four ounces; lesser cardamom seeds, two ounces; myrrh, English saffron, opium, each one ounce; rob of elderberries, thrice the weight of the powders; Canary wine, as much as is sufficient to dissolve the opium. Make them according to art into an electuary.

This composition consists of very powerful ingredients, and is doubtless capable of answering every thing that can be reasonably expected from the more voluminous theriaca of Andromachus. The London college also had formerly their theriaca, composed of the less exceptionable ingredients of Andromachus's. But as these medicines have for a long time been chiefly employed for external purposes, by way of cataplasm, the London theriaca is now omitted; and its place supplied by a cataplasm composed of a few well-chosen articles, under the name of *cataplasma e cynino*, or "cataplasm of cummin." For internal use, none of the theriacas are at present so much regarded as they have been heretofore; practitioners having introduced in their room extemporaneous boluses of Virginian snakeroor, camphor, contrayerva, and the like; which answer all their intentions, with this advantage, that they may be given either with or without opium, an ingredient which renders the others prejudicial in cases where they might otherwise be proper. The present edition of the *Edinburgh pharmacopœia* has also rejected the *theriaca Edinensis*, and in its room adopted the following composition under the title of

#### 903. d. *Thebaic electuary.*

Take of aromatic species, six ounces; Virginian snake-root in powder, three ounces; opium dissolved in white-wine, three drams; clarified honey, thrice the weight of the powders. Mix all together into an electuary.

#### 904. *London philonium.*

Take of white pepper, ginger, caraway seeds, each two ounces; strained opium, six drams; syrup of meconium, boiled to the consistence of honey, thrice the weight of the other ingredients. Heat the syrup, and carefully mix it with the opium, previously dissolved in wine; then add the other ingredients, reduced into powder. *L.*

This is a reformation of the *philonium* described by Galen, which was received in our preceding pharmacopœias with the addition of some superfluous ingredients, and distinguished, but not very properly, by the epithet *Romanum*. The additional articles, and some unnecessary ones that were in the original, are here omitted, and the quantities of the others varied, so as

to preserve the same proportion of opium to the whole, as in the last *L. pharmacopœia*. Thirty-six grains of the composition contain one grain of opium.

905. The mithridate, theriaca, diascordium, confectio Paulina, and philonium, are the only compositions now remaining, of what have been called the *officinal capitals*. They are all medicines of great power; and as, on the one hand, they are applicable, by the judicious physician, to excellent purposes; so, on the other, their imprudent use has often been productive of mischievous consequences. It has been customary among nurses and others, to give diascordium to children, to ease their complaints, and to procure sleep: intentions which it effectually answers; but at the same time never fails to bring on a costive habit, the foundation of many diseases: this medicine has likewise been too unwarily given for restraining fluxes; whose suppression was afterwards followed by more dangerous symptoms. The celebrated alexipharmacs, mithridate and theriaca, have oftentimes aggravated the disorders they were intended to remedy, have converted a common cold into a high fever, and have raised slight febrile complaints into a malignant fever. However strongly, therefore, these kinds of medicines are recommended for easing pain, warming, promoting sweat, expelling malignity, &c. the utmost caution is requisite in the use of them; the cases which demand their assistance are much less frequent than is generally supposed.

#### 906. *Acid electuary.*

Take of conserve of wood-sorrel, one ounce; pulp of tamarinds, half an ounce; weak spirit of vitriol, as much as is sufficient to give a grateful acidity: syrup of lemon-juice, as much as will reduce the whole into the consistence of a soft electuary.

This grateful acid composition is an useful refrigerant and antiseptic in different kinds of inflammatory and putrid disorders.

#### 907. *Alexeterial electuary.*

Take of confection of kermes, one dram; candied ginger, six drams; contrayerva root, Virginian snake-root, each one dram; syrup of orange-peel, as much as is sufficient to make the other ingredients into the consistence of an electuary.

This is a moderately warm electuary, contrived by Boerhaave for raising and recruiting the strength in low fevers, where the pulse is sunk, and the patient languid and dejected. It may be taken to the quantity of a small nutmeg every four or five hours, with any proper julep.

#### 908. *Anti-epileptic electuary.*

Take of Peruvian bark, one ounce; wild valerian root, two drams; syrup of orange-peel, a sufficient quantity to reduce the others into an electuary.

This medicine has been frequently prescribed by Dr Mead, in epileptic cases, with success: he directs one dram to be taken every morning and evening, for three months together; after which, to confirm the cure and prevent a relapse, the same dose is to be repeated for three or four days before every new and full moon for a considerable time.

909. *Anti-dysenteric electuary.*

Take of yellow wax, three drams; spermaceti, two drams; conserve of red roses, an ounce and a half; oil of almonds, half an ounce; balsamic syrup, a sufficient quantity. Let the wax and spermaceti be melted in the oil, over a gentle fire, and then mixed with the conserve and syrup.

Where sharp irritating humours have eroded the intestines, and laid open the mouths of the blood-vessels, this soft healing electuary is often of great use. It is said that fluxes of long standing, contracted in the Indies, which had yielded nothing to medicines of the restraining kind, have been removed by this, which supplies the natural mucus of the bowels that the flux has carried off, heals the excoriations, and obtunds the acrimonious humours.

910. *Aromatic electuary.*

Take of the aromatic species, one dram and a half; conserve of lavender, two ounces; syrup of orange-peel, a sufficient quantity. Make them into an electuary.

This warm cordial medicine is of use in nervous complaints and decays of constitution. The bulk of a small nutmeg may be taken two or three times a-day with a glass of wine or any other proper liquor after it.

911. *Balsamic electuary.*

Take of conserve of roses, two ounces; Locatelli's balsam, one ounce; dissolve the balsam in the yolk of an egg, and then mix therewith the conserve.

This electuary is used in some coughs, and disorders of the breast; as also in the vomica, or suppuration in the stomach, which sometimes happens after dysenteries; and where there is an erosion or rupture of the blood-vessels, as in hæmopties. In these cases, the bulk of a nutmeg may be taken for a dose twice or three a-day.

912. *Chalybeate electuary.*

1. Take of salt of steel, one dram; candied nutmegs, candied ginger, each half an ounce; oil of cinnamon, five drops; conserve of orange-peel, one ounce; balsamic syrup, as much as is sufficient to make them into an electuary.
2. Take of rust of steel, or steel prepared with sulphur, six drams; candied ginger, one ounce; conserve of orange-peel, three ounces; syrup of orange-peel, as much as will reduce them into a proper consistence.

These elegant chalybeate medicines are given not only in cachectic and chlorotic cases, and menstrual obstructions, but likewise in low hysterical and melancholic disorders; and for warming and invigorating the habit in great debilities and decays of constitution. In either of these intentions, the bulk of a small nutmeg is to be taken twice a-day, and its effects promoted by moderate exercise.

913. *Electuary of black hellbore.*

Take of black hellbore root, extract of favin, compound powder of myrrh, each half an ounce; canella alba, two drams; syrup of orange-peel, as

much as is sufficient. Mix, and make them into an electuary.

This is a medicine of great power for promoting the natural evacuations from the uterus. It may be taken to the quantity of half a dram twice a-day.

914. *Nephritic electuary.*

Take of lenitive electuary, an ounce and a half; Venice turpentine, one ounce; egg-shells prepared (or prepared oyster-shells) half an ounce; choice rhubarb, one dram; syrup of marshmallows, as much as is sufficient. Dissolve the turpentine in the yolk of an egg; and then mix the whole together, according to art, so as to make thereof an electuary.

This composition is contrived for cleansing the urinary passage in nephritic disorders. A dram of the electuary may be taken once or twice a-day, along with an infusion of marshmallow roots, sweetened with a spoonful of honey.

915. *Paralytic electuary.*

Take of mustard seed, conserve of rosemary tops, each one ounce; compound spirit of lavender, two drams. Beat the mustard seed with a little water, that the pulp may be pressed thro' a hair sieve; then mix with it the conserve and the spirit.

This is a very efficacious medicine for paralytic disorders, tremors and numbness of the limbs, the decays accompanying old age, and in all cases where the solids require to be stimulated, or sluggish stagnant juices to be put in motion. It ought to be taken every morning and evening, or oftener, to the bulk of a large nutmeg, with a glass of rich wine, or any proper julep, after it.

916. *Electuary of Peruvian bark.*

1. Take of Peruvian bark, three ounces; cascarilla, half an ounce; syrup of orange-peel, a sufficient quantity.
2. Take of Peruvian bark, three ounces; Virginian snakeroot, one ounce; syrup of orange peel, a sufficient quantity.
3. Take of Peruvian bark, three ounces; crude sal ammoniac, three drams; syrup of lemon-juice, a sufficient quantity.
4. Take of Peruvian bark, three ounces; colcothar of vitriol, six drams; simple syrup, a sufficient quantity.
5. Take of Peruvian bark, three ounces; alum, one ounce; syrup of lemon juice, as much as is sufficient.
6. Take of extract of Peruvian bark, one ounce; extract of logwood, extract of liquorice, each half an ounce; mucilage of quince-seeds, as much as is sufficient to reduce the other ingredients into the consistence of an electuary.

All these compositions are very elegant, and efficacious in the intentions for which they are designed. The first is calculated for common intermittent fevers, in the cure of which the virtues of the bark are greatly assisted by the cascarilla. The second and third are given in those intermittents which happen in cachectic habits, and persons subject to obstructions of the viscera, where the bark by itself, on account of its great astringency,

Composi-  
tions.

gency, would be prejudicial. The fourth is a good strengthener in laxities of the solids and decays of constitution; and the fifth, a powerful styptic in fluxes and hæmorrhages, particularly in the diabetes and fluor albus. The bulk of a nutmeg of each may be taken at a time, and repeated according to the exigency of the case. The sixth is a very agreeable form for the exhibition of Peruvian bark to those who are more than ordinarily offended with its taste; the substances here joined effectually covering its taste, at the same time that they coincide with it in virtue. The composition is a very elegant and pleasant one, and well deserves a place in the shops: it may either be given in the form of a bolus or electuary, in the dose of a dram or more; or dissolved in any suitable liquor into a draught.

#### 917. *An acid purgative electuary.*

Take of pulp of tamarinds, two ounces; crystals of tartar, two drams. Make them into an electuary.

This is an useful cooling laxative in hot bilious dispositions, or inflammatory diseases. The bulk of a nutmeg may be taken every hour, or oftener, till it begins to operate, or the same quantity may be taken once a day occasionally in dry costive habits.

#### 918. *Saponaceous electuary.*

Take of hard Spanish soap, two ounces; pareira brava, one ounce; rhubarb, gum of aloes, each three drams; syrup of orange-peel, a sufficient quantity. Mix and make them into an electuary.

This electuary is calculated for jaundices arising from an obstruction of the biliary ducts, or a viscosity of the bile itself: such are those which most commonly occur, in which the stools are of a whitish or ash-colour, and voided with difficulty. The dose is from half a dram to a dram, twice a day.

#### 919. *Binding electuary.*

Take of the Japonic confection, two ounces; extract of logwood, one ounce; syrup of dry roses, as much as will reduce them into a proper consistence for an electuary.

This electuary is calculated for the relief of dysenteries, and other intestinal fluxes, after the acrid humours have been duly evacuated by mild cathartics, &c. The quantity of a nutmeg may be taken every four or five hours.

#### 920. *Electuary of sulphur.*

Take of flowers of sulphur, half an ounce; lenitive electuary, two ounces; syrup of marshmallows, a sufficient quantity to make them into an electuary.

This electuary is designed against the piles, and generally distinguished in the hospitals by the title of *electuarium hæmorrhoidale*: where the disorder is accompanied with febrile or inflammatory symptoms, some nitre is occasionally added, in the proportion of two drams to the quantity here directed. It may be given from a dram to half an ounce at a time.

### SECT. VI. *Lobochs.*

921. A LOBOCH, eclegma, linctus, or lambative, is a soft compound designed to be licked or slowly swallowed down, of a middle consistence between a syrup

and electuary, at least never so thin as the former, nor so thick as the latter.

These preparations are generally composed of expressed oils, mixed with syrups and other like substances. Two ounces of a syrup, a dram of sugar, and an ounce of expressed oil, form a linctus of a due consistence; which may be made thicker at pleasure by adding more oil, or thinner by an increase of the syrup.

The form is an inelegant one, and in the present practice is little regarded.

### SECT. VII. *Emulsions.*

922. THE foregoing section respected compositions in which oils were united with watery liquors, by the mediation of sugar and syrups, into thick unctuous compounds. The present section contains mixtures of oily, resinous, and other like bodies, with water, in a liquid form, of a white colour resembling milk, and hence called *emulsions*.

Emulsions have been generally prepared by grinding the oily seeds of plants, or kernels of fruits, along with common water or any agreeable simple distilled water. In this process, the oil of the subject is, by the mediation of the other matter, united with the aqueous fluid: and hence they possess some share of the emollient virtue of the pure oil; with this advantage, that they are agreeable to the palate, and not apt to turn rancid or acrimonious by the heat of the body, which the pure oils in some inflammatory cases may do.

Emulsions, besides their use as medicines themselves, are excellent vehicles for certain substances which cannot otherwise be so conveniently taken in a liquid form. Thus camphor triturated with almonds, readily unites water into an emulsion, and in this form is conveyed into the remotest parts of the body, with sufficient efficacy to answer intentions of moment, at the same time that its heat and pungency are softened by the unctuousity of the almonds.

Pure oils, balsams, resins, and other similar substances, are likewise rendered miscible with water, into emulsions or milky liquors, by the intervention of mucilages. The white or yolk of an egg unites these bodies also with water, but less elegantly.

Several of the gummy resins, as ammoniacum, galbanum, myrrh, and others, are reducible to emulsions by trituration with water alone; their resinous part being rendered dissoluble by the mediation of the gummy.

#### 923. *Common emulsions.*

Take of sweet almonds blanched, one ounce; gum arabic, half an ounce; double-refined sugar, six drams; barley water, two pints. Dissolve the gum in the barley water warmed; as soon as the water is grown thoroughly cold, pour it by little at a time upon the almonds and sugar, first beat together, continuing to grind the whole, that the liquor may grow milky; after which it is to be passed through a strainer. *L.* Take of sweet almonds, one ounce; bitter almonds, one dram; common water, two pints. Beat the almonds, after having blanched them, in a marble mortar, and gradually pour on them the common water. Then strain off the liquor. *E.*

924. *Arabic emulsion* is made after the same manner, by

Composi-  
tions.

by adding, while the almonds are beating, two ounces and a half of mucilage of gum arabic.

Great care should be taken that the almonds are not become rancid by keeping; which will not only render the emulsion extremely unpleasant, a circumstance of great consequence in a medicine that requires to be taken in large quantities, but likewise give it injurious qualities little expected from preparations of this class. These liquors are principally made use of for diluting and obviating acrimonious humours; particularly in heat of urine and stranguries, arising either from a natural sharpness of the juices, or the operation of cathartics or other irritating medicines: in these cases, they are to be drank frequently, in the quantity of half a pint or more at a time.

#### 925. *A purging emulsion.*

Take of sweet almonds blanched, two drams; fine sugar, one dram; gum arabic, half a dram; scammony, 10 grains; simple cinnamon-water, one ounce. Dissolve the gum in the cinnamon water; and having ground the scammony with almonds and sugar, pour on the liquor by little at a time, continuing to grind them together, so as to make them into an emulsion.

This emulsion is an agreeable and effectual purgative. Some have employed an infusion of liquorice; which appears to be a very proper addition in these kinds of preparations, as it coincides with the almonds in correcting the irritating power of the purgative material.

#### 926. *Emulsion with arum root.*

Take of fresh arum root, gum arabic, each two drams; spermaceti, two scruples; common water, five ounces; nutmeg-water, syrup of orange-peel, each half an ounce. Dissolve the gum arabic with a part of the water, into a mucilage, which is to be beaten with the spermaceti into a smooth paste. To this add the arum root, previously beaten by itself into a pulp; and rub them well together, that they may be thoroughly mixed. Then gradually pour in the waters and the syrup.

Fresh arum root may be taken in this form without the least inconvenience from the pungency with which the root itself so violently affects the mouth. A spoonful of the emulsion has been given every six hours, or oftener, in cases of the rheumatic kind, and generally with great benefit. The more immediate effect experienced from it is that of warming the stomach, and promoting sweat, which in some instances it does profusely.

### SECT. VIII. *Juleps, Mixtures, and Draughts.*

927. *By julep* is commonly understood, an agreeable liquor, designed as a vehicle for medicines of greater efficacy, or to be drank after them, or to be taken occasionally as an auxiliary. In this light their basis is generally common water, or a simple distilled water, with one-fourth or one third its quantity of a distilled spirituous water: this mixture is sweetened with sugar or any proper syrup, or acidulated with vegetable or mineral acids, or impregnated with other medicines suitable to the intention; care being taken that these additions be such as will not render the compound unlighty or unpalatable. The quantity usually

directed at a time, in common prescription, is six or eight ounces, to be taken by spoonfuls.

928. A *mixture*, more strictly so called, receives more efficacious materials, whether soluble in water, as extracts or salts; or indissoluble, as powders; more regard being here had to the medicinal intention, than to the sightliness or palatableness of the compound. There is indeed no precise distinction between the two; the same composition being often called by one a *julep*, and by another a *mixture*; though in general, few would give the name of *julep* to a very disagreeable liquor, or that of *mixture* to a very pleasant one.

929. A *draught* differs from a *julep* or *mixture* only in being prescribed in less quantity, the whole being intended for one dose.

#### 930. *Chalk Julep.*

Take of the whitest chalk prepared, one ounce; double-refined sugar, six drams; gum arabic, two drams; water, two pints. Mix them together.

This julep is designed for heartburns and other like disorders arising from acid juices in the first passages.

#### 931. *Musk julep. L.*

Take of damask-rose water, six ounces by measure; musk, 12 grains; double-refined sugar, one dram. Grind the sugar and musk together, and gradually add to them the rose-water.

This is an improvement upon the *hysteric julep* with *musk* of *Bater*, formerly in use.

#### 932. *Cordial julep.*

Take of alexeterial water, four ounces; aromatic water, two ounces; volatile oily spirit, tincture of saffron, each two drams; white sugar, half an ounce. Mix, and make them into a julep.

This mixture is an useful cordial in all depressions of the spirits, in the sinkings of low fevers, and the languors to which hysterical and hypochondriacal persons are subject. An ounce, or two spoonfuls, may be taken for a dose, two or three times a day.

#### 933. *Diaphoretic julep.*

Take of alexeterial water, four ounces; spirit of Mindererus, two ounces; salt of hartshorn, ten grains; white sugar, six drams. Mix them for a julep.

This excellent composition is a very powerful sudorific, and answers its intention more effectually, and with greater certainty, than many others calculated for the same purpose. Where a copious sweat is to be excited, as in rheumatic diseases, two spoonfuls are to be taken warm in bed every hour, or two hours, till the sweat breaks out; if warm diluting liquors are not afterwards sufficient to keep it up, the same medicine is to be occasionally repeated.

#### 934. *Diuretic julep.*

Take of spirit of Mindererus, four ounces; compound horseradish water, two ounces; syrup of marshmallows, three ounces. Mix them together.

The spirit of Mindererus is an excellent aperient saline liquor, capable of promoting evacuation either by the cutaneous pores, or the urinary passages, according to the manner of exhibiting it. When taken warm in bed, it proves a powerful sudorific, especially if assist-

Composi-  
tions.

ed by volatile salts, small doses of opiates, or other substances which tend to determine its action to the skin. If the patient walks about in a cool air, it operates gently, but for the most part effectually, by urine. The additions here joined to it correspond with this intention, and promote its operation. As this medicine excites the urinary discharge, without heating or irritating the parts, it takes place not only in dropsies, but likewise in inflammatory disorders, wherever this salutary secretion is to be promoted. It is given in the quantity of two spoonfuls thrice a-day.

935. *Fetid julep.*

Take of asafetida, one dram and a half; rue water, six ounces; compound valerian water, two ounces; oil of hartshorn, twenty drops; white sugar, ten drams. Rub the asafetida in the rue water till it dissolves; and having dropped the oil upon the sugar, mix the whole together.

This composition is not a little fetid and unsightly; it is nevertheless a medicine of great efficacy in hypochondriacal and hysterical disorders, asthma, and other nervous complaints: the dose is one spoonful, to be taken thrice a-day. It is sometimes prepared without the oil of hartshorn.

936. *Binding julep.*

Take of alexeterial water, four ounces; aromatic water, two ounces; Japonic confection, two drams; Japan earth, in powder, one dram; liquid laudanum, forty drops; white sugar, half an ounce. Mix them well together.

This julep is calculated against dysenteries and diarrhoeas; in which, after proper evacuations, it generally eases the gripes, and restrains the flux. It is to be given three or four times a-day, in the quantity of a spoonful at a time.

937. *Antidysenteric mixture.*

1. Take of simple cinnamon-water, seven ounces; spirituous cinnamon-water, one ounce; electuary of scordium with opium, half an ounce. Mix them together.
2. Take of extract of logwood, three drams; tincture of Japan earth, two drams; spirituous cinnamon-water, one ounce; common water, seven ounces. Dissolve the extract in the cinnamon-water, and then add the common water and the tincture.

In recent dysenteries, after the necessary evacuations, a spoonful or two of either of these mixtures may be given after every motion, or once in four or five hours: if the first, which is a mild opiate, fails of procuring rest, it is a sign that some of the corrupted humours still remain in the bowels, and that it is more proper to go on with the evacuation than to suppress the flux. These medicines will sometimes likewise take place in the last stage of the disease, when thro' neglect or mismanagement it has continued till the strength is much impaired, the intestines greatly relaxed, and their villous coat abraded; provided there are neither ichorous or involuntary stools, apthæ, petechiæ, hiccup, or great anxiety at the breast. Rhubarb, and these astringents, are to be so interposed, that at the same time that the putrid humours are dis-

lodged, the strength may be supported, and the intestines braced.

Composi-  
tions.938. *Cordial mixture.*

Take of simple cinnamon-water, four ounces; spirituous cinnamon-water, two ounces; extract of saffron, one scruple; confection of kermes, six drams. Mix them together.

In great languors and depressions, a spoonful of this rich cordial mixture may be taken every half hour.

939. *Mixture against the phthisis.*

1. Take of balsam of copaiba, one dram; common water, four ounces; spirituous cinnamon-water, one ounce. Syrup of orange-peel, half an ounce. Let the balsam be dissolved in a proper quantity of yolk of egg, and then mixed with the other ingredients.
2. Take of thebaic extract, one grain; conserve of roses, half a dram. Mix them together for a bolus.
3. Take of oxymel of squills, a dram and a half; thebaic tincture, fifteen drops; spirituous cinnamon-water, two drams; common water, two ounces. Mix them together.

In the advanced state of a consumption, we may distinguish two sorts of coughs, one occasioned by the ulcers, and the other by a thin rheum falling upon the fauces and trachea; which parts, being then deprived of their mucus, become extremely sensible to irritation. It is this last kind, perhaps, which is most painful and teasing to the patient. The first sort requires balsamics, if the ulcer is open, and the matter can be expectorated. For this purpose, the first of the above mixtures is a very elegant and effectual formula; two spoonfuls are to be taken at a time twice a-day: if the balsam purges, two drams of the pargoric elixir, added to the quantity of the mixture here prescribed, will prevent that effect. The other kind of cough can only be palliated by inexpectants; and for that purpose, the second of the above compositions is one of the most successful medicines: the conserve is altogether safe, and otherwise well adapted to the nature of the disease, but of weak virtues: the opiate extract is the most efficacious ingredient, but is to be given with great caution, as opiates in general are apt to heat, to bind the body, and to obstruct expectoration. As these bad qualities are in good measure corrected by squills, as soon as the patient begins to complain of restless nights from coughing, the third mixture may be given at bed-time.

940. *Valerian mixture.*

Take of simple peppermint-water, twelve ounces; wild valerian-root, in powder, one ounce; compound spirit of lavender, half an ounce; syrup of orange-peel, one ounce. Mix them together.

Wild valerian root, one of the principal medicines in epilepsies and vertiges, seems to answer better when thus exhibited in substance, than if given in form of tincture or infusion. The liquors here joined to it excellently coincide with, and by their warmth and pungency greatly improve, its virtues. Two spoonfuls of the mixture may be taken twice or thrice a-day.

941. *Cathartic draught.*

Take of jalap, in powder, one scruple; ipecacoanha, three

three grains; compound juniper-water, one ounce; infusion of lintfeed, an ounce and a half; simple syrup, one dram. Mix them together.

This is a strong cathartic; yet for the most part easy and safe in operation. It is calculated chiefly for hydropic cases; in which it procures copious evacuations, without weakening or fatiguing the patient so much as many other medicines of this kind.

942. *Saline cathartic draught.*

Take of Glauberts cathartic salt, manna, each six drams; boiling water, three ounces; tincture of cardamoms, one dram. Dissolve the salt and manna in the water; and having strained off the liquor, add to it the tincture of cardamoms.

This is a very elegant and agreeable saline purgative. Tincture of cardamoms is one of the best additions to liquors of this kind, or to the purging mineral waters, for rendering them acceptable to the stomach.

943. *Diaphoretic draught.*

Take of spirit of Mindererus, spirit of meconium, each half an ounce; salt of hartshorn, five grains. Mix them together.

This draught is a very powerful saline diaphoretic. It is given with safety, and often with great benefit, in the beginning of inflammatory fevers, after bleeding; where theriaca, and other warm substances usually employed, if they fail in bringing out a sweat, increase the fever.

944. *Diuretic draught.*

1. Take of oxymel of squills, one dram and a half; simple cinnamon-water, one ounce; compound spirit of lavender, syrup of orange-peel, each one dram. Mix them together.
2. Take of vinegar of squills, one dram, or one dram and a half; salt of wormwood, half a dram; lemon-juice, six drams; simple cinnamon-water, an ounce and a half; spirituous peppermint-water, half an ounce; syrup of orange-peel, one dram. Let the salt of wormwood and lemon-juice be first mixed together, and then add to them the other ingredients.

These elegant and efficacious compositions are commended by Dr Mead for promoting urine in hydropic cases. He directs them to be taken every night, or oftener, according to the urgency of the symptoms. The squill, one of the most powerful diuretics, is, by the additions here joined to it, rendered not only more grateful to the palate and stomach, but likewise enabled more effectually to answer the purposes intended by it.

945. *An anodyne diuretic draught.*

Take of ley of tartar, half a dram; thebaic tincture, forty drops; peppermint-water, one ounce; simple cinnamon-water, half an ounce; spirituous cinnamon-water, two drams; syrup of marshmallows, one dram. Mix them together.

Though practitioners have rarely ventured to exhibit opium in dropsies; yet in those which are accompanied with great pain, this anodyne drug, by easing the pain, and removing the stricture of the passages,

which painful sensations always occasion, proves a medicine of great service, and notably promotes the urinary discharge. Dr Mead has given a remarkable instance of the good effects of the mixture above prescribed, in a person labouring under an ascites and tympany at the same time, where the pain was intolerable, the thirst intense, and the urine in very small quantity; the stronger purgatives increased the distemper; soap, alkaline salts, nitre, and other diuretics, were tried in vain: this draught (when the patient seemed to be beyond any assistance from medicine) procured unexpected relief, not only a gentle sleep, and truce from the pain, but likewise a copious discharge of urine: by repeating the medicine for a little time, every eight hours, and afterwards using corroborants, the cure was perfectly completed.

SECT. IX. *Lotions, Gargarisms, Injections, &c.*

946. *Bater's alum water. L.*

Take of alum, white vitriol, each half an ounce; water, two pints. Boil the salts in the water till they are dissolved; let the solution settle, and afterwards filter it through paper.

This liquor is used for cleansing and healing ulcers and wounds, and for removing cutaneous eruptions, the part being bathed with it hot three or four times a-day. It is sometimes likewise employed as a collyrium; and as an injection in the gonorrhoea and fluor albus, when not accompanied with virulence.

947. *Alum water. E.*

Take of corrosive mercury sublimated, alum, each two drams; water, two pints. Let the sublimated and alum be ground into powder, and boiled with water in a glass vessel to the consumption of half the water; then suffer the liquor to settle, and pour it off clear from the sediment.

This composition is designed chiefly for cutaneous pustules and ulcerations.

948. *Sapphire-coloured water.*

Take of lime-water, one pint; sal ammoniac, one dram. Let them stand together in a copper vessel, or along with some plates of copper, until the liquor has acquired a sapphire colour. *L.*

Take of lime-water newly made, half a pint; sal ammoniac, two scruples; powdered verdigrease, four grains. Mix and strain after 24 hours. *E.*

This water is at present pretty much in use, as a detergent of foul and obstinate ulcers, and for taking away specks or films in the eyes.

949. *Blue vitriolic water. L.*

Take of blue vitriol, three ounces; alum, strong spirit (or oil) of vitriol, each two ounces; water, a pint and a half. Boil the salts in the water, until they are dissolved; then add the acid spirit, and filter the mixture through paper.

950. *Styptic water. E.*

Take of blue vitriol, alum, each three ounces; water, two pints. Boil them until the salts are dissolved, then filter the liquor, and add an ounce of oil of vitriol.

These compositions are formed upon the styptic recommended by Sydenham, for stopping bleeding at the nose, and other external hæmorrhages: for this purpose, cloths or doffils are to be dipt in the liquor, and applied to the part.

951. *Vitriolic water.* E.

Take of white vitriol, two drams; water, two pints. Boil till the vitriol is dissolved, and then filter the liquor.

Where the eyes are watery or inflamed, this solution of white vitriol is a very useful application: the slighter inflammations will frequently yield to this medicine, without any other assistance; in the more violent ones, venæsection and cathartics are to be premissed to its use.

952. *Astringent gargarism.*

Take of oak-bark, one ounce; alum, one dram; honey of roses, one ounce; water, a pint and a half. Boil the water with the oak-bark, till such time as the liquor, when strained, will amount only to one pint; to which add the alum and the honey.

953. *Common gargarism.*

Take of tincture of roses, one pint; honey of roses, two ounces. Mix them together. Or, Take of water, six ounces; nitre, one dram; honey of roses, one ounce. Mix them together. Where acids are requisite, forty drops of the weak spirit of vitriol are added to this composition.

954. *Detergent gargarism.*

Take of emollient decoction, one pint; tincture of myrrh, one ounce; honey, an ounce and a half. Mix them together.

955. *Emollient gargarism.*

Take of marshmallow root, two ounces; figs, four in number; water, three pints. Boil them till one pint is wasted, and then strain the liquor.

These liquors are used for washing the mouth and fauces; the first, where the parts are extremely relaxed; the second and third, where ulcerations require to be deterged, or the excretion of the thick viscid saliva promoted; and the fourth, where the mouth is dry, parched and rigid, to moisten and soften it. In some cases, volatile spirits may be advantageously joined to these kinds of preparations. Dr Pringle informs us, that in the inflammatory quinsy, or strangulation of the fauces, he has observed little benefit arising from the common gargles: that such as were of an acid nature seemed to do more harm than good, by contracting the emunctories of the saliva and mucus, and thickening those humours: that a decoction of figs in milk and water seemed to have a contrary effect, especially if some spirit of sal ammoniac was added, by which the saliva was made thinner, and the glands brought to secrete more freely; a circumstance always conducive to the cure.

956. *Starch glyster.*

Take of gelly of starch, four ounces; linseed oil, half an ounce. Liquefy the gelly over a gentle fire, and then mix in the oil. Forty drops of liquid laudanum, are sometimes added.

957. *Anodyne or opiate glyster.*

Take of infusion of linseed, six ounces; liquid laudanum, forty drops. Or, Mutton-broth, five ounces; thebaic extract, three grains.

958. *Glyster against the colic.*

Take of common decoction, half a pint; tinctura sacra, one ounce; common salt, one dram; linseed oil, two ounces. Mix them together.

959. *Astringent glyster.*

Take of lime-water, ten ounces; Japonic confection, half an ounce. Mix them together for a glyster, of which one half is to be injected at a time.

960. *Astringent balsamic glyster.*

This is made by adding to the foregoing half an ounce of Locatelli's balsam, dissolved in the yolk of an egg.

961. *Common glyster.*

Take of common decoction, twelve ounces; lenitive electuary, one ounce; common salt, half an ounce; oil-olive, two ounces. Mix them together.

962. *Domestic glyster.*

Take of cows milk, half a pint; brown-sugar, oil-olive, each one ounce. Mix them together.

963. *Emollient glyster.*

Take of palm-oil, an ounce and a half; cows milk, half a pound. Let the oil be beat up with the yolk of one egg, and then add the milk.

964. *Fetid glyster.*

Take of asafetida, two drams; rue, favin, each half an ounce; oil-olive, one ounce; oil of Amber, half a dram; water, one pint and a half. Boil the water with the rue and favin, till half a pint is wasted; then strain off the remaining decoction, and mix with it the asafetida and the oils. Half the quantity of the composition here directed, is to be injected at a time.

965. *Purging glyster.*

Take of common decoction, half a pint; white soap, one ounce; syrup of buckthorn, an ounce and a half. Mix them together.

966. *Turpentine glyster.*

Take of common decoction ten ounces; Venice turpentine (dissolved in the yolk of an egg), half an ounce; linseed oil, one ounce. Mix them together.

The uses of these compositions are sufficiently obvious from their titles. The starch, anodyne, emollient, and astringent glysters, are used in dysenteries, and other alvine fluxes, to strengthen the tone of the intestines, defend them from being corroded by the acrimonious humours, to heal their excoriated, and ease the pains which accompany these disorders. The turpentine glyster is injected in nephritic cases; the fetid in hystERIC ones. The others are calculated for unloading the intestines of their contents, where the exhibition of purgatives in other forms is improper or unsafe.

Glysters have been looked upon by some as mere topical applications, whose operation was confined to

to the intestines, into which they are received. But experience has shewn, that in many cases their action is extended much farther: thus the turpentine glyster, above described, promotes the discharge by the kidneys, and communicates to the urine a violet smell; and the anodyne glyster proves narcotic, as if a moderate dose of opium had been swallowed: Persons have been inebriated by spirituous glysters; and some affirm, that life has been supported for several days, by those of a nutritious kind.

967. *Balsamic injection.*

Take of balsam of Copaiba, half an ounce; lime-water, six ounces; honey of roses, two ounces. Let the balsam be well beaten up with the yolk of one egg; and then gradually add the lime-water and honey.

968. *Mercurial injection.*

Take of quicksilver, balsam of Copaiba, each half an ounce; rose-water, half a pint. Rub the quicksilver with the balsam, till they are perfectly incorporated; then mix with them the yolk of an egg, and afterwards add the rose-water.

This and the foregoing preparation are designed to be injected into the urethra in violent gonorrhœas, for cleansing and deterring the parts.

SECT. X. *Plasters.*

969. **PLASTERS** are composed chiefly of oily and unctuous substances, united with powders, into such a consistence, that the compound may remain firm in the cold, without sticking to the fingers; that it may be soft and pliable in a small heat; and that by the warmth of the human body it be so tenacious, as readily to adhere both to the part on which it is applied, and to the substance on which it is spread.

There is however a difference in the consistence of plasters, according to the purposes they are to be applied to: thus, such as are intended for the breast and stomach, should be very soft and yielding; whilst those designed for the limbs are made firmer and more adhesive. An ounce of expressed oil, an ounce of yellow wax, and half an ounce of any proper powder, will make a plaster of the first consistence; for a hard one, an ounce more of wax, and half an ounce more of powder, may be added. Plasters may likewise be made of resins, gummy-resins, &c. without wax, especially in extemporaneous prescription: for officinals, these compositions are less proper, as they soon grow too soft in keeping, and fall flat in a warm air.

Calces of lead, boiled with oils, unite with them into a plaster of an excellent consistence, and which makes a proper basis for several other plasters.

In the boiling of these compositions, a quantity of water must be added, to prevent the plaster from burning and growing black. Such water, as it may be necessary to add during the boiling, must be previously made hot: for cold liquor would not only prolong the process, but likewise occasion the matter to explode, and be thrown about with violence, to the great danger of the operator: this accident will equally happen upon the addition of hot water, if the plaster is extremely hot.

970. *Anodyne plaster. E.*

Take of white resin, eight ounces; tacamahaca in powder, galbanum, each four ounces; cummia in seeds, three ounces; black soap, four ounces. Melt the resin and the gums together; then add the powdered seeds and the soap, and make the whole into a plaster.

This plaster generally gives ease in slight rheumatic pains, which it is supposed to effect by preventing the afflux of humours to the part, and putting in motion and repelling such as already stagnate there.

971. *Antihysteric plaster. E.*

Take of strained galbanum, one pound; strained asphaltida, yellow wax, of each half a pound; yellow resin, three ounces. Melt them together into a plaster.

This plaster is applied to the umbilical region, or over the whole abdomen, in hysterical cases, and sometimes with good effect.

972. *Drawing plaster. L.*

Take of yellow resin, yellow wax, each three pounds; tried mutton-suet, one pound. Melt them together; and whilst the mass remains fluid, pass it through a strainer.

This is a very well contrived plaster for the purpose expressed in its title. It is calculated to supply the place of melilot plaster; whose great irritation, when employed for the dressing of blisters, has been continually complained of. This was owing to the large quantity of resin contained in it, which is here for that reason retrenched. It should seem, that, when designed only for dressing blisters, the resin ought to be entirely omitted, unless where a continuance of the pain and irritation excited by the vesicatory is required. Indeed plasters of any kind are not very proper for this purpose: their consistence makes them sit uneasy, and their adhesiveness renders the taking them off painful. Cerates, which are softer and less adhesive, appear much more eligible: the *white cerate* (n° 1019.) will serve for general use, and for some particular purposes the *yellow cerate* (n° 1030.) may be applied.

973. *Wax plaster. E.*

Take of yellow wax, two pounds; white resin, half a pound; hog's lard, one pound. Melt them together into a plaster.

This plaster is similar to the foregoing, but the further reduction of the resin renders it for some purposes more eligible.

974. *Cephalic plaster.*

Take of Burgundy pitch, two pounds; soft labdanum, one pound; yellow resin, yellow wax, each four ounces; the expressed oil, called *oil of mace*, one ounce. Melt the pitch, resin, and wax, together; then add, first the labdanum, and afterwards the oil of mace. *L.*

Take of tacamahaca in powder, yellow wax, Venice turpentine, each four ounces; oil of lavender, two drams; oil of amber, one dram. Melt the tacamahaca

haca with the wax; and then add the turpentine, that a plaster may be formed: when this compound is taken from the fire, and grown almost cold, mix in the oils. *E.*

These plasters are applied, in weakness or pains of the head, to the temples, forehead, &c. and sometimes likewise to the feet. Schulze relates, that an inveterate rheumatism in the temples, which at times extended to the teeth, and occasioned intolerable pain, was completely cured in two days by a plaster of this kind (with the addition of a little opium) applied to the part, after many other remedies had been tried in vain: he adds, that a large quantity of liquid matter exuded, under the plaster, in drops, which were so acrid as to corrode the cuticle.

975. *Common plaster, usually called diachylon.*

Take of oil-olive, one gallon; litharge, ground into a most subtle powder, five pounds. Boil them over a gentle fire, with about two pints of water; keeping them continually stirring, till the oil and litharge unite, and acquire the consistence of a plaster. If all the water should be consumed before this happens, add some more water, previously made hot. *L. E.*

This plaster is the common application in excoriations of the skin, slight flesh wounds, and the like. They keep the part soft, and somewhat warm, and defend it from the air, which is all that can be expected in these cases from any plaster. Some of our industrious medicine-makers have thought these purposes might be answered by a cheaper composition, and accordingly have added a large quantity of common whitening and hogs lard; this, however, is by no means allowable, not only as it does not stick so well, but likewise as the lard is apt to grow rancid and acrimonious. The counterfeit is distinguishable by the eye.

976. *Common sticking plaster.*

Take of common plaster, three pounds; yellow resin, half a pound. Melt the common plaster over a very gentle fire; then add the resin, first reduced into powder, that it may melt the sooner; and mix them all together.

This plaster may otherwise be made, by taking, instead of the common plaster, its ingredients oil and litharge, and adding the resin a little before they have come to the due consistence; then continue the boiling, till the plaster is finished. It turns out the most elegant when made by this last method.

977. *Sticking plaster. E.*

Take of common plaster, two pounds; yellow resin, five ounces. Melt them together, so as to make a plaster.

These plasters are used chiefly as adhesives, for keeping on other dressings, &c.

978. *Common plaster, with gums. L.*

Take of common plaster, three pounds; galbanum strained, eight ounces; common turpentine, frankincense, each three ounces. Melt the galbanum with the turpentine over a gentle fire, and sprinkle in the frankincense reduced to powder: then gradually mix with these the common plaster, previous-

ly liquefied by a very gentle heat. Or, instead of the common plaster already made, you may take the oil and litharge boiled together: as soon as these unite, before they have acquired the consistence of a plaster, the other ingredients are to be added.

979. *Gum plaster. E.*

Take of gum ammoniacum strained, galbanum strained, each three ounces; common plaster, two pounds. Mix them together into a plaster.

Both these plasters are used as digestives and suppuratives; particularly in abscesses, after a part of the matter has been matured and discharged, for suppurating or discussing the remaining hard part.

980. *Cummin plaster. L.*

Take of Burgundy pitch, three pounds; yellow wax, cummin seeds, caraway seeds, bay-berries, each three ounces. Melt the pitch with the wax; then sprinkle in the other ingredients first reduced into a powder, and mix the whole well together.

This plaster stands recommended as a moderately warm discutient; and is directed by some to be applied to the hypogastric region, for strengthening the viscera, and expelling flatulencies.

981. *Defensive plaster. E.*

Take of common plaster, two pounds; yellow wax, yellow resin, of each three ounces; colcothar of vitriol, six ounces. Boil the oil with the litharge, till they have acquired nearly the consistence of a plaster: in this liquefy the wax, and then add the other ingredients, so as to form the whole into a plaster, according to art.

This plaster is laid round the lips of wounds and ulcers, over the other dressings, for defending them from inflammation, and a fluxion of humours; which, however, as Mr Sharp very justly observes, plasters, on account of their consistency, tend rather to bring on than to prevent.

982. *Melilot plaster.*

The London college has substituted to the plaster of this name, the *drawing plaster*, (n° 972.); the Edinburgh the *wax plaster*, (n° 973.)

983. *Mercurial plaster. E.*

Take of common plaster, a pound and a half; quicksilver eight ounces; Venice turpentine, two ounces and a half. Grind the quicksilver in a mortar, with the turpentine, until they are perfectly incorporated; and then, having melted the common plaster, and taken it from the fire, add to it this mixture.

This plaster is looked on as a powerful resolvent and discutient, acting with much greater certainty in these intentions than any composition of vegetable substances alone; the mercury exerting itself in a considerable degree, and being sometimes introduced into the habit in such quantity as to affect the mouth. Pains in the joints and limbs from a venereal cause, nodes, topes, and beginning indurations of the glands, are said sometimes to yield to them.

984. *Strengthening plaster. L.*

Take of common plaster, two pounds; frankincense, half a pound; dragons blood, three ounces. Melt  
the

the common plaster, and add to it the other ingredients reduced into powder. The dragons blood should be reduced to a very fine powder, otherwise the mixture will not be of an uniform colour.

This is a reformation of the laborious and injudicious composition described in preceding pharmacopœias, under the title of *Emplastrum ad berniam*; and though far the most elegant and simple, is as effectual for that purpose as any of the medicines of this kind. If constantly worn, with a proper bandage, it will, in children, frequently do service; though perhaps not so much from any strengthening quality of the ingredients, as from its being a soft, close, and adhesive covering.

#### 985. *Saponaceous plaster.* E.

Take of gum plaster, one pound; Castile soap, sliced, nine ounces; common plaster, two pounds. Melt the plaster, and then put in the soap, letting the whole boil for a short time, that it may become a plaster.

#### 986. *Stomach plaster.*

Take of soft labdanum, three ounces; frankincense, one ounce; cinnamon, the expressed oil, called *oil of mace*, each half an ounce; essential oil of mint, one dram. Having melted the frankincense, add to it, first the labdanum softened by heat, and then the oil of mace; afterwards mix these with the cinnamon and oil of mint; and beat them together in a warm mortar, into a mass, which is to be kept in a close vessel. L.

This is a very elegant stomach plaster. It is contrived so as to be easily made occasionally (for these kinds of compositions, on account of their volatile ingredients, are not fit for keeping;) and to be but moderately adhesive, so as not to offend the skin; and that it may without difficulty be frequently taken off and renewed, which these sorts of applications, in order to their producing any considerable effect, require to be.

Take of yellow wax, eight ounces; tacamahaca in powder, four ounces; cloves, powdered, two ounces; palm-oil, six ounces; expressed oil of mace, an ounce and a half; essential oil of mint, two drams. Melt the wax and tacamahaca with the palm-oil; then removing the mixture from the fire, add the other ingredients, and make them into a plaster, according to art. E.

These plasters are applied to the pit of the stomach, in weakness of that viscus, in vomitings, in the disorder improperly called the *heartburn*, &c. and sometimes with good success. The pit of the stomach, however, as Hoffman has observed, is not always the most proper place for applications of this kind to be made to: if applied to the five lower ribs of the left side, towards the back, the stomach will in general receive more benefit from them; for it appears from anatomical inspection, that greatest part of it is situated there.

#### 987. *Blistering plaster.* L.

Take of drawing plaster, two pounds; cantharides, one pound; vinegar, half a pint. Melt the drawing plaster; and, a little before it grows stiff, mix in the cantharides, reduced into a most subtle powder:

then add the vinegar, and work them well together.

Take of yellow wax, two pounds; yellow rosin, hog's-lard, of each one pound; oil olive, half a pint; cantharides, a pound and a half. Reduce the cantharides first to a very fine powder, then rub them with the oil; and having melted the other ingredients with a gentle heat, add the cantharides to them when pretty cold. E.

#### 988. *An anodyne and discutient plaster.*

Take of cummin plaster, two ounces; camphor, three drams; Thebaic extract, one dram and a half. Grind the camphor, with some drops of oil olive, into a very subtle powder; and then mix it with the other ingredients, according to art, into a plaster.

#### 989. *Warm plaster.*

Take of gum plaster, one ounce; blistering plaster, two drams. Melt them together over a gentle fire.

#### 990. *Suppurating plaster.*

Take of gum plaster, an ounce and a half; Burgundy pitch, half an ounce. Melt them together.

The uses of the three foregoing compositions, which are taken from our hospitals, are sufficiently obvious from their titles. The warm plaster is a very stimulating application, of great use in fixed pains, as in the rheumatism, sciatica, beginning chilblains, &c.

### SECT. XI. *Ointments, Liniments, and Cerates.*

991. OINTMENTS and liniments differ from plasters little otherwise than in consistence. Any of the officinal plasters, diluted with so much oil as will reduce it to the thickness of Riff honey, forms an ointment: by farther increasing the oil, it becomes a liniment. Cerates differ from plasters and ointments only in consistence; being a softer kind of plaster, or harder kind of ointment.

#### 992. *Ointment of verdigris.* E.

Take of white wax, yellow resin, of each two ounces; of oil olive, a pint; verdigris, half an ounce. Having melted the wax and resin with the oil, add the verdigris first ground with a little of the oil, keeping the whole constantly stirring till cold.

#### 993. *Mel Ægyptiacum.* L.

Take of verdigris, reduced into a very subtle powder, five ounces; honey, 14 ounces by weight; vinegar, seven ounces by measure. Boil these ingredients together, over a gentle fire, till they have acquired a due consistence and a reddish colour. On keeping this mixture for some time, the thicker part falls to the bottom; the thinner, which floats on the top, is called *mel Ægyptiacum*.

These preparations are designed only for external use, for cleansing and deterring ulcers, and keeping down fungous flesh: they are serviceable also in venereal ulcerations of the mouth and tonsils. If for particular purposes, the latter should be wanted more acrid, it may be occasionally rendered so by shaking the vessel, so as to mix up the thick matter at the bottom (which contains greatest part of the verdigris) with the upper thin one.—In the former the verdigris is sometimes doubled.

994. *White ointment.* L. E.

Take of oil olive, one pint; white wax, four ounces; spermaceti, three ounces. Liquefy them by a gentle fire, and keep them constantly and briskly stirring, till grown thoroughly cold.

995. *Ointment of white lead, commonly called white ointment.* E.

Take of oil olive, three pints; cerusse, one pound; white wax, nine ounces. Melt the wax in the oil: then gradually add the cerusse, and stir them well together, that they may be thoroughly mixed into an ointment.

This is an useful, cooling, and emollient ointment, of good service in excoriations, and other like frettings of the skin.

996. *Camphorated white ointment.* L.

This is made by adding to the white ointment a dram and a half of camphor, previously ground with some drops of oil of almonds,

This ointment is supposed to be more discutient than the foregoing, and serviceable against cutaneous heats, itching, and lerpiginous eruptions. It should be kept in close vessels, otherwise the camphor will soon exhale: smelling strong of this ingredient is the best mark of its goodness.

997. *Ointment of marshmallows.* L.

Take oil of mucilages, three pints; yellow wax, one pound; yellow resin, half a pound; common turpentine, two ounces. Melt the resin and wax with the oil: then, having taken them from the fire, add the turpentine; and while the mixture remains hot, strain it.

998. *Yellow basilicum ointment.*

Take of oil olive, one pint; yellow wax, yellow resin, Burgundy pitch, each one pound; common turpentine, three ounces. Melt the wax, resin, and pitch, along with the oil, over a gentle fire; then take them from the fire, add the turpentine, and whilst the mixture remains hot strain it. L.

Take of yellow wax, yellow resin, each two ounces; hog's-lard and oil olive, of each one pound. Melt them together with a gentle fire, and having removed them from it, stir them well till they grow cold. E.

These are commonly employed, in dressings, for digesting, cleansing, and incarnating wounds and ulcers. They differ very little, if at all, in their effects, from the liniment of *Arceus*, (n° 1015.)

999. *Black basilicum ointment, or ointment of four ingredients.* L.

Take of oil olive, one pint; yellow wax, yellow resin, dry pitch, each nine ounces. Melt them all together; and whilst the mixture is hot, strain it off.

This ointment was formerly of considerable esteem for healing and incarnating wounds, &c. but is said to have an inconvenience of being apt to render them foul, and produce fungous flesh: at present it is rarely made use of; the yellow basilicum, and the liniment of *Arceus*, being in general preferred.

1000. *Green basilicum ointment.* L.

Take of yellow basilicum, eight ounces; oil olive, three ounces by measure; verdigris prepared, one ounce. Mix, and make them into an ointment.

This ointment is an efficacious detergent.

1001. *Yellow ointment.* E.

Take of quicksilver, one ounce; spirit of nitre, two ounces; hogs-lard, tried, one pound. Dissolve the quicksilver in the spirit of nitre by digestion in a sand-bath; and whilst the solution is very hot, mix with it the lard, previously melted by itself, and just beginning to grow stiff. Stir them briskly together, in a marble mortar, so as to form the whole into an ointment.

1002. *The stronger blue ointment.* L.

Take of hogs lard, tried, two pounds; quicksilver, one pound; simple balsam of sulphur, half an ounce. Grind the quicksilver with the balsam of sulphur till they are perfectly incorporated; then gradually add the lard heated, and mix them carefully together.

1003. *The milder blue ointment.* L.

Take of hogs lard, tried, four pounds; quicksilver, one pound; common turpentine, one ounce. Grind the quicksilver with the turpentine, in a mortar, till it ceases to appear; then gradually add the lard warmed, and carefully mix them together.

This last unguent turns out of a much better blue colour than the foregoing, which is of a very dingy hue. Mercurial unguents have in many cases the same effect with the preparations of this mineral taken internally; and are at present frequently employed, not only against cutaneous disorders, as alterants, but likewise in venereal and other obdurate cases, for raising a salivation. The ptyalism excited by unction is said to be attended with the fewest inconveniences, and to perform the most complete cure. In some constitutions, mercurials taken inwardly, run off by the intestines, without affecting the mouth; and in others, they affect the salivary glands so quickly, as to occasion a copious ptyalism, without extending their action to the remoter parts, and consequently without removing the cause of the disease.

1004. *Ointment of gum elemi.* L.

Take of mutton-suet, fresh and tried, two pounds; gum elemi, one pound; common turpentine, ten ounces. Melt the gum with the suet; and having taken them from the fire, immediately mix the turpentine; then whilst the mass remains fluid, strain it off.

1005. *The ointment, commonly called liniment of Arceus.* E.

Take of hogs-lard, one pound; goats suet, or mutton suet, two pounds; Venice turpentine, gum elemi, each a pound and a half. Melt and strain them, so as to make an ointment according to art.

This unguent has long been in use for digesting, cleansing, and incarnating; and for these purposes is preferred by some to all the other compositions of this kind.

1006. *Emollient ointment.* E.

Take of palm oil, four pints; fresh-drawn linseed oil, three

three pints; yellow wax, one pound. Melt the wax in the oils, over a gentle fire, and strain the ointment, which supplies the place of the *ointment of marshmallows*.

1007. *Mercurial ointment.* E.

Take of hogs lard, three ounces; mutton-suet, one ounce; quicksilver, one ounce. Rub them diligently together in a mortar, till the mercurial globules disappear. This ointment is made also with twice, and with thrice, the quantity of mercury.

This is the most simple of the mercurial ointments, though possibly as efficacious as any. It requires indeed a great deal more labour to extinguish the mercury in the lard alone, than when turpentine or other like substances are joined: but, in recompence, the composition with lard is free from an inconvenience which the others are accompanied with, viz. being apt by frequent rubbing to fret tender skins.

1008. *Ointment of mercury precipitate.* L.

Take of simple ointment, an ounce and a half; precipitated sulphur, two drams; white mercury precipitate, two scruples. Mix them well together, and moisten them with ley of tartar, that they may be made into an ointment.

This is a very elegant mercurial ointment, and frequently made use of against cutaneous disorders.

1009. *Ointment of tar.* L. E.

Take of mutton-suet tried, tar, each equal weights. Melt them together, and strain the mixture whilst hot.

This composition, with the addition of half its weight of resin, has long been used in the shops as a cheap substitute to the black basilicum.

1010. *Saturnine ointment.*

Take of oil olive, half a pint; white wax, an ounce and a half; sugar of lead, two drams. Let the sugar of lead, reduced into a very subtil powder, be ground with some part of the oil, and the wax melted with the rest of the oil. Mix both together, and keep them stirring till the ointment is grown cold. L.

Take of sugar of lead, half an ounce; white wax, three ounces; oil olive, one pint. Liquefy the oil and wax together, and gradually add the sugar of lead, previously ground, with some of the oil; continually stirring them, till, growing cold, they unite into an ointment. E.

Both these ointments are useful coolers and desiccatives.

1011. *The simple ointment.* L.

Take of hogs-lard, tried, two pounds; rose-water, three ounces by measure. Beat the lard with the rose-water, till they are well mixed; then melt them over a very gentle fire, and set them by for some time, that the water may subside: pour the lard off from the water, and keep incessantly stirring and beating it about till it grows cold, so as to reduce it into a light incoherent mass: lastly, add so much essence of lemons as will be sufficient to give a grateful odour.

Vol. VIII.

2

1012. *The rose ointment, commonly called pomatum.* E. On any quantity of hogs-lard, cut into small pieces, and placed in a glazed earthen vessel, pour as much water as will rise above it some inches; and digest them together for ten days, renewing the water every day. Then liquefy the lard with a very gentle heat, and pour it into a proper quantity of rose-water: work them well together; and afterwards pouring off the water, add to the lard some drops of oil of rhodium.

These ointments are in common use for softening and smoothing the skin, and healing chaps.

1013. *Ointment of tutty.* L.

Let any quantity of prepared tutty be mixed with as much purified vipers fat as is sufficient to reduce it into the consistence of a soft ointment.

This ointment is designed for an ophthalmic. What particular virtues it receives from the vipers fat, we shall not presume to determine.

In the present edition of the Edinburgh dispensatory, it is ordered to be made of four ounces of hog's lard, a dram of white wax, and an ounce of prepared tutty.

1014. *Ointment for blisters.*

Take of hog's-lard tried, blistering plaster, each equal weights. Melt them together over a very gentle fire, and keep them constantly stirring till grown cold. L.

Take of oil olive, one pint; yellow wax, four ounces; yellow resin, two ounces; cantharides, an ounce and a half. Melt the wax and resin over a gentle fire with part of the oil; then having taken them off the fire, add the cantharides first finely powdered, and then ground with part of the oil, continually stirring the mixture till it has grown cold. E.

1015. *The milder epispastic ointment.* E.

Take of cantharides, one ounce; white resin, yellow wax, each one ounce; hog's-lard, Venice turpentine, each two ounces; boiling water, four ounces. Infuse the cantharides in the water, in a close vessel, for a night; then strongly press out, and strain the liquor, and boil it with the lard till the watery moisture is consumed; then add the resin, wax, and turpentine, and make the whole into an ointment.

These ointments are added in the dressings for blisters, intended to be made *perpetual*, as they are called, or to be kept running for a considerable time, which in many chronic, and some acute cases, they are required to be.

The last, containing the soluble parts of the cantharides uniformly blended with the other ingredients, is more commodious, and occasions less pain, though not less effectual in its intention than the other with the fly in substance.

1016. *White liniment.* L.

Take of oil olive, three ounces by measure; spermaceti, six drams; white wax, two drams. Melt them together over a gentle fire, and keep them constantly and briskly stirring till grown cold.

This differs only in consistence from the *white ointment*; 994.

34 N

1017. *Green*

1017. *Green balsam.* E.

Take of linseed oil, oil of turpentine, each one pound; verdigris, in powder, three drams. Boil and stir them well together till the verdigris is dissolved.

A balsam, similar to this, is said to have been greatly valued by our surgeons as a detergent.

1018. *Volatile liniment.*

Take of oil of hartshorn, spirit of hartshorn, each equal parts. Mix them together.

Dr Pringle observes, that in the inflammatory quinsy, or strangulation of the fauces, a piece of flannel, moistened with this mixture, and applied to the throat, to be renewed every four or five hours, is one of the most efficacious remedies. By means of this warm stimulating application, the neck, and sometimes the whole body, is put into a sweat; which, after bleeding, either carries off or lessens the inflammation.

1019. *White cerate.* L.

Take of oil olive, a quarter of a pint; white wax, four ounces; spermaceti, half an ounce. Liquefy them all together, and keep them stirring till the cerate is grown quite cold.

This differs from the white ointment and liniment only in being of a thicker consistence.

1020. *Yellow cerate.* L.

Take of yellow basilicum ointment, half a pound; yellow wax, one ounce. Melt them together.

This is no otherwise different from the yellow basilicum, than being of a stiffer consistence, which renders it for some purposes more commodious.

1021. *Eputotic cerate.* L.

Take of oil olive, one pint; yellow wax, calamine prepared, each half a pound. Liquefy the wax with the oil; and as soon as the mixture begins to grow stiff, sprinkle in the calamine; keeping them constantly stirring together, till the cerate is grown quite cold.

1022. *Ointment of calamine.* E.

Take of yellow wax, one pound; oil olive, two pints; calamine prepared, nine ounces. Melt the wax with the oil, and gradually sprinkle in the calamine, mixing and stirring them well together till grown cold.

These compositions are formed upon the cerate which Turner strongly recommends in cutaneous ulcerations and excoriations, and which has been usually distinguished by his name. They appear from experience to be excellent epulotics, and as such are frequently made use of in practice.

1023. *Palsy ointment.*

Take of hog's-lard, oil of bays, each four ounces; strong spirit of vitriol, one ounce. Mix, and make them into an unguent.

This irritating composition is applied to numbed or paralytic limbs: it soon reddens and inflames the skin, and when this effect is produced, must be taken off; after which, the part is to be anointed with any emollient unguent.

1024. *Liniment for the piles.*

Take of emollient ointment, two ounces; liquid laudanum, half an ounce. Mix these ingredients with the yolk of an egg, and work them well together.

1025. *Wax liniment.* E.

Take of oil olive, three ounces; spermaceti, three drams; white wax, two drams. Melt all together over a gentle fire; and keep the whole continually stirring till it cools.

SECT. XII. *Epithems.*1026. *Blistering epithem.* L.

Take of cantharides reduced into a most subtil powder, wheat flour, each equal weights. Make them into a paste with vinegar.

This composition is of a softer consistence than the blistering plasters, and for this reason is in some cases preferred. Practitioners differ with regard to the degree of consistence and adhesiveness most proper for applications of this kind, and sometimes vary them occasionally.

1027. *Cataplasn of cummin.* L.

Take of cummin seeds, half a pound; bay-berries, scordium-leaves dried, Virginian snakeroot, each three ounces; cloves, one ounce; honey, thrice the weight of the powdered species. Make them into a cataplasn.

This is a reformation of the *theriaca Londinensis*, which for some time past has been scarce otherwise made use of than as a warm cataplasn; only such of its ingredients are retained as contribute most to this intention.

1028. *Discutient cataplasn.*

Take of bryony root, three ounces; elder flowers, one ounce; gum ammoniac, half an ounce; sal ammoniac, crude, two drams; camphorated spirit of wine, one ounce. Boil the roots and flowers in a sufficient quantity of water, till they become tender; and having then bruised them, add to them the gum ammoniac dissolved in a sufficient quantity vinegar, and likewise the sal ammoniac and spirit: mix the whole together, so as to make them into a cataplasn.

This composition is as good a discutient as any thing that can well be contrived in the form of a cataplasn.

1029. *Ripening cataplasn.* L.

Take of figs, four ounces; yellow basilicum ointment, one ounce; galbanum, strained, half an ounce. Beat the figs thoroughly in a mortar, occasionally dropping in some spirit of wine or strong ale; then carefully mix with them the ointment, first liquefied along with the galbanum.

This composition is a good suppurant or ripener; though its effects probably depend more on its keeping the part soft, moist, and warm, than on any particular qualities of the ingredients.

1030. *A sinapism.* E.

Take of mustard-seed, in powder, crumb of bread, each equal parts; strong vinegar, as much as is sufficient.

Mix

Composi-  
tions.

Mix and make them into a cataplasm; to which is sometimes added a little bruised garlic.

1031. *Compound sinapis.*

Take of mustard-seed in powder, crumb of bread, each two ounces; garlic, bruised, half an ounce; black soap, one ounce; strong vinegar, a sufficient quantity. Mix and make them into a cataplasm, according to art.

Both these compositions are employed only as stimulants: they often inflame the part, and raise blisters, but not so perfectly as cantharides. They are frequently applied to the soles of the feet in the low state of acute diseases, for raising the pulse and relieving the head.

1031. *Alum curd.*

Take any quantity of the white of eggs. Agitate it with a sufficiently large lump of alum, in a tin dish, until it is coagulated.

This preparation is taken from Riverius. It is an useful astringent epithem for sore, moist eyes; and excellently cools and represses thin disfluxions. Slighter inflammations of the eyes, occasioned by dust, exposure to the sun, or other like causes, are generally removed by fomenting them with warm milk and water, and washing them with the vitriolic water, n° 944. Where

the complaint is more violent, this preparation, after the inflammation has yielded a little to bleeding, is one of the best external remedies. It is to be spread on lint, and applied at bed-time.

1032. *Emollient cataplasm.*

Take of crumb of bread, eight ounces; white soap, one ounce; cows milk, fresh, a sufficient quantity. Boil them a little together.

1033. *Stomachic cataplasm.*

Take of the aromatic cataplasm, one ounce; expressed oil of mace, two drams; anodyne balm, as much as is sufficient to reduce them into a proper consistence.

1034. *Camphorated cataplasm.*

Take of aromatic cataplasm, one ounce; camphor, one dram. Mix them together.

1035. *Isciatric cataplasm.*

Take of mustard-seed, half a pound; white pepper, ginger, each one dram; simple oxymel, as much as will reduce them into a cataplasm.

The use of these compositions, which are taken from the hospitals, may be easily understood from their titles. The last is a very stimulating application, and frequently vesicates the skin.

## P H A

Pharos, PHAROS, (Homer, Strabo, &c.) a small oblong island, adjoining to the continent of Egypt, over-against Alexandria. On this island stood a cognominal light-tower, of four sides, each side a stadium in length; and the tower so high, as to be seen 100 miles off. Some affirm, each of its four corners reited on a large fearb of glass or of hard transparent stone of Ethiopia or Memphis. Others imagine, the crabs were only added externally to the base by way of ornament, or as emblematical of its situation and use. The architect was Solstratus the Cnidian, as appears by an inscription on the tower, under Ptolemy Philadelphus, who laid out 800 talents upon it. On account of the port of Alexandria, the entrance to which was difficult and dangerous, the Pharos was called the *key of the Egyptian sea*, or even of Egypt itself, (Lucan): and Pharos, from being a proper name, is become an appellative, to denote all light-houses.

PHAROS, or *Phare*, a light-house; a pile raised near a port, where fire is kept burning in the night, to guide and direct vessels near at hand. The pharos of Alexandria, built in the island of Pharos, at the mouth of the Nile, was anciently very famous, inasmuch as to communicate its name to all the rest. This most magnificent tower consisted of several stories and galleries, with a lantern at top, in which a light being continually burning, might be seen for many leagues at sea, and along the coast.

PHARSALUS, PHARSALOS, *Pharsalia*, or *Pharsalum*, (anc. geog.) a town of the Phthiotis, a district of Thessaly, near Phææ and Larissa, to which last place Pompey fled from the plains of Pharsalus; watered by the river Enipeus, which falls into the Apidanus, and both together into the Peneus. Between Pharsalus and Enipeus, Pompey drew up his men at the fatal battle of Pharsalia.

In this battle, the advantage with respect to numbers was greatly on the side of Pompey. That general himself was on the left with the two legions which Cæsar had returned to him at the beginning of the war. Scipio, Pompey's father-in-law, was in the centre, with the legions he had brought from Syria, and the reinforcements sent by several kings and states of Asia. The Cilician legion, and some cohorts,

## P H A

which had served in Spain, were in the right, under Pharsalus, the command of Afranius. As Pompey's right wing was covered by the Enipeus, he strengthened the left with his slingers, archers, and the 7000 Roman horse, on whom chiefly his party founded their hopes of victory. The whole army was drawn up in three lines, with very little space between them. In conformity to this disposition, Cæsar's army was drawn up in the following order: The tenth legion, which had on all occasions signalized themselves above all the rest, was placed in the right wing, and the ninth in the left; but as the latter had been considerably weakened in the action at Dyrrhachium, the eighth legion was posted so near it, as to be able to support and reinforce it upon occasion. The rest of Cæsar's forces filled up the space between the two wings. Marc Antony commanded the left wing, Sylla the right, and Cneius Domitius Calvinus the main body. As for Cæsar, he posted himself on the right over-against Pompey, that he might have him always in his sight.

Thus was the whole plain covered, from Pharsalia to the Enipeus, with two armies, dressed and armed after the same manner, and bearing the same ensigns, the Roman eagles. Pompey observing how well the enemy kept their ranks, expecting quietly the signal of battle, and on the contrary how impatient and unsteady his own men were, running up and down in great disorder for want of experience, he began to be afraid lest his ranks should be broken upon the first onset; and therefore commanded the foot in the front to keep their ground, and quietly wait for the enemy. The two armies, though within reach of each other, kept a mournful silence; but at length the trumpets sounded the charge, and Cæsar's army advanced in good order to begin the attack, being encouraged by the example of one Caius Crastinus, a centurion, who at the head of 120 men threw himself upon the enemy's first line with incredible fury. This he did to acquit himself of a promise he had solemnly made to Cæsar, who, meeting him as he was going out of his tent in the morning, asked him, after some discourse, *What his opinion was touching the event of the battle?* To which he, stretching out his hand, replied aloud, *Thine is the victory, Cæsar; thou shalt gloriously conquer,*

Pharſalus. *quer, and I myself this day will be the ſubject of thy praife either dead or alive.* In purſuance of this promiſe, he broke out of his rank, as ſoon as the trumpets ſounded; and, at the head of his company, ran in upon the enemy, and made a great ſlaughter of them. But while he was ſtill preſſing forward, forcing his way through the firſt line, one of Pompey's men ran him in at the mouth with ſuch violence, that the point of his ſword came out at the hind-part of his neck. Upon his death, Pompey's ſoldiers took courage, and with great bravery flood the enemy's onſet. While the foot were thus ſharply engaged in the centre, Pompey's horſe in the left wing marched up confidently; and having firſt widened their ranks, with a deſign to ſurround Cæſar's right wing, charged his cavalry, and forced them to give ground. Hereupon Cæſar ordered his horſe to retreat a little, and give way to the ſix cohorts, which he had poſted in the rear as a body of reſerve. Theſe, upon a ſignal given, coming up, charged the enemy's horſe with that reſolution and good order which is peculiar to men who have ſpent all their lives in camps. They remembered their inſtructions, not ſtriking at the legs or thighs of the enemy, but aiming only at their faces. This unexpected and new manner of fighting had the deſired effect. For the young patricians, whom Cæſar contemptuouſly calls the *pretty young dancers*, not being able to bear the thoughts of having their faces deformed with ſcars, turned their backs, and, covering their faces with their hands, fled in the utmoſt conſuſion, leaving the foot at the mercy of the enemy. Cæſar's men did not purſue the fugitives; but charging the foot of that wing, now naked and unguarded, ſurrounded them, and cut moſt of them in pieces.

Pompey was ſo tranſported with rage, in ſeeing the flower of his forces thus put to flight or cut in pieces, that he left his army, and retired ſlowly towards his camp, looking more like a man diſtracted and beſide himſelf, than one who by his exploits had acquired the name of *the Great*. When he had reached the camp, he retired to his tent, without ſpeaking a word to any; and continued there, like one diſtracted and out of his ſenſes, till his whole army was defeated. Cæſar no ſooner ſaw himſelf maſter of the field, than he marched to attack the enemy's entrenchments, that Pompey might not have time to recollect himſelf. When Pompey was informed that his rival was advancing to attack his entrenchments, he then firſt ſeemed to have recovered his ſenſes, and cried out, *What, into my camp too?* He ſaid no more; but immediately laying aſide the marks of his dignity, and putting on ſuch a garment as might beſt favour his flight, he ſtole out at the decuman gate, and took the road to Lariffa, which city had hitherto ſhewn great attachment to him. In the mean time, Cæſar began the attack on the enemy's camp, which was vigorouſly defended by the cohorts Pompey had left to guard it; but they were at length forced to yield. Cæſar was not a little ſurprized, when, after having forced the entrenchments, he found the enemy's tents and pavilions richly adorned with carpets and hangings, their couches ſtrewed with flowers, their tables ready ſpread, and ſide-boards ſet out with abundance of plate, bowls, and glaſſes, and ſome of them even filled with wine.

So great was the confidence of Pompey's party, that they made preparations before-hand for pleaſures to be enjoyed after the victory, which they thought certain. In Pompey's tent, Cæſar found the box in which he kept his letters; but, with a moderation and magnanimity worthy of himſelf, he burnt them all, without reading one; ſaying, that he had rather be ignorant of crimes, than obliged to puniſh them.

The next day, when the dead were numbered, it appeared that Cæſar had ſcarce loſt 200 men; among whom was about 30 centurions, whom Cæſar cauſed to be buried with great ſolemnity. He did particular honours to the body of Craſſinus, who had begun the battle; and ordered his aſhes to be depoſited in a tomb, which he erected to his memory. On Pompey's ſide, the number of the dead amounted to 15,000 according to ſome, and to 25,000 according to others. Cæſar took 24,000 priſoners, eight eagles, and 180 enſigns.

PHARYNX, in anatomy. See there, n° 353.

PHASEOLUS, the KIDNEY-BEAN; a genus of the decandria order, belonging to the diadelphia claſs of plants. There is only one ſpecies; but of this there are many varieties. Thoſe principally cultivated for the table are, 1. The common white, or Dutch kidney-bean. 2. The ſmaller kidney-bean, commonly called the *Batterſea kidney-bean*. And, 3. The upright ſort, called the *tree kidney-bean*.

1. The firſt ſort was ſome time ago propagated in England, and is ſtill in Holland: it grows very tall, and requires long ſtakes and poles to climb on, and its beans are conſiderably broad: this makes them leſs ſaleable in the markets, people ſuppoſing them to be old becauſe they are broad; and they are hence grown into diſuſe, though a much more valuable kind for eating than any other.

2. The ſecond ſort, or Batterſea bean, is what is more univerſally cultivated: it never grows very tall, nor rambles far, and the air can eaſily paſs between the rows, becauſe of its moderate growth; and this makes it bear plentifully, and ripen well for the table. It is the beſt-taſted bean, except the laſt.

3. The third, or tree kidney-bean, is alſo a plentiful bearer, and never rambles, but grows up in form of a ſhrub; but its beans are broader than the Batterſea kind, and are not ſo well taſted.

They are all propagated from ſeeds, which are to be put into the ground in the latter end of March or beginning of April for an early crop: but theſe ſhould have a warm ſituation and a dry ſoil; they muſt alſo be planted in a dry ſeaſon. The manner of planting them is, to draw lines with a bough over the bed, at two feet and a half diſtance, into which the ſeeds are to be dropped at about two inches aſunder; and the earth is to be drawn over them with the head of a rake, to cover them about an inch deep. In a week after ſowing, the plants will appear, and the earth ſhould be drawn up about their ſtalks as they riſe up; for a few days after this they will require no further care, except to be kept clear from weeds, and, when the beans appear, to have them gathered twice a-week; for if the beans are ſuffered to hang on too long, they not only become of no value, but they weaken the plant. The firſt crop of kidney-beans will continue a month in good order; and to ſupply the table afterwards,

Pharynx,  
Phaseolus.

Phases,  
Phasianus.

wards, there should be fresh sowings in March, April, May, and June, the last of which will continue till the frosts come to destroy them. Some raise their early crops on hot-beds; and this is to be done exactly in the same manner as the raising the early cucumbers.

**PHASES**, in astronomy, from the Greek word *φαειναι*, "to appear;" the several appearances or quantities of illumination of the moon, Venus, Mercury, and the other planets. See **ASTRONOMY**.

**PHASIANUS**, in ornithology, a genus belonging to the order of gallinæ. The cheeks are covered with a smooth naked skin. There are six species, *viz.*

Dunghill  
Cock.

1. The gallus, or common dunghill cock and hen, with a compressed caruncle or fleshy comb on the top of the head, and a couple of caruncles or wattles under the chin. The ears are naked, and the tail is compressed and erected. Of all other birds, perhaps this species affords the greatest number of varieties; there being scarce two to be found that exactly resemble each other in plumage and form. The tail, which makes such a beautiful figure in the generality of these birds, is yet found entirely wanting in others; and not only the tail, but the rump also. The toes, which are usually four in all animals of the poultry kind, yet in a species of the cock are found to amount to five. The feathers, which lie so sleek and in such beautiful order in most of those we are acquainted with, are in a peculiar breed all inverted, and stand staring the wrong way. Nay, there is a species that comes from Japan, which instead of feathers seems to be covered over with hair.

It is not well ascertained when the cock was first made domestic in Europe; but it is generally agreed that we first had him in our western world from the kingdom of Persia. Aristophanes calls the cock the *Persian bird*; and tells us he enjoyed that kingdom before some of its earliest monarchs. This animal was in fact known so early even in the most savage parts of Europe, that we are told the cock was one of the forbidden foods among the ancient Britons. Indeed, the domestic fowl seems to have banished the wild one. Persia itself, that first introduced it to our acquaintance, seems no longer to know it in its natural form; and if we did not find it wild in some of the woods of India, as well as those of the islands in the Indian ocean, we might begin to doubt, as we do with regard to the sheep, in what form it first existed in a state of nature. But the cock is still found in the islands of Tinian, in many others of the Indian ocean, and in the woods on the coast of Malabar, in his ancient state of independence. In his wild condition, his plumage is black and yellow, and his comb and wattles yellow and purple. There is another peculiarity also in those of the Indian woods; their bones, which, when boiled, with us are white, as every body knows, in those are as black as ebony.

In their first propagation in Europe, there were distinctions then that now subsist no longer. The ancients esteemed those fowls whose plumage was reddish as invaluable; but as for the white, it was considered as utterly unfit for domestic purposes. These they regarded as subject to become a prey to rapacious birds; and Aristotle thinks them less fruitful than the former. Indeed, his division of those birds seems taken from

their culinary uses: the one sort he calls *generous and noble*, being remarkable for fecundity; the other sort, *ignoble and useless*, from their sterility. These distinctions differ widely from our modern notions of generosity in this animal; that which we call the *game-cock* being by no means so fruitful as the ungenerous dunghill cock, which we treat with contempt. The Athenians had their cock-matches as well as we; but it is probable they did not enter into our refinement of choosing out the most barren of the species for the purposes of combat.

However this be, no animal in the world has greater courage than the cock when opposed to one of his own species; and in every part of the world where refinement and polished manners have not entirely taken place, cock-fighting is a principal diversion. In China, India, the Philippine islands, and all over the East, cock-fighting is the sport and amusement even of kings and princes. With us it is declining every day; and it is to be hoped it will in time become only the pastime of the lowest vulgar. See the article *Cock-Fighting*.

The cock claps his wings before he sings or crows. His sight is very piercing; and he never fails to cry in a peculiar manner, when he discovers any bird of prey in the air. His extraordinary courage is thought to proceed from his being the most falacious of all other birds whatsoever. A single cock suffices for ten or a dozen hens; and it is said of him that he is the only animal whose spirits are not abated by indulgence. But then he soon grows old; the radical moisture is exhausted; and in three or four years he becomes utterly unfit for the purposes of impregnation. "Hens also, (to use the words of Willoughby), as they for the greatest part of the year daily lay eggs, cannot suffice for so many births, but for the most part after three years become effete and barren: for when they have exhausted all their seed-eggs, of which they had but a certain quantity from the beginning, they must necessarily cease to lay, there being no new ones generated within."

Domestic  
Hen.

The hen seldom clutches a brood of chickens above once a season, though instances have been known in which they produced two. The number of eggs a domestic hen will lay in the year are above 200, provided she be well fed and supplied with water and liberty. It matters not much whether she be trodden by the cock or no; she will continue to lay, although the eggs of this kind can never by hatching be brought to produce a living animal. Her nest is made without any care, if left to herself; a hole scratched into the ground, among a few bushes, is the only preparation she makes for this season of patient expectation. Nature, almost exhausted by its own fecundity, seems to inform her of the proper time for hatching, which she herself testifies by a clucking note, and by discontinuing to lay. The good housewives, who often get more by their hens laying than by their chickens, often artificially protract this clucking season, and sometimes entirely remove it. As soon as a hen begins to cluck, they stint her in her provisions; which, if that fails, they plunge her into cold water; this, for the time, effectually puts back her hatching; but then it often kills the poor bird, who takes cold and dies under the operation.

If left entirely to herself, the hen would seldom lay above 20 eggs in the same nest, without attempting to hatch

*Phasianus.* hatch them: but in proportion as she lays, her eggs are removed; and she continues to lay, vainly hoping to increase the number. In the wild state, the hen seldom lays above 15 eggs; but then her provision is more difficultly obtained, and she is perhaps sensible of the difficulty of maintaining too numerous a family.

When the hen begins to sit, nothing can exceed her perseverance and patience: she continues for some days immovable; and when forced away by the importunities of hunger, she quickly returns. Sometimes also her eggs become too hot for her to bear, especially if she be furnished with too warm a nest within doors, for then she is obliged to leave them to cool a little: thus the warmth of the nest only retards incubation, and often puts the brood a day or two back in the shell. While the hen sits, she carefully turns her eggs, and even removes them to different situations; till at length, in about three weeks, the young brood begin to give signs of a desire to burst their confinement. When by the repeated efforts of their bill, which serves like a pioneer on this occasion, they have broke themselves a passage through the shell, the hen still continues to sit till all are excluded. The strongest and best chickens generally are the first candidates for liberty; the weakest come behind, and some even die in the shell. When all are produced, she then leads them forth to provide for themselves. Her affection and her pride seem then to alter her very nature, and correct her imperfections. No longer voracious or cowardly, she abstains from all food that her young can swallow, and flies boldly at every creature that she thinks is likely to do them mischief. Whatever the invading animal be, she boldly attacks him; the horse, the hog, or the mastiff. When marching at the head of her little troop, she acts the commander; and has a variety of notes to call her numerous train to their food, or to warn them of approaching danger. Upon one of these occasions, the whole brood have been seen to run for security into the thickest part of an hedge, while the hen herself ventured boldly forth, and faced a fox that came for plunder.

Ten or twelve chickens are the greatest number that a good hen can rear and clutch at a time; but as this bears no proportion to the number of her eggs, schemes have been imagined to clutch all the eggs of an hen, and thus turn her produce to the greatest advantage. By these contrivances it has been obtained, that a hen that ordinarily produces but 12 chickens in the year, is found to produce as many chickens as eggs, and consequently often above 200. This contrivance is the artificial method of HATCHING chickens in stoves, as is practised at Grand Cairo; or in a chemical laboratory properly graduated, as has been effected by Mr Reaumur. At Grand Cairo, they thus produce 6000 or 7000 chickens at a time; where, as they are brought forth in their mild spring, which is warmer than our summer, the young ones thrive without clutching. But it is otherwise in our colder and unequal climate; the little animal may without much difficulty be hatched from the shell, but they almost all perish when excluded. To remedy this, Reaumur has made use of a woollen hen, as he calls it; which was nothing more than putting the young ones in a warm basket, and clapping over them a thick woollen canopy.

Capons may very easily be taught to clutch a fresh  
Vol. VIII.

brood of chickens throughout the year; so that when one little colony is thus reared, another may be brought to succeed it. Nothing is more common than to see capons thus employed; and the manner of teaching them is this: First the capon is made very tame, so as to feed from one's hand; then, about evening, they pluck the feathers off his breast, and rub the bare skin with nettles; they then put the chickens to him, which presently run under his breast and belly, and probably rubbing his bare skin gently with their heads, allay the stinging pain which the nettles had just produced. This is repeated for two or three nights, till the animal takes an affection to the chickens that have thus given him relief, and continues to give them the protection they seek for: perhaps also the querulous voice of the chickens may be pleasant to him in misery, and invite him to succour the distressed. He from that time brings up a brood of chickens like a hen, clutching them, feeding them, clucking, and performing all the functions of the tenderest parent. A capon once accustomed to this service, will not give over; but when one brood is grown up, he may have another nearly hatched put under him, which he will treat with the same tenderness he did the former.

The cock, from his falaciousness, is allowed to be a short-lived animal; but how long these birds live, if left to themselves, is not yet well ascertained by any historian. As they are kept only for profit, and in a few years become unfit for generation, there are few that, from mere motives of curiosity, will make the tedious experiment of maintaining a proper number till they die. Aldrovandus hints their age to be 10 years; and it is probable that this may be its extent. They are subject to some disorders; and as for poisons, besides nux vomica, which is fatal to most animals except man, they are injured, as Linnaeus asserts, by elderberries; of which they are not a little fond.

2. The motmot, or Guinea pheasant, is brownish, somewhat red below, with a wedge-like tail, and wants spurs. 3. The colchicus is red, with a blue head, a wedge-shaped tail, and papillous cheeks. It is a native of Africa and Asia. 4. The argus is yellowish, with black spots, a red face, and a blue crest on the back part of the head. It is found in Chinese Tartary. 5. The pictus has a yellow crest, a red breast, and a wedge-shaped tail. It is a native of China. 6. The nechiemerus, is white, with a black crest and belly, and a wedge-shaped tail. It is a native of China.

Pheasants were originally brought into Europe from the banks of the Phasis, a river of Colchis, in Asia Minor; and from whence they still retain their name. Next to the peacock, they are the most beautiful of birds, as well for the vivid colour of their plumes as for their happy mixtures and variety. It is far beyond the power of the pencil to draw any thing so glossy, so bright, or points so finely blending into each other. We are told, that when Cræsus, king of Lydia, was seated on his throne, adorned with royal magnificence and all the barbarous pomp of eastern splendour, he asked Solon if he had ever beheld any thing so fine? The Greek philosopher, no way moved by the objects before him, or taking a pride in his native simplicity, replied, That after having seen the beautiful plumage of the pheasant, he could be astonished at no other finery.

These birds, tho' so beautiful to the eye, are not less delicate when served up to the table. Their flesh is considered as the greatest dainty; and when the old physicians spoke of the wholesomeness of any viands, they made their comparison with the flesh of the pheasant. However, notwithstanding all these perfections to tempt the curiosity or the palate, the pheasant has multiplied in its wild state.

A spirit of independence seems to attend the pheasant even in captivity. In the woods, the hen-pheasant lays from 18 to 20 eggs in a season; but in a domestic state, she seldom lays above 10. In the same manner, when wild, she hatches and leads up her brood with patience, vigilance, and courage; but when kept tame, she never fits well, so that a hen is generally her substitute upon such occasions: and as for leading her young to their food, she is utterly ignorant of where it is to be found; and the young birds starve, if left solely to her protection. The pheasant, therefore, on every account, seems better left at large in the woods than reclaimed to pristine captivity. Its fecundity when wild is sufficient to stock the forest; its beautiful plumage adorns it; and its flesh retains a higher flavour from its unlimited freedom.

However, it has been the aim of late to take these birds once more from the woods, and to keep them in places fitted for their reception. Like all others of the poultry kind, they have no great sagacity, and suffer themselves easily to be taken. At night they roost upon the highest trees of the wood; and by day they come down into the lower brakes and bushes, where their food is chiefly found. They generally make a kind of flapping noise when they are with the females; and this often apprises the sportsman of their retreats. At other times he tracks them in the snow, and frequently takes them in springs. But of all birds they are shot most easily; as they always make a whirring noise when they rise, by which they alarm the gunner, and being a large mark, and flying very slow, there is scarce any missing them.

When these birds are taken young into keeping, they become as familiar as chickens: and when they are designed for breeding, they are put together in a yard, five hens to a cock; for this bird, like all of the poultry kind, is very falacious. In her natural state the female makes her nest of dry grass and leaves; the same must be laid for her in the pheasantry, and she herself will sometimes properly dispose them. If she refuses to hatch her eggs, then a common hen must be got to supply her place, which task she will perform with perseverance and success. The young ones are very difficult to be reared; and they must be supplied with ants-eggs, when is the food the old one leads them to gather when wild in the woods. To make these go the farther, they are to be chopped up with curds or other meat; and the young ones are to be fed with great exactness, both as to the quantity and the time of their supply. This food is sometimes also to be varied; and wood-lice, ear-wigs, and other insects, are to make a variety. The place where they are reared must be kept extremely clean; their water must be changed twice or thrice a-day; they must not be exposed till the dew is off the ground in the morning, and they should always be taken in before sun-set. When they become adult, they very well can shift for

themselves, but they are particularly fond of oats and Phasianus  
barley. Phal.

In order to increase the breed, and make it still more valuable, Longolius teaches us a method that appears very peculiar. The pheasant is a very bold bird when first brought into the yard among other poultry, not sparing the peacock, nor even such young cocks and hens as it can master; but after a time it will live tamely among them, and will at last be brought to couple with a common hen. The breed thus produced take much stronger after the pheasant than the hen; and in a few successions, if they be let to breed with the cock-pheasant, for the mixture is not barren, there will be produced a species more tame, stronger, and more prolific; so that he adds, that it is strange why most of our pheasandries are not stocked with birds produced in this manner.

The pheasant, when full grown, seems to feed indifferently upon every thing that offers. It is said by a French writer, that one of the king's sportsmen shooting at a parcel of crows that were gathered round a dead carcase, to his great surprise upon coming up, found that he had killed as many pheasants as crows. It is even asserted by some, that such is the carnivorous disposition of this bird, that when several of them are put together in the same yard, if one of them happens to fall sick, or seems to be pining, that all the rest will fall upon, kill, and devour it. Such is the language of books; those who have frequent opportunities of examining the manners of the bird itself, know what credit ought to be given to such an account.

PHASMATA, in physiology, certain appearances arising from the various tinctures of the clouds by the rays of the heavenly bodies, especially the sun and moon. These are infinitely diversified by the different figures and situations of the clouds, and the appulses of the rays of light.

PHASSACHATES, in natural history, the name of a species of agate, which the ancients, in its various appearances, sometimes called *leucachates* and *perileucor*.

PHEASANT, in ornithology. See PHASIANUS.

PHELLANDRIUM, WATER HEMLOCK, a genus of the digynia order, belonging to the pentandria class of plants. There are two species; one of which, viz. the aquaticum, is a native of Britain. This grows in ditches and ponds, but is not very common. The stalk is remarkably thick and dichotomous, and grows in the water. It is a poison to horses, bringing upon them, as Linnaeus informs us, a kind of palsy; which, however, he supposes to be owing not so much to the noxious qualities of the plant itself, as to those of an insect which feeds upon it, breeding within the stalks, and which he calls *curculio paraplecticus*. The Swedes give swine's dung for the cure. The seeds are sometimes given in intermittent fevers, and the leaves are by some added to discutient cataplasms. In the winter, the roots and stem, dissected by the influence of the weather, afford a very curious skeleton or network. Horses, sheep, and goats, eat the plant; swine are not fond of it; cows refuse it.

PHENICIA. See PHOENICIA.

PHEONS, in heraldry, the barbed heads of darts, arrows, or other weapons.

PHIAL, a well-known vessel made of glass, used for

Phidias for various purposes.

*Leyden PHIAL*; a phial of glass coated on both sides with tin-foil for a considerable way up the sides, of great use in electrical experiments. See *ELECTRICITY, passim*.

**PHIDIAS**, the most famous sculptor of antiquity, was an Athenian, and a contemporary of the celebrated Pericles, who flourished in the 83d Olympiad. This wonderful artist was not only consummate in the use of his tools, but accomplished in those sciences and branches of knowledge which belong to his profession, as history, poetry, fable, geometry, optics, &c. He first taught the Greeks to imitate nature perfectly in this way; and all his works were received with admiration. They were also incredibly numerous; for it was almost peculiar to Phidias, that he united the greatest facility with the greatest perfection. His Nemesis was ranked among his first pieces: it was carved out of a block of marble, which was found in the camp of the Persians after they were defeated in the plains of Marathon. He made an excellent statue of Minerva for the Plateaus; but the statue of this goddess in her magnificent temple at Athens, of which there are still some ruined remains, was an astonishing production of human art. Pericles, who had the care of this pompous edifice, gave orders to Phidias, whose prodigious talents he well knew, to make a statue of the goddess; and Phidias formed a figure of ivory and gold 39 feet high. Writers never speak of this illustrious monument of skill without raptures; yet what has rendered the name of the artist immortal, proved at that time his ruin. He had carved upon the shield of the goddess his own portrait, and that of Pericles; and this, by those that envied them, made a crime in Phidias. He was also charged with embezzling part of the materials which were designed for the statue. Upon this he withdrew to Elis, and revenged himself upon the ungrateful Athenians, by making for the Elians the Olympic Jupiter: a prodigy of art, and which was afterwards ranked among the seven wonders of the world. It was of ivory and gold; 60 feet high, and every way proportioned. "The majesty of the work did equal the majesty of the god," says Quintilian, "and its beauty seems to have added 'lustre to the religion of the country.'" Phidias concluded his labours with this master-piece; and the Elians, to do honour to his memory, erected, and appropriated to his descendants, an office, which consisted in keeping clean this magnificent image.

**PHIDITIA**, in Grecian antiquity, feasts celebrated with great frugality at Sparta. They were held in the public places and in the open air. Rich and poor assisted at them equally, and on the same footing; their design being to keep up peace, friendship, good understanding and equality among the citizens great and small. It is said that those who attended this feast brought each a bushel of flour, eight measures of wine named *chorus*, five mince of cheese, and as many figs.

**PHILADELPHIA**, the capital of the province of Pennsylvania in North America, situated in W. Lon. 75. o. N. Lat. 40. 30. It is one of the most beautiful and regular cities in the world, being an oblong of two miles, extending from the river Delaware to the Schuylkill, with the east end fronting the river

Delaware, the west the river Schuylkill, and each front a mile in length. The river Delaware is navigable from the sea for large vessels above 200 miles, and that of Schuylkill as far as Philadelphia. Every man in possession of 1000 acres has his house either in one of the fronts facing the rivers, or in the high-street, running from the middle of one front to the middle of the other. Every owner of 5000 acres, besides the above-mentioned privilege, is intitled to have an acre of ground in the front of his house, and all others may have half an acre, for gardens and court-yards. Every quarter of the city forms a square of eight acres; and almost in the centre of it is a square of ten acres, surrounded by the town-house and other public buildings. The high-street is 100 feet wide, and runs the whole length of the town: parallel to it run eight other streets, which are crossed by 20 more at right angles, all of them 30 feet wide, and communicating with canals from the two rivers, which add not only to the beauty, but the wholesomeness of the city. Ships of 400 or 500 tons may come up to the key, which is 200 feet square, and furnished with all the conveniences for ship-building, as well as for loading and unloading goods. Though the whole of this magnificent plan hath not yet been carried into execution, a considerable progress hath been made towards it. The town-house is so stately, spacious, and regular, that it would make a figure in any capital of Europe. The other public buildings are, the court-house, two Quakers meeting-houses, one church of England, one Baptist meeting, one Dutch Lutheran church, one Dutch Calvinist church, one Moravian church, one mals-house, the Quakers school house, the city alms-house, the Quakers alms-house, the hospital, prison, and work-house.

**PHILADELPHIA**, an ancient town of Turkey in Asia, in Natolia; seated at the foot of mount Tmolus, from whence there is a fine view over an extensive plain. The Greeks retain its ancient name, but by the Turks it is called *Allahijur*. It contains 7 or 8000 inhabitants; of whom 2000 are Christians, who have four churches, over which presides an archbishop. E. Lon. 28. 25. N. Lat. 38. 45.

**PHILADELPHUS**, the PIPE-TREE, or *Mock-orange*; a genus of the monogynia order belonging to the icofandria class of plants.

*Species 1.* The coronarius, white syringa, or mock-orange, has been long cultivated in the gardens of this country as a flowering shrub; it is not well known in what country it is to be found native. It rises seven or eight feet high; sending up a great number of slender stalks from the root. These have a gray bark, branch out from their sides, and are garnished with oval spear-shaped leaves. These last have deep indentures on their edges; their upper surface being of a deep green, but the under surface pale, with the taste of a fresh cucumber. The flowers are white, and come out from the sides and at the ends of the branches in loose bunches, each standing on a distinct foot-stalk: they have four oval petals, which spread open, with a great number of stamina within, surrounding the style. Their smell at some distance resembles that of orange-flowers, but is too powerful for most people when near. 2. The nanus, with oval leaves somewhat indented and double flowers, seldom

Philadelph.  
phia,  
Philadelphus.

Philippi. rises above three feet high; the flowers come out singly from the sides of the branches, and have a double or treble row of petals of the same size and form as well as the same scent with the former; but this sort flowers very rarely, so is but little esteemed. 3. The inodorus with entire leaves, is a native of Carolina, and as yet but little known in Europe. It rises with a shrubby stalk of about 16 feet in height, sending out slender branches from the sides opposite, garnished with smooth leaves sharpened like those of the pear-tree, and standing on pretty long foot-stalks. The flowers are produced at the ends of the branches; and are large, white, spreading open, with a great number of short stamina with yellow summits.

*Culture.* The first two species are extremely hardy, but grow taller in light good ground than in such as is stiff. They are usually propagated by suckers, which are produced by the roots in great plenty. The last species cannot be propagated in this country by seeds, which is the reason of its scarcity; however, it may be produced by laying down the branches. It is also liable to be destroyed by cold in severe winters, and therefore ought to be sheltered during that season.

PHILIPPI (anc. geog.), a town of Macedonia, in the territory of the Edones, on the confines of Thrace (Pliny, Ptolemy), situate on the side of a steep eminence; anciently called *Datum* and *Drenides* (Apian), though Strabo seems to distinguish them. This town was famous on several accounts; not only as taking its name from the celebrated Philip of Macedon, father to Alexander the Great, who considered it as a fit place for carrying on the war against the Thracians; but also on account of two battles fought in its neighbourhood between Augustus and the republican party. In the first of these battles, Brutus and Cassius had the command of the republican army; while Octavianus, afterwards Augustus, and Mark Anthony, had the command of their adversaries. The army of Brutus and Cassius consisted of 19 legions and 20,000 horse; the imperial forces of an equal number of legions, but more complete, and 13,000 horse; so that the numbers on both sides were pretty equal. The troops of Brutus were very richly dressed; most of them having their armour adorned with gold and silver; for Brutus, though very frugal in other respects, was thus extravagant with respect to his men, thinking that the riches that they had about them would make them exert themselves the more, to prevent these from falling into the enemy's hands. Both the republican generals appear to have been inferior in skill to Mark Anthony; for as to Octavianus, he is allowed never to have conquered but by the valour of others. A little before the first engagement, Octavianus, who had been indisposed, was carried out of the camp, at the persuasion of Artorius his physician, who had dreamed that he saw a vision directing him to be removed. Brutus's men, who opposed the wing commanded by Octavianus, charged without orders, which caused great confusion. However, they were successful: for part of them, taking a compass about, fell upon the enemy's rear; after which they took and plundered the camp; making a great slaughter of such as were in it, and, among the rest putting 2000 Lacedæmonians to the sword who were newly come to

the assistance of Octavianus. The emperor himself was fought for, but in vain, he having been conveyed away for the reason abovementioned; and as the soldiers pierced the litter in which he was usually carried, it was thence reported that he had been killed. This threw that whole part of the army into such consternation, that when Brutus attacked them in front, they were most completely routed; three whole legions being cut in pieces, and a prodigious slaughter made among the fugitives. But by the imprudence of the general in pursuing too far, the wing of the republican army commanded by Cassius was left naked and separated from the rest of the army; on which they were attacked at once in front and in flank, and thus they were defeated and their camp taken, while Brutus imagined that he had gained a complete victory. Cassius himself retired to an eminence at a small distance from Philippi; whence he sent one of his greatest intimates to procure intelligence concerning the fate of Brutus. That general was on his way, and already in view, when the messenger set out. He soon met his friends; but they surrounding him to inquire the news, Cassius, who beheld what passed, imagined that he was taken prisoner by the enemy, retired to his tent, and in despair caused one of his freedmen to cut off his head. Thus far at least is certain, that he went into the tent with that freedman, and that his head was found separated from his body when Brutus entered. However, the freedman was never afterwards seen.

The second engagement was pretty similar to the first. Brutus again opposed Octavianus, and met with the same success; but in the mean time Anthony, to whom he ought undoubtedly to have opposed himself, having to do only with the lieutenants of Cassius, gained a complete victory over them. What was worst, the fugitives, instead of leaving the field of battle altogether, fled for protection to Brutus's army; where, crowding in among the ranks, they carried despair and confusion wherever they went, so that a total defeat ensued, and the republican army was almost entirely cut in pieces. After the battle, Brutus put an end to his own life, as is related more fully under the article *ROME*.

The city of Philippi is likewise remarkable on account of an epistle written by St Paul to the church in that place. It was a Roman colony, (Luke, Pliny, coin, inscription). It is also remarkable for being the birth-place of Adrastus, the peripatetic philosopher, and disciple of Aristotle.—The town is still in being, and is an archbishop's see; but greatly decayed and badly peopled. However, there is an old amphitheatre, and several other monuments of its ancient grandeur. E. Long. 44. 55. N. Lat. 41. 0.

PHILIPPINE ISLANDS, certain islands of Asia, lying between 114 and 131 degrees of east longitude, and between 5 and 19 of north latitude, about 300 miles south-east of China. The chief of them are those of Luconia or Manila, Tandaga or Samar, Mofbate, Mindora, Luban, Paragosa, Panay, Leyte, Bohol, Sibiu, Sogbu, Negros, St John, Xollo, and Mindanao. They were discovered by Ferdinand Magellan, a Portuguese gentleman, who had served his native country both in the wars of Africa and in the East Indies; particularly under Albuquerque, the famous Portuguese general, who reduced Goa and Malacca to the

Philippine. the obedience of that crown. Magellan, having had a considerable share in those actions, and finding himself neglected by the government of Portugal, and even denied, as it is said, the small advance of a ducat a month in his pay, left the court of Portugal in disgust, and offered his service to Charles V. then emperor of Germany and king of Spain, whom he convinced of the probability of discovering a way to the Spice Islands, in the East Indies, by the west; whereupon, the command of five small ships being given him, he set sail from Seville, on the tenth of August 1519, and standing over to the coast of South America, proceeded southward to 52°, where he fortunately hit upon a strait, since called the *Strait of Magellan*, which carried him into the Pacific Ocean or South Sea; and then, steering northward, repassed the equator; after which, he stretched away to the west, across that vast ocean, till he arrived at Guam, one of the Ladrões, on the sixth of March 1521; and soon after got to the Philippine Islands, which he took possession of in the name of the king of Spain, but happened to be killed in a skirmish he had with the natives of one of them. His people, however, arrived afterwards at the Moluccas, or Clove Islands, where they left a colony, and returned to Spain, by the way of the Cape of Good Hope; being the first that ever sailed round the globe. But there was no attempt made by the Spaniards to subdue or plant the Philippine Islands until the year 1564, in the reign of Philip II. son of Charles V. when Don Lewis de Velasco, viceroy of Mexico, sent Michael Lopez Delagafes thither with a fleet, and a force sufficient to make a conquest of these islands, which he named the *Philippines*, in honour of Philip II. then upon the throne of Spain; and they have ever since been subject to that crown.

The inhabitants of these islands consist of Chinese, Ethiopians, Malays, Spaniards, Portuguese, Pintados or Painted People, and Mestees, a mixture of all these. Their persons and habits resemble those of the several nations whence they derive their original; only, it is observable, that the features of the blacks of these islands are as agreeable as those of the white people. There is not a soil in the world that produces greater plenty of all things for life; as appears by the multitude of inhabitants to be found in the woods and mountains, who subsist almost entirely by the fruits of the earth, and the venison they take. Nor can any country appear more beautiful; for there is a perpetual verdure, and buds, blossoms, and fruit, are found upon the trees all the year round, as well on the mountains as in the cultivated gardens. Vast quantities of gold are washed down from the hills by the rains, and found mixed with the sand of their rivers. There are also mines of other metals, and excellent load-stones found here; and such numbers of wild buffaloes, that a good huntsman on horseback, armed with a spear, will kill 10 or 20 in a day. The Spaniards take them for their hides, which they sell to the Chinese; and their carcases serve the mountaineers for food. Their woods also abound with deer, wild hogs, and goats. Of the last, there is such plenty in one of these islands, that the Spaniards gave it the name of *Cabras*. Horses and cows have been likewise imported into these islands, from New Spain, China,

and Japan, which have multiplied considerably; but the sheep that were brought over came to nothing. The trees produce a great variety of gums; one kind, which is the commonest, by the Spaniards called *brea*, is used instead of pitch; of the others, some are medicinal, others odiferous.

In those islands are monkeys and baboons of a monstrous bigness, that will defend themselves if attacked by men. When they can find no fruit in the mountains, they go down to the sea to catch crabs and oysters; and that the oysters may not close and catch their paws, they first put in a stone to prevent their shutting close: they take crabs by putting their tail in the holes where they lie, and when the crab lays hold of it, they draw him out. There are also great numbers of civet-cats in some of the islands. The bird called *tavan*, is a black sea-fowl, something less than a hen, and has a long neck; it lays its eggs in the sand by the sea-side, 40 or 50 in a trench, and then covers them, and they are hatched by the heat of the sun. They have likewise the bird *saligan*, which builds her nest on the sides of rocks, as the swallows do against a wall; and these are the delicious *Birds-Nests*, so much esteemed, being a kind of jelly that dissolves in warm water.

The Spaniards have introduced several of the American fruits, which thrive here as well as in America; the cocoa or chocolate-nut particularly, which increases so that they have no occasion now to import it from Mexico. Here is also the *Fountain-Tree*, from which the natives draw water; and there is likewise a kind of cane, by the Spaniards called *vaxuco*, which, if cut, yields fair water enough for a draught, of which there are plenty in the mountains, where water is most wanted.

These islands being hot and moist, produce abundance of venomous creatures, as the foil does poisonous herbs and flowers, which do not kill those who touch or taste them, but so infect the air, that many people die in the time of their blossoming.

The orange, lemon, and several other trees, bear twice a year. If they plant a sprig, within a year it becomes a tree, and bears fruit; and therefore, without any hyperbole, says our author, I may affirm, that I never saw such a luxuriant verdant foil, nor woods full of such odd, large, and lofty trees, nor trees that yield more sustenance to man, in any part of the world. However, these islands, besides the inconveniences mentioned above, are also subject to earthquakes, which are sometimes very fatal.

The whole number of them is said to be 1100.

PHILIPPINES, a religious society of young women at Rome, so called from their taking St Philip de Neri for their protector. The society consists of 100 poor girls, who are brought up till they are of age to be married, or become nuns, under the direction of some religious women, who teach them to read, write, and work, and instruct them in the duties of Christianity. They wear a white veil, and a black cross on their breasts. See MACEDONIA.

PHILIP II. king of Macedon, and father of Alexander the Great; equally renowned as a legislator, politician, and warrior. After having conquered Greece, he meditated the conquest of Persia; but while he

Philippine's  
Philip.

Philip,  
Philips.

he was preparing for this expedition, he was assassinated at a banquet by Pausanias, a captain of his guards, in 336 B. C.

PHILIP II. king of Spain, a celebrated politician, but a cruel tyrant through bigotry, by which he lost the 17 provinces of Flanders belonging to the crown of Spain, seven of which form the republic of Holland, and the other ten are subject to France and Austria. For his marriage with Mary queen of England, and his invasion of England under Elizabeth, see the article ENGLAND. He was born in the year 1527, and died in 1528.

PHILIPS (Ambrose), an English poet, was descended from a very ancient and considerable family of that name in Leicestershire. He received his education at St John's college, Cambridge; during his stay at which university, he wrote his pastorals, which acquired him at the time so high a reputation. His next performance was, *The life of Archbishop Williams*, written, according to Mr Cibber, to make known his political principles, which, in the course of it he had a free opportunity of doing, as the archbishop, who is the hero of his work, was a strong opponent to the high-church measures.

When he quitted the university, and came to London, he became a constant attendant at, and one of the wits of, Button's coffee-house; where he obtained the friendship and intimacy of many of the celebrated geniuses of that age, more particularly of Sir Richard Steele, who, in the first volume of his *Tatler*, has inserted a little poem of Mr Philips's, which he calls a *Winter Piece*, dated from Copenhagen, and addressed to the earl of Dorset, on which he bestows the highest encomiums; and, indeed, so much justice is there in these his commendations, that even Mr Pope himself, who had a fixed aversion for the author, while he affected to despise his other works, used always to except this from the number.

The first dislike Mr Pope conceived against Mr Philips, proceeded from that jealousy of fame which was so conspicuous in the character of that great poet; for Sir Richard Steele had taken so strong a liking to the pastorals of the latter, as to have formed a design for a critical comparison of them with those of Pope, in the conclusion of which the preference was to have been given to Philips. This design, however, coming to Mr Pope's knowledge, that gentleman, who could not bear a rival near the throne, determined to ward off this stroke by a stratagem of the most artful kind; which was no other than taking the same task on himself; and, in a paper in the *Guardian*, by drawing the like comparison, and giving a like preference, but on principles of criticism apparently fallacious, to point out the absurdity of such a judgment. However, notwithstanding the ridicule that was drawn on him in consequence of his standing as it were in competition with so powerful an antagonist, it is allowed, that there are, in some parts of Philip's pastorals, certain strokes of nature, and a degree of simplicity, that are much better suited to the purposes of pastoral, than the more correctly turned periods of Mr Pope's veneration. Mr Philips and Mr Pope being of different political principles, was another cause of enmity between them; which arose at length to so great a height, that the former, finding his antagonist too hard for

Philip

him at the weapon of wit, had even determined on making use of a rougher kind of argument; for which purpose he even went so far as to hang up a rod at Button's for the chastisement of his adversary whenever he should come thither; which, however, Mr Pope declining to do, avoided the *argumentum baculinum*, in which he would, no doubt, have found himself on the weakest side of the question. Our author also wrote several dramatical pieces; The Briton, Disaffected mother, and Humphrey duke of Gloucester; all of which met with success, and one of them is at this time a standard of entertainment at the theatres, being generally repeated several times in every season. Mr Philips's circumstances were in general, through his life, not only easy, but rather affluent, in consequence of his being connected, by his political principles, with persons of great rank and consequence. He was concerned with Dr Hugh Boulter, afterwards archbishop of Armagh, the right honourable Richard Welb, esq; lord chancellor of Ireland, the reverend Mr Gilbert Burnet, and the reverend Mr Henry Stevens, in writing a series of papers called the *Free Thinker*, which were all published together by Mr Philips, in three volumes in 12mo.

In the latter part of queen Anne's reign, he was secretary to the Hanover club, who were a set of noblemen and gentlemen who had formed an association in honour of that succession, and for the support of its interests, and who used particularly to distinguish in their toasts such of the fair sex as were most zealously attached to the illustrious House of Brunswick. Mr Philips's station in this club, together with the zeal shewn in his writings, recommending him to the notice and favour of the new government, he was, soon after the accession of king George I. put into the commission of the peace, and appointed one of the commissioners of the lottery. And, on his friend Dr Boulter's being made primate of Ireland, he accompanied that prelate across St George's channel, where he had considerable preferments bestowed on him, and was elected a member of the House of Commons there, as representative for the county of Armagh. At length, having purchased an annuity for life of 400*l. per annum*, he came over to England some time in the year 1748; but having a very bad state of health, and being moreover of an advanced age, he died soon after, at his lodgings near Vauxhall, in Surry.

PHILIPS (Catherine), a very ingenious lady, the daughter of Mr John Fowler merchant; was born at London, in January 1631, and educated at a school at Hackney. She married James Philips of the priory of Cardigan, esq. and went with the vicountess of Dungannon into Ireland, where she translated Corneille's tragedy of *Pompey* into English, which was several times acted there with great applause. Her poems were first printed in the year 1664, tho' without her consent; and after her death a small volume of her letters to Sir Charles Cotterel, was published under the title of *Letters from Orinda to Poliarchus*. She died of the small-pox in London, in June 1664. Besides the above, she translated from the French of Corneille, part of the tragedy called *Horace*, which Sir John Denham completed by adding the fifth act; and soon after her death, her poems and translations were published in a folio volume. This lady, who had few per-

personal graces, was greatly admired for her abilities and many virtues; and was particularly esteemed by several persons of quality and distinction, amongst whom were those illustrious peers, the duke of Ormond, the earls of Orrery and Roscommon, and Dr Taylor bishop of Downe and Connor. Mr Dryden more than once mentions her with honour; and Mr Cowley wrote an excellent ode upon her death.

PHILIPS (John), an eminent English poet, was born in 1676. He was educated at Winchester and Oxford, where he became acquainted with Milton, whom he studied with great application, and traced in all his successful translations from the ancients. The first poem which distinguished our author, was his *Splendid Shilling*, which is in the *Tatler* styled the *finest burlesque poem in the English language*. He wrote also a poem upon Cyder, founded on the model of Virgil's *Georgics*; which is an excellent performance in its kind: with several other pieces. He was beloved by all who knew him; somewhat reserved and silent amongst strangers, but free, familiar, and easy with his friends. He died young, in 1708.

PHILISTÆA (anc. geog.), the country of the Philistines, (Bible); which lay along the Mediterranean, from Joppa to the boundary of Egypt, and extending to inland places not far from the coast. *Palestini*, the people; *Palestina*, the country; (Josephus): Afterwards applied to the whole of the Holy Land and its inhabitants. *Philistæi*, the people, (Septuagint); *Philistini*, (Vulgate); the *Caphtorim* and *Philistim*, originally from Egypt, and descendants of Cham, (Moses). Expelled and destroyed the Hivites the ancient inhabitants, and occupied their country; that is, the region which retained the name of *Philistim*, in which that of *Caphtorim* was swallowed up.

PHILLYREA, mock-PRIVET; a genus of the monogynia order, belonging to the diandria class of plants. There are seven species, all of them shrubby plants, natives of France and Italy, rising from five to 18 or 20 feet high, adorned with small clusters of white

or herbaceous flowers. They are very hardy, and will thrive in any soil or situation.

PHILO, a celebrated Jewish writer of the first century, was born of a distinguished family at Alexandria, and was the chief of the deputation sent by the Alexandrian Jews to the emperor Caligula against the Greek inhabitants of the same city, about the year 40. This deputation was without effect; Caligula gave him audience, heard him, and refused to grant his demands. Philo himself wrote a curious account of this embassy, under the title of, *A discourse against Flaccus*. There are also extant several other of his works, divided into three parts; the first of which relates to the Creation of the World, the second is on the Sacred History, and the third on the Laws and Customs of the Jews; all of which are written in elegant Greek, and interspersed with excellent moral sentiments and allegories. Philo so closely imitated Plato's style and doctrines, that he has been furnished the *Jewish Plato*. The best edition of his works is that of London, printed in 1742, by Dr Mangey, in Gr. and Lat. 2 vols folio.

PHILOCTETES, in fabulous history, the son of Pæan, was the faithful companion of Hercules; who at his death obliged him to swear not to discover the place where his ashes were interred, and presented him with his arrows dipped in the Hydra's blood. The Greeks at the siege of Troy, being informed by an oracle that they could never take that city without those fatal arrows, went to Philoctetes, and insisted upon his discovering where he had left his friend; when Philoctetes, to evade the guilt of perjury, let them know where Hercules was intombed, by stamping upon the place: but he was punished for the violation of his oath, by dropping an arrow upon that foot; which, after giving him great agony, was at length cured by Macao. He was afterwards taken by Ulysses to the siege of Troy, where he killed Paris with one of his arrows.

## P H I L O L O G Y.

UNDER the term PHILOLOGY, some comprehend universal literature; so that each one may there include whatever he thinks proper; as grammar, rhetoric, poetry, antiquities, history, criticism, the interpretation of authors, &c. This seems to be not only making an abuse of words, but creating confusion in those matters where too much regularity and precision cannot be observed. The term *philology* is composed of the Greek words *φιλο* and *λογος*, which imply "a love or study of languages." It appears, therefore, that philology is nothing more than a general knowledge of languages, of the natural and figurative signification of their words and phrases, and, in short, of all that relates to expression in the different dialects of nations, as well ancient as modern.

As, in treating of GRAMMAR, we have given those general rules which are applicable to all possible languages; we shall here confine our observation to the languages themselves, and to those general ideas which philology offers, without leading our readers thro' all the paths of an immense labyrinth.

Languages in general may be divided into,

1. *Ancient languages*; which are those that have become extinct with the people who spoke them, or have been so altered and disfigured that they no longer resemble the languages which were spoken by those people.

2. *Oriental languages*; the study of which is necessary in order to the understanding of the text of the holy scriptures, especially the Old Testament.

3. *Learned languages*; which are those that are indispensably necessary in the study of erudition, and particularly literature; which, while there were people in the world who made them their common language, were called *living*; but as no nation now makes use of them, they are called *dead languages*, and are therefore to be learned from books or in schools.

4. *Modern languages*: in which are distinguished, first, the common languages of the European nations; and secondly, the languages of the people who inhabit the three other parts of the world.

SECT. I. *Ancient languages.*

I. Of the languages that were spoken by the first inhabitants of the world, till the destruction of the tower of Babel, there are not now the least traces remaining; though some zealous theologians pretend that it was the Hebrew as it is found in the Bible, or at least the ancient Chaldean: but all this is mere conjecture; and it is certain, on the contrary, that every vestige of those languages has been totally destroyed by time. The ancient languages that have been in use in the different parts of the world since that period, and the knowledge of which, more or less imperfect, has come down to us, are,

1. The Chaldean.
2. The Syriac and Estrænetic,
3. The Arabic.
4. Coptic or ancient Egyptian.
5. Ancient Ethiopian.
6. Ancient Indian.
7. Ancient Phœnician, which is also called the *Ionie Phœnician*.
8. Punic or Carthaginian.
9. Scythian, and the Scythian of the Huns.
10. Cyrrilian.
11. Glagolitic.
12. Braminian or Brachmanian.
13. Æolian or Æolic.
14. Jacobitian.
15. Celtic.
16. Saracen.
17. Ancient Eclavonian.
18. Gothic.
19. Hetrufcan.
20. Mangiurian; of which the Maronites, Nestorians, and sometimes the Jacobites, made use.
21. Hieroglyphic.
22. Runic.
23. Ancient Vandalian.
24. Ancient Germanic.

And perhaps some others that may be known to philologists. To these may be added,

25. The different alphabets, idioms, and methods of speaking and writing in the middle age.

Philology is therefore employed in making learned researches, not only into these languages, but into many others, which we shall enumerate in the course of this article. It prescribes rules, lays down precepts, points out principles, furnishes etymologies, and makes all the necessary remarks for the understanding and attainment of every known language. It shows the use that may be made of each particular language; in what country, and by what people, it has been spoken; and explains, as far as is possible, all the obscurities and ambiguities that attend the study of each language.

When the alphabet of a language is once discovered and well understood, we may easily attain, or at least with much less difficulty, the knowledge of the rest. Beside numberless philological works, with which each library is crowded, they have, in Germany, a small treatise that is very curious and very instructive, intitled, *The new A. B. C. in a hundred languages*; or, "Fundamental instructions for teaching the youngest scholars not only German, Latin, French, and Italian,

but also the oriental and other languages, as well as Ancient the pronunciation and knowledge of these different languages:" Leipzig, published by Gesner, 1743. In this book are contained the alphabets and first elements of a hundred different languages, as well ancient as modern. This work was reprinted in 1740, and very considerably augmented, under the title of, *The master of the oriental and occidental languages*. To this has been added the Lord's prayer, in two hundred languages ancient and modern, in the characters proper to each, with the dialect or manner of pronouncing the prayer; which contributes greatly to facilitate the attaining an idea of these languages. The author of this equally curious and instructive book is M. John Frederic Frits; and he was assisted by the Danish missionary Schults of Hall. The successors of Homann of Nuremberg have also published four geographico-philological maps, designed by Godfrey Henfel, which bear the following titles: 1. *Europa polyglotta, linguarum genealogiam exhibens, una cum litteris scribendique modis omnium gentium*: 2. *Asia*; 3. *Africa*, with the same title; and, 4. *America, cum supplementis polyglottis*. The four parts of the world are engraved and coloured on these maps; but in every country, instead of the names of its cities and provinces, is seen the beginning of the Lord's prayer, in the characters used in that country; so that, with a single glance of the eye, we see all the languages that are in use in all parts of the known world. These maps are highly curious, and have doubtless cost the inventors immense labour.

Books which teach the particular rules of a language called *grammars, rudiments*, &c.; and those that contain the words and phrases, *dictionaries, lexicons, lexical manuals, vocabularies*, &c. Philology shews the manner in which these books are to be made, and the precautions that are to be observed to render them instructive and agreeable; the method of treating synonymous terms, the gradations that are among words seemingly synonymous, and many other like matters. It shews also the reciprocal influence which the genius and manners of a people have on their language; and their language on their general method of thinking; their manners, urbanity, and refinement.

But as it is impossible to perceive all the force and elegance of the various allusions, metaphors, and comparisons in a language, especially in an ancient language, if we are not properly instructed in their manners, customs, ceremonies, laws, arts, sciences, and professions, and other peculiarities of the nation by whom they have been used, and whose natural idiom they formed, Philology, in order to know the true origin, etymology, and signification of the words, terms, and phrases of a language, remounts to the most distant ages, and, employing all the aids it can receive from literature, it makes use of antiquities, numismatics, and diplomatics, in fixing the meaning of each term and mode of expression, and by these means renders languages and authors intelligible, clear, and agreeable.

These languages, which are no longer in common use, can only be learned by books or manuscripts. But as these have come down to us by the means of copying, they have consequently been frequently mutilated, altered, diminished and disfigured, by those who

Oriental Languages. who have copied them; the text, in general, or at least many passages of these books and manuscripts, is unintelligible at the first reading. From hence there has arisen in modern Europe a particular science, that is called the *Criticism of Languages*, which makes a part of philology, and is employed, 1. In examining the authenticity and truth of the text; 2. In discovering and pointing out the means of correcting the text; 3. In restoring such passages as have been altered, omitted, or mutilated; 4. In explaining the true sense of the text; and, 5. In establishing a language by these means in its full primitive perfection, and making it perfectly intelligible to modern times. The celebrated M. le Clerc has given us an admirable work on this subject, intitled *Arts Critica*, in which he explains, with equal genius and solidity, the rules of sound philological criticism.

That which is of the greatest use in understanding and interpreting an obscure or imperfect passage, or an unintelligible word or phrase, is *confrontation*. The best confrontation is that which is made by comparing an author, book, or manuscript, with itself; by examining if the same word, matter, or phrase, is not repeated elsewhere, or in equivalent expressions. This is the most certain method, and produces an authentic interpretation. The second method is to confront a writer with his contemporaries of the same nation: and the third consists in comparing him with other authors who have written at different times, and in the same language.

#### SECT. II. Oriental Languages.

THOUGH most of the languages we have enumerated in the preceding section, and many of those we shall mention in the fourth, have been, or are still, in use in the eastern countries, we here understand, however, by the term *oriental*, those only which are essentially necessary to the understanding, and interpreting, in an exegetic manner, the holy writings, especially those of the Old Testament; and for this restriction of the term we have the authority of a great number of learned men, who by the oriental languages understand only the Hebrew, Chaldean, Syriac, Arabic, and Coptic: to which we shall add the Samaritan, Rabbinic, and Talmudic. These eight languages merit a more particular examen, as they serve to establish the foundations of the Christian religion, and make a considerable part of the study of a Theologian.

1. The Hebrew, Arabic, and Chaldean, respectively claim the right of seniority: each of them has its advocates; and the point is not easy to be decided. Most zealous divines are inclined to favour the Hebrew; and there are some of them who pretend that it was the language in which God talked with Adam in paradise, and that the saints will make use of it in heaven in those praises which they will eternally offer to the Almighty. These doctors seem to be as certain with regard to what is passed as what is to come. Some philologists give the priority to the Arabic, and others to the Chaldean. This difference is the more difficult to be reconciled, as Moses was not born till 2464 years after the creation, and in Egypt: that is to say, 700 years after the destruction of the tower of Babel, when all languages were mixed and confounded;

for we have no proof, nor even any account, that the Hebrew was exempted, and preserved its purity amidst the general confusion. There is not, moreover, at this time, any one work of antiquity existing that is wrote in Hebrew, except the Old Testament; and of that there are even some parts in Chaldaic; and words of that and other languages are to be found dispersed in different parts of it.

There is one more remark we must here make. The first time we find the word *Hebrew* in the Bible, is in the 13th verse of the xivth chapter of Genesis; and it is manifest that Abraham and his descendants took that name from the patriarch *Heber*, the son of Salah, and third grandfather of Abraham: it is therefore evident, that in the time of Abraham this name was that of a family, and not of a people who had a separate language. We are therefore to suppose, that Abraham, and the patriarchs after him, spoke the customary language of the country where they lived: that this language changed by degrees, as all living languages have done and ever will do: that Jacob and his sons having passed into Egypt, they and their descendants, under the name of the *Children of Israel*, did not preserve the language of their fathers in all its purity; but that they mixed with it many expressions borrowed from foreign languages, and especially from the Egyptian and Coptic: that Moses wrote in the Hebrew language, as the children of Israel then spoke it: that the other books of the Old Testament were wrote still later; and that it is almost impossible for this language to have been preserved without any alteration.

As we have no Hebrew but what is contained in the Holy Bible, this language must naturally be deficient of many words; not only because all the ancient languages, but especially those of the first ages, were not so copious as the modern; but there were in those times fewer objects to be named; and the sacred authors moreover had not occasion to treat on all subjects. The Hebrew language, however, is susceptible of all the ornaments of diction, and is very expressive. It is not, beside, so difficult to learn as some have imagined. The style of the Psalms, of the book of Job, and of all that is written in a poetic manner, is the most difficult to understand. That of Isaiah is noble and elegant, worthy of an author who was of the house of David, and the nephew and grandson of a king. But, notwithstanding all the labours of the learned for so many centuries, we are very far from having a perfect knowledge of the Hebrew language: this inconvenience is the greater, as it gives occasion to many imperfect translations, which disfigure the true sense of the original text; and, what is still more, they have founded, on these passages wrong interpreted, a belief of events that have never arrived in the manner predicted; and even sometimes religious dogmas.

The Hebrew language had originally no vowels. They are marked in the massorets by points under the consonants. This language is written and read from the left to the right: it has thirteen letters, which grammarians divide into guttural, palatic, dental, labial, and gingival. They now distinguish only five vowels in Hebrew, which are the same as ours, *a, e, i, o, u*. But they divide each vowel into two or

Oriental  
Languages.Oriental  
Languages.

three; as *long, short, shortest*. The articles, pronouns, &c. are placed after the substantive; and the same word is sometimes substantive, adjective, and verb. The punctuation and accent are the objects that require the greatest attention in the Hebrew language: they count near forty accents; and there are many whose use is still unknown. They serve in general to distinguish, 1. The period and its members, as the points do in other languages; 2. To determine the quantity of syllables; and, 3. To mark the tone that is to be observed in chanting them. Nineteen of these accents are also called, by grammarians, *disjunctivi* or *accentus regii*; and the others *conjunctivi, servi, or ministri*. There is, properly speaking, only one conjugation in this language, which is of itself simple, but is varied in each verb by seven or eight different manners, that form in fact so many different conjugations, and give a great number of expressions, to represent by one word the various modifications of a verb. These are the principal characteristics of the Hebrew, as we find it in the Holy Scriptures; and which, taken all together, forms a very regular and analogous language.

II. The *Chaldean* is that which was spoken in Chaldaea. Some say that it is a dialect derived from the Hebrew, and others that the Hebrew is a dialect of the Chaldean. This language has twenty-five letters; the forms of which are very different from the Hebrew. It is in like manner wrote from the left to the right.

The *Syriac* is also considered as a dialect of the Hebrew. It has twenty-two letters, which have the same names with the Hebrew, but are of very different forms.

The *Arabic*, or the language of the Arabians, is in like manner a dialect of the Hebrew. It has twenty-eight letters, the names of which have a good deal of resemblance to the Hebrew; but their characters are also very different.

The *Coptic* is the ancient language of the Egyptians, but mixed in process of time with much of the Greek. We have already said, in the preceding section, that the late M. de la Croix has in a manner re-established this language, when we scarce knew more than the name of it; and that he has composed a Coptic grammar and dictionary. F. Kircher, it is true, had before published a Coptic vocabulary and kind of grammar, but very incomplete. There are thirty-two letters in its alphabet, but the characters are almost entirely Greek. There has been no book found in this language but translations of the Holy Scriptures, or ecclesiastical offices, &c.

III. The *Samaritan* is another dialect of the Hebrew. The Samaritans were Jews, and their city Samaria was in Judea. They followed the law of Moses with more rigour, more after the letter than the Hebrews. There is a Samaritan copy of the Pentateuch, which differs indeed but little from that of the Jews in Hebrew; but it is written in different characters, that are commonly called *Samaritan*; and which Origen, St Jerom, and many other writers, as well ancient as modern, suppose to be the first letters of the Hebrews. There are also medals that are called *Samaritan*; they have Hebrew inscriptions, in characters different from those of our Hebrew Bible,

and which are called *square Hebrew*. For a further account of the Samaritan language, consult M. Simon in his customs and ceremonies of the Jews, Eduard Bernhardt Lexicon Samaritanum, F. Kircher, M. Buxtorff, M. de Spanheim, F. Morin, M. Walton. and a great number of others writers.

IV. The *Rabbinic*, or the Hebrew of the Rabbins, is the language of which they have made use in their works. The body of it is composed of Hebrew and Chaldaic, with divers alterations in the words of those two languages, whose significations they have much extended. They have likewise borrowed greatly from the Arabic. The rest is composed of words taken for the most part from the Greek, with some from the Latin, and others from various modern languages, especially that of the country in which each rabbin lived. For we should remember here, that after the return from the last captivity, they spoke scarce any pure Hebrew at Jerusalem and in Judea, but Greek mixed with some Hebraic expressions: the Romans afterward entering Palestine, and becoming conquerors of that country, spoke their own language there; and at last the Jewish nation was totally dispersed. We shall only add, that the Rabbinic is a very copious language; and that there is scarce any part of science of which the Rabbins have not treated, but always with an enthusiasm that is natural to them: there have been among them even poets and orators.

V. The *Talmudic* is another dialect or particular idiom of the Hebrew, in which the Talmud, or the book composed by the Jews, that contains all the explications of their law, is written. This language differs greatly from the pure Hebrew. M. Buxtorff has composed a Chaldaic, Talmudic, and Rabbinic dictionary. We have also a work of the emperor Constantine, intitled *Clavis Talmudica*; and one of Otto, called *Vita doctorum misinorum*; beside several others.

### SECT. III. Of those Languages that are called dead.

LANGUAGES in general, properly speaking, form no science that can enrich the mind with real knowledge, but are to be considered as introductions to the sciences; as keys that open to us the sanctuaries of erudition. In order to attain the knowledge of antiquity in its full extent, the knowledge of those languages that were then in use is of great utility: and properly to judge of modern nations, it is almost indispensably necessary to be acquainted with the principal languages which are now used in the world. There are two languages, however, which are called *learned* by way of eminence, and those are the Greek and the Latin. The former of these not only enables us to read the masterly productions of genius of ancient Greece, but also to form a true judgment of all its antiquities, and of its different ages, which form the most entertaining and interesting periods for the sciences and polite arts of all ancient times. The latter affords us the means of understanding the original texts of all the admirable works of the most celebrated Latian authors, and of becoming acquainted with the city, republic, and monarchy of Rome, as if we had been present with them; and of forming a solid judgement of those precious Roman antiquities of every kind that are still remaining among us.

Dead  
Languages.

But that which has given the Latin an advantage even over the Greek itself, that has rendered it indispensable to every man of letters, and has made it the basis of erudition, is, that during the middle age, and in general in all modern times, the learned of all Europe have made it their common and universal language; so that the Latin forms, if we may use the expression, the natural language of the sciences.

I. All that is written in *Greek* cannot be properly said to be in the same language; for we should carefully distinguish,

(1.) The ancient or literal Greek: an admirable language, in which are written the works of Xenophon, Thucydides, Demosthenes, Plato, Aristotle, Homer, Sophocles, &c. works that have preserved this language in all its purity, and that will make it, with themselves, immortal. There are, however, several idioms or dialects in this tongue, among which four are reckoned principal; and these are, 1. The Attic, which is the most esteemed; 2. The Ionic; 3. The Æolic; and, 4. The Doric; which was a kind of rustic dialect, and in which are written eclogues, idylls, and other pastorals. We must observe by the way, that all these four dialects are to be found in Homer, and produce an odd effect in an heroic poem, notwithstanding the universal approbation that is given to this poet. The Greek language is very copious in words, and its inflexions are as various as they are simple in most modern languages. It has three numbers; the singular, dual, and plural; and many tenses in its verbs, which afford great variety of expression. The use of the participles of the aorist, and of the preterite, and of compound words, which are very numerous in this language, give it force and brevity, without in the least diminishing its perspicuity. Proper names have also a meaning in this as in the oriental languages; and the learned there find likewise the character of their origin. The dialect itself, or the pronunciation, is sonorous, soft, harmonious, and delightful: in a word, the Greek is the language of a polite nation, that had a taste for all the arts and sciences.

(2) The Greek of the middle age. The ancient Greek ended at the time that Constantinople became the capital of the Roman empire; though there were after that time several works, and some by the fathers of the church, which were wrote in Greek, and with sufficient purity: but as theology, law, civil and military policy, the alteration of customs and manners, &c. introduced successively a great number of words that were before unknown, these novelties by degrees altered and corrupted the language. The natural elegance of the ancient Greek was no longer to be found. Those men of exalted genius, who constantly give a true beauty to a language, were no more. And what could be expected from a barbarous age, and from authors that were even below a moderate capacity?

(3.) The modern or vulgar Greek. It commenced at the taking of Constantinople by the Turks, and is the language that is now commonly spoke in Greece, without any regard to improvement. The wretched state to which the Greeks are reduced by the Turks, renders them indolent, and, by a necessary consequence, ignorant. The policy of the Ottoman Porte does not permit its subjects to apply themselves to

Dead  
Languages.

study; and that same spirit which has destroyed the finest monuments of antiquity, which has made, of columns of porphyry and granite, balls for their cannons, has caused the decay and total destruction of the sciences. The principal difference between the ancient and vulgar Greek consists in the terminations of their nouns, pronouns, verbs, and other parts of speech. There are also in the modern many words that are not to be found in the ancient Greek; particles that appear to be expletives, and which custom alone has introduced to distinguish certain senses of their verbs; names of employments and dignities unknown to the ancient Grecians, and a great number of words taken from modern tongues: which altogether form a spurious language, a kind of jargon. There is a glossary of this language composed by du Cange.

(4.) The Greek of the New Testament. The Greek of the Evangelists and Apostles is very different from that of Thucydides, Xenophon, and Demosthenes. At the time of the birth of our Saviour, Greek was commonly spoken in Judea; for after the last captivity, the people no longer understood Hebrew: their Greek, however, was corrupted; mixed with a great number of Hebraisms; with words and terms that related to the worship, to the laws, policy, manners, and customs of the Jews; by which means it became a vulgar language, a provincial and rude dialect, in comparison of the ancient or literal Greek. He that understands the New Testament, will not in consequence understand Homer. It may appear surprising, that Josephus, the Jewish historian, who lived at the time of the destruction of Jerusalem, about 40 years after the death of Christ, should be able to write Greek with so much purity and elegance: but he was at once a courtier, a minister, a general, and a man of letters; had studied the Greek language, and had spoken it at the court of Vespasian in Rome. For the same reason, St Paul also wrote better Greek than the Evangelists and other Apostles.

From all that has been said, it is apparent how much utility attends the study of the Greek tongue, and how much reason the English have for applying themselves to it from their early youth. There are, moreover, in modern languages, an infinity of terms in the arts and sciences, as most of those in astronomy, mathematics, physics, anatomy, botany, and the names of many machines, instruments, and other modern inventions, that are either altogether Greek, or derived from it; which renders this language in a manner indispensable to a man of real learning. We cannot, lastly, determine if modern nations pronounce the Greek language in the manner that the ancient inhabitants of Greece did; but it is very probable, that if Demosthenes or Aristides were now to come upon the earth, they would be very far from understanding what our learned men should say to them in Greek.

II. The *Latin* is the second of those languages that are called dead. It was first spoke in Latium, afterwards at Rome; and by means of the Latin church, and of the labours of the learned, has come down to us. The Latin is not an original tongue; but is formed of the Greek, and especially of the Æolian dialect, and of many words taken from the languages of the Oscei, the Etrurians, and several other ancient

Dead  
Languages.

nations of Italy. It has had different periods of improvement and decadency, which form its different ages.

1. The first age comprehends the ancient Latin that was spoke in Latium, and cultivated at Rome from its first foundation, under the reigns of its kings, and in the first ages of its republic. At the beginning, the Latin tongue was, so to say, inclosed within the walls of Rome; for the Romans did not commonly permit the use of it to their neighbours, or the people they conquered: but when they came to perceive how necessary it was for facilitating their commerce, that the Latin tongue should be spoken every where, and that all nations in subjection to their empire should be united by one common language, they then obliged those they conquered to adopt their language. It is easy to conceive what must have been the original language of a set of freebooters, without manners, and without arts or sciences: this jargon must beside have been necessarily mixed with the language of the Sabines, from whom they stole their wives, and with those of several other foreign nations whom they had conquered, or who were incorporated with their republic. But in proportion as the Romans became polished, their language became refined. There are but very few works of the first age now remaining; among which are reckoned those of Ennius, &c.

2. The second age of the Latin language began about the time of Cæsar, and ended with Tiberius. This is what is called the *Augustan age*, which was perhaps of all others the most brilliant. A period at which it should seem as if the greatest men, and the immortal authors, had met together upon the earth, in order to write the Latin language in its utmost purity and perfection. This age, and the language of this age, are so well known, and we have so great a number of works produced at this period, as makes it unnecessary for us to say any thing further of it here.

3. The third age begins with the reign of Tiberius. Seneca seems to have contributed not a little to have deprived the Latin language of its energy and dignity, and to have substituted the little tricks of style in its stead, and sometimes those childish expressions which the Italians call *conceitti*. Even Tacitus appears not to have been quite free from these faults; for his concise and sententious style is not that of the golden age; nor likewise is that of the poet Lucian.

4. The fourth age of the Latin tongue is that of the remainder of the middle age, and the first centuries of modern times; during which this language fell by degrees into so great a decadency, that it became nothing better than a barbarous jargon. It is to the style of these times that is given the name of *low Latin*; and in fact it was so corrupted, altered, and mixed with foreign expressions, that M. du Cange has formed a voluminous glossary, which contains those words and phrases only that are used in the Low Latin, and which we should not be able to understand without such helps. What indeed could be expected from this language, at a time when the barbarians had taken possession of all Europe, but especially of Italy; when the empire of the East was governed by idiots; when there was a total corruption of morals; when the arts and sciences were in a manner annihilated; when the priests and monks were the only men of let-

Dead  
Languages.

ters, and were at the same time the most ignorant and futile mortals in the world. Under these times of darkness, we must therefore rank that Latin which is called *lingua ecclesiastica*, and which we cannot read without disgust.

5. The fifth and last age of the Latin tongue is that which began with the 16th century, and was that of Leo X. Charles V. Francis I. Henry VIII. of England, &c. A happy period, and ever memorable for the restoration of letters, of arts and sciences, of manners, and of the powers of the human mind, which till then seemed to have remained in a perpetual stupor. It is necessary to remember here, that the art of printing was not invented till about the year 1441; and that the manuscripts of the ancient Greek and Latin authors were become extremely scarce, and highly valuable; so that but few private persons were able to procure them, and to study the Latin of the Augustan age. But since that time we have had many Latin works, as well in verse as prose, in a style that we cannot sufficiently admire, and which, though not altogether so pure and elegant as those of the golden age, yet are not much inferior.

There are, however, in the Latin, and in all dead languages, two great inconveniences which continually attend them with regard to modern ages. The first consists in the pronunciation. As to what concerns the Latin, each nation pronounces it after the manner of its own language, and each of them imagines their pronunciation to be the best. It may be proved, however, by many arguments, that no man now upon earth pronounces Latin in the same manner as did Horace and Cicero. The second inconvenience is the deficiency of the Latin language with regard to us, as it has not terms whereby to express those inventions and discoveries of every kind that have been made since the existence of the Roman empire. There are no Latin words for any of the furniture that surrounds us, for three-fourths of the dishes that come upon our tables, for the dress we wear, for our instruments of war and navigation, for civil and military employments, and, in a word, for all our daily occupations. It is droll enough to hear our authors call a cannon *bombarda*; a peruke, *capilamentum*; and a button of our cloaths, *globulus*, &c. Whoever shall doubt the propriety of this observation, need only read the essays that some able Latinists have made in our days to write gazettes in that language, and they will there see the pains those writers have taken, and the ill success they have had. We shall say no more of a language which every scholar learns from his infancy, which is taught over all Europe in schools and colleges, and of which there are grammars, dictionaries, and other instructive books without number.

#### SECT. IV. Modern Languages.

If we call all the different dialects of the various nations that now inhabit the known earth, languages, the number is truly great; and vain would be his ambition who should attempt to learn them, though but imperfectly. We will begin with naming the principal of them: There are three which may be called original, or mother-languages, and which seem to have given birth to all that are now spoken in Europe. These are the *Latin*, *German*, and *Slavonian*. From  
the

the Latin are derived the languages of all those nations which inhabit the southern and most western countries of this part of the world. From the German, all those of the nations that inhabit the centre and the northern regions; and from the Slavonian, all the languages of the people who dwell in the most eastern part of Europe. The Slavonian is extended even to Asia, and is spoken from the Adriatic sea to the northern ocean, and almost from the Caspian sea to Saxony. But it must not be imagined from the term *original*, which is given to these languages, that they have come down to us from the confusion at Babel without any alteration. No; we have already shown, in the preceding section, of what languages the Latin was formed. With regard to the German, it may be very justly supposed to have been the ancient language of the inhabitants of Germany, as the names of their divinities and heroes (*Mann, Erta, Hermann, &c.* appellative names; which still signify "man, earth, chief of an army," &c.) seem to confirm that opinion. But it is indubitable, that the ancient German has been mixed and corrupted by the languages of those northern nations which in the fourth century deluged Europe; and who, when they penetrated Italy and Africa, did not merely pass through Germany as an army that marches in regular order, but remained there a considerable time, and mixed with the natives of the country. All these Scythian or Celtic people acquired likewise in Germany the name of *Allamandi*, or "Germans:" some were called *Goths*, that is, "good;" others *Quades*, or "bad;" others *Huns*, or "dogs;" others *Normans*, or "men from the north;" and so of the rest. And those nations were from that time known and distinguished by these denominations.

I. With regard to the Slavonian, it is supposed to be in part the ancient language of the Celtes or Scythians, mixed with some particular dialects of different eastern nations. But be that as it may, these three languages appear to have produced the following modern tongues:

From the *Latin* came,

1. The Portuguese.
2. Spanish.
3. French.
4. Italian.

From the *German* or *Allamandi*,

5. The modern German; which so little resembles the ancient, that it is with difficulty we read the authors of the 14th century.
6. The low Saxon or low German.
7. The Dutch.
8. The English; in which almost all the noun-substantives are German, and many of the verbs French, Latin, &c. and which is enriched with the spoils of all other languages.
9. The Danish.
10. The Norwegian.
11. Swedish.
12. Dalecarlian.
13. Laplandish.

From the *Slavonian*,

14. The Polonese, with a mixture of the ancient Sarmatian.

15. The Lithuanian.
16. Bohemian.
17. Hungarian.
18. Transylvanian.
19. Moravian.
20. The modern Vandalian, as it is still spoken in Lusatia, Prussian Vandalia, &c.
21. The Croatian.
22. The Russian or Muscovite.
23. The language of the Calmacs and Cossacs.
24. Thirty-two different dialects of nations who inhabit the north-eastern parts of Europe and Asia, and who are descended from the Tartars and Huno-Scythians. There are polyglott tables which contain not only the alphabets, but also the principal distinct characters of all these languages.  
To all these may be added,
25. The modern Greek, or that which is now spoken in Greece.
26. The modern Hebrew, or vulgar language of the Jews, which is also called the *German Hebrew*, &c. And,
27. The jargon that is called *Lingua Franca*.

II. The common languages of Asia are,

28. The Turkish and Tartarian, with their different dialects.
29. The Persian.
30. The Georgian or Iberian.
31. The Colchic or Mingralian.
32. The Albanian or Circassian.
33. The Armenian.
34. The language of the Jews in Persia, Media, and Babylon.
35. The modern Indian.
36. The Formosan.
37. The Indohtian.
38. The Malabar.
39. The Warugian.
40. The Talmulic or Damulic.
41. The modern Arabic.
42. The Tangutian.
43. The Mungalic.
44. The language of Balabandu, and the Nigarian or Akar Nigarian.
45. The Grusinic or Grusian.
46. The Chinese.
47. The Japonese.

These languages are spoke by the Greek Christians in Asia, under the patriarch of Constantinople.

The Danish missionaries who go to Tranquebar, print books at Hall in these languages.

We have enumerated here those Asiatic languages only of which we have some knowledge in Europe, and even alphabets, grammars, or other books that can give us information concerning them. There are doubtless other tongues and dialects in those vast regions and adjacent islands; but of these we are not able to give any account.

III. The principal languages of Africa are,

48. The modern Egyptian.
49. The Fetutic, or the language of the kingdom of Fetu.
50. The Moroccan; and,
51. The jargons of those savage nations who inhabit the desert and burning regions. The people on the coast of Barbary speak a kind of Turkish. To these may be added the Chilibic language, otherwise called *Tamazeght*; the Negritian, and that of Guinea;

Guinea; the Abyssinian; and the language of the Hottentots.

IV. The languages of the American nations are but little known in Europe. Every one of these, tho' distant but a few days journey from each other, have their particular language or rather jargon. The languages of the Mexicans and Peruvians seem to be the most regular and polished. There is also one called *Poconchi* or *Pocomana*, that is used in the bay of Honduras and toward Guntimal, the words and rules of which are most known to us. The languages of North America are in general the Algonhic, Apalachian, Mohogic, Savanahamic, Virginic, and Mexican: and in South America, the Peruvian, Carabib, the language of Chili, the Cairic, the Tucumanian, and the languages used in Paraguay, Brasil, and Guiana.

V. We have already said, that it would be a vain and senseless undertaking for a man of letters to attempt the study of all these languages, and to make his head an universal dictionary of languages; but it would be still more absurd in us to attempt the analysis of them in this place: some general reflections therefore must here suffice. Among the modern languages of Europe, the French seems to merit great attention; as it is elegant and pleasing in itself; as it is become so general, we may travel from one end of Europe to the other without scarce having any occasion for an interpreter; and as in it are to be found excellent works of every kind, both in verse and prose, useful and agreeable. There are, besides, grammars and dictionaries of this language which give us every information concerning it, and very able masters who teach it; especially such as come from those parts of France where it is spoke correctly; for with all its advantages, the French language has this inconvenience, that it is pronounced scarce any where purely but at Paris and on the banks of the Loire. The language of the court, of the great world, and of men of letters, is moreover very different from that of the common people: and the French tongue, in general, is subject to great alteration and novelty. What pity it is, that the style of the great Corneille, and that of Moliere, should already begin to be obsolete, and that it will be but a little time before the inimitable *chefs d'œuvre* of those men of sublime genius will be no longer seen on the stage! The most modern style of the French, moreover, does not seem to be the best. We are inclined to think, that too much concision, the epigrammatic point, the antithesis, the paradox, the sententious expression, &c. diminish its force; and that by becoming more polished and refined, it loses much of its energy.

VI. The German and Italian languages merit like-

wife a particular application; as does the English, perhaps above all, for its many and great excellencies, (see LANGUAGE.) Authors of great ability daily labour in improving them; and what language would not become excellent, were men of exalted talents to make constant use of it in their works? If we had in Iroquois, books like those which we have in English, Italian, French, and German, should we not be tempted to learn that language? How glad should we be to understand the Spanish tongue, though it were only to read the Araucana of Don Alonzo D'Ercilia, Don Quixote, some dramatic pieces, and a small number of other Spanish works, in the original; or the poem of Camoens, in Portuguese.

VII. The other languages of Europe have each their beauties and excellencies. Among these, we must not omit to mention the *Gaelic*: A language unnoticed by the learned, and almost unknown, or known only to be despised under a barbarous name\*, beyond the mountains where it is spoken, till the translation of the beautiful poems of *Ossian* lately brought it out of obscurity, and presented it as an object of study not unworthy the attention either of the polite scholar or the learned philologist. See the article *OSSIAN*; also the article *GAELIC*, in the APPENDIX.

VIII. The greatest difficulty in all living languages constantly consists in the pronunciation, which it is scarce possible for any one to attain unless he be born or educated in the country where it is spoken: and this is the only article for which a master is necessary, as it cannot be learned but by teaching, or by conversation: all the rest may be acquired by a good grammar and other books. In all languages whatever, the poetic style is more difficult than the prosaic: in every language we should endeavour to enrich our memories with great store of words, (*copia verborum*), and to have them ready to produce on all occasions: in all languages it is difficult to extend our knowledge so far as to be able to form a critical judgment of them. All living languages are pronounced rapidly, and without dwelling on the long syllables (which the grammarians call *moram*): almost all of them have articles which distinguish the genders: all the European languages are written from the left to the right, and almost all the Asiatic from the right to the left.

IX. Those languages that are derived from the Latin have this further advantage, that they adopt without restraint, and without offending the ear, Latin and Greek words and expressions, and which, by the aid of a new termination, appear to be natives of the language. This privilege is forbid the Germans, who in their best translations dare not use any foreign word, unless it be some technical term in case of great necessity.

## P H I

PHILOMATHES, a lover of learning or science.

PHILOMELA, in fabulous history, the daughter of Pandion king of Athens, was the sister of Progne the wife of Tereus king of Thrace. That prince having ravished Philomela, cut out her tongue; and to conceal the knowledge of his incest, shut her up in a close prison: but the princess finding means to embroider her story, sent it to her sister Progne; who

## P H I

thus becoming acquainted with her sister's misfortunes, delivered her from prison, and took her to the palace: then killing Itys, her son by Tereus, she served up his flesh to his father; and after he had done, exposed the child's head to his view. Tereus, in a transport of fury, pursued the sisters; but was changed into a lapwing, Progne into a swallow, Itys into pheasant, and Philomela into a nightingale.

PHILO-

Philonium  
philosophy

**PHILONIUM**, in pharmacy, a kind of somniferous anodyne opiate, taking it name from Philo the inventor.

**PHILOSOPHER**, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature and morality.

**PHILOSOPHER'S Stone**, the greatest object of alchemy, is a long-sought for preparation, which, when found, is to convert all the true mercurial part of metal into pure gold, better than any that is dug out of mines or perfected by the refiner's art; and this only by casting a little quantity thereof upon metals in fusion, whilst that part of the metal which was not mercury is immediately burnt or blown away. But this, like every other scientific chimera, will for ever elude the researches of mankind.

**PHILOSOPHIC**, or **PHILOSOPHICAL**, something belonging to **PHILOSOPHY**.

**PHILOSOPHICAL EGG**, among chemists, a thin glass body or bubble, of the shape of an egg, with a long neck or stem, used in digestions.

**PHILOSOPHY**; the knowledge or study of nature and morality, founded on reason and experience.

The philosophers among the most ancient people of the world were called *sages* or *wise men*, as appears from history both sacred and profane. Thales and Pythagoras in Greece were the first among those that made an open profession of this science, who thought the title of *sage* too fatiguing, and took the more modest name of *philosophers*, or *lovers* or *studiers of wisdom*. Thales, who was a native of Miletus in Ionia, and the first of the seven sages, was the founder of the Ionic sect; his most illustrious disciples were Anaximander, Anaximenes, Anaxagoras, and Archelaus. Anaxagoras employed himself entirely in the contemplation of the stars; and when he was asked if he had no concern for his country, replied, pointing to heaven with his finger, "I incessantly regard my country." Pythagoras founded the sect that was called *Italic*, because it was settled in that part of Italy which was called *Great Greece*, and which now makes part of the kingdom of Naples. He borrowed from the Egyptians a mysterious manner of teaching by numbers; and to that he added a certain harmony, by which he explained the perfection in all objects. He believed the world to be animated, intelligent, and round. Not knowing what to do with the soul after its separation from the body, he invented the doctrine of the metempsychosis. His disciples of greatest note were Ocellus of Lucania, Archytas of Tarentum, Philolaus of Croton, Parmenides and Zeno, both of Elea, and Melissus of Samos. Zeno was the inventor of the dialectic; the others applied themselves closely to the study of natural philosophy, and to the investigation of its principles.

Socrates followed the career of these first philosophers, but turned almost all his studies towards morality. His master was Archelaus the Pythagorean. He was the first who began to reduce the confused ideas of those who had gone before him into method; for which reason he is called by Cicero *the father of philosophy*. His life was a model of frugality, moderation, and patience; and his doctrine abounds with wisdom.

Socrates, discovering a greater genius in Plato than

in any of his other disciples, had a particular attachment to him, and his labours were not lost; for, among all the celebrated men who came out of the school of Socrates, Plato was, doubtless, the most renowned. He taught at Athens, and had in a short time many disciples. He established his school in the academy, which was a place without the town, and from thence his followers were called *Academics*. According to Plato, the soul of man is only a ray from the Divinity. He believed that this particle, united to its principle, knew all things; but when united to a body, it contracted ignorance and impurity by that union. He did not entirely neglect natural philosophy, like Socrates, but inquired into many questions which relate to that science. He believed that all things consisted of two principles, God and matter. He likewise cultivated astronomy. His morality was the same in substance with that of Socrates.

The disciples of Plato formed also many new sects. That of which Aristotle was the founder is doubtless the most illustrious. This philosopher was the first who formed, from the several parts of philosophy, a complete system. No one before him had treated separately, and from principles, the different parts of this science. He did not regard logic as a part of philosophy, but as a proper method whereby to dispose the understanding to discover the truths that it contains. The morality of Aristotle is the most perfect of all his works. His physics consist of notions and terms that are vague, and as trifling as obscure. His disciples and their followers were called the *Peripatetics* of Lyceum, where he had fixed his school.

Aristotle was not the only disciple of Plato who deviated from the sentiments of that great man: there were others who likewise placed themselves at the heads of different sects. Arcesilas was the author of a sect that was called the *Middle Academy*. He declared that there was nothing either certain or true; and that the positive and negative might be maintained in all sorts of subjects. Lacydes, who taught in the same school as Plato, 56 years after Arcesilas, was the chief of another sect that was called the *New Academy*. He acknowledged that there was a degree of probability, but that we could not assuredly know that any thing was absolutely true. Pyrrho, about the same time, placed himself also at the head of a sect. He improved on the dogma of the Academics; and maintained that it was impossible to comprehend any thing: but Pyrrho could not comprehend himself. He believed that there was nothing true, nothing but what might be said to be either this or that. His followers were called *Pyrrhonians*, or more commonly *sceptics*, because they searched without ever being able to discover any one thing.

About the same time arose two sects, who, with principles diametrically opposite, rendered themselves highly celebrated, and divided at first the wits of Greece, and afterward those of the rest of the world; and these were Zeno and Epicurus. Zeno was of Citium, a city in Cyprus. He taught in the porticoes of Athens, from whence his disciples were called *Stoics*. The most famous dogma of Zeno and the Stoics consisted in the principle of morality, which was, to live in conformity to nature, that is to say, according to the object of our desires: on this principle,

Philosophy. ciple, and on divers others, they formed the idea of a philosophy altogether extravagant, and insensible to all external objects. The physics of Zeno had nothing new but the terms. The other sect, which flourished at the same time, was that of Epicurus; and they were called *Epicureans*. This philosopher taught publicly at Athens, his native country, at the age of thirty-two years. He rejected all the chicaneries and subtilties of logic, and fought the truth by means of the senses. He attached himself greatly to morality, to which likewise tended all his other studies: and his morality was as contentaneous to the nature of man, as that of Zeno was contradictory; seeing that his first principle was, that pleasure is the pursuit of man, and that it consists in health of body and tranquillity of mind; and that it is the source and the end of a happy life, &c. Epicurus was also engaged, but with less success, in the labyrinth of metaphysics, and in physics: he adopted the system of atoms, of which Democritus was the first author. In short, malgré the evil interpretations and calumnies of his adversaries, he inculcated by his doctrine, and by his example, frugality and sobriety; and, according to him, death is not an object of terror: "For," says he, "it is nothing so long as life subsists; and when it arrives, life is no more; no man has ever felt his death."

It is evident, that these ancient systems of philosophy are at great variance with each other; and as truth is constantly uniform, it follows, that the greatest part of these opinions cannot be true. This consideration engaged Patomom of Alexandria, under the emperor Augustus, to select all that he found most rational in the doctrines of all the other philosophers, whereof he composed a system, and founded a sect; and he, for that reason, gave to his doctrine the name of the *eclectic philosophy*, from a Greek word which signifies to select.

The doctrine of Plato was at first in greater estimation than any of the others; and there were many celebrated Platonists under the Roman emperors down to Julian the apostate, who was himself one of them. The first Christian doctors likewise declared for this philosophy, as Justin Martyr, Tatian, Athenagoras, Origen, &c. But at length the philosophy of Aristotle, perhaps of all others the most absurd, took the lead; and truth was no longer sought for but in the writings of that philosopher. This violent fondness for his reveries began about the 12th century; at which time a philosophy was formed, that is commonly called the *scholastic*, and which is borrowed in great part from the writings of the Arabs, whom the scholastics, who were all attached to Aristotle, imitated in their subtle, ambiguous, abstract, and capricious manner of reasoning, by which they never hit the truth, but constantly went on one side, or beyond the mark. Toward the end of the 14th century, their spirits were extravagantly heated by logical distinctions, relative to that furious emulation, which was formed on the doctrine of Aristotle, between the Nominalists and Realists. The former had, for their chief, Ocham, an English cordelier, and a disciple of Scotus. They maintained, that the universal natures were nothing but words: and the others, who supported themselves by the authority of Scotus, maintained, that

the same universal natures were beings strictly real. Philosophy. These disputes divided all the universities of Europe: philosophy was no longer employed but in operations of the intellect, conceptions, abstractions, and such like vain subtilties; and became a mere jargon, a confused heap of unintelligible ideas.

At length, in the 16th century, philosophy began to deliver itself from the chains of terminology; men accustomed themselves to philosophize by reason, and not by verbal contention: they began to throw off the yoke, and, without entirely despising Aristotle, they no longer believed him on his word. Nicholas Copernicus, who was born at Thorn, in 1473, and died in 1543, had already borne the torch of reason in the mathematics and astronomy: he had rejected the system of the world that was invented by Ptolemy, and which the Greeks called *most wise* and *most divine*; and had published his book *De motu octavarum sphaerarum*, and his treatise *De revolutionibus*, in which he established his system of the sun's being immovable, and of the motion of the earth. Galileo, who was born at Florence in 1564, adopted the system of Copernicus, confirmed it, and improved it by new observations. This discovery of the truth cost him five or six years confinement in the prison of the inquisition. He introduced a new and excellent method of reasoning in philosophical subjects.

Peter Gassendus, professor of mathematics in Paris, also practised, in the beginning of the 17th century, a new method of philosophizing, which contributed greatly to the progress of that science. Lastly, René Descartes appeared almost at the same time; and, by a method that had been but very imperfectly understood before, discovered more truths in philosophy than all the preceding ages had produced; although, from that weakness which is natural to the human understanding, he has frequently mixed error with truth in his different systems. He treated on almost all the parts of philosophy, especially the mathematics, physics, and metaphysics. Every one is acquainted with his famous system of the *plenum* and *vortices*.

Before Descartes, Francis Bacon, baron of Verulam, chancellor of England, had exposed the errors of the philosophy of the schools, and the wretched method that was there pursued. He was one of the greatest men that has ever appeared upon the earth. It was he who lighted that torch with which all his successors have illuminated philosophy; and in his writings are to be found the seeds of every new discovery, and of every new hypothesis.

After this golden Aurora, the philosophic horizon was at once enlightened by two grand luminaries, which dispersed many of those clouds that hid the truth from mortal eyes, and diffused great lights, at last, on many objects that lay buried in obscurity. See the articles *NEWTON*, *NEWTONIAN Philosophy*, and *LOCKE*.

From the slight draught here given of the history of philosophy, we may draw the following consequences: 1. That philosophers, in their researches concerning the causes of all things, have found themselves obliged to reduce ratiocination into a system; to confine it to certain rules, and form it into an art, which they have called *Logic*. 2. That by endeavouring to explain to mankind the nature, the causes, and effects of  
hap-

Philosophy,  
Philologist.

happens, the investigation of these objects has produced a science that is called *MORALITY*, to which are connected the doctrines of *natural theology, the law of nature, ethics, politics, &c.* 3. That from their endeavours to investigate the nature of those sensible and palpable objects which surrounds us, has resulted a science that is called *PHYSICS, or Natural Philosophy*; which in like manner consists of several branches, that all concur to its perfection, such as *OPTICS, CHEMISTRY, HYDRAULICS, MECHANICS, and their dependent arts*; with many others. 4. That by advancing still further, and by endeavouring to comprehend the nature and properties of subjects that are not discernible by the senses, but whose existence is the result of speculation and of a train of reasoning, a science has arisen that is called *METAPHYSICS*; which has also many branches, as *ontology, psychology, cosmology, pneumatology, &c.* 5. That from a desire to know the extension, the figures, the measures of all bodies, and their distances from each other, &c. they must necessarily have recourse to calculation; from whence result the *mathematical sciences*, whose principal branches are *ARITHMETIC, GEOMETRY, ALGEBRA, ASTRONOMY, &c.*

The essence of philosophy in general consists in the investigation of the causes of all things; and the grand principle of this inquiry consists in that fundamental maxim, that *no effect is produced without a cause*; that *nothing is done without a sufficient reason*. This system of the sufficient reason is, therefore, the basis of all philosophy, and without it nothing is philosophical. To consider the outside of things, is to know them historically; to resolve them, in order to know their principles and their causes, is to learn to know them philosophically; and in this manner even history may be philosophically studied. This admirable system of the sufficient reason, by diffusing the spirit of philosophy in the world, has already purged it of numberless dangerous superstitions: the fables of magicians, forerunners, spectres, ghosts, the absolute sympathy, and a thousand like reveries, have disappeared from among men of sense, to the very great advantage of the human race.

Philosophy may be again divided into *speculative*, which includes the subjects of metaphysics, morality, &c. and *demonstrative or experimental*, which principally regards physics; seeing that, by the improvement of the human mind by ingenious observations and the assistance of numberless admirable instruments, modern philosophers have discovered the means of explaining the principal phenomena of nature by experiments, and of demonstrating their hypotheses to the sight and to the touch, which afford proofs much more evident than those of our ancestors, which were drawn merely from logical inferences.

*Moral PHILOSOPHY.* See *MORALS*.

*PHILOSTORGIUS*, an ecclesiastical historian of the 4th century, was born in Cappadocia, and wrote an abridgment of ecclesiastical history, in which he treats Athanasius with some severity. This work contains many curious and interesting particulars. The best edition is that of Henry de Valois in Greek and Latin. There is also attributed to him a book  
VOL. VIII.

against Porphyry.

*PHILTER, or PHILTRE, (Philtrum)*, in pharmacy, &c. a strainer.

*PHILTER*, is also used for a drug or preparation, which, it is pretended, will excite love.—The word is formed from the Greek φίλος, “I love,” or φίλος, “lover.”

Philters are distinguished into *true and spurious*. The spurious are spells or charms, supposed to have an effect beyond the ordinary laws of nature by some magic virtue; such are those said to be given by old women, witches, &c.—The true philters are those supposed to work their effect by some natural and magnetical power. There are many grave authors, who believe the reality of these philters; and allege matter of fact in confirmation of their sentiments: among the rest, Van Helmont, who says, that upon holding a certain herb in his hand for some time, and taking afterwards a little dog by the foot with the same hand, the dog followed him wherever he went, and quite deserted his former master; which he pretends to account for thus. The heat communicated to the herb, not coming alone, but animated by the emanations of the natural spirits, determines the herb towards the man, and identifies it to him; having then received this ferment, it attracts the spirit of the other object magnetically, and gives it an amorous motion.—But this is mere cant; and all philters, whatever facts may be alleged, are mere chimeras.

*PHILYCA*, in botany. See *PHYLICA*.

*PHIMOSIS*, in medicine, a disorder of the penis, in which the prepuce is so strict or tense, that it cannot be drawn back over the glans. See *SURGERY*.

*PHLEBOTOMY*, the opening of a vein with a proper sharp-edged and pointed instrument, in order to let out a certain quantity of blood either for the preservation or recovery of a person's health. See *SURGERY*.

*PHLEGM*, in the animal economy, one of the four humours whereof the ancients supposed the blood to be composed. The chemists make phlegm or water an elementary body, the characters of which are fluidity, insipidity, and volatility.

*PHLEGMAGOGUES*, in medicine, a term anciently made use of for such medicines as were supposed to be endowed with the property of purging off phlegm; such as hermodactyls, agaric, turbit, jalap, &c.

*PHLEGMATIC*, among physicians, an appellation given to that habit or temperament of body wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c.

*PHLEGMON*, denotes an external inflammation and tumour, attended with a burning heat.

*PHLEGON*, surnamed *TRALLIANUS*, wrote several books, very few of which are now extant. He was the emperor Adrian's freed-man. The history of Adrian published under Phlegon's name, is thought to have been written by Adrian himself. It is said that Phlegon spoke of the darkness which prevailed during our Lord's passion; which has caused several disputes both among ancients and moderns.

*PHLOGISTON*, a term used by chemists to express that invisible and very much unknown substance, which, in conjunction with heat or elementary fire,

Philter  
Phlogiston.

**Phlogiston.** produces the phenomena of flame or ignition, and gives to metals their splendor; which, in other circumstances, contaminates the white colour of some earths and metallic calces, with black, brown, or other shades; and which in some cases renders the air noxious, and incapable of sustaining the life of animals, or supporting flame, &c. &c.

<sup>1</sup> Phlogiston cannot be procured in an uncombined state.

To give a definition of this *principle of inflammability*, as the phlogiston is frequently called, has hitherto been found impossible; because, it is so far from being the subject of investigation by itself, that no person has yet been able to procure it by itself; neither is it possible to expel it from any one body, without suffering it, in the very same moment, to combine with another. In the act of burning, for instance, phlogiston is discharged very copiously by any inflammable body; but some part, and that a very considerable one, goes to the composition of the flame. Part of the remainder is carried off by the air, and goes to the formation of foot; another part contaminates the air, and either converts part of the atmospheric air into what is called *fixable air*, or, according to others, *phlogisticates* it, while the fixable air is separated from the atmosphere itself, of which it is originally a component part: but in all this process, no part of the phlogiston is to be discovered by itself. In like manner, when iron is dissolved in the vitriolic acid, a great quantity of phlogiston is discharged: but in this case also it is altogether invisible, and incapable of being subjected to examination; the only result of this process being a kind of aerial vapour, by Dr Priestley and others called *inflammable air*: and so, in all other phlogistic processes, though we are assured that the principle is discharged in great quantity, yet it constantly eludes our most diligent search.

<sup>2</sup> Arguments for the identity of elementary fire and phlogiston.

From this invisibility of the phlogiston, it has been concluded, either that phlogiston is the matter of fire, heat, and light, or that these elements contain it in great quantity. The arguments for this opinion seem reducible to the following. 1. Phlogiston is in some cases capable of penetrating the substance of the closest bodies, in such a manner as to be capable of reducing calcined metals to their proper state. 2. The light of the sun appears to contain phlogiston; as it will turn the calx of silver black when exposed to it, even though the calx is included within a glass vessel stopped in the most careful manner. In like manner, the green colour which the leaves of plants acquire from the solar light is thought to be owing to a communication of phlogiston from it. 3. Dr Priestley has determined, that the electric fluid either is the phlogiston itself, or contains it; because an electric shock will either reduce metals to a calx, or restore them from a calcined to a metallic state.

<sup>3</sup> Insufficient.

In considering these arguments, however, it is obvious, that it ought first to be proved beyond dispute, that the substance of fire, light, or electric fluid, can be fixed in bodies in such a manner as to gravitate, and sensibly increase the weight of such bodies. That phlogiston can do this, seems to be demonstrable from a known fact in the conversion of iron into steel; for in this case, the steel produced always exceeds in weight the iron originally employed. But in no case whatever can we combine the matter of fire or light directly with any substance in such a manner, that we

can say beyond a doubt, that we have made the flame **Phlogiston.** or the light ponderable. The celebrated Mr Boyle made a vast number of experiments upon this subject, and supposed that he had succeeded, because many bodies, such as lead, become heavier from being exposed to the action of fire. But later experiments have discovered, that this increase of weight is owing to an adhesion of air, and not of fire or light, as was commonly thought. Neither can it be at all proved, that the fire or light is in these cases converted into air, as some have imagined. Besides, in the only case in which any thing like pure phlogiston is ever separated by itself, at least as far as we yet know, it is so far from appearing like what we would expect from light or heat, that it is the very reverse; and if there was such a principle in nature as *positive darkness*, the phlogiston would seem to have a much greater affinity to it than to light. The very remarkable experiment to which we now allude is recorded by Dr Priestley † (its author) in the following words.

“A very singular decomposition of inflammable air I observed in consequence of exposing a great variety of substances to the influence of a sand-heat, which I kept up for several months. Among other things buried in this hot sand, glass tubes hermetically sealed, and previously filled with all the different kinds of air. I filled them in the following manner.

“Having provided myself with glass tubes about four feet long, and about one third or one half of an inch in diameter, and of such a thickness that I could easily melt them with the flame of a couple of candles and a common blow-pipe, I first sealed the tubes at one end, then filled them with quicksilver, and placed them inverted in a basin of the same. After this, either transferring the air in a bladder from the jars in which they had been standing in water, or generating the air afresh, if it was of a kind not to bear the contact of water, I filled the tubes completely with the kinds of air on which I wished to make the experiment, displacing the quicksilver. This being done, I inclined the tube, and applying the flame of my candles, with some care, (holding the blow-pipe in my mouth only, and keeping firm hold of the tube on each side of the place to which I was applying the heat,) I melted the glass, and took off what lengths of it I pleased; and every piece was of course hermetically sealed. These pieces I marked with a file, keeping an account of the meaning of the marks, that when I took them out of the sand I might presently know with what kind of air they had been filled.

“When I was performing this part of the process with inflammable air in flint-glass tubes, I observed that the places to which I applied the heat were generally tinged black: but I gave little attention to this circumstance, thinking it might be something accidental; and, without any particular expectation, I buried these tubes in the sand together with the others. This was on the 25th of September 1777.

“On the 20th of January following, I examined these tubes, together with every thing else that had been exposed to the same heat. The tube containing the inflammable air was 10 inches long, and by some accident was broke; but it was jet black throughout. At this I was very much surprised, but I did not then suspect that it was at all owing to the inflammable air with which

<sup>4</sup> No authentic influence of fire being ponderable.

<sup>5</sup> Experiments in Natural Philosophy, vol. 1. p. 369.

<sup>6</sup> Inflammable air decomposed by heat.

Phlogiston. which it had been filled; thinking it might have been occasioned by some phlogistic matter in the sand, or in some of the vessels that had been burst in the neighbourhood. Reflecting, however, on this odd circumstance, and thinking, from the uniformity of the tinge, that possibly it might have been occasioned by the inflammable air, I filled another small glass tube with the same air; and, sealing it hermetically, buried it deep in sand contained in an iron pot, which I set on the fire, and made very hot, nearly red; and taking it out the next day, I found the tube quite black, except a small part on one side of that end which had been uppermost, about two inches higher than the other, and consequently had not been exposed to so great a degree of heat.

"Being now fully satisfied that the blackness of the tube was certainly occasioned by the inflammable air within it, in circumstances in which it could not expand, I proceeded to examine the state of the air. But, in the first place, to assure myself that there had been no communication between that air and the external air by means of some unperceived crack in the glass, I plunged it in water, and, exhausting the air over it, I did not perceive that any bubble escaped. Then, breaking the end of the tube under water, I examined it, and found it not to be inflammable. Sometimes, however, when I have only made the tube just black throughout, by applying the flame of a candle with a blow-pipe to every part of it in succession, the air has still been inflammable.

"Putting two glass tubes, about four inches in length, and a quarter of an inch in diameter, into a sand furnace, I kept them in it two days; when I took them out, and observed, that the tube which I had placed at the bottom of the sand in the greatest degree of heat was nearly melted, and perfectly blue like indigo; while the other tube, which had not been exposed to so great a degree of heat, was of a beautiful jet black throughout.

"Examining the air in these tubes, I found that in the black tube reduced to one third of its bulk, and mere phlogisticated air. It did not make lime-water turbid, was not affected by nitrous air, and was not inflammable. The air in the blue tube, or that which had been exposed to the greatest degree of heat, was reduced to a very small bubble, so that no experiment could be made upon it. I have no doubt, however, that it was phlogisticated.

"At one time I had a suspicion that this blackness communicated to the glass was something precipitated from the iron by the solution of which the inflammable air had been made; but I was soon convinced of the contrary, by finding that the effect was the very same when the inflammable air was made from zinc.

"I soon found that there was no occasion for such a long process to produce this effect, at least upon the glass. For it began to be discoloured the moment it was red-hot, or rather when it became soft; as was evident by holding one of the tubes in an open fire, or in the flame of a candle; for wherever the heat was applied, the blackness took place immediately, without affecting any other part of the tube.

"When I examined this black tinge narrowly, I found that it did not penetrate the glass; but formed a delicate superficial tinge, leaving the glass as perfect-

ly polished as before the process. But the blackness Phlogiston, was indelible: at least it could not be scraped off without tearing the surface of the glass, and it made no change in it with respect to electricity; for the tube thus blackened was as perfect a non-conductor as ever.

"The blue colour of the glass that was most heated, Mr Delaval informed me, was owing to something of iron in the composition of the glass. That it also depended on the degree of heat, I ascertained by placing one of these tubes in a vertical position in the sand-heat. For the lower end of the tube, which had been most heated, acquired a deep blue colour, and it passed into black at the upper end of the tube without any intermediate colour. There was also no other colour higher than the black; so that the first tinge which the glass receives is a perfect black. Yet, viewing the first tinge that it receives by the light of a candle placed beyond it, it seemed to have a shade of red.

"As I was sensible that the blackness was owing to the precipitation of phlogiston from the inflammable air, I thought it possible that some substance which had a near affinity with phlogiston might discharge it; and trying minium, it succeeded immediately. Having filled one of these black tubes with this metallic calx, the moment I made it red hot, the blackness entirely disappeared, and left the tube as transparent as ever it had been.

"In the first experiment of this kind I used minium out of which all its air had been expelled by heat, and which is of a yellow colour. In this process it became whiter, and adhered a little to the glass. When I scraped it off, I could not be quite sure that any part of it had become real lead, but it evidently approached towards a metallic state, by being of a more compact texture than before.

"In this state of the experiments it was suggested by Mr Bewly, that probably the lead in the glass tubes had attracted the phlogiston; and I presently found this to be the case. For when I had filled a green-glass tube with the inflammable air, and sealed it hermetically, as I had done the flint-glass tubes, I exposed it to a melting heat, which is greater than that which flint-glass will bear, without producing any change of colour in it. What remained of air in the tube that did not escape when part of it was melted, was still strongly inflammable.

"It appears, therefore, from this experiment, that the calx of lead, in the form of glass, has a stronger affinity with phlogiston than any thing in the composition of inflammable air, in a degree of heat capable of melting glass. Or, if there be no proper constituent part of inflammable air besides phlogiston, the attraction of the calx is so great as to reduce the phlogiston from an elastic and uncombined state to a fixed and combined one.

"Having by means of these glass tubes effected a complete decomposition of inflammable air, the phlogiston in it having united with the glass of the lead; I thought, that if there had been any acid in its composition, it would then be disengaged, and be found in the tube. In order to find whether there was any acid in it or not, I poured into one of these tubes a small quantity of water made blue with the juice of turnsole; but it came out as blue as it went in."

**Phlogiston.** From this curious experiment it appears, that phlogiston tends to make bodies opaque even when transparent before; and indeed something of this kind is always observed in whatever manner we apply phlogiston. The calces of lead or tin, made by dissolution and precipitation with the vitriolic acid, though of the purest white, become immediately tinged with black by an union with the smallest particle of phlogiston; or at least their whiteness is so much sullied, that the tendency of phlogiston to produce a black colour is visible on all occasions. Metals also, when combined with phlogiston, are exceedingly opaque; but, when deprived of it, and exposed to a very strong fire, they melt into a transparent glass. Now, if phlogiston was the same thing with fire or light itself, we should be apt to suppose that such bodies as had been longest exposed to the action of fire would contain most of it; but this is not found to be the case. Neither can it

**6**  
Phlogiston tends to make bodies opaque.

**7**  
Fire cannot be supposed capable of expelling itself.

**8**  
Electric fluid cannot be proved to be phlogiston.

well be answered, that fire in an active state is capable of expelling fire in a quiescent state; because it must be with this element as with water: succeeding quantities of water, if they are violently urged on, will expel the quantity which lies before them; but at last, a certain quantity will remain in the substance through which the water passed; and this quantity will be the same whether the substance has been immersed in a swift or slow running stream. In like manner, when a substance is exposed to the action even of the most violent fire, that element can only pass through it, as we might suppose water to pass through a sieve, while it remains in the fire; but when it is taken out, and suffered to cool, a certain quantity of the fire must necessarily be supposed to become quiescent, because it has nothing to expel it. It would seem probable, therefore, that if phlogiston was of the same nature with fire, no other change could be made upon bodies by exposing them to the action of that element, than melting, or altering their form; but we evidently see that the fire carries off one part of their substance, and leaves another.

Again, with regard to the calcination of metals by the electric fluid, it does not appear to act differently from common fire. An electric spark made to pass between two ends of wires, will deprive them of some part of their phlogiston; but this cannot prove that the electric fluid is the phlogiston of which they are deprived, because in this case they would contain less electric matter than before; but of this we can have no certainty, because all bodies seem to be full of this fluid, and we have no method of measuring the quantity contained in different bodies. As to the reduction of metallic calces by the electric spark, the fact is denied by some eminent foreign philosophers; but although it should be granted, yet we must observe, that a spark of electricity cannot be procured but by making the fluid pass through a small space of air interposed between two ends of wires, or some similar substances. Now though in this case the spark should reduce a metallic calx lying between these two wires, yet this could never prove that the electric fluid itself was phlogiston; because, in passing from one wire and entering the other, a quantity of phlogiston must necessarily be extricated from the wires by the violent impulse of the fluid. We must suspect, therefore, that the electric matter in this case only gives to the calx the phlogiston which it takes from the wires:

or, is it not possible that the phlogistic matter may in part be derived from the air, which always contains a quantity of it?

It hath been observed, that by making the electric spark pass a great number of times through a small quantity of air, the latter becomes diminished and phlogisticated. But in this case also the phlogiston is evidently derived from the metallic points between which the spark must pass. The argument therefore drawn by Dr Priestley from this fact, for the phlogistic nature of the electric fluid, cannot hold. It is the same thing as calcining metals confined in a certain quantity of air by a common fire; for in this case the air is always found to be phlogisticated.

The arguments drawn from the blackening of the calces of silver by the solar beams, seem also to be inconclusive. Glass, as appears from Dr Priestley's experiment above related, will imbibe phlogiston, and will also part with it, without losing its texture as glass. Possibly the case may be the same with the calx of silver just now mentioned. The glass, though it appear to us quite clear and transparent, may contain some phlogistic matter, which by the action of the solar light may be transferred to the calx; or it may come from the air contained in the glass. At any rate, it is impossible, from a single experiment, to deduce such an important consequence, especially as it is attended with a singularity which at once overthrows almost every inference we can draw from it. If we suppose the light of the sun to be phlogiston, much more ought we to suppose the light of a common fire to be the same: and if this were the case, then the lunar calx ought to be blackened by exposing it to the light of a common fire as well as to the rays of the sun. But this is found not to be the case; for though we expose the calx of silver to a common fire ever so long, no blackness will take place. It is the same thing with regard to the green colour of plants; for this is produced by the solar light, and by that light only: so that we must own it to be in some respects specifically different from the light of our common fires; but as these differences are totally unknown to us, it is plain, that, until our knowledge in this respect is increased, we cannot argue conclusively concerning the nature either of the one or the other.

In Dr Priestley's treatise on air, he supposes that it is the phlogiston which gives elasticity to that fluid. But in this also that eminent philosopher seems to have been mistaken. It is certain that elasticity is not necessarily connected with phlogiston, since it may be entirely deprived of its elasticity, and fixed in the substance of solid bodies; of which Dr Priestley himself gives a most remarkable instance in the experiment above related of the inflammable air contained in the glass tube. It is impossible that the phlogiston, while in a quiescent inactive state, can either be in a state of expansion, or have a tendency to expand; because this would be supposing it to have two natures diametrically opposite to each other at the same moment. If therefore this substance has some qualities peculiar to its state of quiescence, and others peculiar to its state of expansion, we must of necessity suppose that there is some third substance, by means of which its properties are changed at different times. Now we know, that this third substance is the fire; or rather the fire and

**9**  
Insufficiency of arguments drawn from the blackening of calces of silver by the sun-beams.

**10**  
And of those from the green colour of plants.

**11**  
Air not made elastic by phlogiston.

phlogiston. and air combined, for fire alone will not expel phlogiston. If then the fire originally gives its elasticity to phlogiston, it is in the highest degree probable, that to this element it owes its permanent elasticity also.

Some authors have been of opinion, that heat is produced by what they call the *evolution of phlogiston*; and Dr Dugud Leslie, in his treatise on animal-heat, labours throughout a whole chapter to prove, that the evolution of phlogiston is attended with heat. But granting that it is so, if we suppose this evolution to be the cause of heat, we are certainly wrong; for the cause of heat would then be whatever evolves the phlogiston. Dr Leslie supposes that the action of the blood-vessels evolves the phlogiston; and in this case the action of the vessels, not the evolution of phlogiston, is the cause of heat. But in many cases the argument will not hold: for there are numberless instances where phlogiston is evolved in great quantity, without any considerable degree of heat being produced; and in those where the greatest heat is produced, the phlogiston seems not to properly to be evolved, as to be destroyed in such a manner that it can never afterwards be found.

Some philosophers, and among the rest Mr Schele, have supposed, that fire consists in a chemical combination of phlogiston with dephlogisticated air; in which case, says he, the compound becomes so fine and subtle, that it passes through the pores of the most solid bodies, glass itself not excepted. But this supposition is entirely contrary to the analogy of nature. It is certain, that both the air and phlogiston, separately, are incapable of passing through glass; excepting in certain circumstances, where hot glass is found to be penetrable by phlogistic vapours: nor have we any instance of a mixture of two thick liquids producing a thin one. It seems indeed impossible that this could be the case without a change of nature in both fluids; and no substance can change its nature of itself. Certain substances indeed there are, which appear to change their natures by being mixed; but if we consider the matter fairly, we will find that this change is only in appearance. Thus, if powdered cream of tartar is mixed with chalk or quicklime, the mixture appears to deliquesce in the air, which is a property belonging neither to the chalk nor cream of tartar. But here a quantity of alkaline salt is produced, which naturally deliquesces, and occasions the deception. In like manner, when a neutral salt is formed by an acid and alkali, both of which taken separately will deliquesce in the air, yet the nature of these component parts are not changed though the neutral salt does not deliquesce: only their attraction for each other is so strong, that their attraction for water becomes less than that of the air for the same element; and of consequence the salt remains dry. But at any rate, there is no possibility of making a saline solution more fluid than water. Every substance which can be dissolved in water or an aqueous fluid, always takes something from its fluidity; and the same thing happens with oil, or any other fluid thicker than water. It is incredible that two kinds of oil, both of them having a thick consistence when separate, should yet, by simple mixture, become as fluid as water: yet on a similar supposition, which cannot

be explained by any known fact in nature, proceeds Phlogiston. the whole of Mr Schele's hypothesis.

It may indeed be argued, that phlogiston is by itself capable, in some cases, of pervading solid bodies; and consequently may communicate to the common heat atmosphere, by a chemical combination with it, such glass, and a degree of fluidity, that it will pass through the pores of glass or any other solid substance. In support of this hypothesis it may be urged, that Dr Lewis \* asserts his *Neu-* having seen globules of lead revived by the action of *mann's Che-* the phlogistic vapours of charcoal, even in the middle *mistry*, i. 80. note (i.) of thick pieces of glass, where there was not the least appearance of a crack. It is certain also, that though we deprive mercury of its phlogiston as much as possible by means of the nitrous acid, it will rise in its native form by distillation in the closest vessels.

But in these, and other similar instances, we are to consider, in the first place, that by heat the pores of all bodies are opened, and consequently made liable to receive substances, which in their natural state they would not receive. All fluid substances also have their fluidity increased by heat. Thus, we will find that warm water will pass through a thick cloth in a much more full and copious stream than an equal quantity of cold water will do. Now, when glass is much heated, its properties are remarkably changed. It loses its transparency, and becomes a conductor of electricity; and if it then conducts this fluid, or modification of a fluid, which at other times it cannot do without being shattered to pieces, this evidently shows that it may also conduct, or be penetrable by, vapours of various kinds. This will account in a satisfactory manner for the revival of lead in the heart of solid pieces of glass; for it is not pretended that a revivification of this kind will take place in the cold, even tho' the glass should be exposed to the greatest quantity of phlogistic vapours that can be imagined. Hence the inference must be very strong, not that heat derives any of its activity from phlogiston, but that all the activity which phlogiston possesses is derived from heat.

Again, with respect to the calcination of mercury, Why the and its revival by mere heat, it must be remembered, *calces of* that neither calcinations nor revivifications of metals *mercury* may be revived with- can take place *in vacuo*. Mercury may indeed be reduced to a kind of calx by exposure to the fire, but out addition it must also be exposed to the air at the same time; and indeed the case is the same with all metals. It is probable, therefore, that all of them receive something from the air, and this is abundantly confirmed by experiments; for no calx can be reduced without an emission of air at the time of reduction. The common metals on this occasion emit fixable air; but the calces of mercury emit dephlogisticated air. If the air is dephlogisticated, it is plain that the calx must be phlogisticated; because the air of our atmosphere is not in a pure dephlogisticated state. The phlogiston it contains must therefore be disposed of in some way or other, and it is in the highest degree probable that it remains with the calx. But a phlogisticated calx becomes a metal, when exposed to a proper heat. In the revival of mercury, therefore, the phlogiston probably comes from the air. Silver and gold, which are indestructible by fire, probably owe this quality to their having little attraction for fixed air, but a great deal for phlogiston. The consequence.

of

**Phlogiston.** of this must be, that if a calx of silver or gold is exposed to the air and to the action of heat at the same time, the calx will imbibe the phlogiston rather than fixable air; and of consequence will always appear in a metallic state, though it should be calcined ever so long.

17  
Enumeration  
of the  
properties  
of phlogis-  
tion.

Having thus shewn at some length, that phlogiston cannot with any probability be supposed to have active qualities of its own distinct from those which it receives from the fire, we must next inquire into its nature from the few properties which it is certainly known to possess. These properties may be reduced to the following.

1. It is capable of being reduced to an exceedingly thin, permanently elastic, and light vapour; in which state it has all the properties of a species of air.

2. It may be deprived of this elasticity, and combined with terrestrial bodies; in which case it becomes ponderable, and gives a remarkable degree of opacity to all bodies with which it unites itself.

3. In a great many cases it is a means of producing and preserving flame; especially when combined with terrestrial bodies.

4. In some cases it appears to give a violent explosive power to common air.

5. When combined with air in a certain degree, it deprives it of the very essential properties of supporting flame or animal life.

From a general consideration of these properties, it appears probable that phlogiston is a terrestrial substance, expandible indeed in the highest degree, but which may also be reduced to a solid, and which in that state of solidity seems to be endowed with no other properties than those of passive terrestrial matter, owing all its activity to a combination either with fire or air.

In considering the phlogiston with regard to its property of sustaining flame, we find that the greater quantity of the inflammable principle there is in any substance to be inflamed, the more easily and fiercely it burns; and the same effect follows, if the air is perfectly free from phlogiston, though the inflammable subject should contain a smaller quantity of it. But if we invert this proportion, loading the air with phlogiston, and at the same time giving a great quantity of it to the fuel, the fire will infallibly be extinguished, though made ever so fierce originally.—Now to understand the reason of this, we must call to mind what hath already been delivered in various parts of this work, concerning the nature of electric fluid, heat, vapour, fire, and flame. Under these articles it has been shewn,

18  
Recapitulation  
of the  
properties  
of heat.

1. That fire, heat, light, and electricity, are only so many different modifications of the same fluid, which we shall here call the *etherial fluid*.

2. That the etherial fluid acting as fire or heat, acts from a centre to the circumference, in every part of the heated body.

3. That the same fluid acting as light, vibrates as from a centre, but that the centre from which it vibrates is at a distance from the body on which the light falls.

4. When a great quantity of light falls upon any body, that is, when the vibrations of the etherial fluid towards it are exceedingly vehement, they pene-

trate its substance, however solid it may be, and a phlogiston. new vibration takes place within the substance of the body itself. The centre from which the vibrations proceed being then within the body, heat is the certain consequence; and therefore every intense light will in a short time produce heat.

5. In certain bodies the etherial fluid may have a vibration, or tendency to vibration, within the substance of the bodies themselves, though by reason of their texture this vibration is not observed externally. In this case the heat is said to be *latent*, and the body is cold to the touch, as is the case of vapour.

6. When this tendency to expand becomes exceedingly great, the particles by which the etherial fluid is confined must yield to its impulse, and the body becomes hot to the touch; or if the impulse is very violent, it breaks out into flame, and burns fiercely.

7. Flame cannot exist without a decomposition of vapour; and this decomposition takes place as soon as more latent heat is forced upon the vapour than it can contain.

8. Vapour will absorb heat to a certain degree; and in proportion to this absorption, it cools those bodies which it touches, or extinguishes fire when blown upon it.

9. Vapour, having absorbed as much heat as it can contain, when blown upon a fire, instead of extinguishing it, is instantly decomposed, and is converted into violent flame, returning back all the heat which it had formerly absorbed.

Under the article *FLAME*, it has also been shewn, that probably no vapours whatever are absolutely un-inflammable, though some are set on fire with much more difficulty than others. Those which are easily inflamed we call *inflammable*, and those which cannot be inflamed without a great deal of difficulty are called *uninflammable*. As, therefore, among all this variety of vapours there must be one more inflammable than all the rest, it is very natural, if it is frequently to be met with, to call it the *phlogiston*, or inflammable principle. Now, we find a certain kind of substance so universally diffused throughout nature, that scarce any thing seems to be perfectly divested of it. This substance is oil, and it is universally allowed to contain a great quantity of the phlogiston. But, when we come to analyse the substance of oil itself, we find it composed of an earthy matter which remains in the retort after distillation; and of a fluid, thinner than the oil originally was, which arises in vapour: but if this thin oil be subjected to a second distillation, it again leaves a quantity of fixed matter, and yields a portion of oil still more fluid than before. By a repetition of the process, more earth is still produced, the oil which arises becomes less and less in quantity, till at last it cannot by any means be collected.—Hence it is probable, that oil is composed of earthy particles disposed in such a manner that they are easily fitted for absorbing heat, and thus being converted into vapour; at the same time that they are also very easily capable of being decomposed, and of parting with the heat, after which they resume their original terrestrial form.

From a consideration of all this, we are naturally phlogiston. led to conclude, that the *phlogiston*, properly so called, is only a portion of empyreumatic oil, that is, of oil pyreumatic which oil.

19  
Analysis of  
oil.

phlogiston. which is partly decomposed by having been exposed to a violent heat.—This hypothesis will solve all the phenomena in which phlogiston is concerned.—Alkalies and calcined earths are found to attract phlogiston powerfully, and so likewise they do the grosser oils.—The vitriolic acid unites with phlogiston, and so will it do with oils of almost every kind.—The nitrous acid unites more powerfully with phlogiston than most other substances; but the same acid will unite with many kinds of oils so violently, as to set them on fire.—Phlogiston stains every thing black which it touches, and so does empyreumatic oil.—Phlogiston, when combined with air, will extinguish flame; but oil will do so likewise, if it is thrown on a fire in too great quantity. The reason is the same in both cases. Oil absorbs fire in great quantity before it can be raised in vapour; and until it can be raised in vapour, it cannot be kindled. After it is reduced to vapour, it still absorbs more before the vapour is converted into flame. If then the phlogiston is poured upon flame while it is in this absorbing state, the undoubted consequence must be, that, instead of adding any thing to its heat, it will take something from it, and if the quantity is sufficiently large, the flame must be extinguished. In like manner, when oil in its liquid state is poured upon fire, it absorbs part of the heat; and if the quantity of oil poured on is capable of absorbing more heat than the fire can give, an extinction of the flame will undoubtedly take place. But if phlogiston is poured upon flame, after having absorbed as much fire as it can contain, it will then, instead of extinguishing, increase the fire to a great degree; because the texture of it is entirely decomposed, and it throws out at once all the fire it had imbibed before. In like manner oil, if heated till just ready to inflame, will burn fiercely if thrown into a fire though in ever so large a quantity. Nay, if oil is violently heated in a vessel over the fire, and that vessel afterwards set down upon the cold and moist ground, the oil will be set on fire. The reason of this is, that the superabundant heat contained in the vessel and lower parts of the oil, is, by the cold, violently forced towards the surface, whence a thick vapour is continually arising. This vapour has already as much latent heat as it can contain; but more being continually forced upon it, in attempting to fly from the cold below, the vapour is entirely decomposed, and throws out not only that quantity which the cold forces upon it, but all that the oil had imbibed while it continued over the fire.

Hence we may account for the generation and phenomena of inflammable air. This is produced in the first place by acids, in the second place by the distillation of inflammable substances by a strong fire, and in the third place by the vapour of vitriolic ether.

1. When the vitriolic acid is poured upon filings of iron, a vapour arises, which is not only capable of inflammation by itself, but explodes with violence when mixed with common air, upon the contact of flame. Here we must consider, that the vitriolic acid contains a great deal of latent heat, as is evident from mixing it with water, when the mixture grows very hot, and shrinks in bulk. This will likewise happen when the diluted acid is poured upon iron filings; for then the mixture again grows hot, which shows an

extrication of heat formerly latent somewhere. Along with this heat, the phlogiston of the metal is discharged, and of consequence the latter absorbs as much fire as it conveniently can. The union is here perfectly complete: for as it is made beneath the surface of an aqueous fluid with which the phlogiston has but little tendency to unite, (for oil and water do not readily mix with one another), the inflammable principle absorbs just as much of the fire as it can contain; the superfluous quantity being dissipated in the air. It then remains an invisible, elastic, and very light vapour; because the greatest part of its composition is pure fire, which never could be proved to have any weight; and therefore inflammable air is much lighter than common air, which always has a considerable quantity of water in its composition.—This being the case, it is plain, that when any flaming body is immersed in this vapour, that part of the vapour which touches the flame must be kindled, and the phlogiston, being emptied of the greatest part of the fire it contained, will now combine with the common air, and phlogisticate it; that is, it will combine, loosely with it, and, not having so much fire as it could contain, will greedily attract more from every ignited substance which comes in its way, and will therefore extinguish fire as far as its operation goes.

It remains only now to shew the reason of the explosion of inflammable air when mixed with common air; and this most probably arises from the extreme inflammability of the phlogistic vapour when fully saturated with heat. By this means almost every part of it takes fire at the same instant; and thus a considerable quantity of air being violently heated at the same moment, must expand in proportion, and a considerable explosion take place. When dephlogisticated air is mixed with inflammable air, the explosion is much greater; and the reason is plain, because in common air there is always a quantity of phlogistic vapour not saturated with heat. This vapour absorbs a quantity of the heat thrown out by the decomposed inflammable air; and consequently lessens that which is communicated to the common air, and on which the explosion depends. But in the dephlogisticated air, as little or no vapour of this kind exists, the heat which the inflammable air throws out is almost all communicated to the former, and therefore the explosion is much greater; especially as dephlogisticated air increases the power of any kind of flame to such a degree, that by its means the heat of common fire is made equal to that of a burning mirror.

2. When inflammable air is produced from a distillation of wood or any other kind of inflammable substance, it is emitted at the time that the oil comes over: and therefore we may justly conclude, that it is nothing else than a part of the vapour of that oil which has imbibed so much fire, and is become so intimately combined with it that it cannot be condensed without an entire decomposition; for this is the case with inflammable vapours when they have got a certain quantity of this fluid in them. Thus, the gross vapour is raised by the fire, but is not thoroughly penetrated by it. The fire indeed expands it till it becomes lighter than the common atmosphere. It is hot to the touch, and therefore its heat is ready to be absorbed by every cold substance which.

*Phlogiston*, which it touches; of consequence the vapour condenses without inflammation: but when the fire has entered into a more close combination with it, so that the expansive force of that element is totally confined by the particles of the oil, the vapour is then cold to the touch, yet so full of *internal* or *latent* heat, that it is ready to take fire on the slightest contact of a burning body. The vapour is then inflammable and incondenfible; and, being perfectly transparent and invifible, is called *inflammable air*.

3. The production of inflammable air from vitriolic ether is fo easily accounted for after what has been said, that little further notice needs be taken of it: only it may be obferved, that the vapour of ether itfelf, even when in its condenfible ftate, will explode when mixed with common air; which feems to fhew very clearly, that we are not to look upon inflammable air, when incondenfible and perfectly invifible, as any other thing than an exceedingly fubtile vapour or thin fmoke, and confequently that the *phlogifton* itfelf is only the oily particles which conftitute that vapour.

23  
Diminution  
of air by  
*phlogifton*  
explained.

We muft now inquire into that remarkable property of *phlogifton* by which it always diminifhes air when mixed with it. In order to underftand this, it will be neceffary to confider by what means the bulk of air is diminifhed. This, if we except mechanical compreffion, can only be done by taking away either part of its elafticity, or fome of its other component parts. Now, it hath been fhown under the article *FLUIDITY*, that all fluids contain a great quantity of latent heat; nay, that on this principle their fluidity entirely depends. Of confequence, the air muft contain a great quantity of latent heat; and if any fubftance capable of abforbing this heat is prefented to it, the air muft be diminifhed. This is the cafe with *phlogifton*; and therefore air is always found to be diminifhed in confequence of being *phlogifticated*. But in proportion as the air lofes this heat, and the *phlogifton* imbibes it, it is plain that the latter muft become more and more faturated with it, and of confequence approach nearer and nearer to an inflammable ftate. Hence we may account for the change of nitrous into inflammable air, mentioned by Dr Prieftley. But for a more full difcuffion of all thefe fubjects, fee the articles *INFLAMMABLE Air*, *NITROUS Air*, &c. in the APPENDIX.

Before concluding this article, however, it will be proper to take notice of fome objections which may be brought againft the theory above laid down.

1. It is impoffible, fay the objectors, to prove that there is in nature any fubftance which properly deferves the name of *phlogifton*, or fole principle of inflammability. We fee that bodies are capable of being fet on fire; but before we affume the exiftence of fuch a principle as *phlogifton* in the abftract, we ought to be able at leaft to define it, that fo we might be able to prove its exiftence in different bodies. But, as matters ftand at prefent, it is impoffible for us even to know when we have gained our point. How is it poffible, for instance, to know whether the *phlogifton* in fpirit of wine be exactly the fame with that in fulphur? Or, by what means can we be afcertained that it is the fame principle which gives the fplendor to metals that caufes bodies emit a flame?

To this it may be replied, that philofophers in general have attributed all thefe phenomena to one

Phlogiston  
Phoca.  
caufe: therefore every inquirer ought to fearch among the natural caufes, in order to find one which is capable of producing all thefe phenomena; and if he finds fuch an one, there is the higheft probability that there is no other; for nature doth not multiply caufes where one will ferve. Hence it is incumbent on thofe who would affume two principles of inflammability, to prove the exiftence of them both; but there is not the fame obligation upon thofe who affume the exiftence only of one to prove that no more exift.

2. Though bodies may be inflamed, and have a predifpofition to be inflamed in certain circumftances, we are not therefore bound to fuppofe that this predifpofition confifts in the admixture of any material fubftance with them.

Here we muft attend to the confequence of inflammation, which is a feparation of the body into matter of two different kinds; one of which remains, while the other is carried off. As foon as this volatile matter is entirely diffipated, the inflammation ceafes. The probability therefore is exceedingly ftrong, that this matter either is the principle of inflammability itfelf, or contains it.

*PHLOGONIAE*, a clafs of compound, inflammable, and metallic foffils, found in fmall mafles of determinately angular figures; comprehending the pyricubia, pyroctogonia, and pyripolygonia.

*PHLOMIS*, the *SAGE TREE*, or *Jerufalem Sage*; a genus of the gymnofpermia order, belonging to the didynamia clafs of plants. There are 14 fpecies, all of which have perennial roots, and of many the ftalks alfo are perennial. The latter rife from two to five or fix feet high; and are adorned with yellow, blue, or purple flowers in whorls. They are all ornamental plants; and deferve a place in gardens, as they are fufficiently hardy to endure the ordinary winters in this climate: they require, however, a pretty warm fituation. They may be propagated by offets, or cuttings.

*PHLOX*, *LYCHNIDEA*, or *Bafhard Lychnis*; a genus of the monogynia order, belonging to the pentandria clafs of plants. There are feven fpecies, all of them natives of North America. They have perennial roots, from which arife herbaceous ftalks from nine inches to two feet in height, adorned with tubulated flowers of a purple colour. They are propagated by offets, and will bear the winters in this country. They require a moift rich foil, in which they thrive better and grow taller than in any other.

*PHLYCTENÆ*, in medicine, fmall eruptions on the fkin.

*PHOCA*, in zoology, a genus of quadrupeds of the order of feræ. There are fix parallel foreteeth in the upper jaw, the outermoft being larger; and four blunt, parallel, diftinct, equal fore-teeth in the under jaw. There is but one dog-tooth, and five or fix three-pointed grinders; and the hind feet are united fo as to refemble a fhip's tail. There are three fpecies, viz.

1. The urfina, or fea-bear, has external ears. The male is greatly fuperior in fize to the female. The bodies of each are of a conic form, very thick before, and taper to the tail. The length of a large one is eight feet; the greateft circumference, five feet; near the tail, 20 inches; and the weight is about 800 lb. The nofe projects like that of a pug-dog, but the head riles

24  
*Phlogifton*  
in the ab-  
ftract.

rises suddenly; the teeth lock into one another when the mouth is shut; the tongue is large; the eyes are large and prominent, and may be covered at pleasure by a fleshy membrane. The length of the fore-legs is 24 inches; they are like those of other quadrupeds, not immersed in the body like those of seals; the feet are formed with toes like those of other animals, but are covered with a naked skin, so that externally they seem to be a shapeless mass; the hind-legs are fixed to the body quite behind, like those of seals; but are capable of being brought forward, so that the animal makes use of them to scratch its head.

These animals are found in the northern seas. During the three months of summer they lead a most indolent life: they arrive at the islands vastly fat; but during that time they are scarce ever in motion, confine themselves for whole weeks to one spot, sleep a great part of the time, eat nothing, and, except the employment the females have in suckling their young, are totally inactive. They live in families: each male has from 8 to 50 females, whom he guards with the jealousy of an eastern monarch; and though they lie by thousands on the shores, each family keeps itself separate from the rest, and sometimes, with the young and unmarried ones, amount to 120. The old animals, which are destitute of females, or deserted by them, live apart, and are excessively spleenitic, peevish, and quarrelsome: are exceeding fierce, and so attached to their old haunts, that they would die sooner than quit them. They are monstrously fat, and have a most hircine smell. If another approaches their station, they are roused from their indolence, and instantly snap at it, and a battle ensues; in the conflict, they perhaps intrude on the seat of another: this gives new cause of offence, so in the end the discord becomes universal, and is spread through the whole shore.

The other males are also very irascible: the causes of their disputes are generally these. The first and most terrible is, when an attempt is made by another to seduce one of their mistresses or a young female of the family. This insult produces a combat; and the conqueror is immediately followed by the whole seraglio, who are sure of deserting the unhappy vanquished. The second reason of a quarrel is, when one invades the seat of another: the third arises from their interfering in the disputes of others. These battles are very violent; the wounds they receive are very deep, and resemble the cuts of a sabre. At the end of a fight they fling themselves into the sea, to wash away the blood.

The males are very fond of their young, but very tyrannical towards the females: if any body attempts to take their cub, the male stands on the defensive, while the female makes off with the young in her mouth; should she drop it, the former instantly quits his enemy, falls on her, and beats her against the stones, till he leaves her for dead. As soon as she recovers, she comes in the most suppliant manner to the male, crawls to his feet, and washes them with her tears: he, in the mean time, stalks about in the most insulting manner; but in case the young one is carried off, he melts into the deepest affliction, and shews all signs of extreme concern. It is probable that he feels his misfortunes the more sensibly, as the female ge-

nerally brings but one at a time, never more than two.

They swim very swiftly, at the rate of seven miles an hour. If wounded, they will seize on the boat, and carry it along with vast impetuosity, and oftentimes sink it. They can continue a long time under water. When they want to climb the rocks, they fasten with the fore-paws, and so draw themselves up. They are very tenacious of life, and will live for a fortnight after receiving such wounds as would immediately destroy any other animal.

2. The leonina, or sea-lion, is found near the south pole. One variety of this species is described at some length by the publisher of Anson's voyage. However, according to others who have written on this subject, the name of *sea-lion* belongs not so properly to this as to another, which has a mane like a true lion. Of these we have the following account from Perney's Historical Journal. "The hair that covers the back part of the head, neck, and shoulders, is at least as long as the hair of a goat. It gives this amphibious animal an air of resemblance to the common lion of the forest, excepting the difference of size. The sea-lions of the kind I speak of, are 25 feet in length, and from 19 to 20 in their greatest circumference. In other respects they resemble the sea-lions. Those of the small kind have a head resembling a mastiff's, with close cropt ears.

"The teeth of the sea-lions which have manes, are much larger and more solid than those of the rest. In these, all the teeth which are inserted into the jaw-bone are hollow. They have only four large ones, two in the lower and two in the upper jaw. The rest are not even so large as those of a horse. I brought home one belonging to the true sea-lion, which is at least three inches in diameter, and seven in length, though not one of the largest. We counted 22 of the same sort in the jaw-bone of one of these lions, where five or six were wanting. They were entirely solid, and projected scarce more than an inch or an inch and a half beyond their sockets. They are nearly equal in solidity to flint, and are of a dazzling white. Several of our seamen took them for white flints when they found them upon the shore. I could not even persuade them that they were not real flints, except by rubbing them against each other, or breaking some pieces off, to make them sensible that they exhaled the same smell as bones and ivory do when they are rubbed or scraped.

"These sea-lions that have manes, are not more mischievous or formidable than the others. They are equally unwieldy and heavy in their motions; and are rather disposed to avoid than to fall upon those who attack them. Both kinds live upon fish and water-fowl, which they catch by surprise. They bring forth and suckle their young ones among the corn-flags, where they retire at night, and continue to give them suck till they are large enough to go to sea. In the evening you see them assembling in herds upon the shore, and calling their dams in cries so much like lambs, calves, and goats, that, unless apprised of it, you would easily be deceived. The tongue of these animals is very good eating: we preferred it to that of an ox or calf. For a trial we cut off the tip

of the tongue hanging out of the mouth of one of these lions which was just killed. About 16 or 18 of us eat each a pretty large piece, and we all thought it so good, that we regretted we could not cut more of it.

"It is said that their flesh is not absolutely disagreeable. I have not tasted it: but the oil which is extracted from their grease is of great use. This oil is extracted two ways; either by cutting the fat in pieces, and melting it in large cauldrons upon the fire; or by cutting it in the same manner upon hurdles, or pieces of board, and exposing them to the sun, or only to the air: this grease dissolves of itself, and runs into vessels placed underneath to receive it. Some of our seamen pretended, that this last sort of oil, when it is fresh, is very good for kitchen uses: this, as well as the other, is commonly used for dressing leather for vessels, and for lamps. It is preferred to that of the whale: it is always clear, and leaves no sediment.

"The skins of the sea-lions are used chiefly in making portmanteaus, and in covering trunks. When they are tanned, they have a grain almost like Morocco. They are not so fine, but are less liable to tear, and keep fresh a longer time. They make good shoes and boots, which, when well seasoned, are water-proof.

"One day Mr Guyot and some others brought on board five sea-lionesses. They were about seven feet long, and three and a half in circumference, tho' their intestines were drawn. These gentlemen had landed on a small island, where they found a prodigious number of these animals, and killed eight or nine hundred of them with sticks. No other weapon is necessary on these occasions. A single blow with a bludgeon, three feet or three feet and a half long, almost full at the nose of these animals, knocks them down, and kills them on the spot.

"This is not altogether the case with the sea-lions: their size is prodigious. Our gentlemen encountered two of them for a long time, with the same weapons, without being able to overcome them. They lodged three balls in the throat of one while he opened his mouth to defend himself, and three musket-shot in his body. The blood gushed from his wounds like wine from a tap. However, he crawled into the water and disappeared. A sailor attacked the other, and engaged him for a long time, striking him on the head with a bludgeon, without being able to knock him down: the sailor fell down very near his antagonist, but had the dexterity to recover himself at the instant the lion was going to gorge him. Had he once seized him, the man would infallibly have been lost: the animal would have carried him into the water as they usually do their prey, and there feasted upon him. In his retreat to the sea this animal seized a penguin, and devoured him instantaneously."

3. The vitulina, sea-calf, or common seal, inhabits the European ocean. It has a smooth head without external ears. The common length of those taken on the British coasts is from five to six feet. The fore-legs are deeply immersed in the skin of the body: the hind-legs are placed in such a manner as to point directly backwards: every foot is divided into five toes; and each of those connected by a strong and broad web, covered on both sides with short hair. The toes

are furnished with strong claws, well adapted to assist the animal in climbing the rocks it basks on: the claws on the hind feet are slender, and straight; except at the ends, which are a little incurvated. The head and nose are broad and flat, like those of the otter; the neck short and thick; the eyes large and black; in lieu of external ears, it has two small orifices: the nostrils are oblong: on each side the nose are several long stiff hairs; and above each eye, are a few of the same kind. The form of the tongue is so singular, that were other notes wanting, that alone would distinguish it from all other quadrupeds; being forked, or slit at the end. The cutting teeth are singular in respect to their number, being six in the upper jaw, and only four in the lower. It has two canine teeth above and below, and on each side of the jaw five grinders; the total 34. The whole animal is covered with short hair, very closely set together: the colour of that on the body is generally dusky, spotted irregularly with white; on the belly, white: but seals vary greatly in their marks and colours, and some have been found entirely white.

The seal is common on most of the rocky shores of Great Britain and Ireland, especially on the northern coasts: in Wales, it frequents the coasts of Caernarvonshire and Anglesey. It preys entirely on fish, and never molests the sea-fowl: for numbers of each are often seen floating on the waves, as if in company. Seals eat their prey beneath the water; and in case they are devouring any very oily fish, the place is known by a certain smoothness of the waves immediately above. The power of oil in stilling the waves excited by a storm, is mentioned by Pliny: the moderns have made the experiment with success; and thereby made one advance towards eradicating the vulgar prejudices against that great and elegant writer.

Seals are excellent swimmers, and ready divers; and are very bold when in the sea, swimming carelessly enough about boats: their dens or lodgments are in hollow rocks, or caverns, near the sea, but out of the reach of the tide: in the summer they will come out of the water, to bask or sleep in the sun, on the top of large stones or shivers of rocks; and that is the opportunity our countrymen take of shooting them: if they chance to escape, they hasten towards their proper element, flinging stones and dirt behind them, as they scramble along; at the same time expressing their fears by piteous moans; but if they happen to be overtaken, they will make a vigorous defence with their feet and teeth till they are killed. They are taken for the sake of their skins, and for the oil their fat yields: the former sell for 4 s. or 4 s. 6 d. a-piece; which, when dressed, are very useful in covering trunks, making waistcoats, shot-pouches, and several other conveniences.

The flesh of these animals, and even of porpoises, formerly found a place at the tables of the great; as appears from the bill of fare of that vast feast that archbishop Nevill gave in the reign of Edward IV. in which is seen that several were provided on the occasion. They couple about April, on large rocks, or small islands, not remote from the shore; and bring forth in those vast caverns that are frequent on our coasts; they commonly bring two at a time, which in their infant state are covered with a whitish down, or woolly substance

Phoca.

stance. The seal-hunters in Caithness say, that their growth is so sudden, that in nine tides from their birth (54 hours) they will become as active as their parents. On the coast of that country are immense caverns opening into the sea, and running some hundreds of yards beneath the land. These are the resort of seals in the breeding time, where they continue till their young are old enough to go to sea, which is in about six or seven weeks. The first of these caves is near the Ord, the last near Thrumfer: their entrance is so narrow, as only to admit a boat; their inside very spacious and lofty. In the month of October, or the beginning of November, the seal-hunters enter the mouths of the caverns about midnight, and rowing up as far as they can, they land; each of them being provided with a bludgeon, and properly stationed, light their torches, and make a great noise, which brings down the seals from the farther end in a confused body with fearful shrieks and cries: at first the men are obliged to give way for fear of being overborne; but when the first crowd is past, they kill as many as straggle behind, chiefly the young, by striking them on the nose; a very slight blow on that part dispatches them. When the work is over, they drag the seals to the boat, which two men are left to guard. This is a most hazardous employ; for should their torches go out, or the wind blow hard from sea during their continuance in the cave, their lives are lost. The young seals of six weeks age, yield more oil than their emaciated dams: above eight gallons have been got from a single whelp, which sells from 6d. to 9d. per gallon; the skins from 6d. to 12d. each.

The natural history of this animal may be further elucidated, by the following extracts from a letter of the reverend Dr William Borlase, dated October the 24th, 1763. "The seals are seen in the greatest plenty on the shores of Cornwall, in the months of May, June, and July. They are of different sizes; some as large as a cow, and from that downwards to a small calf. They feed on most sorts of fish which they can master; and are seen searching for their prey near shore, where the whistling fish, wraws, and pollacks, resort. They are very swift in their proper depth of water, dive like a shot, and in a trice rise at 50 yards distance; so that weaker fishes cannot avoid their tyranny, except in shallow water. A person of the parish of Sennan, saw not long since a seal in pursuit of a mullet (that strong and swift fish): the seal turned it to and fro in deep water, as a greyhound does a hare: the mullet at last found it had no way to escape, but by running into shoal water: the seal pursued; and the former, to get more surely out of danger, threw itself on its side, by which means it darted into shoal water than it could have swum in with the depth of its paunch and fins, and so escaped. The seal brings her young about the beginning of autumn; our fishermen have seen two sucking their dam at the same time, as she stood in the sea in a perpendicular position. Their head in swimming is always above water, more so than that of a dog. They sleep on rocks surrounded by the sea, or on the less accessible parts of our cliffs left dry by the ebb of the tide; and if disturbed by any thing, take care to tumble over the rocks into the sea. They are extremely watchful, and never sleep long without moving; seldom longer than a minute; then raise their

heads, and if they hear or see nothing more than ordinary, lie down again, and so on, raising their heads a little and reclining them alternately in about a minute's time. Nature seems to have given them this precaution, as being unprovided with auricles or external ears; and consequently not hearing very quick, nor from any great distance."

PHOCÆA, the last lown of Ionia, (Mela, Pliny); of Æolis, (Ptolemy), because situated on the right or north side of the river Hermus, which he makes the boundary of Æolis to the south. It stood far in the land, on a bay or arm of the sea; had two very safe harbours, the one called *Lampter*, the other *Naustathmos*, (Livy). It was a colony of Ionians, situated in the territory of Æolis, (Herodotus). Massilia in Gaul was again a colony from it. *Phocaenfer*, the people, (Livy); *Phocaicus*, the epithet, (Lucan); applied to *Marseilles*. It was one of the 12 cities which assembled in the panionium, or general council of Ionia.

PHOCION, an Athenian general, and a great orator. Demosthenes himself was afraid of his eloquence. Philip of Macedon had so great an esteem of his courage and military conduct, that he dreaded him. He had as much moderation as Demosthenes had vehemence; and by his prudent counsels diverted Alexander from a war with the Athenians and with all Greece. Alexander sent him presents, and told him he was the only person in Athens whom he acknowledged to be an honest man: Phocion at the same time was drawing water out of the well, and his wife was making of bread; yet he wisely refused the presents. Antipater also offered him great sums of money, which he likewise returned: his innocence and virtue rendered his poverty honourable. He was obliged to take up arms in defence of his country; and his conduct was successful Philip of Macedon, and upon several other occasions. He was at last condemned on a false accusation of treason by his ungrateful fellow-citizens, and put to death 318 B.C. After which the Athenians erected him a statue, and cut off his accuser.

PHOCIS, (Demosthenes, Strabo, Pausanias); a country of Greece, contained between Boeotia to the east, and Locris to the west, but extending formerly from the Sinus Corinthiacus on the south, to the sea of Eubœa on the north, and, according to Dionysius, as far as Thermopylæ; but reduced afterwards to narrower bounds. *Phocenses* the people; *Phocicus*, the epithet, (Justin); *Bellum Phocicum*, the sacred war which the Thebans and Philip of Macedon carried on against them for plundering the temple at Delphi; and by which Philip paved the way to the sovereignty of all Greece, (Justin.)

PHOEBUS, one of the names given by ancient mythologists to the Sun, Sol, or Apollo. See APOLLO.

PHOENICIA, or more properly PHOENICE, the ancient name of a country lying between the 34th and 36th degrees of north latitude; bounded by Syria on the north and east, by Judæa on the south, and by the Mediterranean on the west. Of its name there are various derivations given. Some derive it from a chief named *Phoenix*: others from the Greek word *Phoenix*, signifying a palm or date; as if that tree had abounded remarkably in this country. According to Bochart,

Phocæa  
||  
Phœnicia.Pennant's  
British  
Zoology.

*Phœnicia.* its most probable etymology is *Phene Anak*, that is, "the descendants of Anak."

*Phœnicia.*

It is universally allowed, that the Phœnicians were descendants of the Canaanites. Their country, however, small as it was, comprehended several kingdoms, viz. Sidon, Tyre, Aradus, and Byblus. Of none of these we have any certain history excepting Tyre and Sidon, which is given under these articles in the order of the alphabet. But their language and religion were diffused over several nations who proceeded from them as colonies, particularly the Carthaginians, and are therefore better known.

The language of the Phœnicians was little different from that of the ancient Canaanites, and consequently a dialect of the Hebrew. Their characters were either the very same with the Samaritan, or but little different from them. The same may be said of the language of the Carthaginians, who, being a Phœnician colony, must originally have spoken the same with that of the mother-country. However, it is probable that in after-ages it differed considerably. This indeed has been fully proved by Selden, Scaliger, Pitt, and Bœchart, the last of whom has collected a number of Punic words, and traced all of them up to the Hebrew or Phœnician. A few of these words are given in the following table.

Hebrew or Phœnician.	Punic.
Zachæus	Sichæus.
Amalec	Amilco, or Himilco.
Hinnon, or Hanun	Hanno.
Hannabaal, or Baal-Hanan	Hannibal.
Ezra, or Ezdras-Baal	Akdrubal.
Barac	Barca.
Mago	Mago.
Adar, or Ader-baal	Adherbal.
Mehir, or Maher-baal	Mahebal.

According to Prifcian and St Austin, the Punic or Carthaginian language had an admixture of the Chaldee and Syriac; and Salmasius intimates, that, according to some, the Punic language agreed in many respects with the Egyptian. Nay, M. Maius, professor of the Greek and Oriental languages in the Ludovician University of Giessen, published a small piece in the year 1718, wherein he shows, that the language of the modern Maltese has a great deal of the old Punic in it, and that these words are farther distant from the Arabic than from the ancient Hebrew or Chaldee.

With regard to religion, the Phœnicians were the most gross and abominable idolaters. The Baal-berith, Baalzebub, Baalfamen, &c. mentioned in Scripture were some of the Phœnician gods; as were also the Moloch, Astartoth, and Thammuz, mentioned in the sacred writings.—The word *Baal*, in itself an appellative, was no doubt applied to the true God, until he rejected it on account of its being too much profaned by the idolaters. The name was not appropriated to any particularly deity among the idolatrous nations, but was common to many; however, it was generally imagined that one great God presided over all the rest. Among the Phœnicians this deity was named *Baal-famen*, whom the Hebrews would have called *Baal-schemin*, or the God of heaven. In all probability this was also the principal Carthaginian deity, though his Punic name is unknown. We have many religious rites of

the Carthaginians handed down to us by the Greek and Roman writers; but they all bestowed names of their own gods upon those of the Carthaginians, which leads us to a knowledge of the correspondence between the characters of the Phœnician and European deities. The principal deity of Carthage, according to Diodorus Siculus, was Chronus or Saturn. The sacrifices offered up to him were children of the best families. Our author also tells us, that the Carthaginians had a brazen statue or colossus of this god, the hands of which were extended in act to receive, and bent downwards in such a manner, that the child laid thereon immediately fell down into a hollow where there was a fiery furnace. He adds also, that this inhuman practice seemed to confirm a tradition handed down to the Greeks from very early antiquity, viz. that Saturn devoured his own children.

The goddess Cœlestis, or Urania, was held in the highest veneration by the Carthaginians. She is thought to have been the same with the queen of heaven mentioned in Jeremiah, the Juno Olympia of the Greeks. According to Helychius the same word applied in the Punic language both to Juno and Venus. Nay, the ancient Greeks frequently confound Juno, Venus, and Diana or the moon, all together; which is to be attributed to the Egyptians and Phœnicians, from whom they received their system of religion; who seem in the most ancient times to have had but one name for them all. Besides these there were several other deities of later date, who were worshipped among the Phœnicians, particularly those of Tyre, and consequently among the Carthaginians also. These were Jupiter, Apollo, Mars, and Bacchus. Jupiter was worshipped under the name of *Belus* or *Baal*. To him they addressed their oaths, and placed him for the most part, as there is reason to believe, at the head of their treaties. The same name was also given to the other two, whence they were frequently mistaken for one another. Apollo or the sun went either by this name simply, or by others of which this made a part.

The Carthaginian superstition, however, was not confined to these deities alone. They worshipped also the fire, air, and other elements; and had gods of rivers, meads, &c. Nay, they paid divine honours to the spirits of their heroes, and even to men and women themselves while yet in life; and in this adoration Hannibal the Great had for some time a share, notwithstanding the infamous conduct of his countrymen towards him at last. In order to worship those gods with more convenience on all occasions, the Carthaginians had a kind of portable temples. These were only covered chariots, in which were some small images representing their favourite deities; and which were drawn by oxen. They were also a kind of oracle, and their responses were understood by the motion impressed upon the vehicle. This was likewise an Egyptian or Libyan custom, and Tacitus informs us that the ancient Germans had something of the same kind. The tabernacle of Moloch is thought to have been a machine of this kind, and it is not improbable that the whole was derived from the tabernacle of the Jews in the wilderness.

Besides all the deities abovementioned, we still find another, named the *Dæmon* or *Genius* of Carthage, mentioned

enicop-  
erus,  
phenix.

mentioned in the treaty made by Philip of Macedon and Hannibal. What this deity might be, we know not; however, it may be observed, that the pagan world in general believed in the existence of demons, or intelligences who had a kind of middle nature between gods and men, and to whom the administration of the world was in a great measure committed. Hence it is no wonder that they should have received religious honours. For when once mankind were possessed with the opinion that they were the ministers of the gods, and trusted with the dispensation of their favours, as well as the infliction of their punishments, it is natural to suppose that they would be desirous of making their addresses to them.

**PHOENICOPTERUS**, or **FLAMINGO**, in ornithology, a genus of birds belonging to the order of grallæ. The beak is naked, teetted, and bent as if it was broken; the nostrils are linear; the feet are palmated, and four-toed. There is but one species; viz. the Bahamensis of Catesby, a native of Africa and America.

This bird resembles the heron in shape, excepting the bill, which is of a very singular form. It is two years old before it arrives at its perfect colour; and then it is entirely red, excepting the quill-feathers, which are black. A full-grown one is of equal weight with a wild duck; and when it stands erect, it is five feet high. The feet are webbed. The flesh is delicate; and most resembles that of a partridge in taste. The tongue, above any other part, was in the highest esteem with the luxurious Romans. These birds make their nests on hillocks in shallow water; on which they sit with their legs extended down, like a man sitting on a stool. They breed on the coasts of Cuba, and the Bahama islands in the West Indies; and frequent salt-water only. By reason of the particular shape of its bill, this bird, in eating, twists its neck from side to side, and makes the upper mandible touch the ground. These birds are very stupid, and will not rise at the report of a gun; nor is it any warning to those who survive, that they see others killed by their side; so that, by keeping himself out of a sight, a fowler may kill as many as he pleases.

**PHOENIX**, in astronomy. See there, n° 206.

**PHOENIX**, the *Great Palm*; or *Date-tree*; a genus of plants belonging to the order of palmæ. There is only one species, viz. the *dactylifera*, or common date-tree, a native of Africa and the eastern countries, where it grows to 50, 60, and 100 feet high. The trunk is round, upright, and studded with protuberances, which are the vestiges of the decayed leaves. From the top issues forth a cluster of leaves or branches eight or nine feet long, extending all round like an umbrella, and bending a little towards the earth. The bottom part produces a number of stalks like those of the middle, but seldom shooting so high as four or five feet. These stalks, says Adanson, diffuse the tree very considerably; so that, wherever it naturally grows in forests, it is extremely difficult to open a passage through its prickly leaves. The flowers are male and female upon different roots. The dates, which are the produce of the female plant, grow in large spiral clusters, each being about the bigness and shape of a middling olive, and containing within the pulp, which is of a yellow colour and agreeable taste, a round, strong, hard nut

or stone, of an ash-colour, marked with a deep furrow, running lengthwise. Of the fresh dates and sugar, says Hasselquist, the Egyptians make a conserve, which has a very pleasant taste. The kernels or stones, though hard as horn, they grind in hand-mills, and, in default of better food, give to their camels. Of the leaves are made baskets, or bags, which are much used in Turkey on journeys, and for other economical uses. In Egypt they are used as fly-flaps, for driving away the numerous insects which prove so troublesome in hot countries; and Rauwold relates, that of the fibres of the leaves and covering of the fruit are spun ropes, of pretty large dimensions and considerable strength. The hard boughs are used for fences and other purposes of husbandry; the principal item for building; in fine, no part of this curious tree wants its use. The fruit, before it is ripe, is somewhat astringent; but when thoroughly mature, is of the nature of the fig. The Senegal dates are shorter than those of Egypt, but much thicker in the pulp, which is said to have a sugary agreeable taste, superior to that of the best dates of the Levant.

These plants may be easily produced from the seeds taken out of the fruit, (provided they are fresh), which should be sown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, which should be kept in a moderate temperature of heat, and the earth frequently refreshed with water. When the plants are come up to a proper size, they should be each planted into a separate small pot, filled with the same light earth, and plunged into a hot-bed again, observing to refresh them with water, as also to let them have air in proportion to the warmth of the season and the bed in which they are placed. During the summer-time they should remain in the same hot-bed; but in the beginning of August, you should let them have a great share of air to harden them against the approach of winter; for if they are too much forced, they will be so tender as not to be preserved through the winter without much difficulty, especially if you have not the convenience of a bark-stove to keep them in. The soil in which these plants should be placed, must be composed in the following manner, viz. half of light fresh earth taken from a pasture-ground, the other half sea-sand and rotten dung or tanners bark in equal proportion; these should be carefully mixed, and laid in a heap three or four months at least before it is used, but should be often turned over to prevent the growth of weeds, and to sweeten the earth.

**PHOENIX**, in ornithology, a bird famous among the ancients, but generally looked upon by the moderns as fabulous. The ancients speak of this bird as single, or the only one of its kind; they describe it as of the size of an eagle; its head finely crested with a beautiful plumage, its neck covered with feathers of a gold colour, and the rest of its body purple, only the tail white, and the eyes sparkling like stars; they hold, that it lives 500 or 600 years in the wilderness; that when thus advanced in age, it builds itself a pile of sweet wood and aromatic gums, and fires it with the wasting of its wings, and thus burns itself; and that from its ashes arises a worm, which in time grows up to be a phoenix. Hence the Phœnicians gave the name of *phœnix* to the palm-tree; because when burnt down

Phœnix.

fig. 1.

Pholas.

Plate

CCXXXVIII

fig. 2.

down to the root, it rises again fairer than ever.

PHOLAS, a genus of insects, belonging to the order of vermes testacea. The shell is double-valved and divaricated; the cardo is turned backwards, and connected by a cartilage. There are six species, distinguished by the figure of their shells.

The word *pholas* is derived from the Greek, and signifies something which lies hid. This name they derive from their property of making themselves holes in the earth, sand, wood, or stone, and living in them. The means of their getting there, however, are as yet entirely unknown. All that we can know with certainty is, that they must have penetrated these substances when very small; because the entrance of the hole in which the *pholas* lodges is always much less than the inner part of it, and indeed than the shell of the *pholas* itself. Hence some have supposed that they were hatched in holes accidentally formed in stones, and that the stones naturally grew of such a shape as was necessary to fill the cavity.

The holes in which the *Pholades* lodge are usually twice as deep, at least, as the shells themselves are long; the figure of the holes is that of a truncated cone, excepting that they are terminated at the bottom by a rounded cavity, and their position is usually somewhat oblique to the horizon. The openings of these holes are what betray the *pholas* being in the stone; but they are always very small, in proportion to the size of the fish. There seems to be no progressive motion of any animal in nature so slow as that of the *pholas*; it is immersed in the hole, and has no movement except a small one towards the centre of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion; but it has great time to perform it in, as it only moves downward, sinking itself deeper in the stone as it increases itself in bulk. That part by means of which it performs this, is a fleshy substance placed near the lower extremity of the shell; it is of the shape of a lozenge, and is considerably large in proportion to the size of the animal; and though it be of a soft substance, it is not to be wondered at that in so long a time it is able, by constant work, to burrow into a hard stone. The manner of their performing this may be seen by taking one of them out of the stone, and placing it upon some soft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themselves in the mud in as large a hole as they had taken many years to make in the stone. They find little resistance in so soft a substance, and the necessity of their hiding themselves evidently makes them hasten their work. The animal is lodged in the lower half of the hole in the stone, and the upper half is filled up by a pipe of a fleshy substance and conic figure, truncated at the end: this they usually extend to the orifice of the hole, and place on a level with the surface of the stone; but they seldom extend it any farther than this. The pipe, tho' it appears single, is in reality composed of two pipes, or at least it is composed of two parts separated by a membrane. The use of this pipe or proboscis, is the same with that of the proboscis of other shell-fish, to take in sea-water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a small green vessel, the use of which has not yet

been discovered. This, when plunged in spirit of wine, becomes of a purple colour: but its colour on linen will not become purple in the sun like that of the murex; and even if it would, its quantity is too small to make it worth preserving.

The *pholas* is remarkable for its luminous quality. That this fish is luminous was noticed by Pliny, who observes that it shines in the mouth of the person who eats it; and, if it touch his hands or cloaths, makes them luminous. He also says that the light depends upon its moisture. The light of this fish has furnished matter for various observations and experiments to M. Reaumur and the Bolognian academicians, especially Beccarius, who took so much pains with the subject of phosphoreal light.

M. Reaumur observes, that whereas other fishes give light when they tend to putrescence, this is more luminous in proportion to its being fresh; that when they are dried, their light will revive if they be moistened either with fresh or salt water, but that brandy immediately extinguishes it. He endeavoured to make this light permanent, but none of his schemes succeeded.

The attention of the Bolognian academicians was engaged to this subject by M. F. Marsilius, in 1724, who brought a number of these fishes, and the stones in which they were inclosed, to Bologna, on purpose for their examination.

Beccarius observed, that though this fish ceased to shine when it became putrid, yet that in its most putrid state, it would shine, and make the water in which it was immersed luminous when it was agitated. Galeatus and Montius found that wine or vinegar extinguished this light; that in common oil it continued some days, but in rectified spirit of wine or urine hardly a minute.

In order to observe in what manner this light was affected by different degrees of heat, they made use of a Reaumur's thermometer, and found that water rendered luminous by these fishes increased in light till the heat arrived to 45°, but that it then became suddenly extinct, and could not be revived again.
