ENCYCLOPÆDIA BRITANNICA;  
OR, A  
DICTIONARY  
OF  
ARTS, SCIENCES, &c.

On a PLAN entirely NEW:

BY WHICH,  
THE DIFFERENT SCIENCES AND ARTS  
Are digested into the FORM of Distinct  
TREATISES OR SYSTEMS,  
COMPREHENDING

The HISTORY, THEORY, and PRACTICE, of each,  
according to the Latest Discoveries and Improvements;

AND FULL EXPLANATIONS ARE GIVEN OF THE  
VARIOUS DETACHED PARTS OF KNOWLEDGE,

WHETHER RELATING TO  
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,  
CIVIL, MILITARY, COMMERCIAL, &c.

TOGETHER WITH  
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.  
throughout the WORLD;  
A General HISTORY, Ancient and Modern, of the different Empires, Kingdoms, and States;  
AND  
An Account of the LIVES of the most Eminent Persons in every Nation,  
from the earliest ages down to the present times.

THE WHOLE COMPILED FROM  
THE WRITINGS OF THE BEST AUTHORS, IN SEVERAL LANGUAGES; THE MOST APPROVED DICTIONARIES,  
AS WELL OF GENERAL SCIENCE AS OF PARTICULAR BRANCHES; THE TRANSACTIONS, JOURNALS, AND MEMOIRS, OF LEARNED  
SOCIETIES, BOTH AT HOME AND ABROAD; THE MS. LECTURES OF EMINENT PROFESSORS ON DIFFERENT SCIENCES;  
AND A VARIETY OF ORIGINAL MATERIALS, FURNISHED BY AN EXTENSIVE CORRESPONDENCE.

## OPTICS. PART III.

Of the  
Rainbow.SECT. I. *The Application of the foregoing Theory to several natural Phenomena.*§ 1. *Of the Rainbow.*

THIS beautiful phenomenon hath engaged the attention of all ages. By some nations it hath been desired; though the more sensible part always looked upon it as a natural appearance, and endeavoured, however imperfectly, to account for it. The observations of the ancients and philosophers of the middle ages concerning the rainbow were such as could not have escaped the notice of the most illiterate husbandmen who gazed at the sky; and their hypotheses were such as deserve no notice. It was a considerable time even after the dawn of true philosophy in this western part of the world, before we find any discovery of importance on this subject. Maurolycus was the first who pretended to have measured the diameters of the two rainbows with much exactness; and he reports, that he found that of the inner bow to be 45 degrees, and that of the outer bow 56; from which Des Cartes takes occasion to observe, how little we can depend upon the observations of those who were not acquainted with the causes of appearances.

One *Clichtonax* (the same, it is probable, who distinguished himself by his opposition to Luther, and who died in 1543) had maintained, that the second bow is the image of the first, as he thought was evident from the inverted order of the colours. For, said he, when we look into the water, all the images that we see reflected by it are inverted with respect to the objects themselves; the tops of the trees, for instance, that stand near the brink, appearing lower than the roots.

That the rainbow is opposite to the sun, had always been observed. It was, therefore, natural to imagine, that the colours of it were produced by some kind of reflection of the rays of light from drops of rain, or vapour. The regular order of the colours was another circumstance that could not have escaped the notice of any person. But, notwithstanding mere reflection had in no other case been observed to produce colours, and it could not but have been observed

that refraction is frequently attended with that phenomenon, yet no person seems to have thought of having recourse to a proper refraction in this case, before one *Fletcher* of Breslau, who, in a treatise which he published in 1571, endeavoured to account for the colours of the rainbow by means of a double refraction and one reflection. But he imagined that a ray of light, after entering a drop of rain, and suffering a refraction both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the spectator. He seems to have overlooked the reflection at the farther side of the drop, or to have imagined that all the bendings of the light within the drop would not make a sufficient curvature to bring the ray of the sun to the eye of the spectator. That he should think of two refractions, was the necessary consequence of his supposing that the ray entered the drop at all. This supposition, therefore, was all the light that he threw upon the subject. B. Porta supposed that the rainbow is produced by the refraction of light in the whole body of rain or vapour, but not in the separate drops.

After all, it was a man whom no writers allow to have had any pretensions to philosophy, that hit upon this curious discovery. This was Antonio De Dominis, bishop of Spalatro, whose treatise *De Radiis Visus et Lucis*, was published by J. Bartolus in 1611. He first advanced, that the double refraction of Fletcher, with an intervening reflection, was sufficient to produce the colours of the bow, and also to bring the rays that formed them to the eye of the spectator, without any subsequent reflection. He distinctly describes the progress of a ray of light entering the upper part of the drop, where it suffers one refraction, and after being thereby thrown upon the back part of the inner surface, is from thence reflected to the lower part of the drop; at which place undergoing a second refraction, it is thereby bent, so as to come directly to the eye. To verify this hypothesis, this person (no philosopher as he was) proceeded in a very sensible and philosophical manner. For he procured a small globe of solid glass, and viewing it when it was exposed to the rays of the sun, in the same manner in which he had supposed that the drops of rain were situated

Of the  
Rainbow.

with respect to them, he actually observed the same colours which he had seen in the true rainbow, and in the same order.

Thus the circumstances in which the colours of the rainbow were formed, and the progress of a ray of light through a drop of water, were clearly understood; but philosophers were a long time at a loss when they endeavoured to assign reasons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, which was a discovery reserved for the great Sir Isaac Newton, could furnish a complete solution of this difficulty. De Dominis supposed that the red rays were those which had traversed the least space in the inside of a drop of water, and therefore retained more of their native force, and consequently, striking the eye more briskly, gave it a stronger sensation; that the green and blue colours were produced by those rays, the force of which had been, in some measure, obtunded in passing through a greater body of water; and that all the intermediate colours were composed (according to the hypothesis which generally prevailed at that time) of a mixture of these three primary ones. That the different colours were caused by some difference in the impulse of light upon the eye, and the greater or less impression that was thereby made upon it, was an opinion which had been adopted by many persons, who had ventured to depart from the authority of Aristotle.

Afterwards the same De Dominis observed, that all the rays of the same colour must leave the drop of water in a part similarly situated with respect to the eye, in order that each of the colours may appear in a circle, the centre of which is a point of the heavens, in a line drawn from the sun through the eye of the spectator. The red rays, he observed, must issue from the drop nearest to the bottom of it, in order that the circle of red may be the outermost, and therefore the most elevated in the bow.

Notwithstanding De Dominis conceived so justly of the manner in which the inner rainbow is formed, he was far from having as just an idea of the cause of the exterior bow. This he endeavoured to explain in the very same manner in which he had done the interior, viz. by one reflection of the light within the drop, preceded and followed by a refraction; supposing only that the rays which formed the exterior bow, were returned to the eye by a part of the drop lower than that which transmitted the red of the interior bow. He also supposed that the rays which formed one of the bows came from the superior part of the sun's disk, and those which formed the other from the inferior part of it. He did not consider, that upon those principles, the two bows ought to have been contiguous; or rather, that an indefinite number of bows would have had their colours all intermixed; which would have been no bow at all.

When Sir Isaac Newton discovered the different refrangibility of the rays of light, he immediately applied his new theory of light and colours to the phenomena of the rainbow, taking this remarkable object of philosophical inquiry where De Dominis and Descartes, for want of this knowledge, were obliged to leave their investigations imperfect. For they could give no good reason why the bow should be coloured,

and much less could they give any satisfactory account of the order in which the colours appear.

If different particles of light had not different degrees of refrangibility, on which the colours depend, the rainbow, besides being much narrower than it is, would be colourless; but the different refrangibility of differently coloured rays being admitted, the reason is obvious, both why the bow should be coloured, and also why the colours should appear in the order in which they are observed. Let A, (fig. 2.) be a Plate CCXIV.  
drop of water, and S a pencil of light; which, on its leaving the drop of water, reaches the eye of the spectator. This ray, at its entrance into the drop, begins to be decomposed into its proper colours; and upon leaving the drop, after one reflection and a second refraction, it is farther decomposed into as many small differently-coloured pencils, as there are primitive colours in the light. Three of them only are drawn in this figure, of which the blue is the most, and the red the least refracted.

The doctrine of the different refrangibility of light enables us to give a reason for the size of a bow of each particular colour. Newton, having found that the sines of refraction of the most refrangible and least refrangible rays, in passing from rain-water into air, are in the proportion of 185 to 182, when the sine of incidence is 138, calculated the size of the bow; and he found, that if the sun was only a physical point, without sensible magnitude, the breadth of the inner bow would be 2 degrees; and if to this 30' was added, for the apparent diameter of the sun, the whole breadth would be 2½ degrees. But as the outermost colours, especially the violet, are extremely faint, the breadth of the bow will not, in reality, appear to exceed two degrees. He finds, by the same principles, that the breadth of the exterior bow, if it was every where equally vivid, would be 4° 20'. But in this case there is a greater deduction to be made, on account of the faintness of the light of the exterior bow; so that, in fact, it will not appear to be more than 3 degrees broad.

The principal phenomena of the rainbow are all explained on Sir Isaac Newton's principles in the following propositions.

*When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one reflection and two refractions, may come to the eye of a spectator who has his back towards the sun and his face toward the drop.*

If XY (fig. 6.) is a drop of rain, and the sun shines upon it in any lines *sf, sd, sa*, &c. most of the rays will enter into the drop; some few of them only will be reflected from the first surface; those rays, which are reflected from thence, do not come under our present consideration, because they are never refracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface, will most of them be transmitted through the drop; but neither do those rays which are thus transmitted fall under our present consideration, since they are not reflected. For the rays, which are described in the proposition, are such as are twice refracted and once reflected. However, at the second surface, or hinder part of the drop, at *pg*, some few rays will be

reflected, whilst the rays are transmitted: those rays proceed in some such lines as  $nr, nq$ ; and coming out of the drop in the lines  $rv, qt$ , may fall upon the eye of a spectator, who is placed any where in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines  $sf, sd, sa$ , &c. These rays are twice refracted, and once reflected: they are refracted when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again when they pass out of the drop into the air.

*When rays of light reflected from a drop of rain come to the eye, those are called effectual which are able to excite a sensation.*

*When rays of light come out of a drop of rain, they will not be effectual, unless they are parallel and contiguous.*

THERE are but few rays that can come to the eye at all: for the greatest part of those rays which enter the drop XY (fig. 6.) between X and a, pass out of the drop thro' the hinder surface  $pg$ ; only few are reflected from thence, and come out through the nearer surface between a and y. Now, such rays as emerge, or come out of the drop, between a and Y, will be ineffectual, unless they are parallel to one another, as  $rv$  and  $qt$  are; because such rays as come out diverging from one another, will be so far asunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be sufficient to excite any sensation. But even rays, which are parallel, as  $rv, qt$ , will not be effectual, unless there are several of them contiguous or very near to one another. The two rays  $rv$  and  $qt$  alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation.

*When rays of light come out of a drop of rain after one reflection, those will be effectual which are reflected from the same point, and which entered the drop near to one another.*

ANY rays, as  $sb$  and  $cd$ , (fig. 7.) when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars  $bl, dl$ ; and as the ray  $sb$  falls farther from the axis  $av$  than the ray  $cd$ ,  $sb$  will be more refracted than  $cd$ ; so that these rays, though parallel to one another at their incidence, may describe the lines  $be$  and  $de$  after refraction, and be both of them reflected from one and the same point  $e$ . Now all rays which are thus reflected from one and the same point, when they have described the lines  $ef, eg$ , and after reflection emerge at  $f$  and  $g$ , will be so refracted, when they pass out of the drop into the air, as to describe the lines  $fh, gi$ , parallel to one another. If these rays were to return from  $e$  in the lines  $eb, ed$ , and were to emerge at  $b$  and  $d$ , they would be refracted into the lines of their incidence  $bs, ds$ . But if these rays, instead of being returned in the lines  $eb, ed$ , are reflected from the same point  $e$  in the lines  $eg, ef$ , the lines of reflection  $eg$  and  $ef$  will be inclined both to one another, and to the surface of the drop: just as much as the lines  $eb$  and  $ed$  are. First  $eb$  and  $eg$  make just the same angle with the surface of the

drop: for the angle  $ben$ , which  $eb$  makes with the surface of the drop, is the complement of incidence, and the angle  $gen$ , which  $eg$  makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner we might prove, that  $ed$  and  $ef$  make equal angles with the surface of the drop. Secondly, The angle  $bed$  is equal to the angle  $feg$ ; or the reflected rays  $eg, ef$ , and the incident rays  $be, de$ , are equally inclined to each other. For the angle of incidence  $bel$  is equal to the angle of reflection  $gel$ , and the angle of incidence  $del$  is equal to the angle of reflection  $fel$ ; consequently the difference between the angles of incidence is equal to the difference between the angles of reflection, or  $bel - del = gel - fel$ , or  $bed = gef$ .—Since therefore either the lines  $eg, ef$ , or the lines  $eb, ed$ , are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they were to return in the lines  $eb, ed$ , or are reflected in the lines  $eg, ef$ . But if they were to return in the lines  $eb, ed$ , the refraction, when they emerge at  $b$  and  $d$ , would make them parallel. Therefore, if they are reflected from one and the same point  $e$  in the lines  $eg, ef$ , the refraction, when they emerge at  $g$  and  $f$ , will likewise make them parallel.

But though such rays as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another when they emerge, and so have one condition that is requisite towards making them effectual, yet there is another condition necessary; for rays, that are effectual, must be contiguous, as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Let XY, (fig. 6.) be a drop of rain,  $ag$  the axis or diameter of the drop, and  $sa$  a ray of light that comes from the sun and enters the drop at the point  $a$ . This ray  $sa$ , because it is perpendicular to both the surfaces, will pass straight through the drop in the line  $agh$  without being refracted; but any collateral rays that fall about  $sb$ , as they pass through the drop, will be made to converge to their axis, and passing out at  $n$  will meet the axis at  $b$ : rays which fall farther from the axis than  $sb$ , such as those which fall about  $sc$ , will likewise be made to converge; but then their focus will be nearer to the drop than  $b$ . Suppose therefore  $i$  to be the focus to which the rays that fall about  $sc$  will converge, any ray  $sc$ , when it has described the line  $co$  within the drop, and is tending to the focus  $i$ , will pass out of the drop at the point  $o$ . The rays that fall upon the drop about  $sd$ , more remote still from the axis, will converge to a focus still nearer than  $i$ , as suppose at  $k$ . These rays therefore go out of the drop at  $p$ . The rays, that fall still more remote from the axis, as  $se$ , will converge to a focus nearer than  $k$ , as suppose at  $l$ ; and the ray  $se$ , when it has described the line  $eo$  within the drop, and is tending to  $h$ , will pass out at the point  $o$ . The rays, that fall still more remote from the axis, will converge to a focus still nearer. Thus the ray  $sf$  will after refraction converge to a focus at  $m$ , which is nearer than  $l$ ; and having described the line  $fn$  within the drop, it will pass out at the point  $n$ . Now here we may observe, that

as any rays  $sb$  or  $sc$ , fall farther above the axis  $sa$ , the points  $n$ , or  $o$ , where they pass out behind the drop, will be farther above  $g$ ; or that, as the incident ray rises from the axis  $sa$ , the arc  $gno$  increases, till we come to some ray  $sd$ , which passes out of the drop at  $p$ : and this is the highest point where any ray that falls upon the quadrant or quarter  $ax$  can pass out: for any rays  $se$ , or  $sf$ , that fall higher than  $sd$ , will not pass out in any point above  $p$ , but at the points  $o$  or  $n$ , which are below it. Consequently, tho' the arc  $gnop$  increases, whilst the distance of the incident ray from the axis  $sa$  increased, till we come to the ray  $sd$ ; yet afterwards, the higher the ray falls above the axis  $sa$ , this arc  $pong$  will decrease.

We have hitherto spoken of the points on the hinder part of the drop, where the rays pass out of it; but this was for the sake of determining the points from whence those rays are reflected, which do not pass out behind the drop. For, in explaining the rainbow, we have no farther reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed any where in the lines  $rv$  or  $qt$  with his face towards the drop. Now, as there are many rays which pass out of the drop between  $g$  and  $p$ , so some few rays will be reflected from thence; and consequently the several points between  $g$  and  $p$ , which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore, in respect of those rays which are reflected, we may call  $gp$  the arc of reflection; and many say, that this arc of reflection increases, as the distance of the incident ray from the axis  $sa$  increases, till we come to the ray  $sd$ ; the arc of reflection is  $gn$  for the ray  $sb$ , it is  $go$  for the ray  $sc$ , and  $gp$  for the ray  $sd$ . But after this, as the distance of the incident ray from the axis  $sa$  increases, the arc of reflection decreases; for  $og$  less than  $pg$  is the arc of reflection for the ray  $sc$ , and  $ng$  is the arc of reflection for the ray  $sf$ .

From hence it is obvious, that some one ray, which falls above  $sd$ , may be reflected from the same point with some other ray which falls below  $sd$ . Thus, for instance, the ray  $sb$  will be reflected from the point  $n$ , and the ray  $sf$  will be reflected from the same point; and consequently, when the reflected rays  $nr$ ,  $nq$ , are refracted as they pass out of the drop at  $r$  and  $q$ , they will be parallel, by what has been shewn in the former part of this proposition. But since the intermediate rays, which enter the drop between  $sf$  and  $sb$ , are not reflected from the same point  $n$ , these two rays alone will be the parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays  $rv$ ,  $qt$ , though they are parallel after they emerge at  $r$  and  $q$ , will not be contiguous, and for that reason will not be effectual; the ray  $sd$  is reflected from  $p$ , which has been shewn to be the limit of the arc of reflection; such rays as fall just above  $sd$ , and just below  $sd$ , will be reflected from nearly the same point  $p$ , as appears from what has been already shewn. These rays therefore will be parallel, because they are reflected from the same point  $p$ : and they will likewise be contiguous, because they all of them enter the drop at one and the same place very near to  $d$ . Conse-

quently, such rays as enter the drop at  $d$ , and are reflected from  $p$  the limit of the arc of reflection, will be effectual; since, when they emerge at the fore part of the drop between  $a$  and  $y$ , they will be both parallel and contiguous.

If we can make out hereafter that the rainbow is produced by the rays of the sun which are thus reflected from drops of rain as they fall whilst the sun shines upon them, this proposition may serve to shew us, that this appearance is not produced by any rays that fall upon any part, and are reflected from any part of those drops: since this appearance cannot be produced by any rays but those which are effectual; and effectual rays must always enter each drop at one certain place in the fore-part of it, and must likewise be reflected from one certain place in the hinder surface.

*When rays that are effectual emerge from a drop of rain after one reflection and two refractions, those which are most refrangible, will, at their emergence, make a less angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.*

Let  $fb$  and  $gi$ , (fig. 7.) be effectual violet rays Plate emerging from the drop at  $fg$ ; and  $fn$ ,  $gp$ , effectual red rays emerging from the same drop at the same place. Now, though all the violet rays are parallel to one another, because they are supposed effectual, and though all the red rays are likewise parallel to one another for the same reason; yet the violet rays will not be parallel to the red rays. These rays, as they have different colours, and different degrees of refrangibility, will diverge from one another; any violet ray  $gi$ , which emerges at  $g$ , will diverge from any red ray  $gp$ , which emerges at the same place. Now, both the violet ray  $gi$ , and the red ray  $gp$ , as they pass out of the drop of water into the air, will be refracted from the perpendicular  $ls$ . But the violet ray is more refrangible than the red one; and for that reason  $gi$ , or the refracted violet ray, will make a greater angle with the perpendicular than  $gp$  the refracted red ray; or the angle  $igo$  will be greater than the angle  $pgo$ . Suppose the incident ray  $sb$  to be continued in the direction  $sk$ , and the violet ray  $ig$  to be continued backward in the direction  $ik$ , till it meets the incident ray at  $k$ . Suppose likewise the red ray  $pg$  to be continued backwards in the same manner, till it meets the incident ray at  $w$ . The angle  $iks$  is that which the violet ray, or most refrangible ray at its emergence, makes with the incident ray; and the angle  $pws$  is that which the red ray, or least refrangible ray at its emergence, makes with the incident ray. The angle  $iks$  is less than the angle  $pws$ . For, in the triangle,  $gwk$ ,  $gws$ , or  $pws$ , is the external angle at the base, and  $gkw$  or  $iks$  is one of the internal opposite angles; and either internal opposite angle is less than the external angle at the base. (Euc. b. I. prop. 16.) What has been shewn to be true of the rays  $gi$  and  $gp$  might be shewn in the same manner of the rays  $fb$  and  $fn$ , or of any other rays that emerge respectively parallel to  $gi$  and  $gp$ . But all the effectual violet rays are parallel to  $gi$ , and all the effectual red rays are parallel to  $gp$ . Therefore the effectual violet rays at their emergence make a less angle

angle with the incident ones than the effectual red ones. And for the same reason, in all the other sorts of rays, those which are most refrangible, at their emerſion from a drop of rain after one reflection, will make a leſs angle with the incident rays, than thoſe do which are leſs refrangible.

Or otherwiſe: When the rays  $gi$  and  $gp$  emerge at the ſame point  $g$ , as they both come out of water into air, and conſequently are refracted from a perpendicular, inſtead of going ſtraight forwards in the line  $eg$  continued, they will both be turned round upon the point  $g$  from the perpendicular  $go$ . Now it is eaſy to conceive, that either of theſe lines might be turned in this manner upon the point  $g$  as upon a centre, till they become parallel parallel to  $sb$  the incident ray. But if either of theſe lines or rays were refracted ſo much from  $go$  as to become parallel to  $sb$ , the ray ſo much refracted, would, after emerſion, make no angle with  $sb$ , becauſe it would be parallel to it. And conſequently that ray which is moſt turned round upon the point  $g$ , or that ray which is moſt refrangible, will after emerſion be neareſt parallel to the incident ray, or will make the leaſt angle with it. The ſame may be proved of all other rays emerging parallel to  $gi$  and  $gp$  reſpectively, or of all effectual rays; thoſe which are moſt refrangible will after emerſion make a leſs angle with the incident rays, than thoſe do which are leaſt refrangible.

But ſince the effectual rays of different colours make different angles with  $sb$  at their emerſion, they will be ſeparated from one another: ſo that if the eye was placed in the beam  $fg$ , it would receive only rays of one colour from the drop  $xag$ ; and if it was placed in the beam  $fgn$ , it would receive only rays of ſome other colour.

The angle  $swp$ , which the leaſt refrangible or red rays make with the incident ones when they emerge ſo as to be effectual, is found by calculation to be 42 degrees 2 minutes. And the angle  $ski$ , which the moſt refrangible rays make with the incident ones when they emerge ſo as to be effectual, is found to be 40 degrees 17 minutes. The rays which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between 42 degrees 2 minutes, and 40 degrees 17 minutes.

*If a line is ſuppoſed to be drawn from the centre of the ſun thro' the eye of the ſpectator, the angle which any effectual ray, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.*

LET the eye of the ſpectator be at  $i$ , (fig. 7.) and let  $git$  be the line ſuppoſed to be drawn from the centre of the ſun through the eye of the ſpectator; the angle  $git$ , which any effectual ray makes with this line, will be equal to the angle  $ski$ , which the ſame ray makes with the incident ray  $sb$  or  $sk$ . If  $sb$  is a ray coming from the centre of the ſun, then ſince  $gi$  is ſuppoſed to be drawn from the ſame point, theſe two lines, upon account of the remoteneſs of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line  $ki$  croſſing theſe two parallel lines will make the alternate angles equal. Euc. b. I. prop. 29. Therefore  $kit$  or  $git$  is equal to  $ski$ .

*When the ſun ſhines upon the drops of rain as they are falling; the rays that come from theſe drops to the eye of a ſpectator, after one reflection and two refractions, produce the primary rainbow.*

If the fun ſhines upon the rain as it falls, there are commonly ſeen two bows, as AFB, CHD, (fig. 9.) ; or if the cloud and rain does not reach over that whole ſide of the ſky where the bows appear, then only a part of one or of both bows is ſeen in that place where the rain falls. Of theſe two bows, the innermoſt AFB is the more vivid of the two, and this is called the primary bow. The outer part TFY of the primary bow is red, the inner part VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppoſe the ſpectator's eye to be at O, and let LOP be an imaginary line drawn from the centre of the ſun through the eye of the ſpectator: if a beam of light S coming from the ſun falls upon any drop F; and the rays that emerge at F in the line FO, ſo as to be effectual, make an angle FOP of  $42^{\circ} 2'$  with the line LP; then theſe effectual rays make an angle of  $42^{\circ} 2'$  with the incident rays, by the preceding propoſition, and conſequently theſe rays will be red, ſo that the drop F will appear red. All the other rays, which emerge at F, and would be effectual if they fell upon the eye, are refracted more than the red ones, and conſequently will paſs above the eye. If a beam of light S falls upon the drop E; and the rays that emerge at E in the line EO, ſo as to be effectual, make an angle EOP of  $40^{\circ} 17'$  with the line LP; then theſe effectual rays make likewiſe an angle of  $40^{\circ} 17'$  with the incident rays, and the drop E will appear of a violet colour. All the other rays, which emerge at E, and would be effectual if they came to the eye, are refracted leſs than the violet ones, and therefore paſs below the eye. The intermediate drops between F and E will for the ſame reaſons be of the intermediate colours.

Thus we have ſhewn why a ſet of drops from F to E, as they are falling, ſhould appear of the primary colours, red, orange, yellow, green, blue, indigo, and violet. It is not neceſſary that the ſeveral drops, which produce theſe colours, ſhould all of them fall at exactly the ſame diſtance from the eye. The angle FOP, for inſtance, is the ſame whether the diſtance of the drop from the eye is OF, or whether it is in any other part of the line OF ſomething nearer to the eye. And whiſt the angle FOP is the ſame, the angle made by the emerging and incident rays, and conſequently the colour of the drop, will be the ſame. This is equally true of any other drop. So that although in the figure the drops F and E are repreſented as falling perpendicularly one under the other, yet this is not neceſſary in order to produce the bow.

But the coloured line FE, which we have already accounted for, is only the breadth of the bow. It ſtill remains to be ſhewn, why not only the drop F ſhould appear red, but why all the other drops quite from A to B in the arc ATFB ſhould appear of the ſame colour. Now it is evident, that wherever a drop of rain is placed, if the angle which the effectual rays make with the line LP is equal to the angle FOP, that is, if the angle which the effectual rays make with the incident

cident rays is  $42^{\circ} 2'$ , any of those drops will be red, for the same reason that the drop F is of this colour.

If FOP was to turn round upon the line OP, so that one end of this line should always be at the eye, and the other be at P opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs OP with the opening FOP. In this revolution the drop F would describe a circle, P would be the centre, and ATFYB would be an arc in this circle. Now since, in this motion of the line and drop OF, the angle made by FO with OP, that is, the angle FOP, continues the same; if the sun was to shine upon this drop as it revolves, the effectual rays would make the same angle with the incident rays, in whatever part of the arc ATFYB the drop was to be. Therefore, whether the drop is at A, or at T, or at Y, or at B, or wherever else it is in this whole arc, it would appear red, as it does at F. The drops of rain, as they fall, are not indeed turned round in this manner: but then, as innumerable of them are falling at once in right lines from the cloud, whilst one drop is at F, there will be others at Y, at T, at B, at A, and in every other part of the arc ATFYB: and all these drops will be red for the same reason that the drop F would have been red, if it had been in the same place. Therefore, when the sun shines upon the rain as it falls, there will be a red arc ATFYB opposite to the sun. In the same manner, because the drop E is violet, we might prove that any other drop, which, whilst it is falling, is in any part of the arc AVEXB, will be violet; and consequently, at the same time that the red arc ATFYB appears, there will likewise be a violet arc AVEXB below or within it. FE is the distance between these two coloured arcs; and from what has been said, it follows, that the intermediate space between these two arcs will be filled up with arcs of the intermediate colours, orange, yellow, blue, green, and indigo. All these coloured arcs together make up the primary rainbow.

*The primary rainbow is never a greater arc than a semicircle.*

SINCE the line LOP is drawn from the sun through the eye of the spectator, and since P (fig. 9.) is the centre of the rainbow; it follows, that the centre of the rainbow is always opposite to the sun. The angle FOP is an angle of  $42^{\circ} 2'$ , as was observed, or F the highest part of the bow is  $42^{\circ} 2'$  from P the centre of it. If the sun is more than  $42^{\circ} 2'$  high, P the centre of the rainbow, which is opposite to the sun, will be more than  $42^{\circ} 2'$  minutes below the horizon; and consequently F the top of the bow, which is only  $42^{\circ} 2'$  from P, will be below the horizon; that is, when the sun is more than  $42^{\circ} 2'$  minutes high, no primary rainbow will be seen. If the sun is something less than  $42^{\circ} 2'$  high, then P will be something less than  $42^{\circ} 2'$  below the horizon; and consequently F, which is only  $42^{\circ} 2'$  from P, will be just above the horizon; that is, a small part of the bow at this height of the sun will appear close to the ground opposite to the sun. If the sun is  $20^{\circ}$  high, then P will be  $20^{\circ}$  below the horizon; and F the top of the bow, being  $42^{\circ} 2'$  from P, will be  $22^{\circ} 2'$  above the horizon; therefore, at this height of the sun, the bow will be an arc of a circle whose centre is below the horizon; and conse-

quently that arc of the circle which is above the horizon, or the bow, will be less than a semicircle. If the sun is in the horizon, then P, the centre of the bow, will be in the opposite part of the horizon; F, the top of the bow, will be  $42^{\circ} 2'$  above the horizon; and the bow itself, because the horizon passes through the centre of it, will be a semicircle. More than a semicircle can never appear; because if the bow was more than a semicircle, P the centre of it must be above the horizon; but P is always opposite to the sun, therefore P cannot be above the horizon, unless the sun is below it; and when the sun is set, or is below the horizon, it cannot shine upon the drops of rain as they fall; and consequently, when the sun is below the horizon, no bow at all can be seen.

*When the rays of the sun fall upon a drop of rain, some of them, after two reflections and two refractions, may come to the eye of a spectator, who has his back towards the sun and his face towards the drop.*

If HGW (fig. 8.) is a drop of rain, and parallel rays coming from the sun, as  $zv, yw$ , fall upon the lower part of it, they will be refracted towards the perpendiculars  $vl, wl$ , as they enter into it, and will describe some such lines as  $vh, wi$ . At  $b$  and  $i$  great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines  $bf, ig$ . At  $f$  and  $g$  again, great part of the rays, that were reflected thither, will pass out of the drop. But these rays will not come to the eye of a spectator at  $e$ . However, here again all the rays will not pass out; but some few will be reflected from  $f$  and  $g$  in some such lines as  $fd, gb$ ; and these, when they emerge out of the drop of water into the air at  $b$  and  $d$ , will be refracted from the perpendiculars, and, describing the lines  $dt, bo$ , may come to the eye of the spectator who has his back towards the sun and his face towards the drop.

*Those rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effectual when they emerge after two refractions and two reflections.*

No rays can be effectual, unless they are contiguous, and parallel. From what was said, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they must enter the drop nearly at one and the same place. And if such rays as are contiguous are parallel after the first reflection, they will emerge parallel, and therefore will be effectual. Let  $zv$  and  $yw$  be contiguous rays which come from the sun, and are parallel to one another when they fall upon the lower part of the drop, suppose these rays to be refracted at  $v$  and  $w$ , and to be reflected at  $b$  and  $i$ ; if they are parallel to one another, as  $bf, gi$ , after this first reflection, then, after they are reflected a second time from  $f$  and  $g$ , and refracted a second time as they emerge at  $d$  and  $b$ , they will go out of the drop parallel to one another in the lines  $dt$  and  $bo$ , and will therefore be effectual.

The rays  $zv, yw$ , are refracted towards the perpendiculars  $vl, wl$ , when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface  $vw$ . If this focus is at  $k$ , the rays, after they have passed the focus, will

Rainbow.

will diverge from thence in the directions  $kb$ ,  $ki$ ; and if  $ki$  is the principal focal distance of the concave reflecting surface  $hi$ , the reflected rays  $bf$ ,  $ig$ , will be parallel. These rays  $ef$ ,  $ig$ , are reflected again from the concave surface  $fg$ , and will meet in a focus at  $e$ , so that  $ge$  will be the principal focal distance of this reflecting surface  $fg$ . And because  $hi$  and  $fg$  are parts of the same sphere, the principal focal distances  $ge$  and  $ki$  will be equal to one another. When the rays have passed the focus  $e$ , they will diverge from thence in the lines  $ed$ ,  $eb$ ; and we are to shew, that when they emerge at  $d$  and  $b$ , and are refracted there, they will become parallel.

Now if the rays  $vk$ ,  $wk$ , when they have met at  $k$ , were to be turned back again in the directions  $kv$ ,  $kw$ , and were to emerge at  $v$  and  $w$ , they would be refracted into the lines of their incidence,  $av$ ,  $aw$ , and therefore would be parallel. But since  $ge$  is equal to  $ik$ , as has already been shewn, the rays  $ed$ ,  $eb$ , that diverge from  $e$ , fall in the same manner upon the drop at  $d$  and  $b$ , as the rays  $kv$ ,  $kw$ , would fall upon it at  $v$  and  $w$ ; and  $ed$ ,  $eb$ , are just as much inclined to the refracting surface  $db$ , as  $kv$ ,  $kw$ , would be to the surface  $vw$ . From hence it follows, that the rays  $ed$ ,  $eb$ , emerging at  $d$  and  $b$ , will be refracted in the same manner, and will have the same direction in respect of one another, as  $kv$ ,  $kw$ , would have. But  $kv$  and  $kw$  would be parallel after refraction. Therefore  $ed$  and  $eb$  will emerge in lines  $dp$ ,  $bq$ , so as to be parallel to one another, and consequently so as to be effectual.

*When rays that are effectual emerge from a drop of rain after two reflections and two refractions, those which are most refrangible will at their emergence make a greater angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another.*

Plate  
CCXIII.

If rays of different colours, which are differently refrangible, emerge at any point  $b$ , (fig. 8.) these rays will not be all of them equally refracted from the perpendicular. Thus, if  $bo$  is a red ray, which is of all others the least refrangible, and  $bm$  is a violet ray, which is of all others the most refrangible; when these two rays emerge at  $b$ , the violet ray will be refracted more from the perpendicular  $bx$  than the red ray, and the refracted angle  $xbm$  will be greater than the refracted angle  $xbo$ . From hence it follows, that these two rays, after emergence, will diverge from one another. In like manner, the rays that emerge at  $d$  will diverge from one another; a red ray will emerge in the line  $dp$ , a violet ray in the line  $dq$ . So that though all the effectual red rays of the beam  $bdm$  are parallel to one another, and all the effectual red rays of the beam  $bop$  are likewise parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms. That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if  $yw$  is an incident ray,  $bm$  a violet ray emerging from the point  $b$ , and  $bo$  a red ray emerging from the same point; the angle which

the violet ray makes with the incident one is  $yrm$ , and that which the red ray makes with it is  $yso$ . Now  $yrm$  is a greater angle than  $yso$ . For in the triangle  $bry$  the internal angle  $bry$  is less than  $bsy$  the external angle at the base. Euc. B. I. prop. 16. But  $yrm$  is the complement of  $bry$  or of  $bry$  to two right ones, and  $yso$  is the complement of  $bsy$  to two right ones. Therefore, since  $bry$  is less than  $bsy$ , the complement of  $bry$  to two right angles will be greater than the complement of  $bsy$  to two right angles; or  $yrm$  will be greater than  $yso$ .

Or otherwise: Both the rays  $bo$  and  $bm$ , when they are refracted in passing out of the drop at  $b$ , are turned round upon the point  $b$  from the perpendicular  $bx$ . Now either of these lines  $bo$  or  $bm$  might be turned round in this manner, till it made a right angle with  $yw$ . Consequently, that ray which is most turned round upon  $b$ , or which is most refracted, will make an angle with  $yw$  that will be nearer to a right one than that ray makes with it which is least turned round upon  $b$ , or which is least refracted. Therefore that ray which is most refracted will make a greater angle with the incident ray than that which is least refracted.

But since the emerging rays, as they are differently refrangible, make different angles with the same incident ray  $yw$ , the refraction which they suffer at emergence will separate them from one another.

The angle  $yrm$ , which the most refrangible or violet rays make with the incident ones, is found by calculation to be  $54^{\circ} 7'$ ; and the angle  $yso$ , which the least refrangible or red rays make with the incident ones, is found to be  $50^{\circ} 57'$ : the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between  $54^{\circ} 7'$  and  $50^{\circ} 57'$ .

*If a line is supposed to be drawn from the centre of the sun through the eye of the spectator; the angle, which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes with that line.*

If  $yw$  (fig. 8.) is an incident ray,  $bo$  an effectual ray, and  $qn$  a line drawn from the centre of the sun through  $o$  the eye of the spectator; the angle  $yso$ , which the effectual ray makes with the incident ray, is equal to  $son$  the angle which the same effectual ray makes with the line  $qn$ . For  $yw$  and  $qn$ , considered as drawn from the centre of the sun, are parallel;  $bo$  crosses them, and consequently makes the alternate angles  $yso$ ,  $son$ , equal to one another. Euc. B. I. Prop. 29.

*When the sun shines upon the drops of rain as they are falling; the rays that come from these drops to the eye of a spectator, after two reflections and two refractions, produce the secondary rainbow.*

THE secondary rainbow is the outermost CHD, fig. 9. When the sun shines upon a drop of rain  $H$ ; and the rays  $HO$ , which emerge at  $H$  so as to be effectual, make an angle HOP of  $54^{\circ} 7'$  with LOP a line drawn from the sun through the eye of the spectator; the same effectual rays will make likewise an angle of  $54^{\circ} 7'$  with the incident rays  $S$ , and the rays which emerge at this angle are violet ones, by what was observed above. Therefore, if the spectator's eye

is at O, none but violet rays will enter it: for as all the other rays make a less angle with OP, they will fall above the spectator's eye. In like manner, if the effectual rays that emerge from the drop G make an angle of  $50^{\circ} 57'$  with the line OP, they will likewise make the same angle with the incident rays S; and consequently, from the drop G to the spectator's eye at O, no rays will come but red ones; for all the other rays, making a greater angle with the line OP, will fall below the eye at O. For the same reason, the rays emerging from the intermediate drops between H and G, and coming to the spectator's eye at O, will emerge at intermediate angles, and therefore will have the intermediate colours. Thus, if there are seven drops from H to G inclusively, their colours will be violet, indigo, blue, green, yellow, orange, and red. This coloured line is the breadth of the secondary rainbow.

Now, if HOP was to turn round upon the line OP, like a pair of compasses upon one of the legs OP with the opening HOP, it is plain from the supposition, that, in such a revolution of the drop H, the angle HOP would be the same, and consequently the emerging rays would make the same angle with the incident ones. But in such a revolution the drop would describe a circle of which P would be the centre, and CNHRD an arc. Consequently, since, when the drop is at N, or at R, or any where else in that arc, the emerging rays make the same angle with the incident ones as when the drop is at H, the colour of the drop will be the same to an eye placed at O, whether the drop is at N, or at H, or at R, or any where else in that arc. Now, though the drop does not thus turn round as it falls, and does not pass through the several parts of this arc, yet, since there are drops of rain falling every where at the same time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and these drops will all of them be violet-coloured, for the same reason that the drop H would have been of this colour if it had been in any of those places. In like manner, as the drop G is red when it is at G, it would likewise be red in any part of the arc CWGQD; and so will any other drop, when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the rain, whilst it falls, there will be two arcs produced, a violet coloured one CNHRD, and a red one CWGQD; and for the same reasons the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

*The colours of the secondary rainbow are fainter than those of the primary rainbow; and are ranged in the contrary order.*

THE primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequently will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outside of it, the colours are ranged in this order; red, orange,

yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, orange, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge so as to be effectual after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the lines OP (fig. 9.) than the red ones. But, in the primary rainbow, the rays are only once reflected, and the angle which the effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops, or violet arc, in the primary bow, will be nearer to the centre of the bow, than the red drops or red arc; that is, the innermost colour in the primary bow will be violet, and the outermost colour will be red. And, for the same reason, through the whole primary bow, every colour will be nearer to the centre P, as the rays of that colour are more refrangible,

But the violet rays, when they emerge so as to be effectual after two reflections, make a greater angle with the incident rays than the red ones; consequently the violet rays will make a greater angle with the line OP, than the red ones. But in the secondary rainbow the rays are twice reflected, and the angle which effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, through the whole secondary bow, every colour will be further from the centre P, as the rays of that colour are more refrangible.

## § 2. Of Coronas, Parhelia, &c.

UNDER the articles CORONA and PARHELION a pretty full account is given of the different hypotheses concerning these phenomena, and likewise of the method by which these hypotheses are supported, from the known laws of refraction and reflection; to which therefore, in order to avoid repetition, we must refer.

## § 3. Of the Apparent Place, Distance, Magnitude, and Motion of Objects.

PHILOSOPHERS in general had taken for granted, that the place to which the eye refers any visible object seen by reflection or refraction, is that in which the visual ray meets a perpendicular from the object upon the reflecting or refracting plane. But this method of judging of the place of objects was called in question by Dr Barrow, who contended that the arguments brought in favour of the opinion were not conclusive. These arguments are, that the images of objects appear straight in a plane mirror, but curved in a convex or concave one: that a straight thread, when partly immersed perpendicularly in water, does not appear crooked as when it is obliquely plunged into the fluid; but that which is within the water seems to be a continuation of that which is without. With respect to the reflected image, however, of a perpendicular right line from a convex, or concave mirror, he

Apparent  
place, &c.  
of objects.

Plate  
CCXIII.

Apparent  
place, &c.  
of objects.

he says, that it is not easy for the eye to distinguish the curve that it really makes; and that, if the appearance of a perpendicular thread, part of which is plunged in water, be closely attended to, it will not favour the common hypothesis. If the thread is of any shining metal, as silver, and viewed obliquely, the image of the part immersed will appear to detach itself sensibly from that part which is without the water, so that it cannot be true that every object appears to be in the same place where the refracted ray meets the perpendicular; and the same observation he thinks may be extended to the case of reflection. According to this writer, we refer every point of an object to the place from which the pencils of light, that give us the image of it, issue, or from which they would have issued if no reflecting or refracting substance intervened. Pursuing this principle, he proceeds to investigate the place, in which the rays issuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that, if the refracting surface was plane, and the refraction was made from a denser medium into a rarer, those rays would always meet in a place between the eye and a perpendicular to the point of incidence. If a convex mirror be used, the case will be the same; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be concave. He also determined, according to these principles, what form the image of a right line will take, when it is presented in different manners to a spherical mirror, or when it is seen through a refracting medium.

Probable as Dr Barrow thought the maxim which he endeavoured to establish, concerning the supposed place of visible objects, he has the candour to mention an objection to it, and to acknowledge that he was not able to give a satisfactory solution of it. It is this. Let an object be placed beyond the focus of a convex lens; and if the eye be close to the lens, it will appear confused, but very near to its true place. If the eye be a little withdrawn, the confusion will increase, and the object will seem to come nearer; and when the eye is very near the focus, the confusion will be exceedingly great, and the object will seem to be close to the eye. But in this experiment the eye receives no rays but those that are converging; and the point from which they issue is so far from being nearer than the object, that it is beyond it; notwithstanding which, the object is conceived to be much nearer than it is, though no very distinct idea can be formed of its precise distance. It may be observed, that, in reality, the rays falling upon the eye in this case, in a manner quite different from that in which they fall upon it in other circumstances, we can form no judgement about the place from which they issue. This subject was afterwards taken up by Berkley, Smith, Montucla, and others.

M. De la Hire made several valuable observations concerning the distance of visible objects, and various other phenomena of vision, which are well worth our notice. He also took particular pains to ascertain the manner in which the eye conforms itself to the view of objects placed at different distances. He enumerates five circumstances, which assist us in judging of the distance of objects, namely, their apparent magnitude,

the strength of the colouring, the direction of the two eyes, the parallax of the objects, and the distinctness of their small parts. Painters, he says, can only take advantage of the two first mentioned circumstances, and therefore pictures can never perfectly deceive the eye; but in the decorations of theatres, they, in some measure, make use of them all. The size of objects, and the strength of their colouring, are diminished in proportion to the distance at which they are intended to appear. Parts of the same object which are to appear at different distances, as columns in an order of architecture, are drawn upon different planes, a little removed from one another, that the two eyes may be obliged to change their direction, in order to distinguish the parts of the nearer plane from those of the more remote. The small distance of the planes serves to make a small parallax, by changing the position of the eye; and as we do not preserve a distinct idea of the quantity of parallax, corresponding to the different distances of objects, it is sufficient that we perceive there is a parallax, to be convinced that these planes are distant from one another, without determining what that distance is; and as to the last circumstance, viz. the distinctness of the small parts of objects, it is of no use in discovering the deception, on account of the false light that is thrown upon these decorations.

To these observations concerning deceptions of sight, we shall add a similar one of M. Le Cat, who took notice that the reason why we imagine objects to be larger when they are seen through a mist, is the dimness or obscurity with which they are then seen; this circumstance being associated with the idea of great distance. This he says is confirmed by our being surprised to find, upon approaching such objects, that they are so much nearer to us, as well as so much smaller, than we had imagined.

Among other cases concerning vision, which fell under the consideration of M. De la Hire, he mentions one which is of difficult solution. It is when a candle, in a dark place, and situated beyond the limits of distinct vision, is viewed through a very narrow chink in a card; in which case a considerable number of candles, sometimes so many as six, will be seen along the chink. This appearance he ascribes to small irregularities in the surface of the humours of the eye, the effect of which is not sensible when rays are admitted into the eye through the whole extent of the pupil, and consequently one principal image effaces a number of small ones; whereas, in this case, each of them is formed separately, and no one of them is so considerable as to prevent the others from being perceived at the same time.

There are few persons, M. De la Hire observes, who have both their eyes perfectly equal, not only with respect to the limits of distinct vision, but also with respect to the colour with which objects appear tinged when they are viewed by them, especially if one of the eyes has been exposed to the impression of a strong light. To compare them together in this respect, he directs us to take two thin cards, and to make in each of them a round hole of a third or a fourth of a line in diameter, and, applying one of them to each of the eyes, to look through the holes on a white paper, equally illuminated; when a circle of the paper will appear to each of the eyes, and, placing

Apparent  
place, &c.  
of objects.

the cards properly, these two circles may be made to touch one another, and thereby the appearance of the same object to each of the eyes may be compared to the greatest advantage. To make this experiment with the greatest exactness, it is necessary, he says, that the eyes be kept shut some time before the cards be applied to them.

M. De la Hire first endeavoured to explain the cause of those dark spots which seem to float before the eyes, especially those of old people. They are most visible when the eyes are turned towards an uniform white object, as the snow in the open fields. If they be fixed when the eye is so, this philosopher supposed that they were occasioned by extravasated blood upon the retina. But he thought that the movable spots were occasioned by opaque matter floating in the aqueous humour of the eye. He thought the vitreous humour was not sufficiently limpid for this purpose.

By the following calculation M. De la Hire gives us an idea of the extreme sensibility of the optic nerves. One may see very easily, at the distance of 4000 toises, the sail of a wind-mill, 6 feet in diameter; and the eye being supposed to be an inch in diameter, the picture of this sail, at the bottom of the eye, will be  $\frac{1}{3250}$  of an inch, which is less than the 666th part of a line, and is about the 66th part of a common hair, or the 8th part of a single thread of silk. So small, therefore, must one of the fibres of the optic nerve be, which he says is almost inconceivable, since each of these fibres is a tube that contains spirits. If birds perceive distant objects as well as men, which he thought very probable, he observes that the fibres of their optic nerves must be much finer than ours.

The person who first took much notice of Dr Barrow's hypothesis was the ingenious Dr Berkeley, bishop of Cloyne, who distinguished himself so much by the objections which he started to the reality of a material world, and by his opposition to the Newtonian doctrine of fluxions. In his essay on a new theory of vision, he observes, that the circle formed upon the retina, by the rays which do not come to a focus, produce the same confusion in the eye, whether they cross one another before they reach the retina, or tend to do it afterwards; and therefore that the judgment concerning distance will be the same in both the cases, without any regard to the place from which the rays originally issued; so that in this case, as, by receding from the lens, the confusion, which always accompanies the nearness of an object, increases, the mind will judge that the object comes nearer.

But, says Dr Smith, if this be true, the object ought always to appear at a less distance from the eye than that at which objects are seen distinctly, which is not the case: and to explain this appearance, as well as every other in which a judgment is formed concerning distance, he maintains, that we judge of it by the apparent magnitude of objects only, or chiefly; so that, since the image grows larger as we recede from the lens through which it is viewed, we conceive the object to come nearer. He also endeavours to shew, that, in all cases in which glasses are used, we judge of distance by the same simple rule; from which he concludes universally, that the apparent distance of an object seen in a glass, is to its apparent distance seen by the naked eye, as the apparent magnitude to

the naked eye is to its apparent magnitude in the glass.

But that we do not judge of distance merely by the angle under which objects are seen, is an observation as old as Alhazen, who mentions several instances, in which, though the angles under which objects appear be different, the magnitudes are universally and instantaneously deemed not to be so. And Mr Robins clearly shews the hypothesis of Dr Smith to be contrary to fact in the most common and simple cases. In microscopes, he says, it is impossible that the eye should judge the object to be nearer than the distance at which it has viewed the object itself, in proportion to the degree of magnifying. For when the microscope magnifies much, this rule would place the image at a distance, of which the sight cannot possibly form any opinion, as being an interval from the eye at which no object can be seen. In general, he says, he believes, that whoever looks at an object through a convex glass, and then at the object itself, without the glass, will find it to appear nearer in the latter case, though it be magnified in the glass; and in the same trial with the concave glass, though by the glass the object be diminished, it will appear nearer through the glass than without it.

But the most convincing proof that the apparent distance of the image is not determined by its apparent magnitude is the following experiment. If a double convex glass be held upright before some luminous object, as a candle, there will be seen two images, one erect, and the other inverted. The first is made simply by reflection from the nearest surface, the second by reflection from the farther surface, the rays undergoing a refraction from the first surface both before and after the reflection. If this glass has not too short a focal distance, when it is held near the object, the inverted image will appear larger than the other, and also nearer; but if the glass be carried off from the object, though the eye remain as near to it as before, the inverted image will diminish so much faster than the other, that, at length, it will appear very much less than it, but still nearer. Here, says Mr Robins, two images of the same object are seen under one view, and their apparent distances immediately compared; and here it is evident, that those distances have no necessary connection with the apparent magnitude. He also shews how this experiment may be made still more convincing, by sticking a piece of paper on the middle of the lens, and viewing it thro' a short tube.

M. Bouguer adopts the general maxim of Dr Barrow, in supposing that we refer objects to the place from which the pencils of rays seemingly converge at their entrance into the pupil. But when rays issue from below the surface of a vessel of water, or any other refracting medium, he finds that there are always two different places of this seeming convergence; one of them of the rays that issue from it in the same vertical circle, and therefore fall with different degrees of obliquity upon the surface of the refracting medium; and another, of those that fall upon the surface with the same degree of obliquity, entering the eye laterally with respect to one another. Sometimes, he says, one of these images is attended to by the mind, and sometimes the other, and different images may be observed by different persons. An object plunged in

water

place, &c.  
of objects.

water affords an example, he says, of this duplicity of images.

place  
CCXIII.

If BA, fig. 1. be part of the surface of water, and the object be at O, there will be two images of it, in two different places; one at G, on the caustic by refraction, and the other at E, in the perpendicular AO, which is as much a caustic as the other line. The former image is visible by the rays ODM, Odm, which are one higher than the other, in their progress to the eye; whereas the image at E is made by the rays ODM, Odf, which enter the eye laterally. This, says he, may serve to explain the difficulty of Father Tacquet, Barrow, Smith, and many other authors, and which Newton himself considered as a very difficult problem, though it might not be absolutely infallible.

G. W. Krafft has ably supported the opinion of Dr Barrow, that the place of any point, seen by reflection from the surface of any medium, is that in which rays issuing from it, infinitely near to one another, would meet; and considering the case of a distant object, viewed in a concave mirror, by an eye very near to it, when the image, according to Euclid and other writers, would be between the eye and the object, and the rule of Dr Barrow cannot be applied, he says that in this case the speculum may be considered as a plane, the effect being the same, only the image is more obscure.

Dr Porterfield gives a distinct and comprehensive view of the natural methods of judging concerning the distance of objects.

The conformation of the eye, he observes, can be of no use to us with respect to objects that are placed without the limits of distinct vision. As the object, however, does then appear more or less confused, according as it is more or less removed from those limits, this confusion assists the mind in judging of the distance of the object; it being always esteemed so much the nearer, or the farther off, by how much the confusion is greater. But this confusion hath its limits also, beyond which it can never extend; for when an object is placed at a certain distance from the eye, to which the breadth of the pupil bears no sensible proportion, the rays of light that come from a point in the object, and pass the pupil, are so little diverging, that they may be considered as parallel. For a picture on the retina will not be sensibly more confused, tho' the object be removed to a much greater distance.

The most universal, and frequently the most sure means of judging of the distance of objects is, he says, the angle made by the optic axis. For our two eyes are like two different stations, by the assistance of which distances are taken; and this is the reason why those persons who are blind of one eye, so frequently miss their mark in pouring liquor into a glass, snuffing a candle, and such other actions as require that the distance be exactly distinguished. To convince ourselves of the usefulness of this method of judging of the distance of objects, he directs us to suspend a ring in a thread, so that its side may be towards us, and the hole in it to the right and left hand; and taking a small rod, crooked at the end, retire from the ring two or three paces, and having with one hand covered one of our eyes, to endeavour with the other to

pass the crooked end of the rod thro' the ring. This, says he, appears very easy; and yet, upon trial, perhaps once in 100 times we shall not succeed, especially if we move the rod a little quickly.

Our author observes, that by persons recollecting the time when they began to be subject to the mistakes above-mentioned, they may tell when it was that they lost the use of one of their eyes; which many persons are long ignorant of, and which may be a circumstance of some consequence to a physician. The use of this second method of judging of distances De Chales limited to 120 feet; beyond which, he says, we are not sensible of any difference in the angle of the optic axis.

A third method of judging of the distance of objects, consists in their apparent magnitudes, on which so much stress was laid by Dr Smith. From this change in the magnitude of the image upon the retina, we easily judge of the distance of objects, as often as we are otherwise acquainted with the magnitude of the objects themselves; but as often as we are ignorant of the real magnitude of bodies, we can never, from their apparent magnitude, form any judgment of their distance.

From this we may see why we are so frequently deceived in our estimates of distance, by any extraordinary magnitudes of objects seen at the end of it; as, in travelling towards a large city, or a castle, or a cathedral church, or a mountain larger than ordinary, we fancy them to be nearer than we find them to be. This also is the reason why animals, and all small objects, seen in valleys, contiguous to large mountains, appear exceedingly small. For we think the mountain nearer to us than if it were smaller; and we should not be surpris'd at the smallness of the neighbouring animals, if we thought them farther off. For the same reason, we think them exceedingly small when they are placed upon the top of a mountain, or a large building; which appear nearer to us than they really are, on account of their extraordinary size.

Dr Jurin clearly accounts for our imagining objects, when seen from a high building, to be smaller than they are, and smaller than we fancy them to be when we view them at the same distance on level ground. It is, says he, because we have no distinct idea of distance in that direction, and therefore judge of things by their pictures upon the eye only; but custom will enable us to judge rightly even in this case.

Let a boy, says he, who has never been upon any high building, go to the top of the monument, and look down into the street; the objects seen there, as men and horses, will appear so small as greatly to surprise him. But 10 or 20 years after, if in the mean time he has used himself now and then to look down from that and other great heights, he will no longer find the same objects to appear so small. And if he was to view the same objects from such heights as frequently as he sees them upon the same level with himself in the streets, he supposes that they would appear to him just of the same magnitude from the top of the monument, as they do from a window one story high. For this reason it is, that statues placed upon very high buildings ought to be made of a larger size than those which are seen at a nearer distance,

Apparent  
place, &c.  
of objects.

stance; because all persons, except architects, are apt to imagine the height of such buildings to be, much less than it really is.

The fourth method by which Dr Porterfield says that we judge of the distance of objects, is, the force with which their colour strikes upon our eyes. For if we be assured that two objects are of a similar and like colour, and that one appears more bright and lively than the other, we judge that the brighter object is the nearer of the two.

The fifth method consists in the different appearance of the small parts of objects. When these parts appear distinct, we judge that the object is near; but when they appear confused, or when they do not appear at all, we judge that it is at a greater distance. For the image of any object, or part of an object, diminishes as the distance of it increases.

The sixth and last method by which we judge of the distance of objects is, that the eye does not represent to our mind one object alone, but at the same time all those that are placed betwixt us and the principal object, whose distance we are considering; and the more this distance is divided into separate and distinct parts, the greater it appears to be. For this reason, distances upon uneven surfaces appear less than upon a plane; for the inequalities of the surfaces, such as hills, and holes, and rivers, that lie low and out of sight, either do not appear, or hinder the parts that lie behind them from appearing; and so the whole apparent distance is diminished by the parts that do not appear in it. This is the reason that the banks of a river appear contiguous to a distant eye, when the river is low and not veen.

Dr Porterfield very well explains several fallacies in vision depending upon our mistaking the distances of objects. Of this kind, he says, is the appearance of parallel lines, and long vistas consisting of parallel rows of trees; for they seem to converge more and more, as they are farther extended from the eye. The reason of this, he says, is because the apparent magnitudes of their perpendicular intervals are perpetually diminishing, while, at the same time, we mistake their distance. Hence we may see why, when the two parallel rows of trees stand upon an ascent, whereby the more remote parts appear farther off than they really are, because the line that measures the length of the vistas now appears under a greater angle than when it was horizontal, the trees, in such a case, will seem to converge less, and sometimes, instead of converging, they will be thought to diverge.

For the same reason that a long vista appears to converge more and more the farther it is extended from the eye, the remoter parts of a horizontal walk or a long floor will appear to ascend gradually; and objects placed upon it, the more remote they are, the higher they will appear, till the last be seen on a level with the eye; whereas the ceiling of a long gallery appears to descend towards a horizontal line, drawn from the eye of the spectator. For this reason, also, the surface of the sea, seen from an eminence, seems to rise higher and higher the farther we look; and the upper parts of high buildings seem to stoop, or incline forwards over the eye below, because they seem to approach towards a vertical line proceeding from the spectator's eye; so that statues on the top of such

buildings, in order to appear upright, must recline, or bend backwards.

Our author also shews the reason why a windmill, seen from a great distance, is sometimes imagined to move the contrary way from what it really does, by our taking the nearer end of the sail for the more remote. The uncertainty we sometimes find in the course of the motion of a branch of lighted candles, turned round at a distance, is owing, he says, to the same cause; as also our sometimes mistaking a convex for a concave surface, more especially in viewing seals, and impressions, with a convex glass or a double microscope; and lastly, that, upon coming in a dark night into a street, in which there is but one row of lamps, we often mistake the side of the street they are on.

Far more light was thrown upon this curious subject by M. Bouguer.

The proper method of drawing the appearance of two rows of trees that shall appear parallel to the eye, is a problem which has exercised the ingenuity of several philosophers and mathematicians. That the apparent magnitude of objects decreases with the angle under which they are seen, has always been acknowledged. It is also acknowledged, that it is only by custom and experience that we learn to form a judgment both of magnitudes and distances. But in the application of these maxims to the above-mentioned problem, all persons, before M. Bouguer, made use of the real distance instead of the apparent one; by which only the mind can form its judgment. And it is manifest, that, if any circumstances contribute to make the distance appear otherwise than it is in reality, the apparent magnitude of the object will be affected by it; for the same reason, that, if the magnitude be misapprehended, the idea of the distance will vary.

For want of attending to this distinction, Tacquet pretended to demonstrate, that nothing can give the idea of two parallel lines (rows of trees for instance) to an eye situated at one of their extremities, but two hyperbolic curves, turned the contrary way; and M. Varignon maintained, that in order to make a vista appear of the same width, it must be made narrower, instead of wider, as it recedes from the eye.

M. Bouguer observes, that very great distances, and those that are considerably less than them, make nearly the same impression upon the eye. We, therefore, always imagine great distances to be less than they are, and for this reason the ground-plan of a long vista always appears to rise. The visual rays come in a determinate direction; but as we imagine that they terminate sooner than they do, we necessarily conceive that the place from which they issue is elevated. Every large plane, therefore, as AB, fig. 4. viewed by an eye at O, will seem to lie in such a direction as A*b*; and consequently lines, in order to appear truly parallel on the plane AB, must be drawn so as that they would appear parallel on the plane A*b*, and be from thence projected to the plane AB.

To determine the inclination of the apparent ground-plane A*b* to the true ground-plane AB, our ingenious author directs us to draw upon a piece of level ground, two straight lines of a sufficient length, (for which purpose lines fastened to small sticks are very

Apparent  
place, &c.  
of objects.

Plate  
CCXIII.

con-

Apparent  
place, &c.  
of objects.

convenient), making an angle of 3 or 4 degrees with one another. Then a person, placing himself within the angle, with his back towards the angular point, must walk backwards and forwards till he can fancy the lines to be parallel. In this situation, a line drawn from the point of the angle thro' the place of his eye, will contain the same angle with the true ground-plane which this does with the apparent one.

M. Bouguer then shews other more geometrical methods of determining this inclination; and says, that by these means he has often found it to be 4 or 5 degrees, though sometimes only 2 or  $2\frac{1}{2}$  degrees. The determination of this angle, he observes, is variable; depending upon the manner in which the ground is illuminated, and the intensity of the light. The colour of the soil is also not without its influence, as well as the particular conformation of the eye, by which it is more or less affected by the same degree of light, and also the part of the eye on which the object is painted. When, by a slight motion of his head, he contrived, that certain parts of the soil, the image of which fell towards the bottom of his eye, should fall towards the top of the retina, he always thought that this apparent inclination became a little greater.

But what is very remarkable, and what he says he can assure his reader may be depended upon, is, that, if he look towards a rising ground, the difference between the apparent ground-plan and the true one, will be much more considerable, so that they will sometimes make an angle of 25 or 30 degrees. Of this he had made frequent observations. Mountains, he says, begin to be inaccessible when their sides made an angle from 35 to 37 degrees with the horizon, as then it is not possible to climb them but by means of stones or shrubs, to serve as steps to fix the feet on. In these cases, both he and his companions always agreed that the apparent inclination of the side of the mountain was 60 or 70 degrees.

Plate  
CCXIII.

These deceptions are represented in fig. 3. in which, when the ground plan, AM, or AN, are much inclined, the apparent ground plan  $A_m$ , or  $A_n$ , makes a very large angle with it. On the contrary, if the ground dips below the level, the inclination of the apparent to the true ground-plan diminishes, till, at a certain degree of the slope, it becomes nothing at all; the two plans AP and  $A_p$  being the same, so that parallel lines drawn upon them would always appear so. If the inclination below the horizon is carried beyond the situation AP, the error will increase; and what is very remarkable, it will be on the contrary side; the apparent plan  $A_p$  being always below the true plan AR, so that if a person would draw upon the plan AR lines that shall appear parallel to the eye, they must be drawn converging, and not diverging, as is usual on the level ground, because they must be the projections of two lines imagined to be parallel, on the plan  $A_p$ , which is more inclined to the horizon than AR.

These remarks, he observes, are applicable to different planes exposed to the eye at the same time. For if BH, fig. 2. be the front of a building, at the distance of AB from the eye, it will be reduced in appearance to the distance Ab; and the front of the building will be  $bb$ , rather inclined towards the spectator, unless the distance be inconsiderable.

After making a great number of observations upon

this subject, our author concludes, that when a man stands upon a level plane, it does not seem to rise sensibly but at some distance from him. The apparent plane, therefore, has a curvature in it, at that distance, the form of which is not very easy to determine; so that a man standing upon a level plane, of infinite extent, will imagine that he stands in the centre of a basin. This is also, in some measure, the case with a person standing upon the level of the sea.

He concludes with observing that there is no difficulty in drawing lines according to these rules, so as to have any given effect upon the eye, except when some parts of the prospect are very near the spectator, and others very distant from him; because, in this case, regard must be had to the conical or conoidal figure of a surface. A right line passing at a small distance from the observer, and below the level of his eye, in that case almost always appears sensibly curved at a certain distance from the eye; and almost all figures, in this case, are subject to some complicated optical alteration to which the rules of perspective have not as yet been extended. If a circle be drawn near our feet, and within that part of the ground which always appears level to us, it will always appear to be a circle, and at a very considerable distance it will appear an ellipse; but between those two situations, it will not appear to be either the one or the other, but will be like one of those ovals of Descartes, which is more curved on one of its sides than the other.

On these principles a parterre, which appears distorted when it is seen in a low situation, appears perfectly regular when it is viewed from a balcony or any other eminence. Still, however, the apparent irregularity takes place at a greater distance, while the part that is near the spectator is exempt from it. If AB, fig. 5. be the ground plane, and Aa be a perpendicular, under the eye, the higher it is situated, at O, to the greater distance will T, the place at which the plane begins to have an apparent ascent along  $Tb$ , be removed.

All the varieties that can occur with respect to the visible motion of objects, are succinctly summed up by Dr Porterfield under 11 heads, with which we shall present our readers.

1. An object moving very swiftly is not seen, unless it be very luminous. Thus a cannon-ball is not seen if it is viewed transversely: but if it be viewed according to the line it describes, it may be seen, because its picture continues long on the same place of the retina; which, therefore, receives a more sensible impression from the object.

2. A live coal swung briskly round in a circle appears a continued circle of fire, because the impressions made on the retina by light, being of a vibrating, and consequently of a lasting nature, do not presently perish, but continue till the coal performs its whole circuit, and returns again to its former place.

3. If two objects, unequally distant from the eye, move with equal velocity, the more remote one will appear the slower; or, if their celerities be proportional to their distances, they will appear equally swift.

4. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal

Apparent  
place, &c.  
of objects.

Apparent  
place, &c.  
of objects.

procal one of their distances from the eye.

5. A visible object moving with any velocity appears to be at rest, if the space described in the interval of one second be imperceptible at the distance of the eye. Hence it is that a near object moving very slowly, as the index of a clock, or a remote one very swiftly, as a planet, seems to be at rest.

6. An object moving with any degree of velocity will appear at rest, if the space it runs over in a second of time be to its distance from the eye as 1 to 1400.

7. The eye proceeding straight from one place to another, a lateral object, not too far off, whether on the right or left, will seem to move the contrary way.

8. The eye proceeding straight from one place to another, and being sensible of its motion, distant objects will seem to move the same way, and with the same velocity. Thus, to a person running eastwards, the moon on his right hand appears to move the same way, and with equal swiftness; for, by reason of its distance, its image continues fixed upon the same place of the retina, from whence we imagine that the object moves along with the eye.

9. If the eye and the object move both the same way, only the eye much swifter than the object, the last will appear to go backwards.

10. If two or more objects move with the same velocity, and a third remain at rest, the moveable ones will appear fixed, and the quiescent in motion, the contrary way. Thus clouds moving very swiftly, their parts seem to preserve their situation, and the moon to move the contrary way.

11. If the eye be moved with great velocity, lateral objects at rest appear to move the contrary way. Thus to a person sitting in a coach, and riding briskly through a wood, the trees seem to retire the contrary way; and to people in a ship, &c. the shores seem to recede.

At the conclusion of these observations, our author endeavours to explain another phenomenon of motion, which, though very common and well known, had not, as far as he knew, been explained in a satisfactory manner. It is this: If a person turns swiftly round, without changing his place, all objects about will seem to move round in a circle the contrary way; and this deception continues not only while the person himself moves round, but, which is more surprising, it also continues for some time after he ceases to move, when the eye; as well as the object, is at absolute rest.

The reason why objects appear to move round the contrary way, when the eye turns round, is not so difficult to explain: for though, properly speaking, motion is not seen, as not being in itself the immediate object of sight; yet by the sight we easily know when the image changes its place on the retina, and thence conclude that either the object, the eye, or both, are moved. But by the sight alone we can never determine how far this motion belongs to the object, how far to the eye, or how far to both. If we imagine the eye at rest, we ascribe the whole motion to the object, though it be truly at rest. If we imagine the object at rest, we ascribe the whole motion to the eye, though it belongs entirely to the object; and when the eye is in motion, though we are sensible of its

motion, yet, if we do not imagine that it moves so swiftly as it really does, we ascribe only a part of the motion to the eye, and the rest of it we ascribe to the object, though it be truly at rest. This last, he says, is what happens in the present case, when the eye turns round; for though we are sensible of the motion of the eye, yet we do not apprehend that it moves so fast as it really does; and therefore the bodies about appear to move the contrary way, as is agreeable to experience.

But the great difficulty still remains, viz. Why, after the eye ceases to move, objects should, for some time, still appear to continue in motion, though their pictures on the retina be truly at rest, and do not at all change their place. This, he imagined, proceeds from a mistake we are in with respect to the eye, which, though it be absolutely at rest, we nevertheless conceive it as moving the contrary way to that in which it moved before; from which mistake, with respect to the motion of the eye, the objects at rest will appear to move the same way which the eye is imagined to move; and, consequently, will seem to continue their motion for some time after the eye is at rest.

M. Le Cat well explains a remarkable deception, by which a person shall imagine an object to be on the opposite side of a board, when it is not so, and also inverted, and magnified. It is illustrated by fig. 3. in which D represents the eye, and CB a large black board, pierced with a small hole. E is a large white board, placed beyond it, and strongly illuminated; and *d* a pin, or other small object, held betwixt the eye and the first board. In these circumstances, the pin shall be imagined to be at *F*, on the other side of the board, where it will appear inverted, and magnified; because what is in fact perceived, is the shadow of the pin upon the retina; and the light that is stopped by the upper part of the pin coming from the lower part of the enlightened board, and that which is stopped by the lower part coming from the upper part of the board, the shadow must necessarily be inverted with respect to the object.

There is a curious phenomenon relating to vision, which some persons have ascribed to the inflection of light, but which Mr Melville explains in a very different and very simple manner.

When any opaque body is held at the distance of three or four inches from the eye, so that a part of some more distant luminous object, such as the window, or the flame of a candle, may be seen by rays passing near its edge, if another opaque body, nearer to the eye, be brought across from the opposite side, the edge of the first body will seem to swell outwards, and meet the latter; and in doing so will intercept a portion of the luminous object that was seen before.

This appearance he explains in the following manner: Let AB, fig. 1. represent the luminous object, to which the light is directed, CD the more distant opaque body, GH the nearer, and EF the diameter of the pupil. Join ED, FD, EG, FG, and produce them till they meet AB in K, N, M, and L. It is plain that the parts AN, MB, of the luminous object cannot be seen. But taking any point *a* between N and K, and drawing *aDd*, since the portion *dF* of the

Concavity  
of the Sky.

the pupil is filled with light flowing from that point, it must be visible. Any point *b*, between *a* and *K*, must fill *fF*, a greater portion of the pupil, and therefore must appear brighter. Again, any point *c*, between *b* and *K*, must appear brighter than *b*, because it fills a greater portion *gF* with light. The point *K* itself, and every other point in the space *KL*, must appear very luminous, since they fend entire pencils of rays *EKF*, *ELF*, to the eye; and the visible brightness of every point from *L* towards *M*, must decrease gradually, as from *K* to *N*; that is, the spaces *KN*, *LM*, will appear as dim shadowy borders, or fringes, adjacent to the edges of the opaque bodies.

When the edge *G* is brought to touch the right line *KF*, the penumbras unite; and as soon as it reaches *NDF*, the above phenomenon begins; for it cannot pass that right line without meeting some line *aDd*, drawn from a point between *N* and *K*, and, by intercepting all the rays that fall upon the pupil, render it invisible. In advancing gradually to the line *KDE*, it will meet other lines *bDf*, *cDg*, &c. and therefore render the points *b*, *c*, &c. from *N* to *K*, successively invisible; and therefore the edge of the fixed opaque body *CD* must seem to swell outwards, and cover the whole space *NK*; while *GH*, by its motion, covers *MK*. When *GH* is placed at a greater distance from the eye, *CD* continuing fixed, the space *OP* to be passed over in order to intercept *NK* is less; and therefore, with an equal motion of *GH*, the apparent swelling of *CD* must be quicker; which is found true by experience.

If *ML* represent a luminous object, and *REFQ* any plane exposed to its light, the space *FQ* will be entirely shaded from the rays, and the space *FE* will be occupied by a penumbra, gradually darker, from *E* to *F*. Let now *GH* continue fixed, and *CD* move parallel to the plane *EF*; and as soon as it passes the line *LF*, it is evident that the shadow *QF* will seem to swell outwards; and when *CD* reaches *ME*, so as to cover with its shadow the space *RE*, *QF*, by its extension, will cover *FE*. This is found to hold true likewise by experiment.

#### § 4. Of the Concave Figure of the Sky.

This apparent concavity is only an optical deception founded on the incapacity of our organs of vision to take in very large distances.—Dr Smith, in his Complete System of Optics, hath demonstrated, that, if the surface of the earth was perfectly plane, the distance of the visible horizon from the eye would scarce exceed the distance of 5000 times the height of the eye above the ground, supposing the height of the eye between five and six feet: beyond this distance, all objects would appear in the visible horizon. For, let *OP* be the height of the eye above the line *PA* drawn upon the ground; and if an object *AB*, equal in height to *PO*, be removed to a distance *PA* equal to 5000 times that height, it will hardly be visible by reason of the smallness of the angle *AOB*. Consequently any distance *AC*, how great soever, beyond *A*, will be invisible. For since *AC* and *BO* are parallel, the ray *CO* will always cut *AB* in some point *D* between *A* and *B*; and therefore the angle *AOC*, or *AOD*, will always be less than *AOB*, and

therefore *AD* or *AC* will be invisible. Consequently all objects and clouds, as *CE* and *FG*, placed at all distances beyond *A*, if they be high enough to be visible, or to subtend a bigger angle at the eye than *AOB*, will appear at the horizon *AB*; because the distance *AC* is invisible.

Hence, if we suppose a vast long row of objects, or a vast long wall *ABZy*, built upon this plane, and its perpendicular distance *OA* from the eye at *O* to be equal to or greater than the distance *OA* of the visible horizon, it will not appear straight, but circular, as if it was built upon the circumference of the horizon *acgy*; and if the wall be continued to an immense distance, its extreme parts *YZ*, will appear in the horizon at *yz*, where it is cut by a line *Oy* parallel to the wall. For, supposing a ray *YO*, the angle *YOy* will become insensibly small. Imagine this infinite plane *OAYy*, with the wall upon it, to be turned about the horizontal line *O* like the lid of a box, till it becomes perpendicular to the other half of the horizontal plane *LMY*, and the wall parallel to it, like a vast ceiling over head; and then the wall will appear like the concave figure of the clouds over-head.

But though the wall in the horizon appear in the figure of a semicircle, yet the ceiling will not, but much flatter. Because the horizontal plane was a visible surface, which suggested the idea of the same distances quite round the eye: but in the vertical plane extended between the eye and the ceiling, there is nothing that affects the sense with an idea of its parts but the common line *Oy*; consequently the apparent distances of the higher parts of the ceiling will be gradually diminished in ascending from that line. Now when the sky is quite overcast with clouds of equal gravities, they will all float in the air at equal heights above the earth, and consequently will compose a surface resembling a large ceiling, as flat as the visible surface of the earth. Its concavity therefore is not real, but apparent: and when the heights of the clouds are unequal, since their real shapes and magnitudes are all unknown, the eye can seldom distinguish the unequal distances of those clouds that appear in the same directions, unless when they are very near us, or are driven by contrary currents of the air. So that the visible shape of the whole surface remains alike in both cases. And when the sky is either partly overcast, or perfectly free from clouds, it is matter of fact that we retain much the same idea of its concavity as when it was quite overcast.

The concavity of the heavens appears to the eye, which is the only judge of an apparent figure, to be a less portion of a spherical surface than a hemisphere. Dr Smith says, that the centre of the concavity is much than a hemisphere; and by taking a medium among several observations, he found the apparent distance of its parts at the horizon to be generally between three and four times greater than the apparent distance of its parts overhead. For let the arch *ABCD* represent the apparent concavity of the sky, *O* the place of the eye, *OA* and *OC* the horizontal and vertical apparent distances, whose proportion is required. First observe when the sun or the moon, or any cloud or star, is in such a position at *B*, that the apparent arches *BA*, *BC*, extended on each side of this object towards the horizon

taking the altitude of the object B with a quadrant, or a cross-staff, or finding it by astronomy from the given time of observation, the angle AOB is known. Drawing therefore the line OB in the position thus determined, and taking in it any point B at pleasure in the vertical line CO produced downwards, seek the centre E of a circle ABC, whose arches BA, BC, intercepted between B and the legs of the right angle AOC, shall be equal to each other; then will this arch ABCD represent the apparent figure of the sky. For by the eye we estimate the distance between any two objects in the heavens by the quantity of sky that appears to lie between them; as upon earth we estimate it by the quantity of ground that lies between them. The centre E may be found geometrically by constructing a cubic equation, or as quick and sufficiently exact by trying whether the chords BA, BC, of the arch ABC drawn by conjecture are equal, and by altering its radius BE till they are so. Now in making several observations upon the sun, and some others upon the moon and stars, they seemed to our author to bisect the vertical arch ABC at B, when their apparent altitudes or the angle AOB was about 23 degrees; which gives the proportion of OC to OA as 3 to 10 or as 1 to 3 $\frac{1}{3}$  nearly. When the sun was but 30 degrees high, the upper arch seemed always less than the under one; and, in our author's opinion, always greater when the sun was about 18 or 20 degrees high.

§ 5. Of the Blue Colour of the sky, and of Blue and Green Shadows.

237  
Opinions  
of the an-  
cients, &c.

THE opinions of ancient writers concerning the colour of the sky merit no notice. The first who gave any rational explanation was Fromondus. By him it was supposed, that the blueness of the sky proceeded from a mixture of the white light of the sun with the black space beyond the atmosphere, where there is neither refraction nor reflection. This opinion prevailed very generally even in modern times, and was maintained by Otto Guericke and all his contemporaries, who asserted that white and black may be mixed in such a manner as to make a blue. Mr Bouguer had recourse to the vapours diffused through the atmosphere, to account for the reflection of the blue rays rather than any other. He seems however to suppose, that it arises from the constitution of the air itself, whereby the fainter coloured rays are incapable of making their way through any considerable tract of it. Hence he is of opinion, that the colour of the air is properly blue; to which opinion Dr Smith seems also to have inclined.

238  
Green sha-  
dows ob-  
served by  
M. Buffon.

To this blue colour of the sky is owing the appearance of blue and green shadows in the mornings and evenings.—These were first taken notice of by M. Buffon in the month of July 1742, when he observed that the shadows of trees which fell upon a white wall were green. He was at that time standing upon an eminence, and the sun was setting in the cleft of a mountain, so that he appeared considerably lower than the horizon. The sky was clear, excepting in the west, which, though free from clouds, was lightly shaded with vapours, of a yellow colour, inclining to red. Then the sun itself was exceedingly red, and was

seemingly, at least, four times as large as he appears to be at mid-day. In these circumstances, he saw very distinctly the shadows of the trees, which were 30 or 40 feet from the white wall, coloured with a light green, inclining to blue. The shadow of an arbour, which was three feet from the wall, was exactly drawn upon it, and looked as if it had been newly painted with verdigrise. This appearance lasted near five minutes; after which it grew fainter, and vanished at the same time with the light of the sun.

The next morning, at sun rise, he went to observe other shadows, upon another white wall; but instead of finding them green, as he expected, he observed that they were blue, or rather of the colour of lively indigo. The sky was serene, except a slight covering of yellowish vapours in the east; and the sun arose behind a hill, so that it was elevated above his horizon. In these circumstances, the blue shadows were only visible three minutes; after which they appeared black, and in the evening of fame day he observed the green shadows exactly as before. Six days passed without his being able to repeat his observations, on account of the clouds; but the 7th day, at sun set, the shadows were not green, but of a beautiful sky-blue. He also observed, that the sky was, in a great measure, free from vapours at that time; and that the sun set behind a rock, so that it disappeared before it came to his horizon. Afterwards he often observed the shadows both at sun-rise and sun-set; but always observed them to be blue, though with a great variety of shades of that colour. He shewed this phenomenon to many of his friends, who were as much surprised at it as he himself had been; but he says that any person may see a blue shadow, if he will only hold his finger before a piece of white paper at sun-rise or sun-set.

The first person who attempted to explain this phenomenon was the Abbé Mazzei, in a memoir of the society in Berlin for the year 1752. He observed, that when an opaque body was illuminated by the moon and a candle at the same time, and the two shadows were cast upon the same white wall, that which was enlightened by the candle was reddish, and that which was enlightened by the moon was blue. But, without attending to any other circumstances, he supposed the change of colour to be occasioned by the diminution of the light; but M. Melville, and M. Bouguer, both independent of one another, seem to have hit upon the true cause of this curious appearance, and which hath been already hinted at. The former of these gentlemen, in his attempts to explain the blue colour of the sky, observes, that since it is certain that no body assumes any particular colour, but because it reflects one sort of rays more abundantly than the rest; and since it cannot be supposed that the constituent parts of pure air are gross enough to separate any colours of themselves; we must conclude with Sir Isaac Newton, that the violet and blue making rays are reflected more copiously than the rest, by the finer vapours diffused through the atmosphere, whose parts are not big enough to give them the appearance of visible opaque clouds. And he shews, that in proper circumstances, the bluish colour of the sky-light may be actually seen on bodies illuminated by it, as, he says, it is objected should always happen upon this hypothesis. For that, if on a clear cloudless day a sheet

guer's ex-  
planations.

Blue colour of white paper be exposed to the sun's beams, when any opaque body is placed upon it, the shadow which is illuminated by the sky only will appear remarkably bluish compared with the rest of the paper, which receives the sun's direct rays.

143  
M. Beguelin's explanation of the green shadows.

M. Beguelin, who has taken the most pains with this subject, observes, that as M. Buffon mentions the shadows appearing green only twice, and that at all other times they are blue, this is the colour which they regularly have, and that the blue was changed into green by some accidental circumstance. Green, he says, is only a composition of blue and yellow, so that this accidental change may have arisen from the mixture of some yellow rays in the blue shadow; and that perhaps the wall might have had that tinge, so that the blue is the only colour for which a general reason is required. And this, he says, must be derived from the colour of pure air, which always appears blue, and which always reflects that colour upon all objects without distinction; but which is too faint to be perceived when our eyes are strongly affected by the light of the sun, reflected from other objects around us.

To confirm this hypothesis, he adds some curious observations of his own, in which this appearance is agreeably diversified. Being at the village of Boucholtz in July 1764, he observed the shadows projected on the white paper of his pocket-book, when the sky was clear. At half an hour past 6 in the evening, when the sun was about four degrees high, he observed that the shadow of his finger was of a dark grey, while he held the paper opposite to the sun; but when he inclined it almost horizontally, the paper had a bluish cast, and the shadow upon it was of a beautiful bright blue.

143  
Some curious phenomena observed by him.

When his eye was placed between the sun and the paper laid horizontally, it always appeared of a bluish cast; but when he held the paper, thus inclined, between his eye and the sun, he could distinguish, upon every little eminence occasioned by the inequality of the surface of the paper, the principal of the prismatic colours. He also perceived them upon his nails, and upon the skin of his hand. This multitude of coloured points, red, yellow, green, and blue, almost effected the natural colour of the objects.

At three quarters past six, the shadows began to be blue, even when the rays of the sun fell perpendicularly. The colour was the most lively when the rays fell upon it at an angle of  $45^\circ$  degrees; but with a less inclination of the paper, he could distinctly perceive, that the blue shadow had a border of a stronger blue, on that side which looked towards the sky, and a red border on that side which was turned towards the earth. To see these borders, the body that made the shadow was obliged to be placed very near the paper; and the nearer it was, the more sensible was the red border. At the distance of three inches, the whole shadow was blue. At every observation, after having held the paper towards the sky, he turned it towards the earth, which was covered with verdure; holding it in such a manner, that the sun might shine upon it while it received the shadows of various bodies, but, in this position, he could never perceive the shadow to be blue or green at any inclination with respect to the sun's rays.

At seven o'clock, the sun being still about two de-

grees high, the shadows were of a bright blue, even when the rays fell perpendicularly upon the paper, but were the brightest when it was inclined at an angle of  $45^\circ$ . At this time he was surprised to observe, that a large tract of sky was not favourable to this blue colour, and that the shadow falling upon the paper placed horizontally was not coloured, or at least the blue was very faint. This singularity, he concluded, arose from the small difference between the light of that part of the paper which received the rays of the sun, and that which was in the shade in this situation. In a situation precisely horizontal, the difference would vanish, and there could be no shadow. Thus too much or too little of the sun's light produced, but for different reasons, the same effect; for they both made the blue light reflected from the sky to become insensible. This gentleman never saw any green shadows, but when he made them fall on yellow paper. But he does not absolutely say, that green shadows cannot be produced in any other manner; and supposes, that if it was on the same wall that M. Buffon saw the blue shadows, seven days after having seen the green ones, he thinks that the cause of it might be the mixture of yellow rays, reflected from the vapours, which he observes were of that colour.

144  
Blue shadows not confined to the 19th of July, when the sun has the greatest force, he observed them at three o'clock in the afternoon, but the sun shone through a mist at that evening's time.

If the sky is clear, the shadows begin to be blue; when, if they be projected horizontally, they are eight times as long as the height of the body that produces them, that is, when the centre of the sun is  $7^\circ 8'$  above the horizon. This observation, he says, was made in the beginning of August.

Besides these coloured shadows, which are produced by the interception of the direct rays of the sun, our author observed others similar to them at ever hour of the day, in rooms into which the light of the sun was reflected from some white body, if any part of the clear sky could be seen from the place, and all unnecessary light was excluded as much as possible. Observing these precautions, he says that the blue shadows may be seen at any hour of the day, even with the direct light of the sun; and that this colour will disappear in all those places of the shadow from which the blue sky cannot be seen.

All the observations that our author made upon the yellow or reddish borders of shadows above-mentioned, led him to conclude, that they were occasioned by the interception of the sky-light, whereby part of the shadow was illuminated either by the red rays reflected from the clouds, when the sun is near the horizon, or from some terrestrial bodies in the neighbourhood. This conjecture is favoured by the necessity he was under of placing any body near the paper, in order to produce this bordered shadow, as he says it is easily demonstrated, that the interception of the sky-light can only take place when the breadth of the opaque body is to its distance from the white ground on which the shadow falls, as twice the sine of half the amplitude of the sky to its cosine.

At the conclusion of his observations on these blue shadows, Another kind.

Irradiations  
of the Sun's  
Light, &c.

shadows, he gives a short account of another kind of them, which, he does not doubt, have the same origin. These he often saw early in the spring when he was reading by the light of a candle in the morning, and consequently the twilight mixed with that of his candle. In these circumstances, the shadow that was made by intercepting the light of his candle, at the distance of about six feet, was of a beautiful and clear blue, which became deeper as the opaque body which made the shadow was brought nearer to the wall, and was exceedingly deep at the distance of a few inches only. But wherever the day-light did not come, the shadows were all black without the least mixture of blue.

§ 6. *Of the Irradiations of the Sun's Light appearing through the interfaces of the Clouds.*

THIS is an appearance which every one must have observed when the sky was pretty much overcast with clouds at some distance from each other. At that time several large beams of light, something like the appearance of the light of the sun admitted into a smoky room, will be seen, generally with a very considerable degree of divergence, as if the radiant point was situated at no great distance above the clouds. Dr Smith observes, that this appearance is one of those which serve to demonstrate that very high and remote objects in the heavens do not appear to us in their real shapes and positions, but according to their perspective projections on the apparent concavity of the sky. He acquaints us, that though these beams are generally seen diverging, as represented in fig. 7. it is not always the case. He himself, in particular, once saw them converging towards a point diametrically opposite to the sun: for, as near as he could conjecture, the point to which they converged was situated as much below the horizon, as the sun was then elevated above the opposite part of it. This part is represented by the line  $ED$ , and the point below it in opposition to the sun is  $E$ ; towards which all the beams  $vt$ ,  $vt$ , &c. appeared to converge.

"Observing, (says our author,) that the point of convergence was opposite to the sun, I began to suspect that this unusual phenomenon was but a case of the usual apparent divergence of the beams of the sun from his apparent place among the clouds, as represented in fig. 7. I say, an apparent divergence; for though nothing is more common than for rays to diverge from a luminous body, yet the divergence of these beams in such large angles is not real but apparent. Because it is impossible for the direct rays of the sun to cross one another at any point of the apparent concavity of the sky, in a greater angle than about half a degree. For the diameter of the earth being so extremely small, in comparison to the distance of the sun, as to subtend an angle at any point of his body of but 20 or 22 seconds at most; and the diameter of our visible horizon being extremely smaller than that of the earth; it is plain, that all the rays which fall upon the horizon, from any given point of the sun, must be inclined to each other in the smallest angles imaginable; the greatest of them being as much smaller than that angle of 22 seconds, as the diameter of the visible horizon is smaller than that of the earth. All the rays that come to us from any given point of the sun may therefore be considered

as parallel to each other; as the rays  $eBg$  from the point  $e$ , or  $fBh$  from the opposite point  $f$ ; and consequently the rays of these two pencils that come from opposite points of the sun's real diameter, and cross each other in the sun's apparent place  $B$  among the clouds, can constitute no greater an angle with each other than about half a degree; this angle of their intersection  $eBf$  being the same as the sun would appear under to an eye placed among the clouds at  $B$ , or (which is much the same), to an eye at  $O$  upon the ground. Because the sun's real distance  $OS$  is inconceivably greater than his apparent distance  $OB$ . Therefore the rays of the sun, as  $Bg$ ,  $Bh$ , do really diverge from his apparent place  $B$  in no greater angles  $gBh$  than about half a degree. Nevertheless they appear to diverge from the place  $B$  in all possible angles, and even in opposite directions. Let us proceed then to an explanation of this apparent divergence, which is not self-evident by any means; though at first sight we are apt to think it is, by not distinguishing the vast difference between the true and apparent distances of the sun.

"What I am going to demonstrate is this. Supposing all the rays of the sun to fall accurately parallel to each other upon the visible horizon, as they do very nearly, yet in both cases they must appear to diverge in all possible angles. Let us imagine the heavens to be partly overcast with a spacious bed of broken clouds,  $v$ ,  $v$ , &c. lying parallel to the plane of the visible horizon, here represented by the line  $AOD$ . And when the sun's rays fall upon these clouds in the parallel lines  $sv$ ,  $sv$ , &c. let some of them pass through their intervals in the lines  $vt$ ,  $vt$ , &c. and fall upon the plane of the horizon at the places  $t$ ,  $t$ , &c. And since the rest of the incident rays  $sv$ ,  $sv$ , are supposed to be intercepted from the place of the spectator at  $O$  by the cloud  $x$ , and from the intervals between the transmitted rays  $vt$ ,  $vt$ , &c. by the clouds  $v$ ,  $v$ , &c. a small part of these latter rays  $vt$ ,  $vt$ , when reflected every way from some certain kind of thin vapours floating in the air, may undoubtedly be sufficient to affect the eye with an appearance of lights and shades, in the form of bright beams in the places  $vt$ ,  $vt$ , &c. and of dark ones in the intervals between them: just as the like beams of light and shade appear in a room by reflections of the sun's rays from a smoky or dusty air within it: the lights and shades being here occasioned by the transmission of the rays through some parts of the window, and by their interruption at other parts.

"Now if the apparent concavity of this bed of clouds  $v$ ,  $v$ , to the eye at  $O$ , be represented by the arch  $ABCD$ , and be cut in the point  $B$  by the line  $OBx$  drawn parallel to the beams  $sv$ ; it will be evident by the rules of perspective, that these long beams will not appear in their real places, but upon the concave  $ABCD$  diverging every way from the place  $B$ , where the sun himself appears, or the cloud  $x$  that covers his body, as represented separately in full view in fig. 7.

"And for the same reason, if the line  $BO$  be produced towards  $E$ , below the plane of the horizon  $AOD$ , and the eye be directed towards the region of the sky directly above  $E$ , the lower ends of the same real beams  $vt$ ,  $vt$ , will now appear upon the part  $DE$  of this concave, and will seem to converge towards the point  $E$ , situated just as much below the horizon as the opposite

posite point B is above it: which is separately represented in full view in fig. 8.

"For if the beams  $vt$ ,  $vt$ , be supposed to be visible throughout their whole lengths, and the eye be directed in a plane perpendicular to them, here represented by the line  $OF$ ; they and their intervals will appear broadest in and about this plane, because these parts of them are the nearest to the eye; and therefore their remoter parts and intervals will appear gradually narrower towards the opposite ends of the line  $BE$ . As a farther illustration of this matter, we may conceive the spectator at  $O$  to be situated upon the top of so large a descent  $OHI$  towards a remote valley  $IK$ , and the sun to be so very low, that the point  $E$ , opposite to him, may be seen above the horizon of this shady valley. In this case it is manifest, that the spectators at  $O$  would now see these beams converging so far as to meet each other at the point  $E$  in the sky itself.

"I do not remember to have ever seen any phenomenon of this kind by moon-light; not so much as of beams diverging from her apparent place. Probably her light is too weak after reflections from any kind of vapours, to cause a sensible appearance of lights and shades so as to form these beams. And in the unusual phenomenon I well remember, that the converging sun-beams towards the point below the horizon were not quite so bright and strong as those usually are that diverge from him; and that the sky beyond them appeared very black (several showers having passed that way), which certainly contributed to the evidence of this appearance. Hence it is probable that the thinness and weakness of the reflected rays from the vapours opposite to the sun, is the chief cause that this appearance is so very uncommon in comparison to that other of diverging beams. For as the region of the sky round about the sun, is always brighter than the opposite one; so the light of the diverging beams ought also to be brighter than that of the converging ones. For, though rays are reflected from rough unpolished bodies in all possible directions, yet it is a general observation, that more of them are reflected forwards obliquely, than are reflected more directly backwards. Besides, in the present case, the incident rays upon the opposite region to the sun, are more diminished by continual reflections from a longer tract of the atmosphere, than the incident rays upon the region next the sun.

"The common phenomenon of diverging beams, I think, is more frequent in summer than in winter, and also when the sun is lower than when higher up; probably because the lower vapours are denser and therefore more strongly reflective than the higher; because the lower sky-light is not so bright as the upper; because the air is generally quieter in the mornings and evenings than about noon-day; and lastly, because many sorts of vapours are exhaled in greater plenty in summer than in winter, from many kinds of volatile vegetables; which vapours, when the air is cooled and condensed in the mornings and evenings, may become dense enough to reflect a sensible light."

§ 7. *Of the Illumination of the Shadow of the Earth by the refraction of the Atmosphere.*

THE ancient philosophers, who knew nothing of the refractive power of the atmosphere, were very much perplexed to account for the body of the moon being

visible when totally eclipsed. At such times she generally appears of a dull red colour, like tarnished copper, or of iron almost red hot. This, they thought, was the moon's native light, by which she became visible when hid from the brighter light of the sun. Plutarch indeed, in his discourse upon the face of the moon, attributes this appearance to the light of the fixed stars reflected to us by the moon; but this must be by far too weak to produce that effect. The true cause of it is the scattered beams of the sun bent into the earth's shadow by refractions through the atmosphere in the following manner.

"Let the body of the sun, says Dr Smith, be represented by the greater circle  $ab$ , and that of the earth by the lesser one  $cd$ ; and let the lines  $ace$  and  $bde$  touch them both on their opposite sides, and meet in  $e$  beyond the earth; then the angular space  $ced$  will represent the conic figure of the earth's shadow, which would be totally deprived of the sun's rays, were none of them bent into it by the refractive power of the atmosphere. Let this power just vanish at the circle  $hi$ , concentric to the earth, so that the rays  $ah$  and  $bi$ , which touch its opposite sides, may proceed unrefracted, and meet each other at  $k$ . Then the two nearest rays to these that flow within them, from the same points  $a$  and  $b$ , being refracted inwards through the margin of the atmosphere, will cross each other at a point  $l$ , somewhat nearer to the earth than  $k$ ; and in like manner, two opposite rays next within the two last will cross each other at a point  $m$ , somewhat nearer to the earth than  $l$ , having suffered greater refractions, by passing thro' longer and denser tracts of air lying somewhat nearer to the earth. The like approach of the successive intersections  $k$ ,  $l$ ,  $m$ , is to be understood of innumerable couples of rays, till you come to the intersection  $n$  of the two innermost; which we may suppose just to touch the earth at the points  $o$  and  $p$ . It is plain then, that the space bounded by these rays  $on$ ,  $np$ , will be the only part of the earth's shadow wholly deprived of the sun's rays. Let  $fm$  represent part of the moon's orbit when it is nearest to the earth, at a time when the earth's dark shadow  $onp$  is the longest: in this case I will shew that the ratio of  $tm$  to  $tn$  is about 4 to 3; and consequently that the moon, tho' centrally eclipsed at  $m$ , may yet be visible by means of those scattered rays above-mentioned, first transmitted to the moon by refraction through the atmosphere, and from thence reflected to the earth.

"For let the incident and emergent parts  $ag$ ,  $rn$ , Fig. 2. of the ray  $agorn$ , that just touches the earth at  $o$ , be produced till they meet at  $u$ , and let  $au$  produced meet the axis  $st$  produced in  $x$ ; and joining  $u$  and  $m$ , since the refractions of an horizontal ray passing from  $o$  to  $r$ , or from  $o$  to  $g$ , would be alike and equal, the external angle  $nux$  is double the quantity of the usual refraction of an horizontal ray; and the angle  $aus$  is the apparent measure of the sun's semidiameter seen from the earth; and the angle  $ust$  is that of the earth's semidiameter  $tu$  seen from the sun (called his *horizontal parallax*); and lastly, the angle  $umt$  is that of the earth's semidiameter seen from the moon, (called her *horizontal parallax*); because the elevation of the point  $u$  above the earth, is too small to make a sensible error in the quantity of these angles; whose measures by astronomical tables are as follow:

The

Illumination  
of the  
Earth's  
Shadow.

Measures  
of Light.

The sun's least apparent semidiameter	= ang. $aus = 15-50$
The sun's horizontal parallax	= ang. $ust = 00-10$
<hr/>	
Their difference is	= ang. $tsu = 15-40$
Double the horizontal refraction	= ang. $nux = 67-30$
<hr/>	
Their sum is	= ang. $tnu = 83-10$
The moon's greatest horizontal parallax	= ang. $tmu = 62-10$

Therefore we have  $tm : tn :: (\text{ang. } tnu : \text{ang. } tmu :: 83-10' : 62-10' ::) 4 : 3$  in round numbers; which was to be proved. It is easy to collect from the moon's greatest horizontal parallax of  $62-10''$ , that her least distance  $tm$  is about  $55\frac{1}{2}$  semidiameters of the earth; and therefore the greatest length  $tn$  of the dark shadow, being three quarters of  $tm$ , is about  $41\frac{1}{2}$  semidiameters.

"The difference of the last mentioned angles  $tnu$ ,  $tmu$ , is  $mun=21'$ , that is, about two thirds of  $31'-40''$ , the angle which the whole diameter of the sun subtends at  $u$ . Whence it follows, that the middle point  $m$  of the moon centrally eclipsed, is illuminated by rays which come from two thirds of every diameter of the sun's disk, and pass by one side of the earth; and also by rays that come from the opposite two thirds of every one of the said diameters, and pass by the other side of the earth. This will appear by conceiving the ray  $agorn$  to be inflexible, and its middle point  $o$  to slide upon the earth, while the part  $rn$  is approaching to touch the point  $m$ ; for then the opposite part  $qa$  will trace over two thirds of the sun's diameter. The true proportion of the angles  $num$ ,  $aus$ , could not be preserved in the scheme, by reason of the sun's immense distance and magnitude with respect to the earth.

"Having drawn the line  $ata$ , is is observable, that all the incident rays, as  $aq$ ,  $ax$ , flowing from any one point of the sun to the circumference of the earth, will be collected to a focus  $a$ , whose distance  $ta$  is less than  $tm$  in the ratio of  $62$  to  $67$  nearly; and thus an image of the sun will be formed at  $a\beta$ , whose rays will diverge upon the moon. For the angle  $t\alpha u$  is the difference of the angles  $xu\alpha$ ,  $ust$  found above; and  $t\alpha : tm :: \text{ang. } tnu : \text{ang. } tau :: 62-10' : 67-30''$ .

"The rays that flow next above  $aq$  and  $ax$ , by passing through a thinner part of the atmosphere, will be united at a point in the axis  $ata$  somewhat farther from the earth than the last focus  $a\beta$  and the same may be said of the rays that pass next above these, and so on; whereby an infinite series of images of the sun will be formed, whose diameters and degrees of brightness will increase with their distances from the earth.

"Hence it is manifest why the moon eclipsed in her perigee is observed to appear always duller and darker than in her apogee. The reason why her colour is always of the copper kind between a dull red and orange, I take to be this. The blue colour of a clear sky shews manifestly that the blue-making rays are more copiously reflected from pure air than those of any other colours; consequently they are less copiously transmitted through it among the rest that come from the sun, and so much the less as the tract of air thro' which they pass is the longer. Hence the common colour of the sun and moon is whitest in the meridian, and grows gradually more inclined to diluted yellow,

orange, and red, as they descend lower, that is, as the rays are transmitted through a longer tract of air; which tract being still lengthened in passing to the moon and back again, causes a still greater loss of the blue-making rays in proportion to the rest; and so the resulting colour of the transmitted rays must lie between a dark orange and red, according to Sir Isaac Newton's rule for finding the result of a mixture of colours. We have an instance of the reverse of this case in leaf-gold, which appears yellow by reflected, and blue by transmitted rays. The circular edge of the shadow in a partial eclipse appears red; because the red-making rays are the least refracted of all others, and consequently are left alone in the conical surface of the shadow, all the rest being refracted into it.

### § 8. Of the Measures of Light.

THAT some luminous bodies give a stronger, and others a weaker light, and that some reflect more light than others, was always obvious to mankind; but no person, before Mr Bouguer, hit upon a tolerable method of ascertaining the proportion that two or more lights bear to one another. The methods he most commonly used were the following.

He took two pieces of wood or pasteboard EC and CD, fig. 4. in which he made two equal holes P and Q, over which he drew pieces of oiled or white paper. Upon these holes he contrived that the light of the different bodies he was comparing should fall; while he placed a third piece of pasteboard FC, to prevent the two lights from mixing with one another. Then placing himself sometimes on one side, and sometimes on the other, but generally on the opposite side of this instrument, with respect to the lights, he altered their position till the papers in the two holes appeared to equally enlighten. This being done, he computed the proportion of their light by the squares of the distances at which the luminous bodies were placed from the objects. If, for instance, the distances were as three and nine, he concluded that the light they gave were as nine and eighty-one. Where any light was very faint, he sometimes made use of lenses, in order to condense it; and he inclosed them in tubes or not, as his particular application of them required.

To measure the intensity of light proceeding from the heavenly bodies, or reflected from any part of the sky, he contrived an instrument which resembles a kind of portable camera obscura. He had two tubes, of which the inner was black, fastened at their lower extremities by a hinge C, fig. 5. At the bottom of these tubes were two holes, R and S, three or four lines in diameter, covered with two pieces of fine white paper. The two other extremities had each of them a circular aperture, an inch in diameter; and one of the tubes consisted of two, one of them sliding into the

Measures of  
Light.

the other, which produced the same effect as varying the aperture at the end. When this instrument is used, the observer has his head, and the end of the instrument C, so covered, that no light can fall upon his eye, besides that which comes thro' the two holes S and R, while an assistant manages the instrument, and draws out or shortens the tube DE, as the observer directs. When the two holes appear equally illuminated, the intensity of the lights is judged to be inversely as the squares of the tubes.

In using this instrument, it is necessary that the object should subtend an angle larger than the aperture A or D, seen from the other end of the tube; for, otherwise, the lengthening of the tube has no effect. To avoid, in this case, making the instrument of an inconvenient length, or making the aperture D too narrow, he has recourse to another expedient. He constructs an instrument, represented fig. 6. consisting of two object-glasses, AE and DF, exactly equal, fixed in the ends of two tubes six or seven feet, or, in some cases, 10 or 12 feet long, and having their foci at the other ends. At the bottom of these tubes B, are two holes, three or four lines in diameter, covered with a piece of white paper; and this instrument is used exactly like the former.

If the two objects to be observed by this instrument be not equally luminous, the light that issues from them must be reduced to an equality, by diminishing the aperture of one of the object-glasses; and then the remaining surface of the two glasses will give the proportion of their lights. But for this purpose, the central parts of the glasses must be covered in the same proportion with the parts near the circumference, leaving the aperture such as is represented fig. 7. because the middle part of the glass is thicker and less transparent than the rest.

If all the objects to be observed lie nearly in the same direction, our author observes, that these two long tubes may be reduced into one, the two object-glasses being placed close together, and one eye-glass sufficing for them both. The instrument will then be the same with that of which he published an account in 1748, and which he called a *heliometer*, or *astrometer*.

Our author observes, that it is not the absolute quantity, but only the intensity of the light, that is measured by these two instruments, or the number of rays, in proportion to the surface of the luminous body; and it is of great importance that these two things be distinguished. The intensity of light may be very great, when the quantity, and its power of illuminating other bodies, may be very small, on account of the smallness of its surface; or the contrary may be the case, when the surface is large.

Having explained these methods which M. Bouguer took to measure the different proportions of light, we shall subjoin in this place a few miscellaneous examples of his application of them.

It is observable, that when a person stands in a place where there is a strong light, he cannot distinguish objects that are placed in the shade; nor can he see any thing upon going immediately into a place where there is very little light. It is plain, therefore, that the action of a strong light upon the eye, and also the impression which it leaves upon it, makes it insensible

to the effect of a weaker light. M. Bouguer had the curiosity to endeavour to ascertain the proportion between the intensities of the two lights in this case; and by throwing the light of two equal candles upon a board, he found that the shadow made by intercepting the light of one of them, could not be perceived by his eye, upon the place enlightened by the other, at little more than eight times the distance; from whence he concluded, that when one light is eight times eight, or 64 times less than another, its presence or absence will not be perceived. He allows, however, that the effect may be different on different eyes; and supposes that the boundaries in this case, with respect to different persons, may lie between 60 and 80.

Applying the two tubes of his instrument, mentioned above, to measure the intensity of the light reflected from different parts of the sky; he found, that when the sun was 25 degrees high, the light was four times stronger at the distance of eight or nine degrees from his body, than it was at 31 or 32 degrees. But what struck him the most was to find, that when the sun is 15 or 20 degrees high, the light decreases on the same parallel to the horizon to 110 or 120 degrees, and then increases again to the place exactly opposite to the sun.

The light of the sun, our author observes, is too strong, and that of the stars too weak, to determine the variation of their light at different altitudes: but as, in both cases, it must be in the same proportion with the diminution of the light of the moon in the same circumstances, he made his observations on that luminary, and found, that its light at  $19^{\circ} 16'$ , is to its light at  $66^{\circ} 11'$ , as 1681 to 2500; that is, the one is nearly two thirds of the other. He chose those particular altitudes, because they are those of the sun at the two solstices at Croix, where he then resided. When one limb of the moon touched the horizon of the sea, its light was 2000 times less than at the altitude of  $66^{\circ} 11'$ . But this proportion he acknowledges must be subject to many variations, the atmosphere near the earth varying so much in its density. From this observation he concludes, that at a medium light is diminished in the proportion of about 2500 to 1681, in traversing 7469 toises of dense air.

Lastly, our accurate philosopher applied his instrument to the different parts of the sun's disk, and found that the centre is considerably more luminous than the extremities of it. As near as he could make the observation, it was more luminous than a part of the disk  $\frac{1}{4}$ th of the semi-diameter from it, in the proportion of 28 to 35; which, as he observes, is more than in the proportion of the sines of the angles of obliquity. On the other hand, he observes, that both the primary and secondary planets are more luminous at their edges than near their centres.

The comparison of the light of the sun and moon is a subject that has frequently exercised the thoughts of philosophers; but we find nothing but random conjectures, before our author applied his accurate measures in this case. In general, the light of the moon is imagined to bear a much greater proportion to that of the sun than it really does; and not only are the imaginations of the vulgar, but those of philosophers also, imposed upon with respect to it. It was a great

Light.

surprise to M. De la Hire to find that he could not, by the help of any burning mirror, collect the beams of the moon in a sufficient quantity to produce the least sensible heat. Other philosophers have since made the like attempts with mirrors of greater power, tho' without any greater success; but this will not surprise us, when we see the result of M. Bouguer's observations on this subject.

156  
Mr Bouguer's calculation concerning the light of the moon.

In order to solve this curious problem concerning the comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day-time, and the other in the night following, when the moon was at her mean distance from the earth; and, after many trials, he concluded that the light of the sun is about 300,000 times greater than that of the moon; which is such a disproportion, that, as he observes, it can be no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning-glasses. For the largest of them will not increase the light 1000 times; which will still leave the light of the moon, in the focus of the mirror, 300 times less than the intensity of the common light of the sun.

To this account of the proportion of light which we actually receive from the moon, it cannot be displeasing to the reader, if we compare it with the quantity which would have been transmitted to us from that opaque body, if it reflected all the light it receives. Dr Smith thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as one to about 90,900, if no rays were lost at the moon.

157  
Dr Smith's calculation.

In the first place, he supposes that the moon, enlightened by the sun, is as luminous as the clouds are at a medium. He therefore supposed the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But on this Dr Priestley observes, that it is true, the light of the sun shining perpendicularly upon any surface would be equal to the light reflected from the whole hemisphere, if every part reflected all the light that fell upon it; but the light that would in fact be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere if every part of it shone directly upon the surface to be illuminated.

In his Remarks, par. 97, Dr Smith demonstrates his method of calculation in the following manner:

"Let the little circle  $cf dg$  represent the moon's body half enlightened by the sun, and the great circle  $aeb$ , a spherical shell concentric to the moon, and touching the earth;  $ab$ , any diameter of that shell perpendicular to a great circle of the moon's body, represented by its diameter  $cd$ ;  $e$  the place of the shell receiving full moon-light from the bright hemisphere  $fdg$ . Now, because the surface of the moon is rough like that of the earth, we may allow that the sun's rays, incident upon any small part of it, with any obliquity, are reflected from it every way alike, as if they were emitted. And therefore, if the segment  $df$  shone alone, the points  $a, e$ , would be equally illustrated by it; and likewise if the remaining bright segment  $dg$  shone alone, the points  $b, e$  would be equally illustrated by it. Consequently, if the light at the

point  $a$  was increased by the light at  $b$ , it would be equal to the full moon-light at  $e$ . And conceiving the same transfer to be made from every point of the hemispherical surface  $blik$  to their opposite points in the hemisphere  $kaeb$ , the former hemisphere would be left quite dark, and the latter would be uniformly illustrated with full moon-light; arising from a quantity of the sun's light, which, immediately before its incidence on the moon, would uniformly illustrate a circular plane equal to a great circle of her body, called her *disk*. Therefore the quantities of light being the same upon both surfaces, the density of the sun's incident light, is to the density of full moon-light, as that hemispherical surface  $bek$  is to the said disk; that is, as any other hemispherical surface whose centre is at the eye, to that part of it which the moon's disk appears to possess very nearly, because it subtends but a small angle at the eye: that is, as radius of the hemisphere to the versed sine of the moon's apparent semidiameter, or as 10,000,000 to  $1106\frac{2}{3}$  or as 90,400 to 1; taking the moon's mean horizontal diameter to be  $16' 7''$ .

"Strictly speaking, this rule compares moon-light at the earth with day-light at the moon; the medium of which, at her quadratures, is the same as our day-light; but is less at her full in the duplicate ratio of 365 to 366, or thereabout; that is, of the sun's distances from the earth and full moon: and therefore full-moon light would be to our day-light, as about 1 to 90,900, if no rays were lost at the moon.

"Secondly, I say that full-moon light is to any other moon light as the whole disk of the moon to the part that appears enlightened, considered upon a plane surface. For now let the earth be at  $b$ , and let  $dl$  be perpendicular to  $fg$ , and  $gm$  to  $cd$ ; then it is plain, that  $gl$  is equal to  $dm$ ; and that  $gl$  is equal to a perpendicular section of the sun's rays incident upon the arch  $dg$ , which at  $b$  appears equal to  $dm$ ; the eye being unable to distinguish the unequal distances of its parts. In like manner, conceiving the moon's surface to consist of innumerable physical circles parallel to  $cf dg$ , as represented at  $A$ , the same reason holds for every one of these circles as for  $cf dg$ . It follows then, that the bright part of the surface visible at  $b$ , when reduced to a flat as represented at  $B$ , by the crescent  $pdqmp$ , will be equal and similar to a perpendicular section of all the rays incident on that part, represented at  $C$  by the crescent  $pgqlp$ . Now the whole disk being in proportion to this crescent, as the quantities of light incident upon them; and the light falling upon every rough particle, being equally rarified in diverging to the eye at  $b$ , considered as equidistant from them all; it follows, that full moon-light is to this moon-light as the whole disk  $pdqc$  to the crescent  $pdqmp$ .

"Therefore, by compounding this ratio with that in the former remark, day light is to moon-light as the surface of an hemisphere whose centre is at the eye, to the part of that surface which appears to be possessed by the enlightened part of the moon.

Mr Michell made his computation in a much more simple and easy manner, and in which there is much less danger of falling into any mistake. Considering the distance of the moon from the sun, and that the density

Plate  
CCXV.  
fig. 8.

158  
Mr Michell's calculation.

density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light, at that distance, in proportion to its density at the surface of the sun; and in this manner he found, that if the moon reflected all the light it receives from the sun, it would only be the 45,000th part of the light we receive from the greater luminary. Admitting, therefore, that moon light is only a 300,000th part of the light of the sun, Mr Michell concludes, that it reflects no more than between the 6th and 7th part of what falls upon it.

## SECT. IV. Of Optical Instruments.

### § 1. The Multiplying-glass.

Plate CCXVI.

THE multiplying-glass is made by grinding down the round side *btk* (fig. 1.) of a convex glass AB, into several flat surfaces, as *bb*, *bld*, *dk*. An object C will not appear magnified when seen through this glass by the eye at H; but it will appear multiplied into as many different objects as the glass contains plane surfaces. For, since rays will flow from the object C to all parts of the glass, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray *g/H*, falling perpendicularly on the middle surface, will go through the glass to the eye without suffering any refraction; and will therefore shew the object in its true place at C: whilst a ray *ab* flowing from the same object, and falling obliquely on the plane surface *bb*, will be refracted in the direction *be*, by passing through the glass; and, upon leaving it, will go on to the eye in the direction *eH*; which will cause the same object C to appear also at E, in the direction of the ray *He*, produced in the right line *Hen*. And the ray *cd*, flowing from the object C, and falling obliquely on the plane surface *dk*, will be refracted (by passing through the glass, and leaving it at *f*) to the eye at H; which will cause the same object to appear at D, in the direction *Hfsm*.—If the glass be turned round the line *g/H*, as an axis, the object C will keep its place, because the surface *bld* is not removed; but all the other objects will seem to go round C, because the oblique planes, on which the rays *abcd* fall, will go round by the turning of the glass.

### § 2. Mirrors.

1. *The Plane Mirror, or common Looking-glass.* The image of any object that is placed before a plane mirror, appears as big to the eye as the object itself; and is erect, distinct, and seemingly as far behind the mirror, as the object is before it; and that part of the mirror which reflects the image of the object to the eye (the eye being supposed equally distant from the glass with the object) is just half as long and half as broad as the object itself. Let AB (fig. 3.) be an object placed before the reflecting surface *ghi* of the plane mirror CD; and let the eye be at *o*. Let *Ahb* be a ray of light flowing from the top A of the object and falling upon the mirror at *h*, and *hm* be a perpendicular to the surface of the mirror at *h*; the ray *Ab* will be reflected from the mirror to the eye at *o*, making an angle *mho*, equal to the angle *Ahm*: then will the

Vol. VIII.

top of the image E appear to the eye in the direction of the reflected ray *ob* produced to E, where the right line *Ape*, from the top of the object, cuts the right line *obE*, at E. Let *Bi* be a ray of light proceeding from the foot of the object at B to the mirror at *i*; and *ni* a perpendicular to the mirror from the point *i*, where the ray *Bi* falls upon it: this ray will be reflected in the line *io*, making an angle *nio*, equal the angle *Bin*, with that perpendicular, and entering the eye at *o*; then will the foot F of the image appear in the direction of the reflected ray *oi*, produced to F, where the right line *BF* cuts the reflected ray produced to F. All the other rays that flow from the intermediate points of the object AB, and fall upon the mirror between *h* and *i*, will be reflected to the eye at *o*; and all the intermediate points of the image EF will appear to the eye in the direction of these reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above *h*, will be reflected back above the eye at *o*; and all the rays that flow from the object, and fall upon the mirror below *i*, will be reflected back below the eye at *o*; so that none of the rays that fall above *h*, or below *i*, can be reflected to the eye at *o*; and the distance between *h* and *i* is equal to half the length of the object AB.

Hence it appears, that if a man sees his whole size of a image in a plane looking-glass, the part of the glass looking that reflects his image must be just half as long and half as broad as himself, let him stand at any distance from it whatever; and that his image must appear just as far behind the glass as he is before it. Thus, the man whole AB (fig 4.) viewing himself in the plane mirror CD, which is just half as long as himself, sees his whole image as at EF, behind the glass, exactly equal to his own size. For, a ray AC proceeding from his eye at A, and falling perpendicularly upon the surface of the glass at C, is reflected back to his eye, in the same line CA; and the eye of his image will appear at E, in the same line produced to E, beyond the glass. And a ray BD, flowing from his foot, and falling obliquely on the glass at D, will be reflected as obliquely on the other side of the perpendicular *a b D*, in the direction DA; and the foot of his image will appear at F, in the direction of the reflected ray AD, produced to F, where it is cut by the right line BGF, drawn parallel to the right line ACE. Just the same as if the glass were taken away, and a real man stood at F, equal in size to the man standing at B: for to his eye at A, the eye of the other man at E would be seen in the direction of the line ACE; and the foot of the man at F would be seen by the eye A, in the direction of the line ADF.

If the glass be brought nearer the man AB, as suppose to *cb*, he will see his image as at CDG: for the reflected ray CA (being perpendicular to the glass) will shew the eye of the image as at C; and the incident ray Bb, being reflected in the line *bA*, will shew the foot of his image as at G; the angle of reflection *a b A* being always equal to the angle of incidence *Bba*; and so of all the intermediate rays from A to B. Hence, if the man AB advances towards the glass CD, his image will approach towards it; and if he recedes from the glass, his image will also recede from it.

Plate CCXVI.

Of Optical Instruments

Plate CCXII.

160  
Why three or four images of objects are seen in plane mirrors.

If the object be placed before a common looking-glass, and viewed obliquely, three, four, or more images of it will appear behind the glass.

To explain this, let ABCD (fig. 11.) represent the glass; and let EF be the axis of a pencil of rays flowing from E, a point in an object situated there. The rays of this pencil will in part be reflected at F, suppose into the line FG. What remains will (after refraction at F, which we do not consider here) pass on to H; from whence (on account of the quicksilver which is spread over the second surface of glasses of this kind to prevent any of the rays from being transmitted there) they will be strongly reflected to K, where part of them will emerge and enter an eye at L. By this means one representation of the said point will be formed in the line LK produced, suppose in M: Again, another pencil, whose axis is EN, first reflected at N, then at O, and afterwards at P, will form a second representation of the same point at Q: And thirdly, another pencil, whose axis is ER, after reflection at the several points R, S, H, T, V, successively, will exhibit a third representation of the same point at X; and so on *in infinitum*. The same being true of each point in the object, the whole will be represented in the like manner; but the representations will be faint, in proportion to the number of reflections the rays suffer, and the length of their progress within the glass. We may add to these another representation of the same object in the line LO produced, made by such of the rays as fall upon O, and are from thence reflected to the eye at L.

This experiment may be tried by placing a candle before the glass as at E, and viewing it obliquely, as from L.

2. *Of Concave and Convex Mirrors.* The effects of these in magnifying and diminishing objects have been already in general explained; but for the better understanding the nature of reflecting telescopes, it will still be proper to subjoin the following particular description of the effects of concave ones.

When parallel rays, (fig. 2.) as *dfa*, *Cmb*, *elc*, fall upon a concave mirror AB (which is not transparent, but has only the surface *A b B* of a clear polish) they will be reflected back from that mirror, and meet in a point *m*, at half the distance of the surface of the mirror from C the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the surface of the mirror, as they fell upon it with regard to that perpendicular, but on the other side thereof. Thus, let C be the centre of concavity of the mirror *A b B*; and let the parallel rays *dfa*, *Cmb*, and *elc*, fall upon it at the points *a*, *b*, and *c*. Draw the lines *Cia*, *Cmb*, and *Cbc*, from the centre C to these points; and all these lines will be perpendicular to the surface of the mirror, because they proceed thereto like so many radii or spokes from its centre. Make the angle *Cab* equal to the angle *d a C*, and draw the line *amb*, which will be the direction of the ray *dfa*, after it is reflected from the point *a* of the mirror: so that the angle of incidence *d a C*, is equal to the angle of reflection *C a b*; the rays making equal angles with the perpendicular *Cia* on its opposite sides.

Draw also the perpendicular *Cbc* to the point *c*, where the ray *elc* touches the mirror; and having made the angle *Cci* equal to the angle *Cce*, draw the

line *cm i*, which will be the course of the ray *elc*, after it is reflected from the mirror.

The ray *Cmb* passing thro' the centre of concavity of the mirror, and falling upon it at *b*, is perpendicular to it; and is therefore reflected back from it in the same line *b m C*.

All these reflected rays meet in the point *m*; and in that point the image of the body which emits the parallel rays *d a*, *C b*, and *e c*, will be formed; which point is distant from the mirror equal to half the radius *b m C* of its concavity.

The rays which proceed from any celestial object may be esteemed parallel at the earth; and therefore the images of that object will be formed at *m*, when the reflecting surface of the concave mirror is turned directly towards the object. Hence, the focus *m* of parallel rays is not in the centre of the mirror's concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terrestrial object, are nearly parallel at the mirror: not strictly so, but come diverging to it, in separate pencils, or, as it were, bundles of rays, from each point of the side of the object next the mirror; and therefore they will not be converged to a point at the distance of half the radius of the mirror's concavity from its reflecting surface, but into separate points at a little greater distance from the mirror. And the nearer the object is to the mirror, the farther these points will be from it; and an inverted image of the object will be formed in them, which will seem to hang pendant in the air; and will be seen by an eye placed beyond it (with regard to the mirror) in all respects like the object, and as distinct as the object itself.

Let *A c B* (fig. 3.) be the reflecting surface of a mirror, whose centre of concavity is at C; and let the upright object DE be placed beyond the centre C, and send out a conical pencil of diverging rays from its upper extremity D, to every point of the concave surface of the mirror *A c B*. But to avoid confusion, we only draw three rays of that pencil, as DA, Dc, DB.

From the centre of concavity C, draw the three right lines CA, Cc, CB, touching the mirror in the same points where the foresaid rays touch it; and all these lines will be perpendicular to the surface of the mirror. Make the angle *CAd* equal to the angle DAC, and draw the right line *Ad* for the course of the reflected ray DA: make the angle *Ccd* equal to the angle DcC, and draw the right line *cd* for the course of the reflected ray Dc: make also the angle *CBd* equal to the angle DBC, and draw the right line *Bd* for the course of the reflected ray DB. All these reflected rays will meet in the point *d*, where they will form the extremity *d* of the inverted image *ed*, similar to the extremity D of the upright object DE.

If the pencil of rays E*f*, E*g*, E*h*, be also continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D, they will all meet at the point *e* by reflection, and form the extremity *e* of the image *ed*, similar to the extremity E of the object DE.

And as each intermediate point of the object, between D and E, sends out a pencil of rays in like manner,

161  
Aerial images formed by concave mirrors.

manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities *e* and *d* of the image; and so the whole image will be formed, not at *i*, half the distance of the mirror from its centre of concavity *C*; but at a greater distance, between *i* and the object *DE*; and the image will be inverted with respect to the object.

This being well understood, the reader will easily see how the image is formed by the large concave mirror of the reflecting telescope, when he comes to the description of that instrument.

When the object is more remote from the mirror than its centre of concavity *C*, the image will be less than the object, and between the object and mirror: when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object. Thus, if *DE* be the object, *ed* will be its image: For, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the lesser or greater divergency of the pencils of rays which proceed from the object: for, the less they diverge, the sooner they are converged to points by reflection; and the more they diverge, the farther they must be reflected before they meet.

If the radius of the mirror's concavity, and the distance of the object from it, be known, the distance of the image from the mirror is found by this rule: Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror's concavity, the image and object will be coincident, and equal in bulk.

If a man places himself directly before a large concave mirror, but farther from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, of a less size than himself. And if he holds out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may shake hands with his image. If he reaches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body: and if he moves his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary.

All the while a bystander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

### § 3. Microscopes.

1. *The Single Microscope* is only a very small globule of glass, or a convex lens, whose focal distance is very short. It is represented by *cd*, fig. 6. The object *ab* is placed in its focus, and the eye at the same distance on the other side; so that the rays of each pencil, flowing from every point of the object on the side next the glass, may go on parallel to the eye after passing thro' the glass; and then, by entering the eye at *C*, they will be converged to as many points on the retina, and

form a large inverted picture *AB* upon it. The magnifying power of this microscope is thus explained by Dr Smith. "A minute object *pg*, seen distinctly through a small glass *AE* by the eye put close to it appears so much greater than it would to the naked eye, placed at the least distance *qL* from whence it appears sufficiently distinct, as this latter distance *qL* is greater than the former *qE*. For having put your eye close to the glass *EA*, in order to see as much of the object as possible at one view, remove the object *pg* to and fro till it appear most distinctly, suppose at the distance *Eg*. Then conceiving the glass *AE* to be removed, and a thin plate, with a pin-hole in it, to be put in its place, the object will appear distinct, and as large as before, when seen through the glass, only so bright. And in this latter case it appears so much greater than it does to the naked eye at the distance *qL*, either with the pin-hole or without it, as the angle *pEq* is greater than the angle *pLq*, or as the latter distance *qL* is greater than the former *qE*. Since the interposition of the glass has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye. If the eye be so perfect as to see distinctly by pencils of parallel rays falling upon it, the distance *Eg*, of the object from the glass, is then the focal distance of the glass. Now, if the glass be a small round globule, of about  $\frac{1}{2}$ th of an inch diameter, its focal distance *Eg*, being three quarters of its diameter, is  $\frac{3}{4}$ th of an inch; and if *qL* be eight inches, the distance at which we usually view minute objects, this globule will magnify in the proportion of 8 to  $\frac{3}{4}$ , or of 160 to 1.

2. *The Double or Compound Microscope* (fig. 7.) consists of an object-glass *cd*, and an eye-glass *ef*. The small object *ab* is placed at a little greater distance from the glass *cd* than its principal focus; so that the pencils of rays flowing from the different points of the object, and passing through the glass, may be made to converge, and unite in as many points between *g* and *h*, where the image of the object will be formed: which image is viewed by the eye through the eye-glass *ef*. For the eye-glass being so placed, that the image *gh* may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel after going out of the eye-glass, as at *e* and *f*, till they come to the eye at *i*, where they will begin to converge by the refractive power of the humours; and after having crossed each other in the pupil, and passed through the crystalline and vitreous humours, they will be collected into points on the retina, and form the large inverted image *AB* thereon.

By this combination of lenses, the aberration of the light from the figure of the glass, which in a globular lens is of the kind abovementioned, is very considerable, is in some measure corrected. This appeared so sensibly to be the case, even to former opticians, that they very soon began to make the addition of another lens. The instrument, however, receives a considerable improvement by the addition of a third lens. For, says Mr Martin, it is not only evident from the theory of this aberration, that the image of any point is rendered less confused by refraction through two lenses,

than by an equal refraction through one; but it also follows, from the same principle, that the same point has its image still less confus'd when formed by rays refracted through three lenses, than by an equal refraction through two; and therefore a third lens added to the other two, will contribute to make the image more distinct, and consequently the instrument more complete. At the same time the field of view is amplified, and the use of the microscope rendered more agreeable, by the addition of the other lens. Thus also we may allow a somewhat larger aperture to the object-lens, and thereby increase the brightness of objects, and greatly heighten the pleasure of viewing them. For the same reason, Mr Martin has propos'd a four-glass microscope, which answers the purposes of of magnifying and of distinct vision still more perfectly.

Plate  
CCXVIII.  
fig. 7.

The magnifying power of double microscopes is easily understood, thus: The glass *L* next the object *PQ* is very small, and very much convex, and consequently its focal distance *LF* is very short; the distance *LQ* of the small object *PQ* is but a little greater than *LF*: so that the image *pq* may be formed at a great distance from the glass, and consequently may be much greater than the object itself. This picture *pq* being viewed through a convex glass *AE*, whose focal distance is *qE*, appears distinct as in a telescope. Now the object appears magnified upon two accounts; first, because, if we viewed its picture *pq* with the naked eye, it would appear as much greater than the object, at the same distance, as it really is greater than the object, or as much as *Lq* is greater than *LQ*; and, secondly, because this picture appears magnified through the eye-glass as much as the least distance at which it can be seen distinctly with the naked eye, is greater than *qE*, the focal distance of the eye-glass. For example, if this latter ratio be five to one, and the former ratio of *Lq* to *LQ* be 20 to 1; then, upon both accounts, the object will appear 5 times 20, or 100 times greater than to the naked eye.

Fig. 2. represents a compound microscope with three lenses. By the middle one *GK* the pencils of rays coming from the object-glass are refracted so as to tend to a focus at *O*; but being intercepted by the proper eye-glass *DF*, they are brought together at *I*, which is nearer to that lens than its proper focus at *L*; so that the angle *DIF*, under which the object now appears, is larger than *DLF*, under which it would have appeared without this additional glass; and consequently the object is more magnified in the same proportion. Dr Hooke tells us, that, in most of his observations, he made use of a double microscope with this broad middle-glass when he wanted to see much of an object at one view, and taking it out when he would examine the small parts of an object more accurately; for the fewer refractions there are, the more bright and clear the object appears.

153  
How to preserve the distinctness of objects in different magnifiers.

In microscopical lenses whose focal distances are not much shorter than half an inch, there is no need to contract their apertures for procuring distinct vision; the pupil itself being small enough to exclude the exterior straggling rays. But in smaller lenses, where apertures are necessary, Dr Smith has demonstrated, that, to preserve the same degree of distinctness, their

apertures must be as their focal distances, and then the apparent brightness will decrease in a duplicate ratio of their focal distances: so that, by using smaller glasses, the apparent magnitude and the obscurity of the object will both increase in the same ratio. For the ratio of *PD* to *PF* being invariable, the angle *Fig. 3.* *FPD* is also invariable; and consequently the quantity of light received from the point *F* is also invariable; because the apertures of the lenses, whether smaller or larger, must all be situated at such distances from *F* as just to receive all the rays contained in a cone described by turning the angle *FPD* about the axis *PF*, neither more nor less. But the apparent magnitude of the object, or the surface of its picture upon the retina, is reciprocally as *PF* square; and consequently, the light being the same, its brightness is directly as *PF* square. By this theory it appears, that a minute object cannot be magnified to infinity by a single lens, though it were possible to make it as small as we please, without some method of increasing its light. Nevertheless, this imperfection in single microscopes is not so great as at first sight one would take it to be, or as in fact we find it; the reason may be, because the eye is capable of discerning objects tolerably well by above 20,000 different degrees of light. But though the brightness of the object were increased by throwing new light upon it, yet Huygens observes, that the power of the microscope will still be limited by the breadth of the pencils which enter the pupil; which is equal to the breadth of the aperture. For, if this breadth be less than  $\frac{1}{3}$  or  $\frac{2}{3}$  of a line, he affirms that the edges of the object will begin to appear indistinct. But by double microscopes this author has made it appear, that we may magnify objects at pleasure, provided it was possible to form their object-glasses sufficiently small.

3. *The Solar Microscope* (fig. 4.), invented by Dr<sup>plate</sup> Lieberkuhn, is constructed in the following manner. CCXVII. Having procur'd a very dark room, let a round hole be made in the window-shutter, about three inches diameter, through which the sun may cast a cylinder of rays *AA* into the room. In this hole place the end of a tube containing two convex glasses and an object, viz. 1. A convex glass *aa*, of about two inches diameter, and three inches focal distance, is to be placed in that end of the tube which is put into the hole. 2. The object *bb* being put between two glasses, which must be concave to hold it at liberty, is placed about two inches and a half from the glass *aa*. 3. A little more than a quarter of an inch from the object is placed the small convex glass *cc*, whose focal distance is a quarter of an inch. The tube may be so placed when the sun is low, that his rays *AA* may enter directly into it; but when he is high, his rays *BB* must be reflected into it by the mirror *CC*. Things being thus prepared, the rays that enter the tube will be conveyed by the glass *aa* towards the object *bb*, by which means it will be strongly illuminated, and the rays *dc*, which flow from it through the convex lens *cc*, will make a large inverted picture of the object at *DD*, which, being received on a white paper, will represent the object magnified in length, in the proportion of the distance of the picture from the glass *cc* to the distance of the object from the same glass. Thus, suppose the distance of the object from the glass to be

Of Optical Instruments

Of Optical Instruments

$\frac{1}{10}$  of an inch, and the distance of the distinct picture to be 12 feet or 144 inches, in which there are 1440 tenth parts of an inch; this number divided by 3 gives 380; which is the number of times that the picture is longer or broader than the object; and the length multiplied by the breadth, shews how many times the whole surface is magnified.

164  
Mr Martin's method of increasing the light on any object. Plate CCXVIII. fig. 4.

Mr Martin proposes the following method of increasing the light upon objects without heating them too much. Let AB be the frame or plate of the microscope; CD the hole in the middle, into which the tube is screwed on one side, and the illuminating glass is on the other: the size of this illuminator is commonly  $\frac{1}{2}$  inch diameter; but that not giving sufficient light, we suppose it removed, and another much larger lens GH placed at the end of the reflector (or looking-glass) EF, moveable upon a foot at F. We may suppose this glass GH to be from three to six inches diameter; and therefore, in our example, let it be a lens of 4 inches diameter, and its focal distance 12 inches.

Then the looking-glass EF being properly adjusted, and the lens GH so posited as to receive the rays of the sun *a, b, c*, in a perpendicular direction, they will be refracted through it, tending towards a focus in the axis IL at 12 inches from the lens. But this cone of rays falling upon the glass EF, between K and L, will, by it, be reflected to a focus O in the reflected axis Lg, which is parallel to the horizon.

Now the focus O of any lens being the image of the sun, will of course be a circle; and in the present case of a lens 12 inches focal distance, this circle will be extremely near  $\frac{1}{20}$  of an inch diameter, by allowing 30' for the diameter of the sun. Hence the vertex N of the cone will be  $\frac{1}{10}$  of an inch beyond the focus O. Therefore the diameter of the section of the cone  $\frac{1}{10}$  within the focus, will be  $\frac{1}{10}$  of an inch; at  $\frac{1}{5}$  within the focus, the section will be  $\frac{1}{5}$ ; at  $\frac{1}{2}$  from the focus, the section will be  $\frac{1}{2}$ ; and at  $1\frac{1}{2}$  from the focus, the section will be  $\frac{1}{2}$ , or half an inch in diameter.

Therefore at  $\frac{1}{10}$  of an inch from the focus the section of the cone will be also  $\frac{1}{10}$  of an inch in diameter; and it is found by experience that nearer the focus O no objects can be placed. Therefore the first inch and quarter of the radius cone may be applied for all the various powers of magnifying microscopic objects; and from thence, through the next inch, the megascope may be applied in the greatest perfection.

Let Z be the centre of the hole CD in the frame, then ZO will be about  $5\frac{1}{2}$  of the 12 inches, and consequently long enough for a movement of the microscope and megascope through the 2 inches just mentioned. Hence it will appear, that in this construction of the solar microscope, a much less apparatus of tube-work will be necessary than in the common sort, where DOC makes all the cone, and the length Zg is 7 or 8 inches.

If we put the diameter of the common illuminator CD = 1.5, and the diameter of the lens GH = 3, then, in the same section RS of the cone produced by each lens separately, we have the intensity of light as CD<sup>2</sup> to GH<sup>2</sup>, that is, as 2.25 to 9, or as 1 to 4. If GH = 4, then the ratio of the increase of light will be that of 2.25 to 16, or as 1 to 7.1. Suppose

GH = 5; then 2, 25 : 25 : : 1 : 11 nearly. So that by this construction you may increase the light upon objects, or their images, at least seven times with ease, or ten times with very little trouble or expence.

#### § 4. Telescopes.

##### I. The REFRACTING TELESCOPE.

AFTER what has been said concerning the structure of the compound microscope, and the manner in which the rays pass through it to the eye, the nature of the common astronomical telescope will easily be understood: for it differs from the microscope only in that the object is placed at so great a distance from it, that the rays of the same pencil, flowing from thence, may be considered as falling parallel to one another upon the object-glass; and therefore the image made by that glass is looked upon as coincident with its focus of parallel rays.

1. The 6th figure will render this very plain; in Plate which AB is the object emitting the several pencils CCXVII. of rays *A d c*, *B c d*, &c. but supposed to be at so great a distance from the object-glass *e d*, that the rays of the same pencil may be considered as parallel to each other; they are therefore supposed to be collected into their respective foci at the point *m* and *p*, situated at the focal distance of the object-glass *c d*. Here they form an image *E*, and crossing each other proceed diverging to the eye-glass *h g*; which being placed at its own focal distance from the points *m* and *p*, the rays of each pencil, after passing through that glass, will become parallel among themselves; but the pencils themselves will converge considerably with respect to one another, even so as to cross at *c*, very little farther from the glass *g h* than its focus; because, when they entered the glass, their axes were almost parallel, as coming through the object-glass at the point *A*, to whose distance the breadth of the eye-glass in a long telescope bears very small proportion. So that the place of the eye will be nearly at the focal distance of the eye-glass, and the rays of each respective pencil being parallel among themselves, and their axes crossing each other in a larger angle than they would do if the object were to be seen by the naked eye, vision will be distinct, and the object will appear magnified.

The power of magnifying in this telescope is as the focal length of the object-glass to the focal length of the eye-glass.

DEM. In order to prove this, we may consider the angle *A k B* as that under which the object would be seen by the naked eye; for in considering the distance of the object, the length of the telescope may be omitted, as bearing no proportion to it. Now the angle under which the object is seen by means of the telescope, is *g e h*, which is to the other *A k B*, or its equal *g k h*, as the distance from the centre of the object-glass to that of the eye-glass. The angle, therefore, under which an object appears to an eye assisted by a telescope of this kind, is to that under which it would be seen without it, as the focal length of the object-glass to the focal length of the eye-glass.

It is evident from the figure, that the visible area, or space which can be seen at one view when we look through this telescope, depends on the breadth of the eye-glass, and not of the object-glass; for if the eye-glass be too small to receive the rays *g m*, *p h*, the extremities

tremities of the object could not have been seen at all: a larger breadth of the object-glass conduces only to the rendering each point of the image more luminous by receiving a larger pencil of rays from each point of the object.

It is in this telescope as in the compound microscope, where we see, when we look through it, not the object itself, but only an image of it at CED: now that image being inverted with respect to the object, as it is, because the axes of the pencils that flow from the object cross each other at  $k$ , objects seen through a telescope of this kind necessarily appear inverted.

This is a circumstance not at all regarded by astronomers: but for viewing objects upon the earth, it is convenient that the telescope should represent them in their natural posture; to which use the telescope with three eye-glasses, as represented fig. 7. is peculiarly adapted, and the progress of the rays through it from the object to the eye is as follows:

AB is the object sending out the several pencils  $Acd$ ,  $Bcd$ , &c. which passing through the object-glass  $cd$ , are collected into their respective foci in CD, where they form an inverted image. From hence they proceed to the first eye-glass  $ef$ , whose focus being at  $l$ , the rays of each pencil are rendered parallel among themselves, and their axes, which were nearly parallel before, are made to converge and cross each other: the second eye-glass  $gh$ , being so placed that its focus shall fall upon  $m$ , renders the axis of the pencils which diverge from thence parallel, and causes the rays of each which were parallel among themselves to meet again at its focus EF on the other side, where they form a second image inverted with respect to the former, but erect with respect to the object. Now this image being seen by the eye at  $ab$  through the eye-glass  $ik$ , affords a direct representation of the object, and under the same angle that the first image CD would have appeared, had the eye been placed at  $l$ , supposing the eye-glasses to be of equal convexity; and therefore the object is seen equally magnified in this as in the former telescope, that is, as the focal distance of the object-glass to that of any one of the eye-glasses, and appears erect.

If a telescope exceeds 20 feet, it is of no use in viewing objects upon the surface of the earth; for if it magnifies above 90 or 100 times, as those of that length usually do, the vapours, which continually float near the earth in great plenty, will be so magnified as to render vision obscure.

2. The Galilean Telescope with the concave eye-glass is constructed as follows:

AB (fig. 5.) is an object sending forth the pencils of rays  $gh$ ,  $ik$ , &c. which, after passing through the object-glass  $cd$ , tend towards  $eF$  (where we will suppose the focus of it to be), in order to form an inverted image there as before; but in their way to it are made to pass through the concave glass  $no$ , so pla-

ced that its focus may fall upon E, and [consequently] the rays of the several pencils which were converging towards those respective focal points  $e$ ,  $E$ ,  $f$ , will be rendered parallel among themselves; but the axes of those pencils crossing each other at F, and diverging from thence, will be rendered more diverging, as represented in the figure. Now these rays entering the pupil of an eye, will form a large and distinct image  $ab$  upon the retina, which will be inverted with respect to the object, because the axes of the pencils cross in F; and the angle the object will appear under will be equal to that which the lines  $aF$ ,  $bF$ , produced back through the eye-glass, form at F.

It is evident, that the less the pupil of the eye is, the less is the visible area seen through a telescope of this kind; for a less pupil would exclude such pencils as proceed from the extremities of the object AB, as is evident from the figure. This is an inconvenience that renders this telescope unfit for many uses; and is only to be remedied by the telescope with the convex eye-glasses, where the rays which form the extreme parts of the image are brought together in order to enter the pupil of the eye, as explained above.

It is apparent also, that the nearer the eye is placed to the eye-glass of this telescope, the larger is the area seen through it; for, being placed close to the glass, as in the figure, it admits rays that come from A and B, the extremities of the object, which it could not if it was placed farther off.

The degree of magnifying in this telescope is in the same proportion with that in the other, viz. as the focal distance of the object-glass is to the focal distance of the eye-glass.

For there is no other difference but this, viz. that as the extreme pencils in that telescope were made to converge and form the angle  $geb$  (fig. 6.), or  $ink$  (fig. 7.), these are now made to diverge and form the angle  $aFb$  (fig. 5.); which angles, if the concave glass in one has an equal refractive power with the convex one in the other, will be equal, and therefore each kind will exhibit the object magnified in the same degree.

There is a defect in all these kinds of telescopes, not to be remedied in a single lens by any means whatever, which was \*thought only to arise from hence, viz. that spherical glasses do not collect rays to one and the same point. But it was happily discovered by Sir Isaac Newton, that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears almost no proportion to that which is owing to the different refrangibility of light. This diversity in the refraction of rays is about a 28th part of the whole; so that the object-glass of a telescope cannot collect the rays which flow from any one point in the object into a less room than the circular space whose diameter is about the 56th part of the breadth of the glass (A). Therefore, since each

(A) To shew this, let AB, fig. 1. represent a convex lens, and let CDF be a pencil of rays flowing from the point D: let H be the point at which the least refrangible rays are collected to a focus; and I, that where the most refrangible concur. Then, if IH be the 28th part of EH, IK will be a proportionable part of EC (the triangles HIK and HEC being similar): consequently LK will be the 28th part of FC. But MN will be the least space into which the rays will be collected, as appears by their progress represented in the figure. Now MN is but about half of KL; and therefore it is about the 56th part of CF: so that the diameter of the space, into which the rays are collected, will be about the 56th part of the breadth of that part of the glass thro' which the rays pass. Which was to be shewn.

each point of the object will be represented in so large a space, and the centres of those spaces will be contiguous, because the points in the object the rays flow from are so; it is evident, that the image of an object made by such a glass must be a most confused representation, though it does not appear so when viewed through an eye-glass that magnifies in a moderate degree; consequently the degree of magnifying in the eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible.

Notwithstanding this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for the greater the focal distance of the object-glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object-glass, without rendering the image obscure. Thus, an object-glass, whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little more than an inch, and consequently will magnify almost 48 times: but an object-glass of 40 foot focus will admit of an eye-glass of only four-inch focus, and will therefore magnify 120 times; and an object-glass of 100 foot focus will admit of an eye-glass of little more than six-inch focus, and will therefore magnify almost 200 times.

The reason of this disproportion in their several degrees of magnifying is to be explained in the following manner. Since the diameter of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of the object-glass, it is evident that the degree of confusedness in the image is as the breadth of that glass; for the degree of confusedness will only be as the diameters or breadths of those spaces, and not as the spaces themselves. Now the focal length of the eye-glass, that is, its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confusedness sensible; and therefore it must be as the breadth or diameter of the object-glass. The diameter of the object-glass, which is as the square root of its aperture or magnitude, must be as the square-root of the power of magnifying in the telescope; for unless the aperture itself be as the power of magnifying, the image will want light: the square root of the power of magnifying will be as the square root of the focal distance of the object-glass; and therefore the focal distance of the eye-glass must be only as the square root of that of the object-glass. So that in making use of an object-glass of a longer focus, suppose, than one that is given, you are not obliged to apply an eye-glass of a proportionably longer focus than what would suit the given object-glass, but such an one only whose focal distance shall be to the focal distance of that which will suit the given object-glass, as the square root of the focal length of the object-glass you make use of, is to the square root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying in a greater degree than shorter ones, without rendering the object confused or coloured.

3. *Dollond's Telescopes.*—The general principle on which this artist's celebrated improvement of the refracting telescope depends, hath been already mentioned;

namely, that by the different powers of refraction in two kinds of glass, and by their different powers of dispersing the rays, the errors arising from the different refrangibility of the light are in a great measure, if not totally, corrected.—For this purpose the object-glasses of his telescopes are composed of three distinct lenses, two convex and one concave; of which the concave one is placed in the middle, as is represented in fig. 6. where  $a$  and  $c$  shew the two convex lenses, and  $b$  the concave one, which is by the British artists placed in the middle. The two convex ones are made of green glass, and the middle one of white flint glass, and are all ground to spheres of the same radius. When put together, they re-act the rays in the following manner. Let  $ab, ab$ , be two red rays of the sun's light falling parallel on the first green convex lens  $c$ . Supposing there was no other lens present but that one, they would then be converged into the lines  $be, be$ , and at last meet in the focus  $q$ . Let the lines  $gh, gh$ , represent two violet rays falling on the surface of the lens. These are also refracted, and will meet in a focus; but as they have a greater degree of refrangibility than the red rays, they must, of consequence, converge more by the same power of refraction in the glass, and meet sooner in a focus, suppose at  $r$ .—Let now the concave lens  $d$  be placed in such a manner as to intercept all the rays before they come to their focus. As this lens is ground to the same radius with the convex ones, it must have the same power to cause the rays diverge that the former had to make them converge; that is, supposing them both to be made of the same materials. In this case, the red rays would become parallel, and move on in the line  $oo, oo$ : But the concave lens, being made of white glass, has a greater refractive power, and therefore they diverge a little after they come out of it; and if no third lens was interposed, they would proceed diverging in the lines  $opt, opt$ ; but, by the interposition of the third lens  $ooo$ , they are again made to converge, and meet in a focus somewhat more distant than the former, as at  $x$ . By the concave lens the violet rays are also refracted, and made to diverge: but having a greater degree of refrangibility, the same power of refraction makes them diverge somewhat more than the red ones; and thus, if no third lens was interposed, they would proceed in such lines as  $lmn, lmn$ . Now as the differently coloured rays fall upon the third lens with different degrees of divergence, it is plain, that the same power of refraction in that lens will operate upon them in such a manner as to bring them all together to a focus very nearly at the same point. The red rays, it is true, require the greatest power of refraction to bring them to a focus; but they fall upon the lens with the least degree of divergence. The violet rays, though they require the least power of refraction, yet have the greatest degree of divergence; and thus all meet together at the point  $x$ , or very nearly so.

But, though we have hitherto supposed the refraction of the concave lens to be greater than that of the convex ones, it is easy to see how the errors occasioned by the first lens may be corrected by it, though it should have even a less power of refraction than the convex one. Thus, let  $a, b, a, b$ , fig. 8, be two rays of red light falling upon the convex lens  $c$ , and refracted into the focus  $q$ ; let also  $g, h, g, h$ , be two violet rays

converged into a focus at  $r$ ; it is not necessary, in order to their convergence into a common focus at  $x$ , that the concave lens should make them *diverge*: it is sufficient if the glass has a power of dispersing the violet rays somewhat more than the red ones; and many kinds of glasses have this power of dispersing some kinds of rays, without a very great power of refraction. It is better, however, to have the object-glasses composed of three lenses; because there is then another correction of the aberration by means of the third lens; and it might be impossible to find two lenses, the errors of which would exactly correct each other. It is also easy to see, that the effect may be the same whether the concave glass is a portion of the same sphere with the others or not; the effect depending upon a combination of certain circumstances, of which there is an infinite variety.

By means of this correction of the errors arising from the different refrangibility of the rays of light, it is possible to shorten dioptric magnifying powers. The reason of this is, that the errors arising from the object-glasses being removed, those which are occasioned by the eye-glasses are inconceivable: for the error is always in proportion to the length of the focus in any glass; and in very long telescopes it becomes exceedingly great, being no less than  $\frac{1}{100}$  of the whole; but in glasses of a few inches focus it becomes trifling. Refracting telescopes which go by the name of *Dollond's*, are therefore now constructed in the following manner. Let AB (fig. 1.) represent an object-glass composed of three lenses as above described, and converging the rays 1, 2, 3, 4, &c. to a very distant focus as at  $x$ . By means of the interposed lens CD, however, they are converged to one much nearer, as at  $y$ , where an image of the object is formed. The rays diverging from thence fall upon another lens EF, where the pencils are rendered parallel, and an eye placed near that lens would see the object magnified and very distinct. To enlarge the magnifying power still more, however, the pencils thus become parallel are made to fall upon another at GH; by which they are again made to converge to a distant focus: but, being intercepted by the lens IK, they are made to meet at the nearer one  $z$ ; whence diverging to LM, they are again rendered parallel, and the eye at N sees the object very distinctly.

From an inspection of the figure it is evident, that Dollond's telescope thus constructed is in fact two telescopes combined together; the first ending with the lens EF, and the second with LM. In the first we do not perceive the object itself, but the image of it formed at  $y$ ; and in the second we perceive only the image of that image formed at  $z$ . Nevertheless such telescopes are exceedingly distinct, and represent objects so clearly as to be preferred, in viewing terrestrial things, even to reflectors themselves. The latter indeed have greatly the advantage in their powers of magnifying, but they are much deficient in point of light. Much more light is lost by reflection than by refraction: and as in these telescopes the light must unavoidably suffer two reflections, a great deal of it is lost; nor is this loss counterbalanced by the greater aperture which these telescopes will bear, which enables them to receive a greater quantity of light

than the refracting ones. The metals of reflecting telescopes also are very much subject to tarnish, and require much more dexterity to clean them than the glasses of refractors; which makes them more troublesome and expensive, though for making discoveries in the celestial regions they are undoubtedly the only proper instruments.

## II. The REFLECTING TELESCOPE.

1. *Of Sir Isaac Newton's Reflecting Telescope.* The inconveniences arising from the great length of refracting telescopes are sufficiently obvious; and these, together with the difficulties arising from the different refrangibility of light, induced Sir Isaac Newton to give attention to the subject of reflection, and endeavour to realize the ideas of himself and others concerning the possibility of constructing telescopes upon this principle. The instrument he contrived is represented fig. 9. where ABCD is the tube, BC a concave reflecting metal, EF a plain reflecting metal fixed to the tube by means of the stem HI. MN represents a distant object emitting pencils of rays from each point, two only of which are here represented, and those cut off before they reach the metal, to prevent confusion in the figure. Now it is evident from what has been explained above, that these rays, were they not intercepted in their way, would return after reflection at the concave surface BC, and form an inverted image at OP, supposing that to be the place of the focus of reflected rays. But in this case the reflected rays are intercepted in their return to that place by the plain metal, and are thereby thrown sideways; and instead of forming the image OP, are made to form the image QR: which, because the rays have as yet suffered no refraction, is not liable to the imperfection which arises from the different refrangibility of the rays of light, nor to any other except what may arise from an imperfect polish, or the want of the form of one of the conic sections in the reflector BC; and therefore may be viewed by an eye at T with a very small lens or eye-glasses KL, without appearing either coloured or confused.

2. *The Gregorian telescope.* This remedies the inconvenience of the Newtonian one, by which objects are found with difficulty. This defect, indeed, was in some measure removed by having a small refracting telescope with two hairs, or wires, running thro' the tube in the common focus of the two glasses, and crossing each other at right angles; and the object being first viewed through this small telescope was afterwards easily found by the reflector. But the inconvenience is more effectually remedied by the following construction.

At the bottom of the great tube TTTT (fig. 8.) is placed the large concave mirror DUVF, whose principal focus is at  $m$ ; and in its middle is a round hole P, opposite to which is placed the small mirror L, concave toward the great one; and so fixed to a strong wire M, that it may be moved farther from the great mirror, or nearer to it, by means of a long screw on the outside of the tube, keeping its axis still in the same line Pmn with that of the great one. Now, since in viewing a very remote object, we can scarce see a point of it but what is at least as broad as the great mirror, we may consider the rays of each pencil, which flow

Optical Instruments flow from every point of the object, to be parallel to each other, and to cover the whole reflecting surface DUVF. But to avoid confusion in the figure, we shall only draw two rays of a pencil flowing from each extremity of the object into the great tube, and trace their progress, through all their reflections and refractions, to the eye  $f$ , at the end of the small tube  $tt$ , which is joined to the great one.

Let us then suppose the object AB to be at such a distance, that the rays C may flow from its lower extremity B, and the rays E from its upper extremity A. Then the rays C falling parallel upon the great mirror at D, will be thence reflected converging, in the direction DG; and by crossing at I, in the principal focus of the mirror, they will form the upper extremity I of the inverted image IK, similar to the lower extremity B of the object AB: and passing on to the concave mirror L (whose focus is at  $n$ ) they will fall upon it at  $g$ , and be thence reflected converging, in the direction gN, because  $gm$  is longer than  $gn$ ; and passing through the hole P in the large mirror, they would meet somewhere about  $r$ , and form the lower extremity D of the erect image  $ad$ , similar to the lower extremity B of the object AB. But by passing through the plano-convex glass R in their way, they form that extremity of the image at  $b$ . In like manner, the rays E, which come from the top of the object AB, and fall parallel upon the great mirror at F, are thence reflected converging to its focus, where they form the lower extremity K of the inverted image IK, similar to the upper extremity A of the object AB; and thence passing on to the small mirror L, and falling upon it at  $h$ , they are thence reflected in the converging state  $hO$ ; and going on through the hole P of the great mirror, they would meet somewhere about  $q$ , and form there the upper extremity  $a$  of the erect image  $ad$ , similar to the upper extremity A of the object AB: but by passing through the convex glass R in their way, they meet and cross sooner, as at  $a$ , where the point of the erect image is formed. The like being understood of all those rays which flow from the intermediate points of the object between A and B, and enter the tube TT, all the intermediate points of the image between  $a$  and  $b$  will be formed; and the rays passing on from the image, through the eye-glass S, and through a small hole  $e$  in the end of the lesser tube  $tt$ , they enter the eye  $f$  (which sees the image  $ab$  by means of the eye-glass) under the large angle  $ced$ , and magnified in length under that angle from  $c$  to  $d$ .

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus  $m$  of the great one, where the first image IK is formed, but a little beyond it (with respect to the eye), as at  $n$ : the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge so as to meet in points about  $q, e, r$ ; where they would form a larger upright image than  $ab$ , if the glass R was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye: but then the field of view would be less, and consequently not so pleasant; for which reason, the glass R is still retained, to enlarge the scope or area of the field.

To find the magnifying power of this telescope, multiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glass; then divide the product of the former multiplication by the product of the latter, and the quotient will express the magnifying power.

One great advantage of the reflecting telescope is, that it will admit of an eye-glass of a much shorter focal distance than a refracting telescope will; and, consequently, it will magnify so much the more; for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by passing through a convex-glass, let it be ground ever so true.

The adjusting screw on the outside of the great tube fits this telescope to all sorts of eyes, by bringing the small mirror either nearer to the eye, or removing it farther; by which means the rays are made to diverge a little for short-sighted eyes, or to converge for those of a long sight.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; so that the first image IK will be formed at a greater distance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image must be formed farther from the small mirror than its principal focus  $n$ , this mirror must be always set at a greater distance from the large one, in viewing near objects, than in viewing remote ones. And this is done by turning the screw on the outside of the tube, until the small mirror be so adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never see the object itself, but only that image of it which is formed next the eye in the telescope. For if a man holds his finger or a stick between his bare eye and an object, it will hide part (if not the whole) of the object from his view. But if he ties a stick across the mouth of a telescope before the object-glass, it will hide no part of the imaginary object he saw through the telescope before, unless it covers the whole mouth of the tube: for all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the inside of the tube, between the eye-glass and his eye, it will hide part of the object which he thinks he sees: which proves, that he sees not the real object, but its image. This is also confirmed by means of the small mirror L, in the reflecting telescope, which is made of opaque metal, and stands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at  $e$ , if the two glasses R and S are taken out of the tube.

### § 5. Camera Obscura.

THE camera obscura is made by a convex-glass CD (fig. 2.) placed in a hole of a window-shutter. <sup>plate</sup> Then if the room be darkened, so as no light can enter. Then but what comes thro' the glass, the pictures of all the objects (as fields, trees, buildings, men, cattle,

cattle, &c.) on the outside, will be shewn in an inverted order, on a white paper placed at  $GH$  in the focus of the glass; and will afford a most beautiful and perfect piece of perspective or landscape of whatever is before the glass, especially if the sun shines upon the objects.

If the convex-glass  $CD$  be placed in a tube in the side of a square box, within which is the plane mirror  $EF$ , reclining backwards in an angle of  $45^\circ$  degrees from the perpendicular  $kg$ , the pencils of rays flowing from the outward objects, and passing thro' the convex glass to the plane mirror, will be reflected upwards from it, and meet in points, as  $I$  and  $K$  (at the same distance that they would have met at  $H$  and  $G$ , if the mirror had not been in the way,) and will form the aforesaid images on an oiled paper stretched horizontally in the direction  $IK$ : on which paper the outlines of the images may be easily drawn with a black-lead pencil; and then copied on a clean sheet, and coloured by art, as the objects themselves are by nature.—In this machine, it is usual to place a plane glass, unpolished, in the horizontal situation  $IK$ , which glass receives the images of the outward objects; and their outlines may be traced upon it by a black-lead pencil.

*N. B.* The tube in which the convex-glass  $CD$  is fixed, must be made to draw out, or push in, so as to adjust the distance of that glass from the plane mirror, in proportion to the distance of the outward objects; which the operator does, until he sees their images distinctly painted on the horizontal glass at  $IK$ .

The forming a horizontal image, as  $IK$ , of an upright object  $AB$ , depends upon the angles of incidence of the rays upon the plane mirror  $EF$ , being equal to their angles of reflection from it. For, if a perpendicular be supposed to be drawn to the surface of the plane mirror at  $e$ , where the ray  $Aac$  falls upon it, that ray will be reflected upwards in an equal angle with the other side of the perpendicular, in the line  $edI$ . Again, if a perpendicular be drawn to the mirror from the point  $f$ , where the ray  $Abf$  falls upon it, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line  $fbI$ . And if a perpendicular be drawn from the point  $g$ , where the ray  $Acg$  falls upon the mirror, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line  $giI$ . So that all the rays of the pencil  $abc$ , flowing from the upper extremity of the object  $AB$ , and passing thro' the convex glass  $CD$ , to the plane mirror  $EF$ , will be reflected from the mirror, and meet at  $I$ , where they will form the extremity  $I$  of the image  $IK$ , similar to the extremity  $A$  of the object  $AB$ . The like is to be understood of the pencil  $grs$ , flowing from the lower extremity of the object  $AB$ , and meeting at  $K$  (after reflection from the plane mirror) the rays from the extremity  $K$  of the image, similar to the extremity  $B$  of the object: and so of all the pencils that flow from the intermediate points of the object to the mirror, thro' the convex glass.

If a convex glass, of a short focal distance, be placed near the plane mirror in the end of a short tube, and a convex glass be placed in a hole in the side of the

tube, so as the image may be formed between the last-mentioned convex glass and the plane mirror; the image being viewed thro' this glass, will appear magnified.—In this manner, the *Opera-glasses* are constructed; with which a gentleman may look at any lady at a distance in the company, and the lady know nothing of it.

### § 6. Magic Lantern.

$ABCD$  (fig. 5.) is a tin lantern, with a tube  $nklm$  fixed in the side of it. This tube consists of two joints, one of which slips into the other: and by drawing this joint out, or pushing it in, the tube may be made longer or shorter. At  $kl$ , in the end of the moveable joint of the tube, a convex lens is fixed; and an object painted with transparent colours upon a piece of thin glass is placed at  $de$ , somewhere in the immovable joint of the tube; so that as the tube is lengthened or shortened, the lens will be either at a greater or a less distance from this transparent object. In the side of the lantern there is a very convex lens  $bhc$ , which serves to cast a very strong light from the candle within the lantern upon the object  $de$ . Now when the rays, which shine through the object  $de$ , diverge from the several points as  $d, e$ , &c. in the object, and fall upon the lens  $kl$ , they will be made to converge to as many points  $f, g$ , &c. on the other side of the lens, and will paint an inverted picture of the object at  $fg$  upon a white wall, a sheet, or a screen of white paper, provided the object is farther from the lens than its principal focus. To make this picture appear distinct and bright, it must have no other light fall upon it but what comes through the lens  $kl$ ; and for this reason the whole apparatus is to be placed in a dark room  $EFGH$ . The lens  $kl$  must be very convex, so that the object  $de$  may be very near to it, and yet not be nearer than its principal focus: for by this means, as the object is near to the lens, the picture  $fg$  will be at a great distance from it, and consequently the picture will be much bigger than the object. Since the picture is inverted in respect of the object, in order to make the picture appear with the right end upwards, it is necessary that the object  $de$  should be placed with the wrong end upwards.

SECT. V. *A Description of the above and other Optical Instruments, fitted with their Apparatus; with an account of the methods of applying them to the purposes for which they are intended.*

#### § 1. Camera Obscura and Magic Lantern.

See DIOPTRICS, p. 2477 to p. 2482.

#### § 2. The Graphical Perspective.

This instrument consists of two lenses  $AB$  and  $CD$ , fig. 1. which are placed at twice their focal distance Plate from one another; and in their common focus is another glass  $EF$ , divided into equal parts with the point of a diamond. Though this instrument does not magnify objects, yet the angle under which any object is seen is easily known by it; and since this angle varies with the distance of objects, it is easily applied to the purpose of measuring inaccessible heights and distances.

distances; and since the field of view is divided into equal squares, it is useful in drawing the perspective appearance of objects. As all foreign light is excluded by the tube in which these lenses are inclosed, pictures seen through this machine have a fine relieve; on which account, as also because objects appear inverted through it, the images of a camera obscura are viewed to particular advantage by its means. If a lens of a greater focal length be fixed at a proper distance from the centre of the tube, this instrument will be a telescope, and will magnify the prints which are looked at through it; and if a small lens be used, it will be a microscope, and the same micrometer will serve for both.

### § 3. Of the Single Microscope.

THE famous microscopes made use of by Mr Leuwenhoek, were all, as Mr Baker assures us, of the single kind, and the construction of them the most simple possible, each consisting only of a single lens set between two plates of silver, perforated with a small hole, with a moveable pin before it to place the object on, and adjust it to the eye of the beholder. He informs us also, that *lenses* only, and not *globules*, were used in every one of these microscopes.

The single microscope now most generally known and used is that called *Wilson's Pocket Microscope*. The body is made of brass, ivory, or silver, and is represented by AA, BB. CC is a long fine-threaded male-screw that turns into the body of the microscope. D a convex glass at the end of the screw. \*, Two concave round pieces of thin brass, with holes of different diameters in the middle of them, to cover the above-mentioned glass, and thereby diminish the aperture when the greatest magnifiers are employed. EE, three thin plates of brass within the body of the microscope; one of which is bent semicircularly in the middle, so as to form an arched cavity for the reception of a tube of glass, the use of the other two being to receive and hold the sliders between them. F, a piece of wood or ivory, arched in the manner of the semicircular plate, and cemented thereto. G, the other end of the body of the microscope, where a hollow female screw is adapted to receive the different magnifiers. H, is a spiral spring of steel, between the end G and the plates of brass, intended to keep the plates in a right position, and counteract the long screw CC. I, is a small turned handle, for the better holding of the instrument, to screw on or off at pleasure.

To this microscope belong six or seven magnifying glasses: six of them are set in silver, brass, or ivory, as in the figure K, and marked 1, 2, 3, 4, 5, 6; the lowest numbers being the greatest magnifiers. L, is the seventh magnifier, set in the manner of a little barrel, to be held in the hand for the viewing of any larger object. M, is a flat slip of ivory, called a *slider*, with four round holes thro' it, wherein to place objects between two pieces of glass, or Muscovy talc, as they appear *ddd*. Eight such sliders, and one of brass, are usually fold with this microscope; and some with objects placed in them, and others empty for viewing any thing that may offer: but whoever pleases to make a collection, may have as many as he desires. The brass slider is to confine any small ob-

ject, that it may be viewed without crushing or destroying it.

N, is a forceps, or pair of piers, for the taking up of insects or other objects, and adjusting them to the glasses. O, is a little hair-brush or pencil, wherewith to wipe any dust from off the glasses, or to take up any small drop of liquid, which one would want to examine, and put it upon the talcs, or isinglass. P is a tube of glass contrived to confine living objects, such as frogs, fishes, &c. in order to discover the circulation of the blood. All these are contained in a little neat box, very convenient for carrying in the pocket.

When an object is to be viewed, thrust the ivory slider, in which the said object is placed, between the two flat brass plates EE: observing always to put that side of the slider where the brass rings are, farthest from the eye. Then screw on the magnifying glass you intend to use, at the end of the instrument G; and looking thro' it against the light, turn the long screw CC, till your object be brought to fit your eye; which will be known by its appearing perfectly distinct and clear. It is most proper to look at it first through a magnifier that can shew the whole at once, and afterwards to inspect the several parts more particularly with one of the greatest magnifiers; for thus you will gain a true idea of the whole, and of all its parts. And tho' the greatest magnifiers can shew but a minute portion of any object at once, such as the claw of a flea, the horn of a louse, or the like, yet by gently moving the slider which contains the object, the eye will gradually overlook it all.

As objects must be brought very near the glasses when the greatest magnifiers are made use of, be careful not to scratch them by rubbing the slider against them as you move it in or out. A few turns of the screw CC will easily prevent this mischief, by giving them room enough. You may change the objects in your sliders for what others you think proper, by taking out the brass rings with the point of a pen-knife; the isinglass will then fall out, if you but turn the sliders; and after putting what you please between them, by replacing the brass rings you will fasten them as they were before. It is proper to have some sliders furnished with talcs, but without any object between them, to be always in readiness for the examination of fluids, salts, sands, powders, the farina of flowers, or any other casual objects of such sort as need only be applied to the outside of the talc.

The circulation of the blood may be easiest seen in the tails or fins of fishes, in the fine membranes between a frog's toes, or best of all in the tail of a water-newt. If your object be a small fish, place it within the tube, and spread its tail or fin along the side thereof: if a frog, choose such an one as can but just be got into your tube; and, with a pen, or small stick, expand the transparent membrane between the toes of the frog's hind foot as much as you can. When your object is so adjusted, that no part of it can intercept the light from the place you intend to view, unscrew the long screw CC, and thrust your tube into the arched cavity, quite thro' the body of the microscope; then screw it to the true focal distance, and you will see the blood passing along its vessels with a rapid motion, and in a most surprising manner.

The third or fourth magnifiers may be used for frogs or fishes: but for the tails of water-newts, the fifth or sixth will do; because the globules of their blood are twice as large as those of frogs or fish. The first or second magnifier cannot well be employed for this purpose; because the thickness of the tube in which the object lies, will scarce admit its being brought so near as the focal distance of the magnifier.

### § 5. *The Single Microscope with Reflection.*

Plate  
CCXIX.

In fig. 2. A is a scroll of brass fixed upright on a round pedestal of wood B, so as to stand perfectly firm and steady. C is a brass screw, that passes thro' a hole in the upper limb of the scroll, into the side of the microscope D, and screws it fast to the said scroll. E, is a concave speculum set in a box of brass, which hangs in the arch G by two small screws ff; that screw into the opposite sides thereof. At the bottom of this arch is a pin of the same metal, exactly fitted to a hole *h* in the wooden pedestal, made for the reception of the pin. As the arch turns on this pin, and the speculum turns on the ends of the arch, it may, by this twofold motion, be easily adjusted in such a manner as to reflect the light of the sun, of the sky, or of a candle, directly upwards through the microscope that is fixed perpendicularly over it; and by so doing, may be made to answer almost all the purposes of the large double reflecting microscope. The body of the microscope may also be fixed horizontally, and objects viewed in that position by any light you choose, which is an advantage the double reflecting microscope has not. It may also be rendered further useful by means of a slip of glass, one end of which being thrust thro' between the plates where the sliders go, and the other extending to some distance, such objects may be placed thereon as cannot be applied in the sliders: and then, having a limb of brass that may fasten to the body of the microscope, and extend over the projecting glass a hollow ring wherein to screw the magnifiers, all sorts of subjects may be examined with great convenience, if a hole be made in the pedestal, to place the speculum exactly underneath, and thereby throw up the rays of light.

The pocket-microscope, thus mounted, says Mr Baker, "is as easy and pleasant in its use; as fit for the most curious examination of the animalcules and salts in fluids, of the farinæ in vegetables, and of the circulation in small animals; in short, is as likely to make considerable discoveries in objects that have some degree of transparency, as any microscope I have ever seen or heard of."

### § 5. *Of the Double Refracting and Reflecting Microscopes.*

DOUBLE microscopes are so called as being a combination of two or more lenses.

The only advantage which the double *refracting* microscope hath over the single one is, that it takes in a larger field of view; and therefore hath yielded to the double *reflecting* microscope, which gives a clearer view of objects, with a greater power of magnifying at the same time.

The body of this microscope AAAA is a large tube, supported by three brass pillars *b b b*, rising from

a wooden pedestal C; in which pedestal is a drawer D, to hold the object-glasses and other parts of the apparatus. A lesser tube *ee* slides into the greater, and sends from its bottom another tube *f*, much smaller than itself, with a male screw *g* at the end thereof, whereon to screw the object-glass or magnifier. There are five of these magnifiers, numbered 1, 2, 3, 4, 5; which numbers are also marked on the inner tube, to direct whereabouts to place it according to the magnifier made use of: but if when it fits not the eye exactly, slide the inner tube gently higher or lower, or turn the screw of the magnifier gradually, till the object appears distinct. The greatest magnifiers have the smallest apertures and the lowest numbers.

L, is a circular plate of brass fixed horizontally between the three brass pillars, and in the centre thereof a round hole M is adapted to receive a proper contrivance N for holding ivory sliders wherein objects are placed: this contrivance consists of a spiral steel wire confined between three brass circles, one whereof is moveable for the admission of a slider. O is a round brass plate with several holes for placing objects in, some of which are usually furnished with them at the shops: but two holes are commonly reserved for small concave glasses, whereon to place a drop of any liquid, in order to view the animalcules, &c. There is also a piece of white ivory, and a piece of black ebony, of the same size and shape as the holes for objects: the ivory is for holding such opaque objects as are black, and the ebony such as are white, by which contrariety of colours they will be seen more distinctly. At the bottom of this object-plate is a button to slip into a slit P, that fits it, on the circular plate of brass: and by turning it round on this, all the objects may be examined successively with very little trouble.

Q, is a concave speculum set in a box of brass, and turning in an arch R, upon two small screws *rr*. From the bottom of the arch comes a pin, which being let down into a hole *z*, in the centre of the pedestal, enables the speculum to turn either vertically or horizontally, and to reflect the light directly upwards on the object to be viewed. V, is a plano-convex lens, which by turning on two screws *\*\**, when the pin at the bottom of it is placed in the hole W, for its reception in the circular plate L, will transmit the light of a candle to illuminate any opaque object that is put on the round piece of ivory or on the ebony for examination: and it may be moved higher or lower, as the light requires. This glass is of service to point the sunshine or the light of a candle upon any opaque object, but in plain day-light is of no great use. X, is a cone of black ivory, to fasten on a shank underneath the brass circular plate L, principally when the first or second magnifier is made use of, and the object very transparent: for objects are rendered much more distinctly visible, by intercepting some part of the oblique rays which come from the speculum. The brass fish-pan Y is to fasten any small fish upon, to see the circulation of the blood in its tail. For this purpose, the tail of the fish must be expanded across the oblong hole at the smallest end of the pan: then by slipping the button on the backside of the pan into the slit P thro' the circular plate L,

*Fig. 3.**Fig. 4.*

L, the spring that comes from the button will make it steady, and prevent it well to view. But if it be a frog, a newt, or an eel, in which the circulation is desired to be shewn, a glass tube I is fittest for the purpose. The tail of a newt or eel, or, in a frog, the web between the toes of the hind-feet, are the parts where it may be seen best. When the object is well expanded on the inside of the tube, slide the tube along under the circular brass plate L, (where there are two springs and a cavity made in the shank to hold it), and bring your object directly under the magnifier.

There are three of these glass tubes smaller one than another, and the size of the object must direct which of them is to be used; but, in general, the less room the creature has to move about in, the easier will it be managed.

The cell 2, with a concave and a plane glass in it, is intended to confine fleas, lice, mites, or any small living objects, during pleasure; and by placing it over the hole M, in the middle of the circular brass plate, they may be viewed with much convenience. Three loose glasses, viz. one plane, and two concave, belong also to this microscope; and are designed to confine objects, or to place them upon occasionally. The long steel wire 3, with a pair of plyers at one end, and a point on the other, to hold fast or stick objects upon, slips backward or forward in a short brass tube where-to a button is fastened, which fits into the little hole z, near the edge of the brass plate L: and then the object may be readily brought to a right position, and a light be cast upon it either by the speculum underneath, or, if it be opaque, by the plano-convex lens V. 4, Is a flat piece of ivory called a *slider*, with four round holes thro' it, and objects placed in them, between Muscovy talcs or isinglasses, kept in by brass wires. It is proper to have a number of these sliders, filled with curious objects, always ready, as well as some empty ones for any thing new that offers. When made use of, thrust them between the brass rings of the contrivance on purpose for them, which shoots into the round hole M, in the centre of the brass plate L. This keeps them steady, and at the same time permits them to be moved to and fro for a thorough examination. 5, Is a little round ivory box to hold pieces of isinglass for the sliders; 6, a small hair-brush to wipe off any dust from the glasses, or to apply a drop of any liquid; 7, a pair of nippers to take up any object to be examined.

#### § 6. The Microscope for Opaque Objects.

THIS microscope remedies the inconvenience of having the dark side of an object next the eye, which formerly was an unfurmoutable objection to the making observations on opaque objects with any considerable degree of exactness or satisfaction: for, in all other contrivances commonly known, the nearness of the instrument to the object (when glasses that magnify much are used) unavoidably overhadows it so much, that its appearance is rendered obscure and indistinct. And, notwithstanding ways have been tried to point light upon an object, from the sun or a candle, by a convex glass placed on the side thereof, the rays from either can be thrown upon it in such an acute angle only, that they serve to give a confused glare, but are insufficient to afford a clear and perfect

view of the object. But in this microscope, by means of a concave speculum of silver highly polished, in whose centre a magnifying lens is placed, such a strong and direct light is reflected upon the object, that it may be examined with all imaginable ease and pleasure. The several parts of this instrument, made either of brass or silver, are as follow.

Thro' the first side A, passes a fine screw B, the Plate other end of which is fastened to the moveable side C. CCXIX. D is a nut applied to this screw, by the turning of <sup>fig. 4.</sup> which the two sides A and C are gradually brought together. E, is a spring of steel that separates the two sides when the nut is unscrewed. F a piece of brass, turning round in a socket, whence proceeds a small spring-tube moving upon a rivet, thro' which tube there runs a steel wire, one end whereof terminates in a sharp point G, and the other hath a pair of plyers H fastened to it. The point and plyers are to thrust into, or take up and hold, any insect or object; and either of them may be turned upwards, as best suits the purpose. I, is a ring of brass, with a female screw within it, mounted on an upright piece of the same metal; which turns round on a rivet, that it may be set at a due distance when the least magnifiers are employed. This ring receives the screws of all the magnifiers. K, is a concave speculum of silver, polished as bright as possible; in the centre of which is placed a double convex lens, with a proper aperture to look thro' it. On the back of this speculum, a male screw, L, is made to fit the brass ring I, to screw into it at pleasure. There are four of these concave specula of different depths, adapted to four glasses of different magnifying powers, to be used as the objects to be examined may require. The greatest magnifiers have the least apertures. M, is a round object-plate, one side of which is white and the other black: The intention of this is to render objects the more visible, by placing them, if black, on the white side, or, if white, on the black side. A steel ring, N, turns down on each side to make any object fast; and insuring from the object-plate is a hollow pipe to screw it on the needle's point G. O is a small box of brass, with a glass on each side, contrived to confine any living object, in order to examine it: this also has a pipe to screw upon the end of the needle G. P, is a turned handle of wood, to screw into the instrument when it is made use of. Q, a pair of brass plyers to take up any object, or manage it with convenience. R is a soft hair-brush for cleaning the glasses, &c. S, is a small ivory box for isinglasses, to be placed, when wanted, in the small brass box O.

When you would view any object with this microscope, screw the speculum, with the magnifier you think proper to use, into the brass ring I. Place your object, either on the needle G in the plyers H, on the object-plate M, or in the hollow brass box O, as may be most convenient: then holding up your instrument by the handle P, look against the light thro' the magnifying lens; and by means of the nut D, together with the motion of the needle, by managing its lower end, the object may be turned about, raised, or depressed, brought nearer the glass, or removed farther from it, till you hit the true focal distance, and the light be seen strongly reflected from the speculum upon the object, by which means it will be shewn in a

Optical  
Instruments

manner surprisingly distinct and clear; and for this purpose the light of the sky or of a candle will answer very well. Transparent objects may also be viewed by this microscope: only observing, that when such come under examination, it will not always be proper to throw on them the light reflected from the speculum; for the light transmitted thro' them, meeting the reflected light, may together produce too great a glare. A little practice, however, will shew how to regulate both lights in a proper manner.

### § 7. *The Solar Microscope.*

THIS instrument is composed of a tube, a looking-glass, a convex lens, and Wilson's single pocket microscope before described. The sun's rays being directed thro' the tube, by means of the looking-glass, upon the object, the image or picture of the object is thrown distinctly and beautifully upon a screen of white paper, or a white linen sheet, placed at a proper distance to receive the same; and may be magnified to a size not to be conceived by those who have not seen it: for the farther the screen is removed, the larger will the object appear; inasmuch, that a louse may thus be magnified to the length of five or six feet, or even a great deal more; though it is more distinct, when not enlarged to above half that size.—The apparatus for this purpose is as follows.

Plate  
CCXXX.  
fig. 1.

A, a square wooden frame, thro' which pass two long screws assisted by a couple of nuts 1, 1. Fasten it firmly to a window-shutter, wherein a hole is made for its reception; the two nuts being let into the shutter, and made fast thereto. A circular hole is made in the middle of this frame to receive a piece of wood, B, of a circular figure; whose edge, that projects a little beyond the frame, composes a shallow groove 2, wherein runs a catgut 3; which, by twisting round, and then crossing over a brass pulley 4, (the handle whereof, 5, passes thro' the frame) affords an easy motion for turning round the circular piece of wood B, with all the parts affixed to it. C is a brass tube covered with seal-skin; which, screwing into the middle of the circular piece of wood, becomes a case for the uncovered brass tube D to be drawn backwards or forwards in. E is a smaller tube, of about one inch in length cemented to the end of the larger tube D. F is another brass tube, made to slide over the above described tube E; and to the end of this the microscope must be screwed, when we come to use it. 5, a convex lens, whose focus is about 12 inches, designed to collect the sun's rays, and throw them more strongly upon the object. G is a looking-glass of an oblong figure, set in a wooden frame, fastened by hinges in the circular piece of wood B, and turning about therewith by means of the abovementioned cat-gut. H is a jointed wire, partly brass, and partly iron; the brass part whereof, 6, which is flat, being fastened to the looking-glass, and the iron part, 7, which is round, passing thro' the wooden frame, enable the observer, by putting it backwards or forwards, to elevate or depress the glass according to the sun's altitude. There is a brass ring at the end of the jointed wire, whereby to manage it with the greater ease. The extremities of the cat-gut are fastened to a brass pin, by turning of which it may be braced up, if at any time it becomes too slack.

Optical  
Instruments

When this microscope is employed, the room must be rendered as dark as possible; for on the darkness of the room, and the brightness of the sunshine, depend the sharpness and perfection of your image. Then putting the looking-glass G thro' the hole in your window-shutter, fasten the square frame A to the shutter by its two screws and nuts 1, 1. This done, adjust your looking-glass to the elevation and situation of the sun, by means of the jointed wire H, together with the cat-gut and pulley, 3, 4. For the first of these raising or lowering the glass, and the other inclining it to either side, there results a twofold motion, which may easily be so managed as to bring the glass to a right position, that is, to make it reflect the sun's rays directly thro' the lens, 5, upon the paper screen, and form thereon a spot of light exactly round. But tho' the obtaining a perfect circular spot of light upon the screen before you apply the microscope, is a certain proof that your looking-glass is adjusted right, that proof must not always be expected: for the sun is so low in winter, that if it shines in a direct line against the window, it cannot then afford a spot of light exactly round; but if it be on either side, a round spot may be obtained, even in December. As soon as this appears, screw the tube C into the brass collar provided for it in the middle of your wood-work, taking care not to alter your looking-glass: then screwing the magnifier you choose to employ to the end of your microscope, in the usual manner, take away the lens at the other end thereof, and place a slider, containing the object to be examined, between the thin brass plates, as in the other ways of using the microscope.

Things being thus prepared, screw the body of your microscope to the short brass tube F; which slip over the small end E of the tube D, and pull out the said tube D less or more, as your object is capable of enduring the sun's heat. Dead objects may be brought within about an inch of the focus of the convex lens, 5; but the distance must be shortened for living creatures, or they will soon be killed.

If the light falls not exactly right, you may easily, by a gentle motion of the jointed wire and pulley, direct it thro' the axis of the microscopic lens. The short tube F, to which the microscope is screwed, renders it easy, by sliding it backwards or forwards on the other tube E, to bring the objects to their focal distance; which will be known by the sharpness and clearness of their appearance: they may also be turned round by the same means, without being in the least disordered.

The magnifiers most useful in the solar microscope are in general, the fourth, fifth, or sixth. The screen on which the representations of the objects are thrown, is usually composed of a sheet of the largest elephant paper, strained on a frame which slides up or down, or turns about at pleasure on a round wooden pillar, after the manner of some fire-screens. Larger screens may also be made of several sheets of the same paper pasted together on cloth, and let down from the ceiling with a roller like a large map.

“This microscope (says Mr Baker) is the most entertaining of any; and perhaps the most capable of making discoveries in objects that are not too opaque: as it shews them much larger than can be done  
any

any other way. There are also several conveniences attending it, which no other microscope can have: for the weakest eyes may use it without the least straining or fatigue: numbers of people together may view any object at the same time, and, by pointing to the particular parts thereof, and discoursing on what lies before them, may be able better to understand one another, and more likely to find out the truth, than in other microscopes, where they must peep one after another, and perhaps see the object neither in the same light nor in the same position. Those also, who have no skill in drawing, may, by this contrivance, easily sketch out the exact figure of any object they have a mind to preserve a picture of; since they need only fasten a paper on the screen, and trace it out thereon either with a pen or pencil, as it appears before them. It is worth the while of those who are desirous of taking many draughts in this way, to get a frame, wherein a sheet of paper may be put in or taken out at pleasure; for if the paper be single, the image of an object will be seen almost as plainly on the back as on the fore side, and, by standing behind the screen, the shade of the hand will not obstruct the light in drawing, as it must in some degree when one stands before it."

#### § 8. Universal Microscope.

ABC, is the body of the microscope.

D, is a joint, by which it is moveable vertically.

E, is a hollow square socket, with

F, a screw, by which it is fixed to the part at D.

DOR is a strong brass pillar or stand.

S, T, V, the tripod, or three feet, on which it stands.

GHI is a stage on which objects of different sorts are placed to be viewed.

K, is a strong screw by which the stage is rendered moveable horizontally.

MN, are two brass sockets, connected by an adjusting screw, and moveable up and down upon the square part of the stand.

O is a screw for fixing the socket M.

P is a long adjusting screw by which the socket N is moveable, and the objects upon the stage adjusted to the view.

W is a concave mirror, or speculum, fixed at

X, just under the central part of the stage, for illuminating transparent objects.

Y is a concave lens moveable at

Z, in a spring socket; by this lens opaque bodies are sufficiently enlightened for the view.

This compound microscope is in the best manner adapted to view transparent objects; for if they are such as can be put into the concave glass in the middle of the stage at H, then they will be sufficiently enlightened by the reflector W below, in one side of which is a plane speculum, and in the other a concave one, as both sorts are occasionally necessary.

If the transparent objects are such as may be included between talcs in the ivory sliders, then there is a part ABCD, called the *slider-holder*, which is fitted to the hole at H in the middle of the stage, and in which all the variety of objects in sliders may be viewed to great perfection by reflected light from the speculum W below.

As some curious experiments with transparent objects require the light to be very pure, and adjusted to a proper degree, there is an inverted cone of brass, ABC, to be placed in the under part of the hole at Fig. 3. H by its broad end or base AC; and by the narrow end B only the interior and purer light contained in the upper and denser part of the large cone of rays reflected by the speculum W, can illuminate the objects to be viewed. This cone is indeed of more immediate use in the single microscope, to be mentioned by and by. Thus, it is plain, in one or other of these ways all kinds of transparent objects are to be viewed in the utmost perfection.

In this construction it is also as evident, that every opaque object may be shewn as well in this as in that which is usually called the *opaque microscope*: because here is all the same apparatus for that purpose, and much more; for this is both a single and compound opaque microscope.

Thus, if any opaque object be laid upon the glass at H, it may be very strongly illuminated by the lens Y, moveable higher or lower in the socket Z, to make the light upon the object greater or less, as occasion requires. In this case you have the advantage of a large and delightful field of view, and objects of all shapes and sizes are immediately viewed upon the stage GHI, as it is so easily moved up and down by the sliding sockets M and N, fastened in any position by the screw O, and adjusted for the most accurate inspection by the screw P.

In many cases it may be requisite to view light-coloured objects upon a dark ground, and the contrary: therefore, to answer such purposes, there is provided a round flat piece of ivory, with one side white and the other black, fitted into the hole at G, and to be taken in and out at pleasure.

To answer these purposes still more generally, there is a pair of piers, AB, moveable in a brass spring Fig. 4. socket at C, and by the shank at D it is fitted in the hole of the stage at I, where it has a horizontal motion, and also a vertical motion (up and down) by its joint at E. By the pincers at the end A any object may be very readily adjusted to the view, and illuminated by the lens Y. Also at the other end of the piers B, there is a small cylindric piece of ivory F screwed on, with one end black, the other white, for the above-mentioned purposes.

But oftentimes objects will be found which require the use of the piers AB, and are seen to the greatest advantage by light reflected upon them; for which purpose a small concave metallic speculum AB is screwed into the end CD of a tube CDEF, which is Fig. 5. made to go on upon the pipe of the microscope; and the large cone of reflected light from the mirror W will pass through the hole H to this small concave AB, by which it will be reflected upon the object in the piers at A, but more especially upon the ivory at F, where exceeding small objects require the greatest degree of light they can bear.

Further, to make this microscope answer all the ends of a single opaque microscope, there is a brass piece AB, with a square hole or socket, to go on upon the Fig. 6. shank at D (fig. 1.) when the body of the microscope ABC is taken off, and is there made fast by the screw C.

C. To this is annexed a strong brads ring DE, into which are screwed the same *Liberkhuus*, as they are called, or concaves with a small lens in the middle of each, as are used in the single opaque microscope; and being applied to objects on the stage GHI, or in the plying, they are viewed in the same manner here as they are there; with this additional advantage, that in the present microscope, the light is much more intense from the speculum W, than the common light but once reflected in the usual form of this instrument.

Lastly, every thing shewn in the aquatic microscope is to be seen equally in this; because, since the hole at H in the stage is very large, it will admit of a concavity sufficiently capacious for any purposes of viewing objects in water, of any sort whatsoever. And not only the magnifiers, but the mode of applying them, is nearly the same here as in those of the common form. But in this construction, you have both the single and compound aquatic microscope: for the stage GHI being moveable horizontally, and the magnifier at A moving vertically on the joint at D, it is plain, every part of the water in the concave glass at H may be brought under it, and the most minute objects well enlightened by the concave AB, and shewn with great distinctness.

The other parts of the apparatus are common to all microscopes. Every body knows the use of the ivory sliders, for holding and applying transparent objects as above directed, (fig. 7.). But in fig. 8. you have the form of a brads slider, with several small glass concaves fixed in one side, and over them a slip of clear plain glass is made to slide in the frame, and thereby to confine in the hollow of the glasses very small living objects, as a flea, louse, mite, &c. and prevent their crawling out of the field of view.

There is also what is called a *bug-box*, consisting of two parts: the lowest contains a large concave; and the upper part contains a plane glass, which, being screwed upon the concave, will confine any larger animal, as a bug, an ant, a spider, a small fly, &c.

As the circulation of the blood is one of the noblest experiments of the microscope, so ample provision is made for it by a set of glass tubes of different sizes for applying the transparent parts of proper objects for that purpose, such as small fish, tadpoles, and water-nets, the best subject of all; such a tube is AB (fig. 9.) It being necessary to stop the open end B, when the animal is in, with a cork, there is a small hole at the other end A to give air to the animal. These tubes are applied to the hole H in the stage by two steel springs on the under part, bent to receive them.

In case it be required to view the circulation in the tail of a large fish, as a gudgeon, loach, &c. there is an instrument of brads called the *fish-pan*, (fig. 10.) contrived of a proper form to hold and confine it; where ABD is the incurved plate to receive the body of the fish; CFG is a ribbon to tie the fish to the said plate or pan, and is kept tight by a spring behind at H. At the end AD, is a long transverse hole or slit, over which the transparent tail of the fish is placed; and then by the Shank at E, on the under side, it is put upon the stage thro' a hole at I, and there easily adapted to the magnifier A, by moving it every way under the same.

It is often required to see what many small objects are, and how they are best disposed in sliders, glasses, tubes, &c. for which purpose there is a hand-magnifier ABC, (fig. 11.) containing a lens of about one inch focal distance, to be used upon all such occasions.

Besides the above particulars, there is a pair of nippers (or forceps) to take up small objects, in order to place them on the stage, between the talcs, &c. also a camel-hair brush, for cleansing talcs, glass, &c. A small wire, with a spiral screw at the end, for holding cotton, &c. for cleansing the glass tubes. A little ivory box with spare talcs, and wires to fasten them in the sliders. A piece of shammy leather is useful upon all occasions for wiping the glasses of every sort, as it will cleanse them well without hurting their surfaces.

#### § 9. Clark's Improved Pocket Microscope.

THIS is represented in Plate CCXX. where ABC DEF (fig. 2. n° 1.) is a box three inches broad, four inches long, and one inch deep, covered with shagreen, and having the lid open, which when shut is fastened by clasps as in the figure. This box serves for the pedestal as well as case of the instrument. *abcd*, is a solid piece of wood, fixed in the middle of the box; on which is screwed a brads plate *ef*, having in the middle a female screw for holding the other parts now to be described.

*aβ*, n° 2. Is a piece of brads of the shape represented in the plate, having a male screw at *a*, answering to the female one abovementioned at *g*, and by which this part is firmly fixed upright in the middle of the box. On the lower part of this piece of brads is fastened, but in such a manner as to be moveable at the joint *s*, a semicircle of brads *cs*, in which is a concave speculum *iiii*, ground to a focus of about eight inches: it is moveable in the ring, by means of two pivots; and as the ring itself is also moveable, it is plain that the speculum may be moved to a proper distance from the standard. The face of it is placed next the standard when the instrument is put into the case, in order to prevent the polished surface from injury. *γ* Is a piece of solid brads, which goes into a dovetail slit in the part next to be described, and which Mr Clark calls the *stage*. This consists of two pieces, n° 3. One of these, *xxxx*, is a parallelogram of brads, in which the other part *yzyz* slides up or down by means of the screw *mn*. From the upper part of this, proceeds at right angles another piece *yzrs*. This is formed of two pieces of brads riveted at *y* and *z*, and joined to each other at their extremities by the cross piece *rs*. Upon this slides another piece *1, 2, 3, 4*, having in it a round hole *5*, and which can be made to approach either to *yz* or to *rs* as occasion requires. This part, by means of the dovetail slit at *xx*, may be put on the solid piece of brads at *γ* of the former, and secured in a perpendicular position on the top of it.

The last part of this microscope is represented n° 4. It consists of a solid piece of brads *opqt*, to which is fixed at right angles the piece *opv*; *v* is a small plane speculum, with the reflecting side downwards, and, by means of a joint, capable of being raised up or let down as the observer finds necessary. To the under side

Fig. 11.

*Fig. 3**Fig. 4.**Fig. 5.**Fig. 6.**Fig. 7.*

side of the fore-part of this is placed a small brass circle, the edges of which appear at  $w$  and  $x$ , and which is fully represented in  $n^{\circ}$  5. Round this circle the magnifiers are disposed, and over against each of them is engraved its magnifying power, expressed by 1, 2, 3, 4, 5, the highest numbers magnifying most. This circle is movable; and so disposed, that, as it turns round, the magnifiers appear successively through the hole at  $w$ , at the same time that the power of each is shewn by the cipher which appears through the little square hole at  $y$ ,  $n^{\circ}$  4. This whole part of the machine slides up and down on the back of the other, by means of a dovetail; and thus, though the part  $a p q v$  is always above and parallel to the stage, yet it may be brought nearer to it or removed farther off at pleasure.

On the solid back plate are marked the numbers 1, 2, 3, 4, 5, to shew the foci of the different magnifiers. Concerning the proper method of using this microscope, Mr Clark gives the following directions.

When the case is opened, take out the microscope, which consists of two separate parts; screw the under part (on which the speculum is) into the brass plate in the inside of the case, which is the base for the instrument while in use.—Put the other end into the dovetail slit behind the handle of the adjusting screw  $m n$ ,  $n^{\circ}$  3. place the microscope so as the speculum may front the light; then gently move up the back part by the button for that purpose, till the figure 1, on the plate  $p q r t$ , ( $n^{\circ}$  4.) appears just above the stage: then turn round the circular plate which contains the magnifiers, being five in number, till 1 appear in the square hole  $a$ -top. Put the slider with the objects into the stage; give the concave speculum such an inclination as to throw the rays through the object immediately under the magnifier: thereabout distinct vision will be had; if not entirely so, a turn or two of the adjusting screw will either raise or depress the stage, as the eye or object requires: and so on with each magnifier and corresponding figure, always taking care that the speculum be in such a situation as to throw the light properly up.

The slider for opaque objects consists of three divisions; first, ebony, for laying all white or light-coloured objects on, such as seeds, sands, mineral, &c. The second division ivory, for all dark and black bodies. The third division glass, which opens and shuts; when open, for the circulation of the blood in tadpoles, &c. when shut, for confining any live object to be examined, and for all kinds of animalcules in fluids, solutions of salts, &c. Likewise there are on the side of the above slider, a pair of small forceps, that turn out at pleasure, to hold any opaque or transparent object, such as a fly, spider, &c. which may be viewed with the aid of one or both speculums to great advantage. See  $n^{\circ}$  6.

When this microscope is employed for examining an opaque object, the upper speculum must be bent down to such an angle as to throw the rays reflected from the under speculum upon the opaque object in view: with the sun or candle-light, those two speculums have a most delightful effect. The rays from the under speculum, passing through the square opening  $g z$ , 1, 2, ( $n^{\circ}$  3.) behind the stage, fall on the small upper plane speculum, which, moving on an axis, may

be placed in a direction so as to illuminate the opaque object with the whole light proceeding from the large concave speculum. In this operation all the magnifiers but  $n^{\circ}$  5. may be used with success and satisfaction.

#### § 10. Of Extempore Microscopes.

For those who cannot conveniently procure the apparatus of any of the above-mentioned microscopes, it may afford some entertainment to try the magnifying power of small globules of water, which in some cases is very considerable. The inventor of this method of viewing objects was Mr Stephen Gray, who gives an account of it in the Philosophical Transactions  $N^{\circ}$  221, 223. "Having observed, says he, some irregular particles within the glass globules (for microscopes), and finding that they appeared distinct, and prodigiously magnified when held close to my eye; I concluded, that if I conveyed a small globule of water close to my eye, in which there were any opacous or less transparent particles than water, I might see them distinctly. I therefore took on a pin a small portion of water, which I knew to have in it some minute animals, and laid it on the end of a small piece of brass wire that then lay by me, about  $\frac{1}{2}$  of an inch in diameter, till there was formed somewhat more than an hemisphere of water. Then keeping the wire erect, I applied it to my eye, and, standing at a proper distance from the light, I saw them and some irregular particles, as I had predicted; but mostly enormously magnified. For, whereas they were scarce discernable by my glass microscope, they appeared within the globule not much different in form, nor less in magnitude, than ordinary peas. They cannot be well seen by day-light, unless the room be darkened; but most distinctly by candle-light. They may also be very well seen by the light of the full moon."

But Mr Gray tells us, that these little animals will appear more distinctly, if drops of water be conveyed by a pin's point into a round hole made in a brass plate whose thickness is about one tenth of an inch, and the diameter of the cylindrical hole a little less than half a tenth; observing to fill it till near an hemisphere of water be extant on each side of it. Now, supposing the axis of this cylinder of water to be terminated by equal spherical surfaces, and to be exactly equal to three diameters of the spheres of those surfaces; in that case the little animals seen by reflection from the farther surface, will appear just twice as big in diameter, as if they were placed in the focus of one of those spheres of water, and were seen thro' it as in common microscopes. His description of the animalcules thus observed is curious. "They are (says he) of a globular form, and but little less transparent than the water they swim in. They have sometimes two dark spots diametrically opposite; but these are rarely seen. There are sometimes two of these globular insects sticking together, and the place of junction is opacous: possibly they may be in the act of generation. They have a twofold motion; a swift progressive regular one, and at the same time a rotation about their axes, at right angles to the diameter that joins their dark spots; but this is only seen when they move slowly. They are almost of an incredible minuteness. Mr Leeuwenhoek is moderate

enough in his computation, when he tells us that he saw insects in water so small that 30,000 of them could scarcely equal a grain of coarse sand. But I believe it will seem a paradox to him when he is told, that he may see them by only applying his eye to a portion of water wherein they are contained. I have examined many transparent fluids, as water, wine, brandy, vinegar, beer, spittle, urine, &c. and do not remember to have found any liquors without these insects. But I have not seen many in motion, except in common water that has stood, for sometimes a longer, at others a shorter time. In the rivers, after the water has been thickened by rain, there are such infinite numbers of them, that the water seems in great part to owe its opacity and whiteness to those globules. Rain-water, as soon as it falls, has many, and snow-water has more of them. The dew that stands on glass windows has many of them: and for as much as rains and dews are continually ascending and descending, I believe we may say the air is full of them. They seem to be of the same specific gravity with the water they swim in; the dead remaining in all parts of the water. Of the many thousands that I have seen, I could discern no sensible difference in their diameters; they appear of equal bignesses in water that has been boiled: they retain their shapes, and will sometimes revive."

The same ingenious author describes another water-microscope of his own invention, as follows. "AB I call the frame of the microscope; it may be about  $\frac{1}{8}$  of an inch in thickness. At A there is a small hole near  $\frac{1}{2}$  of an inch in diameter, in the middle of a spherical cavity about  $\frac{1}{4}$  of an inch in diameter, and in depth somewhat more than half the thickness of the brass. Opposite to this, at the other side of the brass, there is another spherical cavity, half as broad as the former; and so deep as to reduce the circumference of the small hole above-mentioned, almost to a sharp edge. In these cavities the water is to be placed, being taken upon a pin or a large needle, and conveyed into them till there be formed a double convex lens of water; which, by the concavities being of different diameters, will be equivalent to a double convex lens of unequal convexities. By this means I find the object is rendered more distinct than by a plano-convex of water, or by a double convex formed on the plane surfaces of a piece of metal. CDE is the supporter whereon to place the object; if it be water, in the hole C; if a solid, on the point F. This is fixed to the frame of the microscope by the screw E, where it is bent upwards, that its upper part CF may stand at a distance from the frame AB. It is moveable about the screw E as a centre, in order that either the hole C, or the point F, may be exposed before the microscope A, and that the object may be brought to, and fixed in its focus. There is another screw, about half an inch in length, which goes through a round plate in the frame of the microscope AE, the screw and plate taking hold of the supporter about D, where there is a slit somewhat larger than the diameter of the screw. This is requisite for the admission of the hole C, or point F, according to the nature of the object, into the focus of the watery lens at A. For, by turning the screw G, the supporter is carried to or from the same; which may be

sooner done, if, while one turns the screw with one hand, the other holds the microscope by the end B; and one be looking through the water, till the object be seen most distinctly. The supporter must be made of a thin piece of brass, well hammered, that, by its spring, it may better follow the motion of the screw. I choose rather to fix the supporter by the screw E, than by a rivet; because it may now, by the help of a knife, be unscrewed, and, by the other screw G, be brought close to the frame of the microscope, without weakening its spring, and so become more conveniently portable. If the hole C in the supporter be filled with water, but not so as to be spherical, all objects that will bear it are seen therein more distinctly. The hole at B is made for seeing animals in water by reflection from its farther surface as above described."

§ 11. To find the Magnifying Power of Glasses employed in Single Microscopes.

THE apparent magnitude of any object, as must appear from what hath been already delivered, is measured by the angle under which it is seen; and this angle is greater or smaller, according as the object is near to or far off from the eye; and of consequence the less the distance at which it can be viewed, the larger it will appear. The naked eye is unable to distinguish any object brought exceedingly near it: but looking through a convex lens, however near the focus of that lens be, there an object may be distinctly seen; and the smaller the lens is, the nearer will be its focus, and in the same proportion the greater will be its magnifying power. From these principles it is easy to find the reason why the first or greatest magnifiers are so extremely minute; and also to calculate the magnifying power of any convex lens employed in a single microscope: For as the proportion of the natural light is to the focus, such will be its power of magnifying. If the focus of a convex lens, for instance, be at one inch, and the natural light at eight inches, which is the common standard, an object may be seen through that lens at one inch distance from the eye, and will appear in its diameter eight times larger than it does to the naked eye: but as the object is magnified every way, in length as well as in breadth, we must square this diameter to know how much it really is enlarged; and we then find that its superficies is magnified 64 times.

Again, suppose a convex lens whose focus is only one-tenth of an inch distant from its centre; as in eight inches, the common distance of distinct vision with the naked eye, there are 80 such tenths, an object may be seen through this glass 80 times nearer than with the naked eye. It will, of consequence, appear 80 times longer, and as much broader, than it does to common sight; and therefore is 6400 times magnified. If a convex glass be so small that its focus is only  $\frac{1}{10}$  of an inch distant, we find that eight inches contains 160 of these twentieth-parts; and of consequence, the length and breadth of any object seen through such a lens will be magnified 160 times, and the whole surface 25,600 times. As it is an easy matter to melt a drop or globule of a much smaller diameter than a lens can be ground, and as the focus of a globule is no farther off than a quarter of its own diameter,

diameter, it must of consequence magnify to a prodigious degree. But this excessive magnifying power is much more than counterbalanced by its admitting so little light, want of distinctness, and shewing such a minute part of the object to be examined; for which reason, these globules, though greatly in vogue some time ago, are now almost entirely rejected. Mr Leeuwenhoek, as has been already observed, made use only of single microscopes consisting of convex lenses, and left to the Royal Society a legacy of 26 of those glasses. According to Mr Folkes's description of these, they were all exceedingly clear, and shewed the object very bright and distinct; "which (says Mr Folkes) must be owing to the great care this gentleman took in the choice of his glass, his exactness in giving it the true figure, and afterwards, among many, reserving only such for his use as upon trial he found to be most excellent. Their powers of magnifying are different, as different objects may require: and as on the one hand, being all ground glasses, none of them are so small, and consequently magnify to so great a degree, as some of those drops frequently used in other microscopes; yet, on the other hand, the distinctness of these very much exceeds what I have met with in glasses of that sort. And this was what Mr Leeuwenhoek ever proposed to himself; rejecting all those degrees of magnifying in which he could not so well obtain that end. For he informs us in one of his letters, that though he had, above 40 years by him, glasses of an extraordinary smallness, he had made but very little use of them; as having found, in a long course of experience, that the most consider-

able discoveries were to be made with such glasses as, magnifying but moderately, exhibited the object with the greatest brightness and distinctness."

In a single microscope, if you want to learn the magnifying power of any glass, no more is necessary than to bring it to its true focus, the exact place whereof will be known by an object's appearing perfectly distinct and sharp when placed there. Then, with a pair of small compasses, measure, as nearly as you can, the distance from the centre of the glass to the object you was viewing, and afterwards applying the compasses to any ruler, with a diagonal scale of the parts of an inch marked on it, you will easily find how many parts of an inch the said distance is. When that is known, compute how many times those parts of an inch are contained in eight inches, the common standard of sight, and that will give you the number of times the diameter is magnified: squaring the diameter will give the superficies; and, if you would learn the solid contents, it will be shewn by multiplying the superficies by the diameter.

The superficies of one side of an object only can be seen at one view; and to compute how much that is magnified, is most commonly sufficient: but sometimes it is satisfactory to know how many minute objects are contained in a larger; as suppose we desire to know how many animalcules are contained in the bulk of a grain of sand; and to answer this, the cube, as well as the surface, must be taken into the account. For the greater satisfaction of those who are not much versed in these matters, we shall here subjoin the following

TABLE of the MAGNIFYING POWERS of CONVEX GLASSES, employed in *Single Microscopes*, according to the distance of their focus: Calculated by the scale of an inch divided into 100 parts.

Shewing how many times the DIAMETER, the SUPERFICIES, and the CUBE of an OBJECT, is magnified, when viewed through such glasses, to an eye whose natural sight is at eight inches, or 800 of the 1000th-parts of an inch.

		Magnifies the Dia- meter.	Magnifies the Super- ficies.	Magnifies the Cube of an Object.	Times.
The focus of a glass at	$\frac{1}{2}$ , or 50	16	256	4,096	
	$\frac{4}{10}$ , or 40	20	400	8,000	
	$\frac{1}{3}$ , or 30	26	676	17,576	
	$\frac{1}{4}$ , or 20	40	1,600	64,000	
	15	53	2,809	148,877	
	14	57	3,249	185,193	
	13	61	3,721	226,981	
	12	66	4,356	287,496	
	11	72	5,184	373,248	
	$\frac{1}{10}$ , or 10	80	6,400	512,000	
	9	88	7,744	681,472	
	8	100	10,000	1,000,000	
	7	114	12,996	1,481,544	
	6	133	17,689	2,352,637	
	$\frac{1}{5}$ , or 5	160	25,600	4,096,000	
	4	200	40,000	8,000,000	
	3	266	70,756	18,821,096	
	$\frac{1}{2}$ , or 2	400	160,000	64,000,000	
	1	800	640,000	512,000,000	

The greatest magnifier in Mr Leeuwenhoek's cabinet of microscopes, presented to the Royal Society, has its focus, as nearly as can well be measured, at one-twentieth of an inch distance from its centre; and consequently magnifies the diameter of an object 160 times, and the superficies 25,600. But the greatest magnifier in Mr Wilson's single microscopes, as they are now made, has usually its focus at no farther distance than about the 50th part of an inch; whereby it has a power of enlarging the diameter of an object 400, and its superficies 160,000 times.

The magnifying power of the solar microscope must be calculated in a different manner; for here the difference between the focus of the magnifier and the distance of the screen or sheet whereon the image of the object is cast, is the proportion of its being magnified. Suppose, for instance, the lens made use of has its focus at half an inch, and the screen is placed at the distance of five feet, the object will then appear magnified in the proportion of five feet to half an inch: and as in five feet there are 120 half-inches, the diameter will be magnified 120 times, and the superficies 14,400 times; and, by putting the screen at farther distances, you may magnify the object almost as much as you please; but Mr Baker advises to regard distinctness more than bigness, and to place the screen just at that distance where the object is seen most distinct and clear.

With regard to the double reflecting microscope, Mr Baker observes, that the power of the object-lens is indeed greatly increased by the addition of two eyeglasses; but as no object lens can be used with them of so minute a diameter, or which magnifies of itself near so much as those that can be used alone, the glasses of this microscope, upon the whole, magnify little or nothing more than those of Mr Wilson's single one; the chief advantage arising from a combination of lenses being the sight of a larger field or portion of an object magnified in the same degree.

§ 12. To find out the real Size of Objects seen by Microscopes.

THOUGH, by the directions already given, the magnifying powers of microscopes may be easily calculated; yet if we examine extremely minute objects, the real size of them will still remain uncertain. For, though we may know that they are magnified so many thousand times, we can by that make but a very imperfect computation of their natural and true size; nor indeed can we come to any certain conclusion as to that, but by the mediation of some larger object whose dimensions we really know. For as bulk itself is merely comparative, the only way we can judge of the bigness of any thing is by comparing it with something else, and finding out how many times the lesser is contained in the larger body. The plainest and most practicable methods of doing this in microscopical objects are the following.

1. Mr Leeuwenhoek's method of computing the size of salts in fluids, of the animalcules in *semine masculino*, in pepper-water, &c. was by comparing them with a grain of sand. By this, however, we must understand the coarse sea-sand, usually called *scouring-sand*, which is equal in bigness to several grains of writing sand. But to make our calculations still more certain, we must suppose them to be of such a size, that 100 of them placed in a row shall extend an inch in length. Mr Leeuwenhoek then made his calculations in the following manner.

He viewed thro' his microscope a single grain of sand, which we will suppose to be magnified as the round figure ABCD. Then, observing an animalcule swimming or running across it, (which suppose to be of the size 1,) considering and measuring this by his eyes, he concludes, that the diameter of this animalcule is only  $\frac{1}{12}$  of the diameter of the grain

of sand; consequently, according to the common rules, the superficies of the grain of sand is 144 times, and the whole contents 1728 times, larger than the animalcule.

Suppose again, that he sees among these another and smaller species of animalcules; one of which, 2, he likewise measures by his eye, and computes its diameter to be four times less than the former: then, according to the foregoing rules, the surface of this second animalcule will be 16, and the whole bulk 64, times less than the animalcule 1.

If farther, upon a nicer view, he discovers a third kind of animalcule, 3, so exceedingly minute, that, examining it in the former manner, he concludes the diameter to be 10 times smaller than the second sort; it will then follow, that 1000 of them are only equal in bigness to one of that sort. Hence, of the first sort, 1728 would be contained in a grain of sand; of the second, 110,592; and of the third, 110,592,000.

In this manner may the comparative size of small objects be judged of with tolerable certainty: particularly in the solar microscope; since the image of the object and of the grain of sand, or whatever else is thought proper to compare with it, may be really measured by a ruler or a pair of compasses, and the difference of their diameters most exactly found.

2. Mr Hooke describes his method in the following words. "Having rectified the microscope to see the desired object thro' it very distinctly; at the same time that I look upon the object thro' the glass with one eye, I look upon other objects at the same distance with my other bare eye: by which means I am able, by the help of a ruler divided into inches and small parts, and laid on the pedestal of the microscope, to cast as it were the magnified appearance of the object upon the ruler, and thereby exactly to measure the diameter it appears of thro' the glass; which being compared with the diameter it appears of to the naked eye, will easily afford the quantity of its being magnified." This method is recommended by Mr Baker as very good for multitudes of objects; and he declares from his own experience, that a little practice will render it exceedingly easy and pleasant.

3. Another very curious method for this purpose is described by Dr Jurin in his *Physico-Mathematical Dissertations*. Wind a piece of the finest silver-wire you can get a great many times about a pin, or some other such slender body, so closely as to leave no interval between the wire-threads; to be certain of which, they must be carefully examined with a glass. Then, with a small pair of compasses, measure what length of pin the wire covers; and applying the compasses with that measure to a diagonal scale of inches, you will find how much it is; after which, by counting the number of wire-rounds contained in that length, you will easily discover the real thickness of the single wire. This being known, cut it into very small pieces; and, when you examine the object, if it be opaque, screw some of these wires upon it; if transparent, under it; and by your eye compare the parts of the object with the thickness of such bits of wire as lie fairest to the view. By this method, Dr Jurin observed, that four globules of human blood would generally cover the breadth of a wire which he had found to be  $\frac{1}{14}$ th part of an inch; and consequently that

that the diameter of a single globule was  $\frac{1}{144}$ th of an inch; which was also confirmed by Leeuwenhoek, from observations made on the blood with a piece of the same wire.

4. Mr Martin in his Optics gives another method sufficiently easy. On a circular piece of glass, let a number of parallel lines be carefully drawn, with the fine point of a diamond, at the distance of  $\frac{1}{100}$ th of an inch from each other. If this be placed in the focus of the eye-glass of a microscope, the image of the object will be seen upon these lines, and the parts thereof may be compared with the intervals: whereby its true magnitude or dimensions may be very nearly known; for the intervals of these lines, tho' scarce discernible to the naked eye, appear very large thro' the microscope. A contrivance of this kind may also be invented for such microscopes as a glass cannot be applied to in the above manner, by placing it under or behind the object, which will answer the same purpose. Here it will be easy to find what proportion an object, or any part thereof, bears to an interval between two lines, and then determine it in parts of an inch: for if the width of an object appears just one interval, we shall know it to be just one fortieth part of an inch; if half an interval, the 80th; if a quarter of an interval, the 160th; if one fifth, only the 200th part of an inch.

5. Dr Smith has an invention similar to this for taking exact draughts of objects viewed in double microscopes: for he advises to get a lattice made with small silver wires, or small squares drawn upon a plane glass by the strokes of a diamond, and to put into the place of the image formed by the object-glass. Then, by transferring the parts of the object seen in the squares of the glass or lattice upon similar corresponding squares drawn upon paper, the picture thereof may be exactly taken. A micrometer may also be applied to microscopes of the same form with those applied to telescopes; for by opening the hairs of the micrometer till they exactly correspond to a certain length, suppose  $\frac{1}{100}$ th of an inch, and by observing the number of revolutions in this opening, the diameter of any other object, answering to a known number of revolutions, may be found by the golden rule.

#### § 13. Of the Field of View in Microscopes.

This is always in proportion to the diameter of the lens made use of, and its power of magnifying, by which it may be determined: since, if the lens is extremely small, it magnifies a great deal, and consequently a very minute portion of an object only can be distinguished thro' it; for which reason the greatest magnifiers never should be employed but for the most minute objects. This consideration will direct to the use of such magnifiers as are most proper to be employed, which is of the utmost consequence in microscopical observations. On this subject Mr Baker gives the following short rule, viz. that the field of view differs not greatly from the size of the lens; and that the whole of any object much beyond that size, cannot be conveniently viewed thro' it. There is some difference, as to the visible area of an object, as seen thro' single or double microscopes; for the double shew a larger portion of it than the single, tho' magnified as much.

#### § 14. Of Microscopic Objects, and the Method of preparing them for being examined.

Mr Hooke gives a general account of microscopic objects under the following denominations, viz. "exceeding small bodies, exceeding small pores, and exceeding small motions." The first must either be the parts of larger bodies; or things, the whole of which is exceedingly minute, such as small seeds, insects, sands, salts, &c. The second are the interstices between the solid parts of bodies, as in stones, minerals, shells, &c. or the mouths of minute vessels in vegetables, the pores in the skins, bones, &c. of animals, — Exceeding small motions are the movements of the several parts or members of minute animals, or the motion of the fluids contained either in animal or vegetable bodies.

Many, as Mr Baker observes, even of those who have purchased microscopes, are so little acquainted with their general and extensive usefulness, and so much at a loss for objects to examine by them, that, after diverting themselves and their friends some few times with what they find in the sliders bought with them, or two or three more common things, the microscopes are laid aside as of little farther value; and a supposition that this must be the case, prevents many others from buying them: whereas, among all the inventions that ever appeared in the world, none perhaps can be found so constantly capable of entertaining, improving, and satisfying the mind of man.

An examination of objects, in order to discover truth, requires a great deal of attention, care, and patience, together with some considerable skill and dexterity, (to be acquired by practice chiefly), in the preparing, managing, and applying them to the microscope. When any object comes to be examined, the size, contexture, and nature of it, should be duly considered, in order to apply it to such glasses and in such a manner as may shew it best. The first step towards this should constantly be, to view it thro' a magnifier that can take in the whole at once: for, by observing how the parts lie as to one another, we shall find it much easier to examine and judge of them separately if there be occasion. After having made ourselves acquainted with the form of the whole, we may divide it as we please; and the smaller the parts into which it is divided, the greater must be the magnifiers with which we view them.

The transparency or opacity of an object must also be regarded, and the glasses made use of must be suited to it accordingly: for a transparent object will bear a much greater magnifier than one that is opaque; since the nearness required in a large magnifier unavoidably darkens an opaque object, and prevents its being seen, unless by the microscope contrived on purpose for such objects. Most objects, however, become transparent by being divided into extremely thin or minute parts. Contrivance therefore is requisite to reduce them into such thinness or smallness as may render them most fit for examination.

The nature of the object, whether it be alive or dead, a solid or a fluid, an animal, a vegetable, or a mineral substance, must likewise be considered, and all the circumstances attended to, that we may apply it in the most convenient manner. If it be a living animal,

mal, care must be taken to squeeze, hurt, or decompose it as little as possible, that its right form, posture, and temper, may be discovered. If a fluid, and too thick, it must be thinned with water; if too thin, we must let some of its watery parts evaporate. Some substances are fittest for observation when dry, others again when moistened; some when fresh, and some after being kept a while.

Light is a thing next to be taken care of; for on this the truth of all our examination depends, and a very little experience will shew how differently objects appear in one position and kind of it, from what they do in another. So that we should turn them every way, and view them in every degree of light, from brightness even to obscurity; and in all positions to each degree; till we are certain of their true form, and that we are not deceived. For, as Mr Hooke says, it is very difficult, in many objects, to distinguish between a prominence and a depression, between a shadow and a black stain; and, in colour, between a reflection and a whiteness. The eye of a fly, for instance, in one kind of light, appears like a lattice drilled through with abundance of holes; in the sunshine, like a surface covered with golden nails; in one position like a surface covered with pyramids, in another with cones, and in other positions of quite other shapes.

The degree of light must be duly suited to the object: which if dark, will be best seen in a full and strong light; but, if very transparent, the light should be proportionably weak; for which reason there is a contrivance both in the single and double microscope to cut off abundance of its rays when such transparent objects are viewed by the greatest magnifiers.

The light of a candle, for many objects, and especially such as are exceedingly minute and transparent, is preferable to day-light. For others, day-light is best; that is, the light of a bright cloud. As for sun-shine, it is reflected from objects with so much glare, and exhibits such gaudy colours, that nothing can be determined by it with certainty; and therefore it is to be accounted the worst light that can be had.

This opinion of sunshine, however, must not be extended to the solar microscope, which cannot be used to advantage without its brightest light: for in that way we see not the object itself, wherein the sunshine is cast, but only the image or shadow of it exhibited upon a screen; and therefore no confusion can arise from the glaring reflection of the sun-beams from the object to the eye, which is the case in other microscopes: but then, in this way, we must rest contented with viewing the true form and shape of an object without expecting to find its natural colour, since no shadow can possibly wear the colours of the body it represents.

Most objects require some management in order to bring them properly before the glasses. If they are flat and transparent, and such as will not be injured by pressure, the best method is to inclose them in sliders, between two Muscovy talcs or iinglafs. This way, the feathers of butterflies, the scales of fishes, the farinae of flowers, &c. the several parts and even whole bodies of minute insects, and a

thousand other things, may very conveniently be preserved. Every curious observer, therefore, will have them always ready to receive any accidental object, and secure it for future examination: and a dozen or two of these sliders properly furnished are a fine natural history.

In making a collection of objects, the sliders should not be filled promiscuously, but care taken to sort the objects according to their size and transparency; in such a manner that none may be put together in the same slider but what may be properly examined by the same magnifier: and then the slider should be marked with the number of the magnifier its objects are fittest for: that is, the most transparent, or minutest objects of all, which require the first magnifier to view them by, should be placed in a slider or sliders marked with number I, those of the next degree in sliders marked with number II, and so of the rest. This method will save abundance of time and trouble in shifting the magnifiers, which, without such sortment, must perhaps be done two or three times, in overlooking a single slider. The numbers marked out upon the sliders will likewise prevent our being at any loss what glass to apply to each. In placing your objects in sliders, a convex glass of about an inch focus, to hold in the hand, and thereby adjust them properly between the talcs, before you fallen them down with the brads rings, will be found very convenient.

Small living objects, such as lice, fleas, gnats, small bugs, minute spiders, mites, &c. may be placed between these talcs, without killing or hurting them, if care be taken not to press down the brads rings that keep in the talcs, and will remain alive even for weeks in this manner. But if they are larger than to be treated thus, either put them in a slider with concave glasses intended for that use, or in the cell described above, or else examine them stuck on the pin or held between the plyers; either of which ways they may be viewed at pleasure.

If fluids come under examination, to discover the animalcules that may be in them, take up a small drop with your pen or hair-pencil, and place it on a single iinglafs, which you should have in a slider ready, or else in one of the little concave glasses, and so apply it. But in case, upon viewing it, you find, as often happens, the animalcules swarming together, and so exceedingly numerous, that, running continually over one another, their kinds and real form cannot be known; some part of the drop must be taken off the glass, and then a little fair water added to the rest, will make them separate, and shew them distinct and well. And this mixture of water is particularly necessary in viewing the semen masculinum of all creatures; for the animalcules therein contained are inconceivably minute, and yet crowded together in such infinite numbers, that, unless it be diluted a great deal, they cannot be sufficiently separated to distinguish their true shape.

But if we view a fluid, to find what salts it may have in it, a method quite contrary to the foregoing must be employed: for then the fluid must be suffered to evaporate, that the salts, being left behind upon the glass, may the more easily be examined.

Another, and indeed the most curious way of examining

aming fluids, is by applying them to the microscope in exceedingly small capillary tubes made of the thinnest glass possible. This was Mr Leeuwenhoek's method of discovering the shapés of salts floating in vinegar, wine, and several other liquors; and such tubes should be always ready to use as occasion requires.

For the circulation of the blood, frogs, newts, or fishes, are commonly made use of; and there are glass tubes in the single microscope, and a fish-pan as well as tubes in the double one, on purpose to confine these creatures, and bring the proper parts of them to view: these parts, in newts and fishes, are the tails, and in frogs the fine filmy membrane between the toes of the hinder legs. Though, if we can contrive to fasten down the creature, and bring our object to the magnifier, the circulation cannot possibly be seen so plainly any where as in the mesentery, or thin transparent membrane which joins the guts together; and this part, by pulling out the gut a little, may easily be adjusted to the magnifier.

To dissect minute insects, as fleas, lice, gnats, mites, &c. and view their internal parts, requires a great deal of patience and dexterity; yet this may be done in a very satisfactory manner, by means of a fine lancet and needle, if they are placed in a drop of water: for their parts will then be separated with ease, and lie fair before the microscope, so that the stomach and other bowels may be plainly distinguished and examined.

We should always have ready for this purpose, little slips of glass, about the size of a slider, to place objects on occasionally; some of which slips should be made of green, blue, and other coloured glass, many objects being much more distinguishable when placed on one colour than on another. We should likewise be provided with glass tubes of all sizes, from the finest capillaries that can be blown, to a bore of half an inch diameter.

There is, perhaps, no better way of preserving transparent objects in general, than by placing them between clear isinglass in sliders: but opaque bodies, such as sands, seeds, woods, &c. require different management, and a collection of them should be prepared in the following manner.

Cut cards into small slips, about half an inch in length, and one tenth of an inch in breadth: wet them half their length with a strong but very transparent gum-water, and with that stick on your object. As the spots of cards are red and black, by making your slips of such spots, you will obtain a contrast to objects of almost any colour; and by fixing black things on the white, white on the black, blue or green on the red or white, and all other coloured objects on slips most contrary to themselves, they will be shewn to the best advantage. These slips are intended chiefly for the microscope for opaque objects, to be applied between the nippers: but they will also be proper for any other microscope that can shew opaque bodies. A little square box should be contrived to keep these slips in, with a number of very shallow holes in it just big enough to hold them. If such holes were cut through that pasteboard of which the covers of books are made, exactly fitted to the box, and a paper pasted on one side of it to serve for a bottom to it, three or four such pasteboards stowed with objects might lie upon one another in same box, and contain 100 or more

slips; with objects fastened on them, always ready for examination. It will not be found amiss to provide some slips larger than others, for the reception of different sized objects. But this will, perhaps, be better understood by an inspection of fig. 3. The box should likewise be furnished with a pair of pliers, to take up and adjust the slips, and therefore a convenient place is contrived therein to hold them, as is shewn in the figure.

There is no advantage in examining any object with a greater magnifier than what shews the same distinctly; and therefore, if you can see it well with the third or fourth glass, never use the first or second; for the less a glass magnifies, the better light you will have, the easier you can manage the object, and the clearer it will appear. It is much to be doubted, whether the true colours of objects can be judged of when seen through the greatest magnifiers: for as the pores or interstices of an object must be enlarged according to the magnifying power of the glass made use of, and the component particles of matter must by the same means appear separated many thousands of times farther than they do to the naked eye, their reflections of the rays of light will probably be different, and exhibit different colours. And indeed the variety of colouring which some objects appear dressed in, may serve as a proof of this.

The motions of living creatures themselves, or of the fluids contained within them, as seen through the microscope, are likewise not to be determined without due consideration: for, as the moving body, and the space wherein it moves, are magnified, the motion must probably be so too; and therefore that rapidity wherewith the blood seems to pass along through the vessels of small animals must be judged of accordingly.

#### § 15. Dollond's Achromatic Telescope.

Mr Dollond's telescopes are of two kinds. 1. Those in which only the eye-piece slides, so as to be drawn out as far as is necessary for procuring distinct vision. Of this form are all the larger instruments; which are therefore generally fixed upon a stand, for viewing objects with greater steadiness.—2. Those which are composed of several sliding tubes, for the convenience of being put into the pocket.

The usual method of making the sliding tubes of telescopes has been with paper covered with vellum; but as such tubes have been found liable to several inconveniences from being affected by the moisture of the air, they are now contrived to be made exceedingly thin of brass, and the outside of mahogany.

The sliding tubes are all made to slip, when drawn out to the proper length; so that, by applying one hand to the outside tube A, fig. 4. and the other hand to the end of the smallest tube B, the telescope may be, at one pull, drawn out to its whole length, as is represented by fig. 5; then any of the tubes may be slipped in a little while you look through, and the object rendered distinct to any sight.

To make the tubes slide properly, they all pass thro' short springs or tubes, which are screwed in at a, b, and c, fig. 5. These springs may be unscrewed from the ends of the sliding tubes by means of the milled edges which project above the tubes, and the tubes taken from one another when required.

There

There are four convex eye-glasses to these telescopes, whose surfaces and focal-lengths are so proportioned as to render the field of view very large.— These eye-glasses are all contained in the smallest sliding tube; three of them may be seen by unscrewing the tube at *eee*; and the fourth, which is at the end of the tube, may be come at by unscrewing the spring at *c*.

These telescopes are of three different lengths and sizes, usually called 1 foot, 2 feet, and 3 feet.

Length when in Use.	Length when shut up.	Aperture of the Achromatic Object-glass.	Weight.
14 Inches.	5 Inches.	1,1 Inches.	6 Ounces.
28 ditto.	9 ditto.	1,6 ditto.	16 ditto.
40 ditto.	10 ditto.	2,0 ditto.	30 ditto.

The best achromatic telescopes which Mr Dollond has yet made, are those with a triple object-glass of about 45 inches focal distance, with an aperture of  $3\frac{1}{2}$  inches. Some of these magnify the diameters of objects 150 times, with great distinctness, and light sufficient for most astronomical purposes. When fitted (for terrestrial objects) with an eye-piece magnifying about 70 or 80 times, they give most agreeable vision.

The object-glass of one of these telescopes was found to have the following radii (in inches) of curvature for its different surfaces, beginning with that next the object,  $26\frac{1}{2}$ ,  $37\frac{1}{2}$ ,  $19\frac{1}{2}$ ,  $26\frac{1}{2}$ ,  $26\frac{1}{2}$ . But it does not appear that Mr Dollond and the best artists abide by a fixed rule in their constructions; for telescopes of the same length and magnifying power, and made by the same artist, have different constructions of the object-glass. This may be expected, when we consider the variable nature of the flint-glass. It is probable, that these very fine object-glasses have been produced by trials *pro re nata* of different curvatures.

Till some method can be discovered of making flint glass free from veins, which differ in their refracting power, it is not probable that larger telescopes than those now mentioned will be produced.

#### § 16. Of the Newtonian Reflecting Telescope.

FIG. 1. shews one of those telescopes made by the Hon. Samuel Molyneux, and presented by him to king John V. of Portugal. ABC represents a triangular board or table supported by the globe D, and by the annexed carvings and masks, and which serves for the basis or pedestal of the instrument. Upon occasion this board may be taken off by unscrewing three iron screws, the heads of which lie near the three volutes at the three corners. At E is represented a small key or handle which turns some wheel-work, concealed under the board of the table, and which serves to give an horizontal circular motion to the pillar F placed in the middle, and to the superincumbent tube HIKL. If this should ever be out of order by taking off the upper board, it may be rectified. At G is represented another handle which gives the tube its perpendicular motion; so that while the observer sits with his right side applied to the side of the table AC at the end C, by turning the two handles E and G, he can give the tube any required elevation or azimuth, and thereby follow the motion of the heavenly bodies very commodiously.

The telescope itself consists of two metalline specula and an eye-glass, which are to be duly placed in the tube HIKL left open at the end HL. The large concave spherical speculum *ik* is to be placed within the tube at IK; in which are fixed three stops, or bits of wood, against which the polished surface of the speculum being applied, the axis of reflection will fall exactly in the axis of the tube. In the brass plate which closes this end of the tube, there are three screws intended for holding the metal in this situation; but many cautions are requisite with regard to this metal and the placing of it. In the first place, it is never to be touched, but by screwing into the backside of it a handle *l*, which fits the hole therein. In the next place, great care must be taken not to breathe on it, or to expose it to damp air. If any thing of that kind happens, it must be wiped thoroughly dry with a linen cloth before a fire; and it may be sometimes in like manner cleaned with a rag wetted in spirit of wine; provided the spirit be not left to evaporate, for that would leave an humid sediment which would hurt the polish. In the third place, unless when in use, it should be constantly kept with its face downwards on a piece of plane glass made on purpose.

The speculum is a portion of a concave sphere whose diameter is about eight feet eight inches, and which of consequence collects the rays into a focus about 26 inches distant from its surface. The laws of reflection are such, that any error in the figure of this speculum will produce about six times as great an irregularity in the picture formed in its focus, as the like irregularity would cause in a common refracting telescope. It hath been found by experiment, that an error of less than 1000th part of an inch is capable of vitiating its figure; so that great care must be taken in placing the metal in the tube for use, against the three stops above-mentioned; and that the three screws at IK be gently screwed, only just sufficient to bear the metal truly against the stops; for the smallest excess of stress in the screws against the back of the metal may distort and very much damage its figure. There is also a piece of wood *m*, having a round hole *p* in it, and carrying a small brass arm *n*, which holds the other smaller speculum *o*, which is plane. This speculum must be always preserved from the air when out of use. When the telescope is to be used, the cover of the small speculum must first be taken off; then place it in the tube at the hole M, which exactly fits the above-said square piece. Press it in pretty tight and true; which, if duly performed, the centre of the small speculum will be placed in the axis of the large concave one, and will reflect the parallel rays which enter at the open end HL, to the round hole *p* in the said square piece, *q* which hole one of the two eye-glasses in its cell *q* is to be placed; and then the instrument is prepared for use. The observer is therefore to place himself at the side of the tube, and to look in at M, where he will see the images of the objects which lie at his left-hand. In taking out or putting in the little speculum at *o*, great care must be used to avoid shaking or bending the arm; for the smallest accident of that kind will certainly disorder its situation. There are three screws at the back, the middlemost of which fixes it to the arm *mn*; the other two only press upon the back, and serve to adjust

just its situation to an exact angle of  $45^\circ$  with the axis of the great speculum. There are two eye-glasses, whereof the one that hath the largest aperture being made use of, the instrument will magnify as much as a common refracting telescope of about 20 or 22 feet long; and with the eye-glass that hath the smallest apertures, it will magnify as much and as distinctly as one of 35 or 40 feet.

At P stands a round button of ivory; and at Q is represented a small pin of ivory, which may be seen with a small white thread fixed to it, at the end of the tube H. This thread at the other end is fixed in the inside of the tube; and towards the middle of it, it is wound once round the inward end of the ivory button P. From this disposition, by turning round the ivory button P, the whole slider of black ebony wood NO, with the small speculum and the eye-glass applied at M, may be made to approach to or recede from the large speculum at the other end IK: and by this means its true distance, and the distinct appearance of the object, must be found, for various distances of the same object, and for the various eyes of different observers; which variety in different persons, from the great magnifying power of the eye-glass in this instrument, will be considerably more sensible than in a refracting telescope. But the true distance of the specula will immediately be found in all cases, by turning this ivory pin P backwards and forwards very slowly and gently; and, for celestial objects, the true distance being once found for the observer's eye, a small mark may be made across the slider, and upon the edge of the tube, to bring it speedily, and without any difficulty, to its proper place at another time. By the little ivory pin at Q, the string may be tightened or relaxed to make the slider NO move most easily as occasion requires. Either of the eye-glasses being applied in the cylindrical hole  $p$ , in the square piece  $np$ , may also be made to approach to or recede from the focus, by turning round the small tube  $q$  in which they are inserted, the outside whereof is wrought into a fine screw for that purpose. Distinct vision may also by that means be obtained for different eyes, without moving the whole slider NO.

RS represents a small refracting telescope, whose axis is parallel to the axis of the reflector. In its focus there are placed two cross-hairs, and its only use is to find out any object more readily by the reflector. The eye being applied at S, turn the two handles at E and G, till the point of the object to be viewed in the reflector falls exactly on the cross-hairs; then the eye applied at M to the reflector, will see the same object distinctly; with this caution, that as the whole instrument with its basis can easily be moved, the most convenient situation for the observer will be to keep the tube HI nearly at right angles to the side AC, and to sit with the side AC flat against his right side near C, as hath been already mentioned. And in finding the object at first with the small refracting telescope, it is most convenient to stand at the corner of the table C. The handle G, may be inserted at either side of the pillar F, as convenience shall require. At the small pillars TV, which support and hold the small telescope RS, there are some small screws near T, which being relaxed, the direction of the tube RS may be altered horizontally by pushing the tube with the hand sidewise, either way, as occasion requires, and then tightening the screws

again. And at V there are screws and a spring-piece of brass, which, being relaxed or tightened, will in like manner alter its elevation, so as to restore the parallelism of the tubes in case of any accident that may have disturbed them. In making observations, it will be found convenient not to touch the table, but only to move the handles, as the motions of the star or other celestial body direct; for in an instrument that magnifies so much, the least motion or trembling is magnified proportionably.

In this telescope Dr Smith takes notice of a remarkable deception; namely, that, when the reflector is compared with a refracting telescope of equal magnifying power, the observer always imagines that the latter has the advantage. For this he does not pretend to account, but looks upon it to be an optical deception common to all mankind.

#### § 17. The Gregorian Reflecting Telescope.

THIS is represented, fig. 16. O is a three-footed plate pedestal of wood or metal, in the middle of which CCXXIX. is fastened, by means of the large screw R, the stand AB. On the top of this stand is fastened the plate CD, having in it a socket to receive the brass ball D. This plate is composed of two parts; and by means of the screws L, M, the socket is tightened or loosened on the ball, so that it can either allow it a free motion, or keep it firm in its place. This ball is fully shewn at fig. 17.; and, with its stalk F, is soldered into the piece of brass FG, which is again fastened on the body of the telescope by means of the screws HI. The whole length of the telescope is represented by  $ab$ ; the eye-piece, or the part which contains the eye-glasses, by  $ar$ ; the other part, containing the specula, is represented by  $cb$ . Fig. 4. and 5. shew the proportional size of the two specula to one another. The larger is placed at  $c$ , in the same manner and with the same precautions as have been already mentioned with regard to the Newtonian telescope; the other is placed on a short arm within the tube, in such a manner, that it occupies exactly the middle of it: and by means of a rod  $rpgmo$ , having the upper end of it turned into a screw, the little speculum can be removed from the other, or brought nearer to it, as occasion requires. In the eye-piece,  $ar$ , are two eye-glasses, which receive the light reflected from the little speculum; and the eye being applied at  $a$ , the observer sees those objects which are placed directly before the mouth of the tube.

The following are the proportions of an excellent Gregorian telescope, made by Mr James Short of Edinburgh, which may serve as a model for calculating others of any given length.

	Inches.
Focal distance of the larger speculum	9.6
Its breadth or aperture	2.3
Focal distance of the lesser speculum	1.5
Its breadth	0.6
Breadth of the hole in the larger speculum	0.5
Distance between the lesser speculum and the next eye-glass	14.2
Distance between the two eye-glasses	2.4
Focal distance of the eye-glass next the metals	3.8
Focal distance of the eye-glass next the eye	1.1

This telescope was found by experiment to magnify

60 times in diameter, and to take in an angle of  $19^\circ$  to the naked eye; and of consequence the magnified angle was equivalent to  $19^\circ$ .

For finding the magnifying power of a telescope by experiment, Dr Smith tells us, that the following method was pursued by Mr Hawksbee, Mr Folkes, and Dr Jurin. Having fixed a paper circle of one inch diameter upon a wall, at the distance of 2674 inches from the eye-glass of the telescope, they viewed it in the telescope with one eye, while, with the other eye naked, they viewed two parallel lines drawn upon paper, 12 inches asunder, moving them gradually to and fro, till they appeared to touch two opposite points of the circle seen in the telescope; and then the perpendicular distance of the lines was found to be 132 inches. In this position of the objects, the angle at the eye made by the rays that came from the extremities of the diameter of the one-inch circle, was equal to the angle subtended at the other eye by the 12-inch interval of the parallel lines; and therefore the ratio of this angle to that which the said circle would subtend at the naked eye, viewing it at the said distance of 2674 inches, is the magnifying power of the telescope; and is compounded of the direct ratio of the subtenses of these angles, and the inverse ratio of the distances of the subtenses from the eye; that is, of 12 to 1, and of 2674 to 142: which make the ratio of 226 to 1, very nearly.

Supposing a larger paper circle had been placed at so great a distance, that its picture might have been formed by the speculum in its principal focus; the telescope would have magnified it more than our one-inch circle, in the ratio of the distance of this latter circle from the principal focus, to its distance from the centre of the sphere of the speculum: because the diameter of the picture of the remoter circle would have been greater, in this ratio, than that of the one-inch circle, supposing these circles to subtend the same angle at the centre of the speculum. But this ratio, in the present experiment, being only 2674 to 2671, gives only an inconsiderable increase to the magnifying power already determined.

Thus we have an easy and accurate method of examining the goodness of a telescope of any kind. First, by giving it the least eye-glass that will shew the new moon, or rather Jupiter and Saturn, with sufficient light and distinctness when the air is quiet and pure; and then by finding how much it magnifies by the method abovementioned. But if several telescopes of the same kind have nearly the same length, those are the best in their kind with which you can read a print at the greatest distance. That the reader may have some notion of the powers of telescopes in this way, we shall subjoin a short account of the effects of some reflectors made by Mr James Short of Edinburgh, as related by Mr Maclaurin.

With a reflecting telescope, of which the speculum was quick-silvered glass, and focal distance 15 inches, the Philosophical Transactions could easily be read at the distance of 230 feet; by another of the same dimensions, the Transactions could be read at 280 feet distance. By a telescope of the same kind, whose focal distance was nine inches, Mr Maclaurin read in the Transactions at the distance of 138 feet; and another much smaller print at the distance of 125 feet.

It is not mentioned whether these telescopes were of the Newtonian or Gregorian form; though it is most probable that they were of the former kind.

As the light produced by these glass speculums was very faint, Mr Short next applied himself to the construction of metallic ones, and the effects of these were vastly greater; but as they were of the Gregorian form, it is doubtful whether we are to ascribe their superiority entirely to the use of metalline speculums, or to the more advantageous construction of them. These telescopes had focal distances of two inches and 6-tenths; of four inches; six, nine, and 15 inches. By those of four inches, the satellites of Jupiter were seen very distinctly; and he could read the Philosophical Transactions at above 125 feet distance. By those of six inches focus, he read at 160 feet distance; by those of 9 inches, he read at 220 feet distance; and by those of 15 inches, he was able to read the Transactions at 500 feet distance. With these last he also several times saw the five satellites of Saturn. The effects of these 15-inch telescopes of Mr Short's therefore were equal to those of the best 17-feet refractors ever known; for it was thought wonderful that Cassini should observe all the satellites of Saturn with a 17-feet refracting telescope.

#### § 18. The Solar Telescope.

This instrument is of the nature of the camera obscura, and shews the image of the sun in a darkened room, as that of an insect is shewn by the solar microscope. AB, fig. 6. represents a part of the window-shutter of a darkened room; CD the frame, which, by means of a screw, contains the scioptical ball EF, in a hole of the said shutter adapted to its size. This ball is perforated with a hole *abcd*. Through the middle, on the side *bc*, is screwed into the said hole a piece of wood, and in that is screwed the end of a common refracting telescope GHIK, with its object-glass GH, and one eye-glass at IK; and the tube is drawn out to such a length, that the focus of each glass may fall near the same point. This being done, the telescope and ball are moved about in such a manner, as to receive the sunbeams perpendicularly on the lens GH, through the cylindric hole of the ball: by this glass they will be collected all in one circular spot *m*, which is the image of the sun. The lens IK is to be moved nearer to, or farther from, the said image *m*, as the distance at which the secondary image of the sun is to be formed requires, which is done by sliding the tube IKLM backward and forward in the tube LMNO. Then of the first image of the sun *m*, will be formed another, PQ, very large, luminous, and distinct.

In this manner the sun's face may be viewed at any time without offence to weak eyes; and whatever changes happen herein may be duly observed. The spots are here all of them conspicuous, and easy to be observed under all their circumstances of beginning to appear, increase, division of one into many, &c. By the solar telescope also we view an eclipse of the sun to the best advantage; as having it by this means in our power to represent the sun's disk as large as we please, and consequently to render the eclipse proportionably conspicuous. Also the circle of the sun's disk may be so divided by lines and circles drawn thereon, that the quantity of eclipse, estimated in digits, may thus

OPTICS.  
*Fig. 1.*  
 Binocular Telescope.

Plate CCXXIV.

this way be most exactly determined; also the moments of the beginning, middle, and end of it, for determining the longitude of the place. The transits of Mercury and Venus over the sun are thus also beautifully represented, and the planets appear very round, black, and well-defined. Their comparative diameters with that of the sun may also be thus observed, the times of ingress and egress, &c. better than by any other method hitherto invented.

By the solar telescope the clouds are most beautifully represented passing before the sun, according to their various degrees of rarity or density; but these, Mr Martin says, are best observed by the camera obscura. He takes notice of an unusual phenomenon which he once observed in looking at the image of the sun by this instrument. The window looked towards the west, and the spire of Chichester cathedral was directly before it at the distance of about 50 or 60 yards. The images of the sun and spire were very large, being made by a lens of 12 feet focal distance, and it was very agreeable to observe the manner in which the sun was for some time eclipsed by the spire. Once, as he observed the occultation of the sun behind the spire, just as the disk disappeared, he saw several small, bright, round balls, running towards the sun from the dark part of the room, even to the distance of 20 inches. Their motion was a little irregular, but rectilinear, and seemed accelerated as they approached the sun. These luminous globules also appeared on the other side of the spire, and preceded the sun, running out into the dark room, sometimes more, sometimes less together, in the same manner as they followed the sun at its occultation. "They appeared, says he, to be in general about  $\frac{1}{8}$  of an inch in diameter; and therefore must have been very large luminous globes in some part of the heavens, whose light was extinguished by that of the sun, so that they appeared not in open day-light; but whether of the meteor kind, or what sort of bodies they might be, I could not conjecture."

#### § 19. The Heliostat.

THE use of this machine is to take off the inconveniences which arise from the motion of the earth, in making experiments on the solar light. By this motion it happens, that the image of the sun formed by the solar telescope can never be steady, but continually shifts its place on the screen upon which it is thrown; and the like may be said of the solar microscope. Any contrivance therefore by which this apparent motion can be prevented, and the light of the sun fixed upon any particular spot, or in one certain direction, must certainly be of the highest utility. The heliostat answers the purpose completely; and is an invention of Dr Gravesande, who gives the following description of it.

"This machine consists of two principal parts, each of which consists of many smaller parts. The first is a plane metallic speculum, supported by a stand; the other is a clock, which directs the speculum.

"We make use of a metallic speculum, because there is a double reflection in a glass one. The magnitude and figure of it are not material; mine is rectangular, four inches long and three broad.

"This is put into a wooden frame, which is surrounded with wooden rulers, cut in, whereby the speculum is retained.

"To sustain this, without hindering its motion, to Plate the said wooden frame, behind, is applied the brads CXXIV. fig. 2. plate *aa*, whose ends, being bent, are fastened to the wood sidewise.

"This speculum S is suspended by the handle AA, small screws being put through holes in the end of it, which go into the ends *a, a*, of the said frame, and whose parts, which are in the holes of the handle, are cylindrical, so that the speculum turns freely upon its axis, which, if it were made sensible, would pass along the surface of the speculum.

"The handle is joined to the cylinder C, whose axis, if it were continued, would concure with the middle point of the said axis of the revolution of the speculum.

"To the same point answers the tail DE, which is joined perpendicularly to the hind part of the speculum. This tail is cylindrical; and is made of a brass wire, which is straight, firm, and whose diameter is about a sixth part of an inch.

"The cylinder C is put upon the wooden stand P, whose upper part is represented by itself: whilst this is done, the iron cylinder *c*, whose surface is smooth, goes into a cavity in the cylinder C, which is of copper; by which means this turns freely about its axis, so that, by the motion of the tail DE, the position of the speculum is very easily altered as you please.

"This is raised and depressed, by means of the three brass screws B, B, B, which are turned with a key, and go through a plate of the same metal, which is applied to the bottom of the stand for that purpose; and which stands out in three places, to receive the screws.

"If the speculum is to be raised higher, as may easily be done, we put the speculum together with its stand, upon a small board, which has low feet, and is made for that purpose.

"The other part of the machine is a clock, as has been said above. This is represented at H; the index performs its revolution in 24 hours.

"The plane of the clock is inclined to the horizon, according to the inclination of the equator in the place where the machine is made use of; that is, in this our city of Leyden is  $52^{\circ} 49'$ .

"But this machine may be made use of in other places, whose latitudes differ one or two degrees from this place, as will appear.

"The clock is sustained by the copper pillar FG; this consists of two parts, which are joined by the screws *d, d*, between which, as in a sheath, is moved an iron plate, in the middle of which there is a slit, through which the said screws *d, d*, pass. This plate is joined fast to the lower plate of the clock itself, which is raised and depressed by this method, and fastened by the screws *d, d*. It may also be raised higher by the screws I, I, which go thro' the thick copper plate LLM, upon which the pillar FG stands.

The extreme parts of this plate L, L, are terminated in such manner, that *bc* and *cb* make one right line, through which we suppose a vertical plane to pass: this will

will be perpendicular to the horizontal lines, which may be drawn on the plane of the clock; such as are *fg, hi*.

"The machine is so ordered, that the plane of the clock may have the inclination beforementioned, when the plane LLM is horizontal; in which situation it is easily placed by means of the screws I, I, I, by help of the plumb-line Q, whose point should answer to the point *o*, which is marked upon the surface LLM.

"If the machine were to be used in another place, whose latitude differed from that for which the machine was constructed, another point, as *o*, would be marked, in which case the plane LLM would be inclined to the horizon.

"The axis of the wheel, which moves the index, is pretty thick, and is perforated cylindrically; but the cavity inclines a little to a conical figure, for towards the bottom it is somewhat narrower.

"The index itself is represented at ON. This is of brass, and its tail *pq* exactly fills the cavity mentioned last, into which it is thrust tight, that it may stick, and that the wheel may carry the index with it as it moves; whose situation may yet be altered, and set to any hour.

"This tail has also a cylindrical hole; and through this passes the small brass wire *ld*, which remains in any situation, whilst it is raised or depressed.

"At the end O of the index there is a small cylinder *n*, which is perforated cylindrically.

"The length of the index is measured in the line, perpendicular to *ld*, drawn from the axis of the cylinder *n* to the axis of the wire *ld*. In my machine this length is six inches.

"The iron tail *l* of the piece T goes into the cavity of the cylinder *n*; this tail exactly fills the cavity, but yet moves freely in it.

"Between the legs of the piece T, the small pipe R may be suspended at different heights, thro' which the tail DE of the speculum may be moved freely, which fills the pipe very exactly. This small pipe is suspended, as was said of the speculum. The small

"These things being thus ordered; to fix the machine, it is put upon a plane that is horizontal, or nearly so.

"First we join the placer to the stand P, which we raise as much as is necessary, that the ruler YZ being reduced to a just length, which we turn at pleasure, and incline in every respect, that is with respect to the place and direction, may agree to the sun's ray, which we undertake to fix.

"We so order the other part of the machine, that the lines *bc, bc*, may agree to a meridian line which has been drawn on the plane; and it is so disposed by means of the screws I, I, I, that the plumb-line Q may answer to the point *o*.

screws *r, r*, pass through the said legs, and the ends of them go into the parts *m, m*, of the pipe, and remain there: then the pipe turns freely about the axis which passes through *mm*; for the parts of the small screws are cylindrical, which answer to the holes in the legs of the piece T.

"When the machine is to be fixed, we make use of another machine, which we shall call a *placer*.

"The cylinder C, together with its speculum, is removed from the stand P, upon which is placed the brass pillar VX. This sticks tighter to *e* than the cylinder C, that the pillar may keep its place, whilst the machine is settled.

"Upon the head X the ruler YZ moves round a centre, so that it may be inclined to the horizon as you please, and keep its position. The length of the arm YX is determined at pleasure. The arm XZ is of a peculiar construction, and a certain length.

"To the said ruler, which is not extended beyond *y*, there are applied two others, as *xZ*, between which the first is inclosed: these are joined at Z, and also cohere by means of the screws *z, z*, which pass thro' a slit in the first ruler. On this ruler is marked the small line *vx*, whose length is equal to nine hundredth-parts of the length of the index, and which is divided in the manner which will be mentioned presently.

"The arm XZ is equal to the length of the index, if it be measured between the centre of motion at X and the end Z, when the end *x* of the outward ruler agrees to *v*, where the divisions of the small line *vx* begin.

"The divisions of this small line are unequal, and determine the length of the arm at different times of the year, by applying *x* to the division which answers to the day in which the machine is used.

"But in order to mark the divisions, we suppose the length of the arm to be divided into 1000 equal parts, that is, *vx* into 90 equal parts; but the distances from the point *v* are set down in the following small table.

1 Fe.	21 Ja.	11 Ja.	21 Dec.
47.	64.	77.	90.
11 No.	21 No.	1 Dec.	21 Dec.

drawn a small line, which accurately answers to *vx*, table.

11 May	21 May	1 Jun.	21 Jun.
51.	66.	79.	90.
1 Au.	21 Jul.	11 Jul.	21 Jul.

"The index NO is turned, that the sun's rays may pass directly thro' the pipe R, which is turned and inclined, as is required. The brass wire *ld* is then raised or depressed, that the shadow of the end of it may pass through the middle of the pipe.

"This whole part is moved to the placer, which is ordered as has been said before. But the clock is so moved towards the placer, and raised, that the end *l* of the brass wire *lk* may agree to the end Z of the ruler YZ.

"We must continually have regard to the plummet Q, that it may always answer to the point *o*; we must also take care, that after the clock is moved, the sun's rays and the shadow of the point *l* may pass thro' the

the small pipe R as before, that the position with respect to the meridian may not be disturbed.

"The pillar VX with its ruler YZ is removed, the stand P being left in its place, on which the cylinder C with its speculum is put. The piece T is taken out of its place, that the tail DE of the speculum may be put thro' the pipe R; when the piece T is put in the same place again, every thing is ready.

"Then the rays reflected from the middle of the speculum, to which all the other rays, reflected from the speculum, are parallel, agree, as to place and direction, with the position which the ruler of the plazer had; and whilst the tail of the speculum is moved, as the clock moves, whose index follows the sun, its situation is altered with respect to the sun; but the rays, reflected from the middle point of the speculum, remains fixed.

"If the index NO being taken away, we substitute the index K, the machine may be used as a common clock.

"The experiments concerning light must be made in the dark; for this reason the machine, when made use of in the experiments, must be shut up in a box or case.

"This case is represented at A; it stands upon feet that have rollers joined to them, that it may be easily moved. It is open at one end, which end is moved to a window, through which the sun's rays come freely to the speculum.

"But the box is every way larger than the window, that, by being applied close to the wall, the light may be hindered from entering into the chamber; to this end, the box is moved as near the wall as possible, and the screws C, C, which are fastened to the fore-feet, are turned till they touch the ground.

"The door in my machine is opposite to the window; it might have been otherwise disposed. We transmit the rays through the fore part B; we make choice of this, by reason of the make of the place in which the experiments concerning light were made. In this part there are two apertures three inches broad, and about 18 inches high, one of which is represented open at DE.

"These are closed on the outside by pieces of wood, which are moveable between wooden rulers. Each piece serves either aperture, that they may be changed. One of them F is three feet long, and has a hole in its middle. The aperture *ab* is five inches long, and two broad.

"This is closed by the copper plate GH, in which there are two holes, *c, d*; the diameter of that is two thirds of an inch, the diameter of this is less. These holes are stopp'd by the plates I and K, which are applied to the first plate GH, and are moveable about the centres *i* and *k*: the magnitudes of the holes may also be varied, by turning the last plates, as the figure shews.

"The board F is hollowed behind, in order to receive the object-glass of a telescope of 16, 20 or 25 feet, according to the magnitude of the place in which the experiments are made; the centre of this glass ought to answer to the centre of the hole *c*.

"This board F is pretty long; the holes of the small plate may answer to any part of the aperture of the box, the other part of the aperture remaining shut.

For this reason the second board is shorter; it is sufficient if the aperture be closed with this. These boards are fastened by the screws M, M.

"We have shewn how the box is to be applied to the window; but this cannot be done thus, if we would make the experiments in the hours in which the sun's rays enter the window very obliquely. In this case, that the rays may come to the speculum, the box must answer to a part of the window only; the remaining part is closed any other way: I make use of a curtain to exclude all the sun's rays."

#### § 20. Equatorial Telescope, or Portable Observatory.

The Equatorial Telescope was contrived by Mr James Short; and consists of two circular planes or plates AA, supported upon four pillars; and these again supported by a cross-foot or pedestal moveable at each end by the four screws BBBB. The two circular plates AA are moveable, the one above the other, and called the *horizontal plates*, as representing the horizon of the place; and upon the upper one are placed two spirit-levels, to render them at all times horizontal: these levels are fixed at right angles to each other. The upper plate is moved by a handle C which is called the *horizontal handle*, and is divided into  $360^\circ$ , and has a nonius index divided into every three minutes.—Above this horizontal plate is a femicircle DD; divided into twice  $90^\circ$ , which is called the *meridian femicircle*, as representing the meridian of the place; and is moved by a handle E, called the *meridian handle*; and has a nonius index divided into every three minutes. Above this meridian femicircle is fastened a circular plate, upon which are placed two other circular plates FF, moveable the one upon the other, and which are called the *equatorial plates*; one of them, representing the plane of the equator, is divided into twice twelve hours, and these subdivided into every ten minutes of time. This plane is moved by a handle G, called the *equatorial handle*, and has a nonius index for shewing every minute. Above this equatorial plate there is a femicircle HH, which is called the *declination femicircle*, as representing the half of a circle of declination, or horary circle, and is divided into twice  $90^\circ$ , being moved by the handle K, which is called the *declination handle*. It has also a nonius index, for subdividing into every three minutes. Above this declination femicircle is fastened a reflecting telescope LL, the focal length of its great speculum being 18 inches.

In order to adjust this instrument for observation, the first thing to be done is to make the horizontal plates level by means of the two spirit-levels, and the four screws in the cross pedestal. This being done, you move the meridian femicircle, by means of the meridian handle, so as to raise the equatorial plates to the elevation of the equator in the place, which is equal to the complement of the latitude, and which, if not known, may also be found by this instrument. By this telescope the following problems may be solved.

To find the Hour of the Day, and Meridian of the Place. First find, from the astronomical tables, the sun's declination for the day, and for that particular time of the day; then set the declination femicircle to the declination of the sun, taking particular notice whether it is north or south, and set the declination femicircle

circle accordingly. You then turn about the horizontal handle and the equatorial handle, both at the same time, till you find the sun precisely concentric with the field of the telescope. If you have a clock or watch at hand, mark that instant of time; and by looking upon the equatorial plate and nonius index, you will find the hour and minute of the day, which comparing with the time shewn by the clock or watch, shews how much either of them differ from the sun.

In order to find the meridian of the place, and consequently to have a mark by which you may always know your meridian again, you first move the equatorial plate by means of the equatorial handle, till the meridian of the plate, or hour-line of 12, is in the middle of the nonius index; and then by turning about the declination handle till the telescope comes down to the horizon, you observe the place or point which is then in the middle of the field of the telescope, and a supposed line drawn from the centre of this field to that point in the horizon, in your meridian line. The best time of the day for making this observation for finding your meridian, is about three hours before noon, or as much after it. The meridian of the place may be found by this method so exactly, that it will not differ from the true meridian above 10" in time; and if a proper allowance be made for refraction at the time of observation, it will be still more exact. The line thus found will be of use afterwards, as being the foundation of all astronomical observations.

To find a *Star or Planet in the Day-time*. The instrument remaining rectified as already directed, you set the declination semicircle to the declination of the star or planet you want to see; and then you set the equatorial plate to the right ascension of the star or planet at that time; and looking through the telescope, you will see the star or planet: and having once got it into the field of the telescope, you cannot lose it again; for as the diurnal motion of a star is parallel to the equator, by moving the equatorial handle so as to follow it, you will at any time, while it is above the horizon, recover it, if it is gone out of the field.

The easiest method for seeing a star or planet in the day-time is this: Your instrument being adjusted as before directed, you bring the telescope down, so as to look directly at your meridian mark; and then you set it to the declination and right ascension, as before mentioned. By this instrument most of the stars of the first and second magnitude have been seen even at noon-day, when the sun was shining very bright; as also Mercury, Venus, and Jupiter. Saturn and Mars are not so easily seen, on account of the faintness of their light, except when the sun is but a few hours above the horizon.

And in the same manner, in the night-time, when you can see a star, planet, or any new phenomenon, such as a comet, you may find its declination and right ascension immediately, by turning about the equatorial handle and declination handle, till you see the object: and then, looking upon the equatorial plate, you find its right ascension in time; and you find, upon the declination semicircle, its declination in degrees and minutes.

In order to have the other uses of this instrument, you must make the equatorial plates become parallel

to the horizontal plates; and then this telescope becomes an *equal altitude* instrument, a *transit instrument*, a *theodolite*, a *quadrant*, an *azimuth instrument*, and a *level*. The method of applying it to these different purposes is obvious. As there is also a box with a magnetic needle fastened in the lower plate of this instrument, by it you may adjust it nearly in the meridian, and by it you may also find the variation of the needle. If you set the horizontal meridian and the equatorial meridian in the middle of their nonius indexes, and direct your telescope to your meridian mark, you observe how many degrees from the meridian of the box the needle points at, and this distance or difference is the variation of the needle.

### § 21. The Binocular Telescope.

The *binocular telescope* consists of two distinct telescopes severally directed from each eye to the same object, and combined together in the following manner. In fig. 1. *ab* and *cd* are two equal telescopes laid in a long box, nearly parallel to each other; the intervals between the eye-stops *a* and *c* being equal to the interval of the pupils, and that of the centres of the object-glasses somewhat less than the other. Both ends of the telescopes pass through oblong slits in both ends of the box; and the interval between them may be widened or contracted at either end by a long screw-pin laid over each end of both the telescopes; the threads of each half of the screws being wrought contrary ways, and called a *right* and *left handed screw*. For these halves being put through two nuts *e, f*, fixed to the upper sides of the telescopes, it comes to pass, that by turning the screw-pin one way, the two telescopes will accede to, and the other way they will recede from, each other; till, by one of these screw-pins, the interval between the eye-stops *a, c*, becomes equal to the intervals of the pupils of the observer; and by the other, the axes of the telescope become directed to the same object; which will be known exactly if there are cross hairs in the focus of each telescope, and even without them. For before this position is obtained, the objects will appear double, and afterwards single; and a much stronger and brighter appearance of the object will be obtained than by a single telescope.—There are other contrivances, besides that of a two-handed screw, by which the telescopes may be made to approach to or recede from each other. To exclude all useless and hurtful light from the eyes, the eye-stops are made hollow and very broad, to cover some part of the temples; and their inner parts are cut away, to admit the upper part of the nose between them. Two reflecting telescopes, as well as two refracting ones, might be combined into a binocular telescope; and, for the purpose of celestial discoveries, promises to be a very useful instrument.

### § 22. Of making Celestial Observations.

In the day-time there is little difficulty in finding the exact time of the transit of such stars as are capable of being discovered by the telescope over the middle of the field, because the cross-hairs placed in the focus of the object-glass receive a sufficient quantity of light to render them visible. But, in the night-time, these hairs are not visible, and therefore the observer

server hath not any mark to direct him : hence astronomers are obliged to enlighten the cross-hairs artificially, in order to render them visible, and this without letting the luminous body interfere with the object which they intend to view ; and, for doing this, two ways are proposed.

1. The object-glass of the telescope may be obliquely enlightened by placing a candle near to it in an oblique situation, so that its smoke or flame may not interfere with the object. But if the object-glass should happen to be pretty deep in the tube, it cannot be sufficiently enlightened by this means ; and besides, if the telescope is above six feet long, there will be a considerable difficulty in throwing a sufficient quantity of light upon the cross hairs.

2. By some an opening is made in the side of the tube near the focus of the object-glass, through which the cross hairs are illuminated by means of a candle. But this method also is attended with inconveniencies ; for the observer is incommoded by the light being so near his eyes, and the hairs themselves become liable to accidents through their exposed situation. An error also attends this method ; which is, that, according to the position of the light illuminating these hairs, they will appear in different situations. For example, when the horizontal hair is enlightened above, we perceive a luminous line which may be taken for the hair itself, and which appears at its upper superficies. On the other hand, when the hair is enlightened underneath, the luminous line will appear at the under surface of it ; and the error will be the diameter of the hair, which often amounts to more than six seconds. M. de la Hire, however, found a remedy for this inconvenience. He often observed, that in moon-shine nights, when the weather was a little foggy, the cross hairs were distinctly seen ; but when the heavens were serene, they could scarcely be perceived : he therefore covered with a piece of gauze, or fine silk-crape, that end of the tube next the object-glass ; and this method succeeded so well, that a link placed at a good distance from the telescope so enlightened the crape, that the cross-hairs distinctly appeared, and the light of the stars was by no means obscured.

In making solar observations, a smoked glass must be used for preserving the eyes ; and which may be thus prepared. Take two equal and well polished round pieces of flat glass ; upon the surface of one of which, all round its limb, glue a pasteboard ring ; then put the other piece of glass into the smoke of a lamp, taking it several times out, and putting it in again, till the heat should break it, until the smoke be so thick, that the lamp can scarcely be seen through it : but the smoke must not be all over of the same thickness, that so a place may be chosen answering to the splendour of the sun. This being done, the glass, thus blackened, must be glued to the pasteboard ring abovementioned, with its black side next to the other glass, that the smoke may not be rubbed off.

There are two kinds of observations relating to the stars : one is, when they are in the meridian ; the other, when they are in vertical circles. If the position of the meridian be known, the quadrant with which the observation is made, must be placed in the plane of that circle, and then the meridian altitudes are easily observed by means of the plumb-line. The meridian

altitude of a star may likewise be had by a pendulum clock, if the exact time of the star's passing by the meridian be known. It must be observed, however, that stars have the same altitude a minute before and after their passing the meridian, if they be not in or near the zenith ; but if they be, their altitudes must be taken every minute when they are in or near the meridian, and then their greatest or least altitudes will be those in question. The position of a given vertical circle must be found by the following method. 1. The quadrant and telescope remaining in the same situation wherein it was when the altitude of a star, together with the time of its passage by the intersection of the cross hairs in the focus of the object-glass, was taken, we observe the time when the sun, or some fixed star, whose longitude and latitude is known, arrives to the vertical hair in the telescope ; and from thence the position of the said vertical circle will be had, and also the observed star's true place. But if the sun, or some other star, does not pass by the mouth of the tube ; and if a meridian line be otherwise well drawn upon a floor, or very level ground, in the place of observation ; a plumb-line must be suspended from a fixed place, at about 18 or 20 feet from the quadrant ; under which a mark must be made on the floor, in a right line with the plumb-line. You must next put a thin piece of brass or pasteboard very near the object-glass, in the middle of which there is a slit vertically placed, and passing through the centre of the circular figure of the object-glass. Now, by means of this slit, the before-mentioned plumb-line may be perceived through the telescope, which before could not be seen, because of its nearness. Then the plumb-line must be removed and suspended, so that it be perceived in a right line with the vertical hair in the focus of the object-glass, and a point marked on the floor directly under it. And if a right-line be drawn through this point, and that marked under the plumb-line before it was removed, the said line will meet the meridian drawn upon the floor ; and so we shall have the position of the vertical circle in which the observed star is, with respect to the meridian, the angle whereof may be measured in assuming known lengths upon the two lines from the point of concurrence ; for if, through the extremities of these known lengths, a line or bafe be drawn, we shall have a triangle, whose three sides being known, the angle at the vertex may be found, which will be the angle made by the vertical circle and meridian.

Under the article QUADRANT, is shewn the proper method of fixing that instrument exactly in the meridian : but where the observer has no convenience of this kind, it will be proper to use a portable quadrant ; by means of which the altitude of a star must be observed a little before its passage over the meridian, every minute, if possible, until its greatest or least altitude be had ; by which means, though we have not the true position of the meridian, yet we know the meridian altitude of the star. But although this method is very good, yet if a star passes by the meridian near the zenith, we cannot have its meridian altitude by repeated observations every minute, unless by chance ; because in every minute of an hour, the altitude augments 15 minutes of a degree ; and in these kind of observations, the inconvenient situation of the observer, the variation of the star's azimuth several de-

greens in a little time, the alteration that the instrument must have, and the difficulty in well replacing it vertically again, hinders our making observations oftener than once in four minutes, during which time the difference in the star's altitude will be one degree. In these cases, therefore, it will be better to have the true position of the meridian, in order to place the instrument exactly in it; or to move it so that one may observe the altitude of the star the moment it passes the meridian.

The refraction may be found in the following manner. Having the meridian altitudes, and the declination of two stars of nearly equal altitudes, find also, by the directions already given, the apparent meridian altitude of some star near the pole; and if the complement of that star's declination be added thereto or taken therefrom, we shall have the apparent height of the pole. After the same manner may the apparent height of the equator be found by means of the meridian altitude of some star near it, and adding or subtracting its declination. Then these heights of the pole and equator being added together, they will always make more than 90 degrees, because both of them are raised by the refraction: but taking 90 degrees from this sum, the remainder will be double the refraction of either of the stars observed at the same height; and therefore taking this refraction from the apparent height of the pole, or equator, we shall have their true altitude.

To illustrate this: Suppose the meridian altitude of a star observed below the north pole to be  $30^{\circ} 15'$ , and complement of its declination  $5^{\circ}$ ; whence the apparent height of the pole will be  $35^{\circ} 15'$ . Also let the apparent meridian altitude of some other star, observed near the equator, be  $30^{\circ} 40'$ , and its declination  $40^{\circ} 9'$ ; whence the apparent height of the equator will be  $54^{\circ} 49'$ . Therefore the sum of the heights of the pole and equator thus found will be  $90^{\circ} 4'$ ; from which subtracting  $90^{\circ}$ , there remain  $4'$ , which is double the refraction at  $30^{\circ} 28'$  of altitude, which is about the middle of the heights found. Therefore at the altitude of  $30^{\circ} 15'$ , the refraction will be somewhat above  $2'$ , viz.  $2' 1''$ ; and at the altitude of  $30^{\circ} 40'$ , the refraction will be  $1' 59''$ . Lastly, if  $2' 1''$  be taken from the apparent height of the pole,  $35' 15''$ , the remainder  $35^{\circ} 12' 59''$  will be the true height of the pole; and so the true height of the equator will be  $54^{\circ} 47' 1''$ , as being the complement of height of the pole to  $90^{\circ}$ . The refraction and height of the pole found according to this way, will be so much the more exact as the height of the stars is greater; for if the difference of the altitudes of the stars should be even  $2^{\circ}$  when their altitudes are above  $30^{\circ}$ , we may by this method have the refraction and the true height of the pole; because, in this case, the difference of refraction in altitudes differing only two degrees is not perceptible.

The quantity of refraction may also be found by the observation of one star only, whose meridian altitude is  $90^{\circ}$ , or a little less: for the height of the pole or equator above the place of observation being otherwise known, we shall have the star's true declination by its meridian altitude; because refractions near the zenith are insensible. Now, if we observe by a pendulum the exact times when the said star comes to every

degree of altitude, as also the time of its passage by the meridian, which may be known by the equal altitudes of the star being east and west, the refraction may be found by the solution of a case in spherical trigonometry: for here, in a spherical triangle, we have the distance between the pole and zenith, the complement of the star's declination, and the angle comprehended by the arcs abovementioned; namely, the difference of mean time between the passage of the star by the meridian and its place, converted into degrees and minutes, to which must be added the proper proportional part of the mean motion of the sun in the proportion of  $59' 8''$  per day; therefore the true arc of the vertical circle between the zenith and true place of the star may be had. But the apparent arc of the altitude of the star is had by observation, and the difference of these arcs will be the quantity of refraction at the height of the star.

To find the time of the equinox and solstice by observation, we must proceed in the following manner. Having found the height of the equator, the refraction, and the sun's parallax at the same altitude, it will not be difficult afterwards to find the time in which the centre of the sun is in the equator; for if, from the apparent meridian altitude of the sun's centre the same day that it comes to the equinox, be taken the convenient refraction, and then the parallax be added thereto, the true meridian altitude of the sun's centre will then be had. Now the difference of this altitude and the height of the equinoctial will shew the true time of the true equinox before or after noon: and if the sum of the seconds of that difference be divided by 59, the quotient will shew the hours and fractions which must be added to or subtracted from the true hour of noon to have the time of the true equinox. The hours of the quotient must be added to the time of noon, if the meridian altitude of the sun be less than the height of the equator about the time of the vernal equinox; but they must be subtracted, if it be found greater. We must proceed in a contrary manner when the sun is near the autumnal equinox.

The solstices are found with much more difficulty; for one observation only is not sufficient, because about this time the difference between the meridian altitudes in one day and the next succeeding day is almost insensible. The exact meridian altitude of the sun must therefore be taken for 12 or 15 days before the solstice, and as many after, that so one may find the same meridian angle by little and little; to the end that, by the proportional parts of the alteration of the sun's meridian altitude, we may the more exactly find the time when the sun's altitude is the same before and after the solstice, being in the same parallel to the equator. Now, having found the time elapsed between both situations of the sun, you must take half of it, and seek in the tables the true place of the sun at these three times. This being done, the difference of the extreme place of the sun must be added to the mean place, in order to have it with comparison to the extremes; but if the mean place found by calculation does not agree with the mean place found by comparison, you must take the difference, and add to the mean time, that which answers to that difference, if the mean time found by calculation be lesser; but, if greater, it must be subtracted, in order to have the time of the solstice.

Alice. Here it must be noticed, that an error of a few seconds in the observed altitude of the sun will make an alteration of an hour in the true time of the solstice; whence it is plain, than the true time of the solstice cannot be had but with instruments very well divided, and several very exact observations.

With regard to eclipses, the beginning, end, and total emersion may be estimated with sufficient exactness without telescopes; excepting the beginning and ending of lunar eclipses, where an error of one or two minutes may be made, because it is difficult to determine with certainty the extremity of the shadow. But the quantity of the eclipse, that is, the eclipsed portion of the sun and moon's disk, which is measured by digits, or the 12th part of the sun and moon's diameter, and minutes, or the 60th part of digits, cannot be well known without a telescope joined to some instrument. One method of observing them by the solar telescope hath been already described; but this applies only to eclipses of the sun, those of the moon not being discoverable by reason of the faintness of the light: for these therefore micrometers must be used, which are to be placed in the focus of the telescope, and of which various kinds are described under the article MICROMETER. The eclipses of the satellites of Jupiter are to be observed in the same manner, but require a better telescope than what is necessary for observing the eclipses of our moon.

It is here proper to take notice of the method of obviating a difficulty formerly taken notice of; namely, that in a serene night we often find the light of Jupiter and its satellites observed through the telescope to diminish by degrees, so that it is impossible to determine exactly the true times of the immersion and emersion of the satellites. This proceeds from the dew which falls upon the surface of the object-glass, and intercepts the light. A very fine remedy is, to make a tube of blotting paper, about two feet long, and of a sufficient bigness to go about the end of the tube of the telescope next to the object-glass, which will very effectually drink up the dew, and hinder it from coming to the object-glass; and by this means we may make our observations with sufficient exactness.

§ 15. *Telescopic Instruments for finding Time by observing when the Sun or any Star has equal Altitudes on each side of the Meridian.*

ONE of these instruments was made by Mr Roger Cotes, and was contrived by him for the purpose of regulating a pendulum-clock presented to the Royal Society by Sir Isaac Newton, to whom he sent the following description. "AB is a strong wooden axis about six feet in length: CD and DE on one side, EF and FG on the other, are pieces framed to each other and to the axis as firmly as was possible. Into the piece CD, and at the angle F, were fixed strong wooden pins nearly parallel to each other, and perpendicular to the plane CDEFG. PQ is the cylindrical brass tube of a five-foot telescope (belonging to our sextant;) this was well fastened with iron staples and screws to the piece of wood IKML, whose under plane surface is here represented as objected to view. Into this surface there was perpendicularly fixed a strong wooden pin N, which was designed to hang the upper end of

the telescope upon any of the pins in CD, whilst its lower end rested upon the pin F. Now, that the telescope might be taken off, and yet afterwards be again placed accurately in the same position, I ordered the edges IK and CD, which touched each other, to be rounded like the surface of a cylinder, as also the edge EF into which the pin F was fixed, and against which the cylindrical tube of the telescope rested, so that the contact in both places might be made in a point. Upon the same account the pins in CD were made a little hollow, as is represented at R; and the pin F was a frustum of a cone, that thereby the telescope might more surely touch the edges CD and EF. Into the two ends of the wooden axis were strongly fixed two pieces of well-tempered steel: that at the upper end A was a cylinder well turned, which moved in a collar, whose cavity, represented by S, was figured like two hollow and inverted frustums of cones joined together; the lower at B was a cone moving in a conical socket of a somewhat larger angle. This socket had liberty to be moved horizontally, and to be fixed in any position by two screws, which pressed against it sideways at right angles to each other. The instrument being thus prepared, I fixed a needle V, at the lower end of the wooden axis, whose point stood out from it about an inch; then suspending a fine plumb-line TVX from the upper end of the same axis, I altered the position of the instrument by the screws, until the plumb-line came to beat against the point of the needle in the whole revolution of the instrument, and there I fixed it as prepared for use."

So far Mr Cotes. The plumb-line or fine wire TVX was suspended by a loop T upon a brass pin that screwed into the top of the axis AB; a nick being filed round the pin to stay the loop from sliding out of it. Then by screwing the pin in or out, the plumb-line was brought to the same distance from the axis AB as the point of the needle is at V: which was fixed in the end of a thick wooden pin Y, not in the axis of it, but towards one side; so that by turning the pin round itself, in a hole bored through the axis AB, the needle's point might describe a small circle, and be brought to touch the plumb-line when parallel to the axis of motion of the wood AB.

Dr Smith gives the following description of an excellent instrument of this kind, in the noble collection of the right honourable the earl of Ilay. "It is made of all of brass, except a square steel axis *ab* 30 inches in length. To one side of the upper part of this axis there is fixed a small sextantal arch *cd* represented separately at E; its centre *a* being at the top of the axis *ab*. The telescope MN is also 30 inches long, and is fixed along the diameter of a semicircle of the same radius as the sextant, and concentric to it. The telescope with the semicircle being moveable about this centre upon the plane of the fixed sextant *acd*, may be fastened to it in any elevation by two nuts and screws *e, d*, fixed in the ends of the sextantal arch; a circular slit being made all along the limb of the semicircle for these screw-pins to slide in. Close under these arches, the axis *ab* is surrounded by a short cylinder *e*, about an inch in diameter, well turned and polished. The lower end of the axis is formed into a fine conical point *b*. The frame in which the axis turns, is a long hollow parallelopiped wanting two

Instruments;

sides. Its other sides  $fg$ , are two brass plates, equal in length to the part  $be$  of the axis, and are screwed together edgewise. It has for its bases two equal plates  $b, i$ , four inches square. In the middle of the upper square there is a round hole large enough to receive the cylinder  $c$ , without touching it; and over this hole is fixed a triangular hole in another plate; one of whose sides is moveable by a screw, to make all the sides of the triangle touch the cylinder. Upon the lower square there lies a smaller plate  $i$ , with a fine centre-hole to receive the point  $b$  of the axis. This centre-plate is moveable sideways by two screws at right angles to each other, which, when the frame is firmly fixed into a niche of a free-stone pillar, will bring the axis  $ab$  exactly perpendicular to the horizon. This position is known by a spirit-level  $lm$  fixed at right angles to the axis above the cylinder, upon the side opposite to the femicircle. Along the top of the level there is a sliding pointer to be set to the end of the air-bubble; and when the position of the axis is so adjusted by the screws below, that the air-bubble keeps to the pointer for a whole revolution of the instrument, the axis  $ab$  is certainly perpendicular to the horizon; and then the line of sight through the telescope describes a circle of equal altitudes in the heavens. There are several of these circles described in the heavens, even when the telescope is fixed to the sextantal arch. For the round hole in its focus has five wires parallel to the horizon at equal intervals from one another, as at  $k$ ; and they are crossed at right angles in the middle by two other upright wires at a small distance from each other. The design of so many wires is to observe when the same star is successively covered by every one of the five, both in the east and west; so that the time of its passage over the meridian may be had more accurately, by taking a medium among all the observations. The distances between the five wires need be no greater than to afford time enough to write down the several observations, which must be taken when the star is between the perpendicular wires.

169  
Uses of these  
instruments.

Time shewn by a clock may be called *mechanical*, to distinguish it from *solar* and *sidereal time*. By observing when a star has equal altitudes before and after its culmination or appulse to the meridian, we have the mechanical time of its culmination. Then by subtracting the sun's right ascension computed to this mechanical time, from the star's right ascension determined for the same time, we have the solar time of the star's culmination, and consequently the difference between the mechanical and solar times.

Thus, by finding the mechanical times, when the same star culminates any two nights, rather at a distance from each other than successive, we have the difference between a sidereal day and a mechanical day; and consequently between a mechanical day and a solar day of a mean length.

Hence any number of mechanical minutes may be converted into solar or into sidereal minutes by the rule of three.

These observations will answer the purpose the more exactly as the star is nearer to the prime vertical; because the variation of its altitude is here greater in a given time, than if it were situated in any other vertical oblique to the meridian. In the latitude of

50 degrees an error of one minute in altitude, at any point of the prime vertical, will cause an error of 63 seconds in time; and in the latitude of 55 degrees it will cause an error of near 7 seconds; as that excellent geometer Mr Cotes has shewn in his treatise concerning the *Estimation and Limits of Errors* in mixed mathematics, published at the end of his admirable book called *Harmonia Mensurarum*. It is also the safest to choose a star as high as possible, lest a different state of the atmosphere should cause a different refraction of the visual rays, and consequently an error in the times of observation.

The solar time may also be found by observing when the sun himself has equal altitudes in the morning and evening; if we correct the time of the latter observation by a just allowance for the variation of the sun's declination, as follows. Upon a celestial globe let the pole be at  $P$ ; the vertex of the observer's place at  $V$ ; the complement of its latitude  $PV$ ; its meridian  $PVBG$ ; a circle of equal altitudes  $ABCD$ , described about its pole  $V$ ; and passing thro' the sun's centre at  $A$  at the time of the morning observation, and through it at  $D$  at the time of the evening observation; two circles of declination,  $PAF$ ,  $PDI$ , cutting the equator  $FGHI$ , in  $F$  and  $I$ ; a parallel of declination  $ACE$ , cutting the circle  $PDI$  in  $E$ , and  $ABD$  in  $C$ ; three equal vertical arches  $VA$ ,  $VC$ ,  $VD$ ; and lastly, a third circle of declination  $PCH$  cutting the equator in  $H$ . Now, had not the sun varied his declination from  $A$  or  $E$  to  $D$ , in the evening he would have had the same altitude at  $C$  as in reality he has at  $D$ . And then as the angles  $VPC$ ,  $VPA$ , would have been equal, so the times of the evening and morning observations would also have been equidistant from noon; being measured by those angles, or by the arches  $GF$ ,  $GH$ . Therefore the angle  $CPD$ , or the arch  $IH$ , which measures it, is also the measure of a portion of time to be subtracted from the evening observation, if the sun's declination varies northwards, otherwise to be added, to give the time sought equidistant from noon. Let another circle of declination  $P\hat{K}I$  bisect the small angle  $HPI$ , and consequently the small arches  $CD$  and  $HI$  in  $k$  and  $l$ . Draw the vertical arch  $kV$ ; and in the triangle  $kPV$ , we have given  $PV$  the complement of the latitude, and  $P\hat{k}$  half the sum of the given complements,  $PC$  or  $PA$  and  $PD$ , of the sun's declinations at the times of the two observations, and lastly, the included angle  $kPV$ , by converting half the interval of time between the observations into degrees and minutes. Hence by trigonometry we have the angle  $P\hat{k}V$ , of an intermediate magnitude between  $PCV$  and  $PDV$ , and therefore fitter to be used instead of either of them. Hence also we shall have the arch  $I\hat{H}$ ; by taking it in proportion to  $DE$  the difference of the declinations, as the co-tangent of the angle  $PCV$ , to the sine of the arch  $PC$  or  $P\hat{k}$ . For  $I\hat{H}$  is to  $DE$  in a ratio compounded of  $I\hat{H}$  to  $CE$  and of  $CE$  to  $DE$ , that is, of the radius to the sine of the arch  $PC$ , and of the co tangent of the angle  $DCE$  or  $PCV$  to the radius: as appears by taking away the common angle  $DCP$  from the right angles  $ECP$  and  $DCV$ ; and by considering the small triangle  $DCE$ , right-angled at  $E$ , as if it was rectilinear. The calculation supposes the sun's centre has equal altitudes at  $A$  and  $D$ ; which is agreeable to the

Mechanism of Optical Instruments observations that determine when his upper or his under limb has equal altitudes."

SECT. VI. *Of the Mechanism of the principal Optical Instruments.*

As part of the mechanism of optical instruments depends on a knowledge of the arts of casting, polishing and folding brasis and other metals, of turning wood, &c. we must necessarily confine ourselves in this section to some directions concerning the grinding and polishing of the glasses and specula for microscopes and telescopes, with the method of putting them together and adjusting them; leaving the fabrication of the other parts to be learned by the ingenuity and industry of those who choose to employ themselves in that manner, and for which scarce any rules that would be of much service can be laid down.

§ 1. *Of making Glass-globules for Microscopes.*

THOUGH these are not found to be of such use as small convex lenses, yet as they are easily made, and are still used through choice by some persons, we shall here give some of the best methods of making them. Mr Butterfield's method of making these was by the flame of a spirit-lamp, which, instead of a wick, had several folds of fine silver-wire doubled up and down like a skin of thread. Having prepared some fine glass, beaten to powder and washed very clean, he took a little of it upon the sharp point of a silver needle wetted with spitale, and held it in the flame, turning it about till it become quite round, but no longer, for fear of burning it. The art lies in giving the globules an exact roundness, which can only be learned by experience. When a great many globules were thus formed, he rubbed them clean with soft leather. Then, having several small pieces of thin brass plates, twice as long as broad, he doubled them up into the form of a square, and punched a fine hole through the middle of them; and having rubbed off the bur about the holes with a whetstone, and blacked the insides of the plates with the smoke of a candle, he placed a globule between the two holes, and tacked the plates together with two or three rivets.

Dr Hooke, for the same purpose, used to take a very clear piece of glass, and draw it out into long threads in a lamp; then he held these threads in the flame, till they ran into round globules at the end. He next fastened the globules with sealing-wax to the end of a stick, so that the threads stood upwards, and grinding off the ends of the threads upon a whetstone, polished them upon a smooth metal plate with a little putty.

Mr Stephen Gray tells us, that, for want of a spirit-lamp, he laid a small particle of glass, about the bigness of the intended globule, upon the end of a piece of charcoal, and by the help of a Blow-Pipe, with the flame of a candle, he soon melted it into a globule. By this means he made them indifferently clear, and the smallest very round; but the larger, by resting upon that side, became a little flatted, and received a roughness on that side. He was therefore wont to grind and polish them upon a brass plate till he reduced them to hemispheres; but he found, that the small round globules, besides that they magnified more, shewed objects more distinctly than the hemispheres.

§ 2. *Of grinding Lenses for Telescopes and Microscopes.*

A LENS is more easily made of an equal convexity on both sides than of any other figure, because the same tools will serve for grinding both its surfaces. And a glass of this figure will make as perfect an image as any other, because the aberrations of the rays occasioned by the spherical figures of the surfaces, whatever be the proportion of the semidiameters, are inconsiderable in long telescopes, in proportion to what is occasioned by the different refrangibility of the rays, which last error Mr Dollond has shewn how to correct. If it be proposed, then, to make a glass of equal convexities, that shall have a given focal distance, the radius of the spherical surface will be found by taking it in proportion to the given focal distance as 12 to 11, putting the sine of incidence to the sine of refraction out of air into glass as 17 to 18, which Sir Isaac Newton hath accurately determined it to be. The focal distance of the glass being given, its aperture may be found by the following table.

Length of the telescope, or focal distance of the object-glass.	Linear aperture of the object glass.	Focal distance of the eye-glass.	Linear amplification, or magnifying power.

500	12.25	13.47	445
600	13.42	14.76	488

These proportions, in Huygens's table for refracting telescopes, are measured by the Rheinland foot, which is to the English foot as 139 to 135: so that, taking their lengths of as many English feet, their apertures and eye-glasses and linear amplifications should be severally diminished in the subduplicate ratio of 139 to 135; that is, nearly in the ratio of 139 to 137, or about  $\frac{7}{8}$ , or  $\frac{7}{8}$ th part of the whole.

Because the figure of the glass cannot be made exactly true to its very edges, the breadth of it may be about half an inch more than the diameter of its aperture, or even three quarters, or a whole inch more, if its focal distance be between 50 and 200 feet. Mr Huygens directs in general to make the breadth of the concave tool or plate in which an object-glass must be ground, almost three times the breadth of the glass; though in another place he speaks of grinding a glass whose focal distance was 200 feet, and breadth  $8\frac{1}{2}$  inches, in a plate only 15 inches broad. But for eye-glasses, and others of a shorter radius, the tool must be in proportion to the breadth of these glasses, to afford sufficient room for the hand in polishing. Huygens made his tools of copper or cast brass; which, for fear they should change their figures by bending, can hardly be cast too thick: nevertheless he found by experience, that a tool 14 inches broad and half an inch thick was sufficient for grinding glasses to a sphere of 36 feet diameter; when the tool was strongly cemented upon a cylindrical stone an inch thick, with hard cement made of pitch and althes.

In order to make moulds for casting such tools as are pretty much concave, he directs that wooden patterns should be turned in a lathe all little thicker and broader than the tools themselves. But for tools that belong to spheres above 20 or 30 feet diameter, he says it is sufficient to use flat boards turned circular to the length and breadth required. When the plates are cast, they must be turned in a lathe exactly to the concavity required. And for this purpose it is requisite to make a couple of brass gauges in the following manner.

Take a wooden pole a little longer than the radius of the spherical surface of the glass intended, and through the end of it strike two small steel points at a distance from each other, equal to the radius of the sphere intended; and by one of the points hang up the pole against a wall, so that this upper point may have a circular motion in a hole or socket made of brass or iron firmly fixed in the wall. Then take two equal plates of brass or copper well hammered and smoothed, whose length is somewhat more than the breadth of the tool of cast brass, and whose thickness may be a tenth or a twelfth part of an inch, and the

breadth two or three inches. Then having fastened these plates flat against the wall in an horizontal position, with the moveable point in the pole strike a true arch upon each of them. Then file away the brass on one side exactly to the arch struck, so as to make one of the brass edges convex and the other concave; and, to make the arches correspond more exactly, fix one of the plates flat upon a table, and grind the other against it with emery. These are the gauges to be made use of in turning the brass tools exactly to the sphere required.

But if the radius of the sphere be very large, the gauges must be made in the following manner. Suppose the line AE, fig. 1. drawn upon the brass plate, to be the tangent of the required arch AFB, whose radius, for example, is 36 feet, and diameter 72. From A set off the parts AE, EE, &c. severally equal to an inch, and let them be continued a little beyond half the breadth of the tool required. Then, as 72 feet or 864 inches is to one inch, so let one inch be to a fourth number; this will be the number of decimal parts of an inch in the first line EF, reckoning from A. Multiply this fourth number successively by the numbers 4, 9, 16, 25, &c. the squares of 2, 3, 4, 5, &c. and the several products will be the numbers of decimal parts contained in the 2d, 3d, 4th, and 5th EF respectively. But because these numbers of parts are too small to be taken from a scale by a pair of compasses, subtract them severally from an inch represented by the lines EG; and the remainders being taken from a scale of an inch divided into decimal parts, and transferred by the compasses from G to F, will determine the points F, F, &c. of the arch required; after which the brass plate must be filed away exactly to the points of this arch, and polished as before.

To apply the brass tool to a turning lathe in order to turn the concave surface of it exactly spherical, let the brass fig. 2. represent a view of some part of the lathe, taken from a point directly over it; let *ab* represent a strong flat disk of brass half an inch thick at least, having a strong iron screw-pin firmly fixed in the centre of it, and standing out exactly perpendicular to one side; by which it may be screwed into the end *c* of the mandrel or axis of the lathe, represented by *cd*. This disk is represented separately in fig. 3. and must be well soldered to the backside of the tool *ef*, which therefore, in the middle of it, must be made plane, and exactly parallel to the circumference of its opposite surface, in order that the circumference may be carried round the axis of the lathe in a plane perpendicular to it. The mandrel or axis *cd* turns upon a point *d* in the puppet-head of the lathe, and in an iron collar represented by *st*.

Let *ghik* represent a board nailed fast on the other puppet-head; and let the concave gauge *gh* be laid upon this board, with its concave arch parallel to the concavity of the tool *ef*, and be screwed down to the board with flat-headed screws sunk into the brass. Let *lmno* represent such another board lying upon the former, with the convex gauge *lm* screwed to the under side of it; so that, by moving this upper board, the arch of the concave gauge may be brought to touch the concave one, and to slide against it. The turning tool *pq* is laid upon the moveable board, and is held fast to it by a broad-headed screw at *r*, to be turned

Method of making the moulds.

175  
Of making the gauges.

Mechanism of Optical Instruments or turned by the hand upon occasion. To know whether the concave gauge be exactly parallel to the concavity of the tool *ef* screwed fast to the mandrel, direct the point *p* of the turning tool *pg* to touch any point of the tool *ef* near its circumference: then having fixed the turning tool *pg* by its screw *r*, turn the brass tool *ef* half round, and move the upper board till the point *p* of the turning tool be brought over-against the same mark upon the tool *ef*; and if it just touches it as before when the gauges coincide, all is right. If not, the position of the head of the lathe may be altered a little by striking it with a mallet. But the best way is, to make this examination of the situation of the concave gauge, when only one end of it is fixed to the lathe by a single tack or screw, about which it may easily be moved into its true position. And while the tool or plate *ef* is turning, the same examination of its parallelism to the gauge must be frequently repeated; otherwise its surface will take a false figure. It is convenient that the upper board *luno* should project over both the gauges; and to keep its surface parallel to that of the under board, two round-headed nails, or a plate of brass, as thick as the gauges, must be fixed to its under surface, towards the opposite side *no*. Care must be taken to drill the holes in the gauges, through which they are screwed to the boards, not too near the polished arches for fear of altering their figure by the yielding of the brass. The tool and all the parts of the lathe must be fixed very firm; because any trembling motion will cause the graving tool *pg* to indent the brass. After the tool is well turned, it must be separated from the brass *ab* by melting the solder with live coals laid upon it. In a similar manner may a convex tool be turned by transposing the gauges.

Mr Huygens advises first to form the plates or tools in a turning lathe; and then to grind them together with emery; that is to say, the concave and convex tool of the same sphere together. But the tools of very large spheres, he would have ground at first quite plane by a stone-cutter; and then ground hollow with a round flat stone and emery to the proper gauge. And he prescribes to use for this grinding first a stone half as broad as the tool, and after that another nearly of the whole breadth of it; and in this way of forming the tools, it will be convenient to tie a little frame of thick paper, or rather of thin pasteboard, about an inch high, round the tool, in order to keep in the emery; and in grinding, the whole must be made extremely firm. When the tool is to be polished, it must still remain upon the stone pedestal; otherwise it will be in danger of bending a little in the operation.

For polishing the tools when ground, Mr Huygens directs the concave tool to be daubed with soap; after which, he takes the round stone above-mentioned, somewhat less than the tool, (or the convex tool itself), and heats it; then he pours upon it some hot melted cement (made of pitch and fine powdered and sifted ashes, as much as he can mix with it), and then he turns over the stone and cement upon the concave tool, into which also he had poured a good quantity of the same cement; having first laid three little pieces of brass, of equal thicknesses, on the circumference of it, in order to press and keep this crust of cement of an exact equal thickness

in all its parts; and thus he lets them cool together. Then taking the stone from the tool, and turning it up, he lifts upon the cement that sticks to it a crust of very fine emery; and with a flat iron spatula, about one third of an inch thick, gently warmed, he presses lightly the emery, to stick to and incrustate upon the cement. The whole is then gently warmed, *viz.* the stone, cement, and emery, and he again replaces it upon the concave tool, and leaves it again to cool; so that he has by this means a crust of emery exactly of the figure of his tool; and with this he polishes the tool dry, without the addition of any wet, pressing it hard on the surface of the tool. To press it the harder, he places upon it a long pole, a little bent, to make it spring, whose upper end is fixed to the ceiling of the room, or else is pressed downwards by a strong iron spring; and he thinks it is necessary to have two persons to rub the stone upon the tool. Here, however, it must be observed, that great care must be taken in this, and in all cases where this way of grinding by a pole is made use of, to fix the point of pressure exactly in the middle.

To bring the concave tool still nearer to perfection, take equal pieces, about an inch square, of blue hone, such as are used by engravers for polishing their copper, and place as many of them as you can upon the surface of the tool to be polished, laying the grain of them, some one way, some another; sticking them as close as you can to one another with soap and common white starch: then fill up all the interstices of the hones with clean dry sand, to about two thirds of the thickness of the hones; then having a border of paper or pasteboard put round the tool as before, shake the tool gently, that the sand may equally subside, and blow it every where to an equal depth with a pair of bellows. Then take some hard cement, extremely hot, and pour it all over the hones; then having cleaned the stone, or convex tool, which before was incrustated with pitch and emery, place this stone (or convex tool) warmed, on the top of the cement, and let all cool together. Then rubbing the tool with this polisher made with hones, by applying your pole to the top of the stone as before, you will know when the tool is brought to perfection, by wiping off the filth, in which case all parts of it will appear equally bright by looking upon it obliquely against the light. If you would use this polisher again, it must be kept in a cool cellar, leaving the hones uppermost; otherwise in warm weather they will change their situation in the cement, even by their own weight.

The cement used for fastening the glasses is made of several different compositions, according to the fancy of the operator. Cherubin informs us, that it was usually made of common black pitch and fine sifted vine-ashes: but he himself made it of rosin and ochre, or rosin and Spanish white; pounding the rosin first, and mixing it with a due quantity of the powder, and then sifting the mixture upon hot melted pitch, and while hot, well mixing and incorporating the whole. By others, the cement is made of pitch and common coal-ashes sifted fine. In all cases, it is harder or softer, as more or less of the ashes or other fine powder is put into it: and in the present case, for polishing these tools, it must be made as hard as possible, by putting in a large quantity of ashes; for otherwise, if the cement

ment

Mechanism  
of  
Optical  
Instruments

ment is not hard enough, the particles of the emery will be loosened by the heat in grinding, and then will only run round upon the tool, without working out the little inequalities thereof. If the emery should be found to grow blunt, a very little more of it may be dusted dry upon the tool, by which its sharpness and cutting quality will be a little recovered; but if the cement be sufficiently hard at first, the emery will always remain sufficiently sharp.

179  
Of choosing  
the glass.

The best kind of glass is perfectly white; but great care must be taken in choosing it totally free from veins. To discover these veins, one should look very obliquely against a small light in a room otherwise dark. In this manner one may examine pieces of a polished looking-glass, of which object-glasses are sometimes made; but because these are seldom of a sufficient thickness for this purpose, it will be proper to take some pieces of the same sort of glass before it is polished, and get it ground to an equal thickness and polished a little by the common glass-grinders, in order to judge what pieces are fit for use. Sometimes little veins will appear like fine threads, which scarce do any harm. Sometimes their imperfections cannot be discovered by the former way of trial; and yet after the glass is well formed and polished, they will appear by reflection in the following manner. In a dark room place the glass upright upon a table, turning that surface from you which is suspected to be faulty; then holding a lighted candle in your hand, so that the middle of the broad light reflected from the first surface may fall upon your eye, recede from the glass till the rays reflected from the back surface shall just begin to invert the candle; then the whole glass will appear all over bright, and then you will discover its defects, and the imperfections of the polish. When the glass is a portion of a large sphere, we use a small perspective, three or four inches long, to magnify the defects.

180  
How glasses  
are to be  
smoothed  
and round-

The pieces of glass above-mentioned should be much broader than the intended object-glasses, that there may be room enough for choosing the best part of them. For planing and smoothing these large pieces of glass, plates of cast-iron may be made use of; such as are sold at the iron-mongers shops, after they have been ground and planed on a stone-cutter's engine. Upon the plate of glass, with a diamond-pointed compass, strike a circle representing the object-glass; and also another concentric circle, with a radius about a tenth or twelfth part of an inch bigger: And also two other such circles, on the other side of the glass, directly opposite to the former; which may be done by means of the circular glass to be afterwards described. The larger parts of the glass may be separated from the outward circle by a red-hot iron, or by a strong broad vice, opened exactly to the thickness of the glass. The remaining inequalities may be taken off by a grind-stone; beginning with the largest first, and taking care that they do not splinter. Then, having warmed the glass, cement a wooden handle to it, and in a common deep tool for eye-glasses, making use of white clear sand and water, grind the circumference of the glass exactly true to the innermost circle on each side of it. Then, having made a great many small cavities with a punch upon one side of a round copper-plate, and having fixed the

other side of it upon the middle of the round glass, by Mechanism of Optical Instruments cement made with two parts of rosin or hard pitch, and one part of wax, place the steel-point of the spring pole above described, being 14 or 15 feet long, into that cavity of the copper plate which lies nearest the thickest part of the glass; then work the glass by the pole with sand and water upon a flat plate of cast iron, of a round figure, the plate having been planed with sand and water by a stone-cutter. Then having examined the thickness of the glass in several places by a hand-vice, which is better than a pair of calipers, by repeating the same operation, it will soon be reduced to an equal thickness in all its parts. Towards the end of this operation it will be convenient to make use of sifted emery, because the sand will scratch too deep: and then it will also be necessary to place the steel-point of the pole exactly over the centre of the under surface of the glass; otherwise that surface will take a cylindrical or convex figure, even though it was exactly plane before you began to grind it; and when concave glasses are to be polished, it is also absolutely necessary to place the point of pressure exactly over the centre of the under surface of the glass. To bring one of the little cavities in the copper-plate exactly over that centre, a circular glass is made use of, formed from a broken looking-glass with the quick-silver rubbed off. On this must be described, with a diamond-pointed compass, eight or ten concentric circles, about a quarter of an inch distant from each other, so that the larger circles may be somewhat bigger than the circumference of the glass to be polished. Lay this circular glass upon the surface of the glass to be polished; and move it to and fro till you perceive that the circumference of the glass to be polished is exactly parallel to the nearest circle upon the circular glass; then, having inverted both the glasses, lay the circular glass upon a table, and having laid a small live coal upon the copper plate, to make it moveable on the cement, place one point of a pair of compasses in one of the little cavities, and move the copper till a circumference described with the other point coincides exactly with any one circle upon the circular glass, and the business is done. It is convenient to paste three slender shreds of fine linen directed towards the centre of the circular glass, that the other glass may not slide too easily upon it, and that they may not scratch one another. The cavities punched in the copper plate, and also in the point of the pole, should be triangular, to hinder the rotation of the glass; which is still more necessary in giving it the last polish. Here also we must observe whether the circumference remains exactly circular on both sides of it, which must be tried with compasses: and if it be not, it must be corrected again by grinding it exactly circular in a common tool for making eye glasses; which will contribute very much to its taking an exact spherical surface when it comes to be ground in its proper tool. For if any part of the circumference be protuberant, it will hinder the adjoining parts of the surface from wearing so much as they should do; and of consequence will spoil its surface.

When the glass is thoroughly planed and rounded as above, take away the plate with the several cavities, and, with some of the same cement, fix on a smaller round piece of brass or rather steel truly flat, and

Mechanism of Optical Instruments and turned about the bigness of a farthing, but thicker, having first made in the centre thereof, with a triangular steel punch, a hole about the bigness of a goose-quill, and about the depth of  $\frac{1}{4}$  of an inch; and at the very bottom of this triangular hole, a small round hole must be punched, somewhat deeper, with a very fine steel punch. A small steel point about an inch long must be truly shaped and fitted to this triangular hole, and, at the very apex, to the small, round, deeper impression. Nevertheless, it must not be fitted to exactly, but that it may have some liberty to move to and fro; the apex always continuing to press upon the surface of the round hole below. This steel triangular point must be fixed to one end of a pole; to the other end of which another round iron point must be fixed, of about five or six inches long, to play freely up and down in a round hole in a piece of brass let into a board fixed in the ceiling for that purpose, perpendicularly over the bench, and over the centre of the tool, which must be strongly and truly fixed horizontally thereon. Mr Huygens directs the brass plate to be fixed to the glass by means of cement, and takes no notice of any other method whatever; though it is plain, that it is hardly possible, in this, or any other case, to bring the cement to a fluidity sufficient to fix two plane surfaces exactly parallel to one another, without heating the glass, and the brass also, to a very great degree, and thus endangering the glass considerably. To avoid this, some have used plaster of Paris; others cement an intermediate glass to the brass or wood, and then fix the glass to be ground to the outward surface of the cemented glass with common glue. It may easily be done, however, with common isinglass or fish-glue, which will run very fluid, and will fix the glass and the brass of itself strongly together. Some common soft red wax is to be stuck on the edges of the brass, to keep wet from getting to the glue.

For grinding glasses truly plane by this method, Mr Huygens prescribes the pole to be about 15 feet long; but, in grinding upon a concave plate, the pole is most conveniently made of the same length with the radius of the sphere, though Dr Smith is of opinion that it would not be material if made considerably shorter, as the height of the room may allow. It is necessary to have, lying by, an ordinary piece of coarse glass ground in the same tool, called a *bruiser*; whereby, when any new emery is laid on the tool in grinding the glass, it must be first run over and smoothed, for fear that any little coarse grains should remain and scratch the glass.

Things being thus prepared, some pots of emery of various finenesses must be prepared. Take of the roughest sort a small half-pugil, wetting and daubing it pretty equally on the tool: then lay on your glass, and fix up the pole, continuing to grind for a quarter of an hour; not pressing upon the pole, but barely carrying the glass round thereby: then take the like quantity of some fine emery, and work another quarter of an hour therewith; and then take the like quantity of emery still finer; and work for the same time: after which you must work for an hour and an half with some of the finest emery you have, taking away by little and little some of the emery with a wet sponge. It must neither be

Mechanism of Optical Instruments kept too moist nor too dry, but about the consistence of pap. Much depends on this last circumstance. For, if it is too dry, the emery will clog and stick, and incorporate in such a manner as to cut little or none at all, unless here and there, where its body chances to be broke; and in those places it will scratch and cut the glass irregularly: or if it is too much diluted, it will, from the irregular separation of its parts, cut in some places more than in others, as in the former case.

But Mr Huygens tells us, that this method of using various sorts of fresh emery is not good; as in this way, he finds by experience, that the best glasses are often scratched. For this reason, he advises to take a large quantity of emery of the first or second sort, and work with it from first to last, taking away by little and little every half hour, or quarter of an hour, more and more of the emery with a wet sponge. By this means he could bring the glass extremely smooth and fine, so that a candle or sash window could be seen through it pretty well defined; which is a mark of its being sufficiently well ground for receiving the last polish. But, if the glass has not acquired this degree of transparency, it is certain, says Mr Huygens, that too much emery remains; and therefore it must still be diminished, and the operation continued. He found common well-water most proper in this operation of grinding; and he took care to move the glass in circles, taking an inch beyond the centre of the tool, and somewhat beyond its outside; and he found in a glass of 200 feet, whose diameter was  $8\frac{1}{2}$  inches, which he ground in a tool of 15 inches diameter, that the figure of the tool in grinding would alter considerably, unless he carried the glass round an inch beyond the centre of the tool one way, and  $3\frac{1}{2}$  inches beyond the skirts of it another way; but if he carried it no farther than a straw's breadth beyond the skirts of the tool, and of consequence farther beyond the centre, the glass would always grind falsely, so that he could never afterwards bring the outsides of it to a true and fine polish.

When you first begin to grind, and the emery begins to be smooth, the glass will stick a little to the tool and run stiff. Then fresh emery is to be added. When it afterwards comes to be polished, it will, if large, require a considerable strength to move it; but this inconvenience will happen less in grinding by the pole than in grinding with the hand. For the warmth of the hand makes the substance of the glass swell; and not only increases the sticking of the glass, but in some measure may spoil the figure of it, as also of the tool. When it is ground with the pole, it never sticks very strongly, unless when you take the glass off from the tool, and keep it from it for some time, and then apply it to the tool again: and this in large glasses; for by this means the glass gets from the air a greater warmth than it had on the tool; and being again applied to the tool, its lower surface is suddenly contracted by the cold, and thus sticks to the tool. Wherefore, says Mr Huygens, you must in that case wait till the glass and the tool come to be of one temperature. The like effect is observable in grinding when there is a fire in the room; and hence we may see the great nicety requisite in grinding these large glasses, and the necessity of attending even to the minutest circumstances.

Instead of emery, Father Cherubin prescribes the grit of a hard grind-stone, well beaten into fine powder, and sifted. The same thing hath been done by common white-sand washed clean, taking away by little and little the grit as it became finer and finer. Nay, glasses have been frequently polished off in this manner without the use of any other material whatever. This method is called *drying off on sand*; because, as the matter grows finer and finer, they wet it less and less, till for the last quarter of an hour (the whole work lasting nearly two hours) they only wet it by breathing upon it; and at the very last, not at all. This method, however, is now entirely disused; for which Dr Smith assigns, as one reason, the violent labour requisite at the last: another and better reason, he says, may be, the great improbability of grinding or polishing true by this method, by reason of the uncertain and unequal force of the hand. But if this last is the reason, Dr Smith is of opinion, that the method might be restored, and greatly improved by adding a pole, and spring to press down the pole, or some analogous contrivance. And in all methods of grinding hitherto invented, the artist must allow time to bring his glass by grinding to the smoothest and finest surface that he possibly can, before he attempts to give the last polish. For the smoother you bring it in grinding, the less labour you will have in polishing; in which consists not only the greatest difficulty, but the greatest danger of spoiling all you have already done.

In order to give the last and finest polish to glasses, Mr Huygens directs us to proceed as follows. "Having removed the little brass plate from the glass, take a very thick slate, or rather a block of blue or grey stone; let it be half an inch thick, and let it be ground true and round at the stone-cutter's; its diameter being somewhat smaller than the diameter of your glass, leaving a hole quite through in the centre, of about an inch diameter. Then make some cement of two parts rosin or hard pitch, and one part wax; and taking a piece of thick kersey cloth, truly and equally wrought, cut this cloth round, and leave a like hole one inch diameter in the middle. Then warming the stone and also warming the glass, and spreading thinly and equably upon them some of this cement, lay on the cloth, and thereupon lay also the glass, having left in the middle a space the breadth of a shilling uncemented and blacked with a candle. Then provide an hollow conical plate of iron or steel (shaped like an high-crowned hat) having the basis of the cone 1 inch diameter, and having round the basis a flat border about  $2\frac{1}{2}$  inches diameter, and having the depth or altitude of the cone exactly of the thickness of the slate, cloth, and cement, to which the glass is fixed. The vertex of this cone must go down thro' the slate and cloth; so that being cemented on the slate, the said vertex may approach to the glass within a hair's breadth, and lie perpendicularly over the centre of the lower surface of the glass; and this must be adjusted by the circular glass described above. Within the vertex of this hollow cone, the lower point of the pole is to be applied in polishing; but it may be first proper to be observed, that fish-glue and a brass plate, in lieu of the dimensions of the aforesaid slate, may perhaps be better. Mr Huygens observes also, that the angle of the cone should be 80 or 90 de-

grees, and that the hollow vertex of it should be solid enough to receive a small impression from a round steel punch, to put the point of the pole into, which might otherwise have too much liberty, and slip from the vertex. The design of the black spot in the middle of the glass, is to discover by the light of a candle obliquely reflected from your glass, after it has been polished some time, whether it be perfectly clear, and free from the appearance of any bluish colour like that of althes.

Before the work of polishing is begun, it is proper to stretch an even well wrought piece of linen over the tool, dusting thereupon some very fine tripoly. Then taking the glass in your hand, run it round 40 or 50 times thereupon; and this will chiefly take off the roughness of the glass about the border of it, which otherwise might too much wear away the lower parts of the tool, in which the glass is chiefly to obtain its last polish. This cloth is then to be removed, and the glass is to be begun to be polished upon the very naked tool itself. But first there is to be prepared some very fine tripoly, and also some blue vitriol, otherwise called *cyprion*, English and Hungarian vitriol finely powdered: mix four parts of tripoly with one of vitriol: 6 or 8 grains of this mixture (which is about the quantity of two large peas) is sufficient for a glass 5 inches broad. This compound powder must be wetted with about 8 or 10 drops of clear vinegar in the middle of the tool; and it must be mixed and softened thoroughly with a very fine small mullet. Then with a coarse painting brush, take great care to spread it thinly and equably upon the tool, or at least upon a much larger space in the middle of it than the glass shall run over in the polishing. This coat must be laid on very thin, (but not too thin neither), otherwise it will waste away too much in the polishing, and the tool will be apt to be furrowed thereby, and to have its figure impaired; inasmuch that sometimes a new daubing thereof must be laid on, which it is not easy to do so equably as at first. This daubing must be perfectly dried by holding over it a hot clean frying-pan, or a thin pan of iron, with light charcoal therein for that purpose; then leave all till the tool is perfectly cold. Then having some other very fine tripoly very well washed and ground with a mullet, and afterwards dried and finely powdered, take some of the same and throw it thinly and equably on the tool so prepared; then take your coarse glass which lay by you, and smooth all the said tripoly very equably and finely: then take your glass to be polished, and wipe it thoroughly clean from all cement, grease, or other filth which may stick to it, with a clean cloth dipped in water, a little tinged with tripoly and vitriol; then taking your glass in your hand, apply it on the tool, and move it gently twice or thrice, in a straight line, backwards and forwards; then take it off, and observe whether the marks of the tripoly, sticking to the glass, seem to be equably spread over the whole surface thereof; if not, it is a sign that either the tool or the glass is too warm; then you must wait a little and try again till you find the glass takes the tripoly every where alike. Then you may begin boldly to polish, and there will be no great danger of spoiling the figure of the glass; which in the other case would infallibly happen. If the tool be warmer than the glass, it will touch the glass harder

Mechanism  
of  
Optical  
Instruments

Mechanism  
of  
Optical  
Instruments

er in the middle than towards its circumference; because the upper surface of the tool being swelled by heat will become too flat. On the contrary, if the glass be warmer than the tool, it will wear harder towards its circumference than at the centre; because the inferior surface of the glass is contracted by the coldness of the plate, more than the superior.

Mr Huygens says, that if the work of polishing were to be performed by strength of hand only, it would be a work of very great labour, and even could not be performed in glasses of 5 or 6 feet focal distance: and he seems to think it absolutely necessary that an extraordinary great force or pressure should be applied upon the glass. For this purpose he has therefore contrived and described two methods for sufficiently increasing the pressure; both of which chiefly consist in applying the force of a strong spring to press down the centre of the glass upon the polisher.

†Scene 285.

181  
Sir Isaac  
Newton's  
method of  
polishing.

This operation of polishing, as it is one of the most difficult and nice points of the whole, hath been very variously attempted and described by various authors. Sir Isaac Newton, Pere Cherubin, Mr Huygens, and the common glass-grinders, have taken different methods in this matter. Sir Isaac is the only person who seems not to insist on the necessity of a very violent and strong pressure. In the English 8vo edition of his Optics, p. 95. he hath these words: "An object-glass of a 14 foot telescope, made by an artificer at London, I once mended considerably, by grinding it on pitch with putty, and leaning very easily on it in the grinding, lest the putty should scratch it. Whether this may not do well enough for polishing these reflecting glasses, I have not yet tried. But he that shall try either this or any other way of polishing which he may think better, may do well to make his glasses ready for polishing by grinding them without that violence wherewith our London workmen press their glasses in grinding: for by such violent pressure, glasses are apt to bend a little in the grinding, and such bending will certainly spoil their figure."

As to his own method of polishing glass, he no where expressly describes it; but his method of polishing reflecting metals he doth; and it was thus, in his own words, p. 92. "The polish I used was in this manner. I had two round copper plates each six inches in diameter, the one convex the other concave, ground very true to one another. On the convex I ground the object-metal or concave, which was to be polished, till it had taken the figure of the convex and was ready for a polish. Then I pitched over the convex very thinly, by dropping melted pitch upon it, and warming it to keep the pitch soft, whilst I ground it with the concave copper wetted to make it spread evenly all over the convex. Thus by working it well, I made it as thin as a groat; and after the convex was cold I ground it again, to give it as true a figure as I could. Then I took putty, which I had made very fine by washing it from all its grosser particles; and laying a little of this upon the pitch, I ground it upon the pitch with the concave copper till it had done making a noise; and then upon the pitch I ground the object-metal with a brisk motion for about two or three minutes of time, leaning hard upon it. Then I put fresh putty upon the pitch, and ground it again till it had done making a noise, and afterwards ground the object-metal upon it as before. And this work I re-

peated till the metal was polished, grinding it the last time with all my strength for a good while together, and frequently breathing upon the pitch to keep it moist, without laying on any more fresh putty. The object-metal was 2 inches broad, and about  $\frac{1}{4}$  of an inch thick to keep it from bending. I had two of these metals, and when I had polished them both, I tried which was best, and ground the other again to see if I could make it better than that which I kept. And thus by many trials I learned the way of polishing, till I made those two reflecting perspectives I spoke of above. For this art of polishing will be better learned by repeated practice than by my description. Before I ground the object-metal on the pitch, I always ground the putty on it with the concave copper, till it had done making a noise; because, if the particles of the putty were not by this means made to stick fast in the pitch, they would, by rolling up and down, grate and fret the object-metal, and fill it full of little holes. It seems not improbable, that glass may also be polished, with proper care, by the same method."

Pere Cherubin polishes with tripoly or putty; or first with tripoly, and afterwards with putty. But what he seems most to approve of is putty alone. He polishes in the same tool he grinds in, and describes various ways of doing it. He prescribes to stretch very tight a fine thin leather, fine English fustian, or fine Holland, or any fine linen, or fine silk taffety or satin, all of an equable thickness, as near as may be, upon the tool; then he daubs thinly on this surface, thus stretched, a streak of putty wetted to the consistency of thick syrup, about as broad as the glass, or a little more, passing through the centre of the tool directly from him; then smoothing the putty by running his bruiser, and pressing it backwards and forwards to him and from him, he at length lays on the glass cemented to its handle, and giving it always the same motion, strongly pressing to him and from him along the streak of putty, and by such pressure forcing the surface of the silk, already somewhat stretched, close to the surface of the tool, to which the figure of the glass was exactly adapted, he says that he could by that means obtain an excellent fine polish on any of the abovementioned substances. Before every stroke, he turned the glass a little on its axis; and its handle was on this occasion considerably heavier than usual in grinding, which he commends as very useful in this business; and if new putty was wanting, he made no difficulty in laying it on as often as necessary, always carefully smoothing it thereon with the bruiser before the glass was applied.

This method, according to Dr Smith, might be improved by moving the glass, not by hand, but by the pole and spring, somewhat after the manner of Huygens; especially if the pole were contrived not to move loose in a round brass hole above, but on a strong point pressed down by some spring; the length of the pole being equal to the radius of the tool, and the point where the spring presses the upper end of the pole, being truly perpendicular over the centre of the tool, and exactly in the centre of its sphere.

Another method prescribed by Cherubin is as follows. He takes a sheet of very fine paper; and examining it carefully by looking upon it, and thro' it, he takes off with a sharp pen-knife all the little lumps,

Mechanism  
of  
Optical  
Instruments

Mechanism  
of  
Optical  
Instruments

hard parts, and inequalities, that he can find; then he soaks it in clean water; then he dries it between two fine linen cloths, tho' not so much as to make it quite dry, but to leave it dampish; then, with some very thin starch or paste, he daubs equably all over the surface of his tool as thin as possible, but some every where; then he lays on his paper very gently and slowly, letting it touch and stick first at one side, and by degrees more and more towards the middle, and at last so as to cover the whole. This is done slowly, in order to let the air get out; then, with the palm of his hand he presses the centre, and every where round about it towards the circumference, to make the paper stick every where; and this he does three or four times while it is drying, to get out all the air. He lets it dry of itself, then revives with his knife as before: then he hath a very coarse bruiser of glass, whose circumference is sharply ground round, and at right angles to its surface, which he had coarsely ground before in the same tool. With this, and with a very heavy handle, he smooths and polishes and rubs off all the remaining inequalities of the paper; and when this is done, he lays on a streak of tripoly, and polishes in his other method.

Plate  
CCXXVII.  
fig. 7.

185  
Mr Huygens's  
machines for  
polishing.

At CC is represented a square beam of wood, a little longer than the diameter of the tool, and about  $1\frac{1}{2}$  inch thick: the two extremities of it at C and C are bent downwards, and then are again directed parallel to the whole length, and serve for handles for the workman to lay hold of. In the middle of this beam there is fixed an iron spike, so long, that when the lower surfaces of the handles, C, C, are placed upon a plane, the point of the spike shall just touch the plane. This point presses upon the apex of the hollow cone, which descends through the hole in the slate, which, by the interposition of a cloth, was cemented to the glass B lying upon the tool A. To increase this pressure, a foot of bow, DED, is shaped out of a deal-board, half an inch thick, and five feet long, being seven inches broad in the middle, and tapered narrower towards its extremities, so as almost to end in a sharp point. The middle of the bow is fixed to the floor by an iron staple at E driven cross it; and is bent into an arch by a rope FIIF; to which two other ropes are tied at I and I; the interval II being equal to the length of the beam CC. One of these ropes ICCG goes over the back of the beam CC, passing through a hole in each handle at C and C, and then is lapped round a cylindrical peg at G, that passes through two wooden chaps, to the bottom of which the other rope is tied that comes from the other I. So that, by turning the peg G, to lap the rope about it, the bow DD may be bent as much as you please. The tool A is placed upon a strong square board fixed to the table O on one side, and supported on the other side by the post P. Then the workman sits down, and taking hold of the handles CC, he draws the glass to him and from him over the tool A, with a moderate motion; and after every 20 or 24 strokes, he turns the glass a little about its axis. This way of polishing took up two or three hours, and was very laborious as well as tedious; because the glass, being so much pressed downwards, was moved very slowly.

Fig. 8.

Instead of the bow DD, Mr Huygens afterwards invented another spring by sloping the flat ends of a couple

of dealboards  $\alpha\beta$ ,  $\alpha\gamma$ ; and by nailing the flat slopes together very firmly, that the boards might make an acute angle  $\beta\alpha\gamma$ . One of these boards  $\beta$  joined was laid upon the floor under the polishing table, the ends  $\beta\gamma$  being under the middle of the tool A. So that they lay quite out of the way of the workman, who before was a little incommoded by the ends of the bow DD. The boards at the end  $\alpha$  were 8 or 10 inches broad, and from thence went tapering almost to a point at  $\beta$  and  $\gamma$ . The board  $\alpha\gamma$  lying upon the floor, the end  $\beta$ , of the upper board, was pulled downwards by a rope  $\beta\epsilon\zeta$  that passed under a pulley  $\gamma$ , fixed to the floor, and then was lapped round a strong peg  $\zeta$  that turned stiff in a hole in the floor. Under the end  $\gamma$  the middle of a strong stick  $\delta\gamma\delta$  was fixed at right angles to the board  $\alpha\gamma$ , and cords were tied to each end of this stick at  $\delta$ ,  $\delta$ , which went over the polishing beam C, C, as in the former machine. This stick was lifted up but very little from the floor at the time of polishing; and by consequence the ropes  $\delta$  C,  $\delta$  C were long enough to give liberty of motion to the polishing beam CC. Two iron pins  $\theta$ ,  $\theta$ , passing through the ends of the boards at  $\alpha$ , were screwed into the floor; but the heads of the pins stood up above the boards, to give them liberty to rise up when the rope  $\beta\epsilon\zeta$  was stretched.

To facilitate the labour of moving the glass back. Fig. 7. wards and forwards in the tool, Dr Smith made the following addition to the machine. At M is represented a strong hand made of wood or iron, having a square cavity cut through the bottom of it, for the polishing beam CC to pass through, not tight, but at some liberty. To one side of this hand M is annexed a long board LL, by means of an iron bolt. The breadth of the lower surface of this board LL is equal to the breadth of the hand M, being  $2\frac{1}{2}$  inches; its thickness is half an inch, and its length equal to three femidiameters of the tool. The board LL must be drawn backwards and forwards lengthwise over a block H firmly fixed to a table O; the thickness of the block being such, that the board LL may lie an inch higher than the surface of the tool A. The wooden hooks at  $\pi$ , and the pins at  $\pi$ , keep the motion of the board in the same direction, by hindering it from slipping either upwards or sideways. Over this board, at right angles to it, and over the middle of the block H, there lies a wooden roller, having a strong iron axis which turns in the holes of two iron plates fixed to the ends of the block. The thickness of the roller is about an inch and an half. Thro' two holes bored thro' this roller, and made wider at one end of them, two strong cords are made to pass with knots at one end of them, to be drawn into the wider parts of the holes, that they may neither slip through, nor stand out from the roller. Then each cord is lapped round the cylinder several times; and one end of each is pegged firmly into the board LL at the end towards M, and the other ends of them are lapped round a peg at N; which being turned round, will stretch the cords as much as you please. At one end of the axis of this roller there is a handle Q, which being turned round backwards and forwards alternately, the board LL with the glass annexed to it is moved to and fro, so far, that about a third part of its diameter shoots both ways over the margin of the tool.

The

The spike in the middle of the beam CC presses the glass a little obliquely, because the hand M holds the beam CC, not tight, but somewhat loosely, to the end that the glass may pass over the tool without trembling. Nevertheless this inclination of the spike must be very small; and may easily be increased or diminished several ways. Two pins or stops must be fixed to the under surface of the board LL, to determine the length of the stroke. The tool A, or rather the stone to which it is cemented, is squeezed fast between the block H, and a strong stop on the opposite side of the stone, by the interpolation of a wedge. The workman sits upon a round stool; and, when one hand is tired with turning the roller, he applies the other; and therefore is not so soon tired as with the other machine, which required both hands, and also a reciprocating motion of the whole body. A longer handle Q<sub>z</sub> was also made, which turned at both ends, for the convenience of using both hands at once.

After every 20 or 24 strokes, it is necessary to give the glass a small turn about its axis; which is easily done by laying hold of the plate fixed to it, with one hand, while the other hand goes on with the polishing motion. The tool must also be moved a little after every 25 or 50 strokes, by drawing it half a straw's-breadth towards that part of it which the glass has left, and by drawing it back again after as many more strokes. At the beginning of the work the tripoly will be gathered into little lumps in some places of the tool, but will be dispersed again in a little time; and then the area of the tool will become perfectly smooth. If the tripoly does not appear to stick equally to the glass in all parts, and to be diffused over it in slender straight streaks, the frying-pan with coals in it must be held over the tool again, till you perceive the area, or coat of tripoly is not quite so cold as the other parts of the tool. Then let tripoly be rubbed upon the tool again, and let the glass be pressed over it with your hand, to try whether it sticks equally to the glass in every place. When it does, you may proceed in the work of polishing. But when vitriol is used instead of verdigrease, all that is said about warming the tool may be omitted; because these coats always touch the glass as they should do, and stick better than before. The tool ought also, without being warmed, to be rubbed with tripoly over the coat, that the latter may be preserved more entire, and that the glass may touch it better, which must always be repeated after 200 or 400 strokes in polishing. The glass should also be taken from the tool after 200 strokes, by withdrawing the bolt L, which connects the hand M to the board LL, and by removing the beam CC. Then rub your finger upon the glass, or a clean rag, or a bit of leather, to examine how much it is polished.

186  
Method of  
counting  
the strokes  
used in po-  
lishing.

To save the trouble of counting the strokes, there is a wooden wheel  $\Delta$  X, seven or eight inches broad, placed against a board fixed to the side of a wall. It turns easily about an axis, and has 24 teeth, like those of a saw, which are pushed round by a bended wire T Y X in the following manner. The wire turns about a centre Y; and while one end of it is pulled by the string TV tied to the end of the board LL, the opposite end YX pushes back a long spring RS, fixed to the board at R; which, by pressing upon the wire at

S, causes the part YX to bend a little, and so the point X, in returning to the wheel (the string being relaxed) falls a little lower into the next tooth, and pushes it forward in the position represented in the figure. There is a springing catch at  $\Delta$ , which stays the wheel after every stroke at X. Lastly, there is a pin fixed in the circumference of the wheel at Z, which, by pressing the tail of a hammer, and letting it go again, causes a bell to sound after every revolution of the wheel, and gives notice that the glass must be turned a little about its centre. It is easy to understand, that another piece of wheel-work, having three or four indexes, whose revolutions are in decimal progression, may be fixed to the block H, and impelled by the strokes of the board LL; by which means, without any trouble of counting, one may be informed how many strokes go to polish a glass. A glass five or six inches broad requires about 3000 strokes upon each surface to bring it to perfection. You must carefully examine the middle of the glass opposite to the blacking, whether any place appears darkish or of an ash-colour; or whether any small spots appears by an oblique reflection of the light of a candle, or of a small beam of light let into a dark room; for the other parts of the glass will appear perfectly fine much sooner than the middle.

After the glass has been sufficiently polished, let the stone, the cloth, and the cement, be warmed over a pan of charcoal, till the cement grows so soft that the glass may be separated from it by a side-motion. Then, whatever cement remains upon the glass must be wiped off with a hot cloth dipped in oil or tallow, and last of all with cleaner cloths. Then if it does not appear perfectly polished, (for we are often deceived in this point), the work must be repeated again, by glueing the glass to the plate as before; then it must be wiped very clean, and made a little rough, as we said before. We must also lay a new fund, or coat, upon the tool, if the old one be spoiled; provided no other glass has been polished in the tool in the mean time. The old fund may be washed off from the tool with a little vinegar. Lastly, take care always to choose the thickest and clearest pieces of glass, to avoid a great many difficulties that arise from the unequal pressure in polishing.

### § 3. To Centre an Object-glass.

A circular object-glass is said to be truly centered when the centre of its circumference is situated in the axis of the glass, and to be ill centered when the centre of the circumference lies beside the axis. Thus, let  $d$  be the centre of the circumference of an object-glass  $abc$ ; and suppose  $e$  to be the point where its axis cuts its upper surface. If the points  $d$  and  $e$  do not coincide, the glass is ill centered. Let  $afg$  be the greatest circle that can be described about the centre  $e$ ; and by grinding away all the margin without this circle, the glass will become truly centered. The best method for finding the centre  $e$  which lies in the axis of the glass, according to Dr Smith, is as follows.

Let a couple of short cylindrical tubes be turned in wood or brass, and let the convexity of the narrower be so fitted to the concavity of the wider as just to turn ill-centered, round in it with ease, but without waddling; and let

187  
How to  
know when  
a glass is  
truly-centered.  
Fig. 2.

the planes of the bases of the tubes be exactly perpendicular to their sides. Place the base of the narrower tube upon a smooth brass plate or a wooden board of an equal thickness; and with any sharp-pointed tool describe a true circle upon the board round the outward circumference of the base; and upon the centre of this circle, to be found when the tube is removed, describe a larger circle upon the board. These two circles should be so proportioned, that the one may be somewhat greater, and the other somewhat smaller, than any of the glasses intended to be centered by them. Then, having cleared out all the wood within the inner circle, put the end of the tube into this hole, and there fasten it with glue, so that the base of the tube may lie in the surface of the board: then, having fixed the wider tube very firmly in a hole made in a window-shutter, and having darkened the room, lay the glass to be centered upon the board fixed to the narrower tube; and having placed the centre of it as nearly as you can guess over the centre of the hole, fix it to the board with two or three lumps of pitch, or soft cement, placed at its circumference. Then put the narrower tube into the wider as far as it can go, and fix up a smooth screen of white paper to receive the pictures of objects that lie before the window; and when they appear distinct upon the screen, turn the inner tube round upon its axis; and if the centre of the glass happens to be in this axis, the picture will be perfectly at rest upon the screen; if not, every point of it will describe a circle. With a pencil mark the highest and lowest places of any one circle, described by some remarkable point in that part of the picture which appears most distinct; and when this point of the picture is brought to the highest mark, stop the circular motion of the tube, and keeping it in that position depress the object-glass till the point aforesaid falls exactly in the middle between the two marks. Then turn the tube round again, and the point of the picture will either rest there, or will describe a much smaller circle than before; which must be reduced to a quiescent point by repeating the same operation. The centre of refraction of the glass will then lie in the axis of the tube, and by consequence will be equidistant from the circumference of the large circle described upon the board fixed to it. Now to describe a circle upon the glass *fgb* about its centre of refraction, let a long slender plate of brass *acb* be bent square at each end, as represented in the figure, leaving a piece in the middle equal in length to the diameter of the large circle *adbe* that was described upon the board; and let the square ends of the plate be filed away, so that a little round pin may be left in the middle of each. Then, having laid it over the glass, along any diameter of the large circle *adbe*, make two holes in the board to receive the pins *a* and *b*; and find the centre of this circle upon the long plate. Then upon the centre *c*, describe a circle as large as you can, upon the glass underneath, with a diamond-pointed compass, and grind away all the margin as far as this circle *fi k*, in a deep tool for grinding eye-glasses; and then the glass will be truly centered. If the pitch or cement be too soft to keep the glass from slipping, while the circle is describing, it may be fixed firmer with wax or harder cement.

*hi*, and of the window-shutter *no*. Imagine the plane of this section, or of the scheme, to pass through *e*, a point in the glass which keeps its place while the rest are turning round it by the motion of the tube. Let it also pass through *l* the centre of refraction in the glass, and cut an object in the line *PQR*; then let a pencil of rays flowing from any point *Q* be collected to the focus *q* upon the screen *ST*; and the points *Q, l, q*, will be in a straight line described by the axis, or principal ray of the pencil. Draw *Q, e, f*, cutting the screen in *f*; and while the tube is turning round, the line *Qlg* will describe a conical surface whose axis is the fixed line *Qef*; and therefore the focus *q*, or image of the point *Q*, will describe a circle *ggx* about *f*, to be found upon the screen by bisecting the interval *qx* between the highest and lowest points of the circle. Now, as *f* is the centre of this circle, so *e* is the centre of another circle described by *l*: therefore by depressing the glass *kl* along the surface of the board *ab*, till the image *q* falls upon the mark *f*, the point *l* will be depressed to *e* the centre of motion; and then it will be in the axis of the tube, and consequently equidistant from the circumference of the circle described on the board *ab*; and here it is plain that the image *q* will be at rest in the point *f*. It is not necessary for the accuracy of the practice, that the point *Q* should be in the axis of the glass. For in fig. 7. (Plate CCXXXII.) if the glass *KLM* be turned about its axis *QLg*, the image *p* of any collateral point *P* will remain at rest; because the points *PL* are at rest, and the axis *PLp* of the oblique pencil is a straight line.

The chief advantage of having a glass well centered is this, that the rays coming through any given hole, whose centre coincides with the axis of the glass, will form a distincter image than if that centre lay beside the axis; because the aberrations of the rays from the geometrical focus of the pencil, are as the distances of their points of incidence from the centre of refractions in the glass.

If the picture be received upon the unpolished side of a piece of plane glass, instead of the paper *ST*, its motion may be discerned more accurately by viewing it from behind through a convex eye-glass; as in a telescope where cross hairs are usually strained over a hole put into the place of the rough glass. Therefore as object-glasses are commonly included in cells that screw upon the end of the tube, one may examine whether they be pretty well centered, by fixing the tube, and by observing, while the cell is unscrewed, whether the hairs kept fixed upon the same lines of an object seen through the telescope.

#### § 4. Of the Composition of the Metals for the Specula of Reflecting Telescopes.

THE properties required in the metal for the speculum of a reflecting telescope are, whiteness, hardness, and immunity from rust, or at least that it may be as little liable to tarnish as possible. Various compositions have been recommended; but the best is that published by Mr Mudge in the Phil. Trans. for 1777. His metal is a composition of copper and tin, in the proportion of two pounds of the former to 14½ ounces of the latter. If the proportion of tin was increased only by a single half ounce, the metal became so hard that

OPTICS.

it could not be polished. Nevertheless he tells us, that one Mr Jackson, a mathematical instrument-maker, used the tin in as large a proportion as one third of the whole. This indeed gives the metal its utmost whiteness, but at the same time renders it so exceedingly hard, that the finest washed emery will not cut it without breaking up its surface; and the common blue stones used in grinding specula will not touch it. With great pains, however, Mr Jackson found a stone which would work upon this metal, and was at the same time of a texture sufficiently fine not to injure its surface; but what this stone was, or where it was to be found, he would not discover.

Another very essential property in the metal for specula is its compactness; and in this every one of those formerly tried was deficient; neither was Mr Mudge able to remove this defect till after a great many experiments. Sometimes, indeed, he says that he succeeded in casting a single metal, or perhaps two or three, without this imperfection; but most frequently he was unsuccessful, without his being in any degree able to assign a reason. The pores were so very small, that they were not perceptible when the metal had received a good face and figure upon the hones, nor till the last and highest polish had been given: then it frequently appeared as if dusted over with millions of microscopic pores, which were exceedingly prejudicial in two respects; for, first, they became in time a lodgement for a moisture which tarnished the surface; and, secondly, on polishing the speculum, the putty necessarily rounded off the edges of the pores, in such a manner as to spoil a great part of the metal, by the loss of as much light and sharpness in the image as there were defective points of reflection in the metal; and, to add to the misfortune, this fault was not discovered till a great deal of pains had been taken in grinding, and even polishing the speculum; which was at once rendered useless by this mortifying discovery.

At last Mr Mudge was extricated from these difficulties by accident. Having made a great number of experiments, and entirely exhausted his copper, he recollected that he had some metal which was preserved out of curiosity, and was part of one of the bells of St Andrew's which had been recast. This he melted with a little fresh tin, and, contrary to his expectation, it turned out perfectly free from pores, and in every respect as fine a metal as could be desired. At first he could not account for this success, but afterwards discovered it by reflecting on the circumstances of his process. He had always melted the copper first, and, when it was sufficiently fused, he added the proportional quantity of tin; and as soon as the two were mixed, and the scoria taken off, the metal was poured into the moulds. He now began to consider that putty was calcined tin, and suspected that the excessive heat which copper necessarily undergoes before fusion, was sufficient to reduce part of the tin to this state of calcination, which therefore might fly off from the competition in the state of putty, at the time the metal was poured out. On this idea he furnished himself with some more Swedish copper and grain-tin. The former he melted as usual, and mixed the tin along with it, casting the mixture into an ingot. This was porous, as he had expected; but after a second

fusion, it became perfectly close; nor, after this, did he ever meet with the above-mentioned imperfection in a single instance. All that is necessary to be done, therefore, in order to procure a metal with the requisite properties for a speculum, is to melt the copper and tin in the above-mentioned proportions; then, having taken off the scoria, cast it into an ingot. This metal must be a second time melted to cast the speculum; but as it will fuse with a small heat in this compound state, it should be poured off as soon as melted, giving it no more heat than is absolutely necessary. It must be observed, however, that the same metal, by frequent melting, loses something of its hardness and whiteness; when this is the case, it becomes necessary to enrich that metal by the addition of a little tin, perhaps of half an ounce to a pound. And indeed, when the metal is first made, if, instead of adding the  $14\frac{1}{2}$  ounces of tin to the copper all at once, about an ounce of the former is reserved, and added to it in the second melting, the composition will be more beautiful, and the grain much finer. That the metal may have a good surface, it is necessary, before it is poured off, to throw into the crucible a spoonful of charcoal-dust; immediately after which the metal must be stirred with a wooden spatula, and poured into the moulds.

§ 5. *Of preparing the Moulds; Grinding, Casting, and Polishing, the Metal.*

For this purpose Dr Smith prescribes the following method. "Having in the first place considered of what length one would propose the instrument to be, and consequently what diameter it will be necessary to make the give to the large speculum, for which there are ample instructions by Sir Isaac Newton's table in the Philosophical Transactions aforesaid, allowing about an inch more than the aperture in the table for the false figure of the edges, which very often happens; I say, having determined these things, take a long pole of fir deal, or any wood, of a little more than double the length of the instrument intended, and strike through each end of it two small steel points, and by one of them hang up the same against a wall perpendicularly; then take two pieces of thin plate-brass well hammered, a little thicker than a sixpence; these may be about an inch and a half broad, and let their length be in respect of the diameter of the speculum as 3 to 2, viz. if the speculum be 8 inches diameter, these may be about 12. Fix each of these strongly with rivets between two thin bits of waincot, so that a little more than a quarter of an inch in the breadth may stand out from between the boards. Then fix up these pieces horizontally against the wall under your pole; and therewith, as with a beam compass, strike an arch upon each of them: then file each of them with a smooth file to the arch struck, so as one may be a convex and the other a concave arch of the same circle. These brasses are the gauges to keep the speculum, and the tools on which it is ground, always to the same sphere. And that they may be therefore perfectly true to each other, it is necessary to grind them with fine emery one against the other, laying them on a flat table for that purpose, and fixing one of them to the table.

"When the gauges are perfectly true, let a piece of wood be turned about 2 tenths of an inch broader for the purpose than the intended speculum, and somewhat thicker, which

Instruments

which it is best to cast in no case less than 2 tenths of an inch thick, and for specula of 6, 8, or 10 inches broad, this should be at least 3 or 4 tenths thick when finished. This board being turned, take some common pewter, and mix with it about  $\frac{1}{10}$  of regulus of antimony; and with that wooden pattern cast one of this pewter, which will be considerably harder than common pewter. Let this pewter pattern be truly turned in a lathe, and examined by means of the gauges aforesaid, as a pattern for casting the specula themselves; and take care when it is turned that it be at least  $\frac{1}{10}$  of an inch thicker, and about  $\frac{1}{10}$  of an inch broader, than the speculum intended to be cast therefrom.

“The manner of making the moulds for casting is now to be explained; and will serve for a direction as well for casting this pewter pattern, as afterwards for casting thereby the speculum itself. The flasks had best be of iron, and must be at least two inches wider every way than the speculum intended. In each flask there should be the thickness at least of one inch of sand. The casting-sand which the common foundry use from Highgate, will do as well as any; and any sand will do which is mixed with a small proportion of clay to make it stick. The sand should be as little wet as may be, and well beaten but not too hard. The ingates should be cut so as to let the metal flow in, in four or five streams, over the whole upper part of the mould; otherwise whatever pores happen in the metal will not be so equally dispersed as they should be over the whole face of the metal, these pores generally falling near the ingate streams. Let the flasks dry in the sun for some hours, or near a very gentle fire; otherwise they will warp, and give the speculum, when cast, a wrong figure. For besides saving the trouble in grinding, it is best on many accounts to have the speculum cast of a true figure; and it is for this reason, that it is best to cast it from a hard pewter pattern, and not from a wooden one as foundry usually cast.”

With regard to the proper metal, opticians have been greatly at a loss, till of late that Mr Mudge has discovered a composition which answers every purpose as well as can be expected, and of which an account hath been already given. “The metal being duly cast, the surface of it is to be ground quite bright upon a common grindstone; keeping it, by means of your convex gauge, as near the figure as may be. When all the outward surface and sand-holes, false parts, and inequalities, are ground off, then provide a good thick stone; a common small grindstone will do very well. Let its diameter be to the diameter of the speculum as 6 to 5; with another coarse stone and sharp sand or coarse emery rub this stone till it fits the concave gauge; and then with water and coarse emery at first, and afterwards with finer, rub your speculum upon this stone until it forms itself into a true portion of a sphere fitting your convex gauge. A different method of moving the metal upon the stone will incline it to form itself somewhat of a smaller or larger sphere. If it be struck round and round, after the manner of glass-grinders, the stone will wear off at the outsidings, and the metal will form itself into the portion of a less sphere. If it be struck cross and cross the middle, it will flat the stone, and become somewhat of a larger

sphere. There should be used but very little emery at a time, and it ought to be frequently changed; otherwise the metal will always be of a smaller sphere than the stone, and will hardly take a true figure, especially at the outside. For the better grinding the metal, it is necessary, that this stone should be placed firm upon a strong round board fixed firmly on a post to the floor, as is usual with glass-grinders; and the same table or pillar will serve for the further grinding and polishing the speculum.

“When the metal is cast and rough-figured, which should be done with taking off as little of the surface of the metal as possible, (because that crust seems generally to be harder and more solid than the inner parts) the sides and back of it should be smoothed and finished; left the doing that afterwards should make the metal cast, and spoil the figure of the fore-side.

“A round brass plate must be cast of sufficient breadth and thickness (for a speculum of six inches in diameter Mr Hadley used a brass plate 8 or 9 inches broad, and half an inch thick.) Let one side be turned to the concavity you design your speculum to have, on the other side let it have such an handle fastened as may make it easily manageable. This handle should be as short as conveniently it can, and be fixed to the plate's back rather by some other method than either by screwing it into a hole in the metal, or by a broad shoulder screwed against the back of it, for fear of bending the plate. Have ready a round marble of about  $\frac{3}{4}$  or  $\frac{1}{2}$  broader than the brass plate, and an inch or an inch and a quarter thick: let this be cut by a stone-cutter to the same convexity on one side as the concavity of the plate, and then grind it with the plate and emery till all the marks of the chisel are out. This marble is to be covered with pieces of the finest blue hone or whetstone, choosing those that are nearest of a breadth and thickness; but chiefly those that when wetted appear most even and uniform in their colour and grain. They are to be cut into square bits; and these, having each one side ground concave on the convex marble with emery or fine sand, are to be fixed close down on it with some tough and strong cement in the manner of a pavement, leaving a space of a small straw's breadth between each; their grain being likewise placed in an alternate direction, as represented in the figure. I choose rather to disperse the squares that come out of the same whetstone, than to keep them together. They must then be reduced to one common convex surface to fit the brass plate; and if the cement happen to rise any where between them, so as to come up even with the surface, it must be dug out; and so, from time to time, as often as the hones wear down to it. Upon these square pieces of whetstone the last figure is to be given to the speculum.

“Besides these, there will be wanted for the last polish, either a very thick round glass plate, (its diameter being about the middle size between that of the brass tool and the speculum itself,) or if that cannot be procured of near half an inch in thickness, a piece of true black marble of the evenest grain and free from white veins or threads, may do in its stead. This glass or marble must be figured on one side to the brass tool likewise, and is to serve for finishing of the polish

Dr Smith's  
method of  
rough-  
grinding  
the specu-  
lum.

Mechanism of Optical Instruments of the speculum, when covered with farcenet as shall be directed.

“ A smaller brasa or metal plate of the same concavity with the larger will be useful, as well to help to reduce the figure of the hones whenever it appears to be too convex, as to serve for a bruifer to rub down any gritty matter happening to be amongst your putty before you put the speculum on the polisher, when you renew the powder. Any of the speculums which prove bad in eating, will serve for this purpose.

“ When all is thus far ready, let the marble with the blue hones be fixed in such a manner that it may be often washed during your work, by throwing upon it about half a quarter of a pint of water at a time without inconvenience. Then place the brasa tool on the hone pavement; and rub it backwards and forwards with almost a direct motion; yet carrying it by turns a little to the right and left, so as to go a little over the edges of the pavement every way, regularly turning the tool on its own axis, and also changing the direction of the stroke on the hones. This continue, keeping them always very wet, till you have got out all the rings remaining in the plate from the turning, and the blackness from grinding the marble or glass in it; and, towards the latter end, often washing away the mud which comes from the whetstones. When this is done, lay the brasa tool down, and in it grind again with fine emery the glass or marble designed for the last polisher, giving it as true a figure as possible.

“ Choose a piece of fine farcenet as free from wove and great threads as you can. Let it be three or four inches broader than the glass or marble; and turn down the edges of the farcenet round the sides of the glass, &c. Strain it by lacing it on the backside as tight and smooth as you can, having first cleared it of all wrinkles and folds with a smooth iron, and drawn out the knots and gouty threads. Then wet it all over as evenly as you can with a pretty strong solution of common pitch in spirit of wine; and when the spirit is dried out, repeat the same; and if any bubbles or blisters appear under the farcenet, endeavour to let them out with the point of a needle. This must be repeated till the silk is not only stuck every where firmly down to the glass or marble, but is quite filled with the pitch. A large painter's pencil, made of squirrel's hair, is of use for spreading this varnish equally on the silk, especially when it begins to be full. It must then be set by for some days, for the spirit to dry well out of it, and the pitch to harden, before any thing more be done to it. If you do not care to wait so long, the pitch may be melted into the silk without dissolving it in spirits. In order to this, strain a second thin silk over the first, but you need not be curious in the choice of it; and having heated all together as hot as you think the silk or glass will safely bear, pour on it a little melted pitch (first strained through a rag) so much as you judge sufficient to fill both silks; it must be kept hot for some time till the pitch seems to have spread itself evenly all over. If you cannot get it to sink all into the upper silk, but it stands above it any where, it is a sign that there was too much pitch laid on, which should be taken away in those places while it remains liquid, with a hot rag pressed down on it. When all is cold again, strip off the outward silk, and cut away the useless loose edges

of the inward. To take off the superfluous pitch where it lies too thick, and reduce the whole to a regular surface, it must be rubbed in the brasa tool with a little soap and water, till they are coloured of a pretty deep brown with the pitch; then wash them away, and repeat the same with more soap and water, till the weaving of the silk appears every where as equally as you can make it. As this work takes up some time, you may expedite it by putting a few drops of spirit of wine to the soap and water (which will help them to dissolve and wear away the pitch somewhat faster till it comes towards a conclusion; and if there are any places where the pitch lies very thick, you may scrape it away with a sharp knife.

This polisher must be carefully kept from all dust and grit, but particularly from emery and filings of hard metals, and therefore should not be used in the place where the others come. After they have served a good while, they are more apt to sleek the metals than at first; to prevent which, their surfaces may be taken off by rubbing them with soap and water in the tool as before, and then striking them over once or twice with the abovementioned solution of pitch with a pencil, proceeding as before; only that you must not now put any spirit to your soap and water, nor will you need to change them above once or twice.

“ You may now begin to give the figure to your speculum on the hones, rubbing it and the brasa tool on them by turns, till both are all over equally bright; having first fixed on to the middle of the back of your speculum a small and low handle, with only pitch strained through a rag. For of all cements, that seems the least apt to bend the metals in sticking these handles, &c. on them.

“ The polisher being fixed likewise in a proper manner for your work, rub either the metal itself, or rather the before-mentioned bruifer, being first also figured on the hones, with a little putty, washed very fine, and fair water, till it begins to shew some polish. Then if you find it takes the polish unequally, that is, more or less about the edges than in the middle, it is a sign the brasa tool and metal, &c. are more or less concave than to answer the convexity of the polisher; and must be reduced to the curvature of this, rather than to attempt an alteration in the figure of the polisher, which would be a much more difficult as well as laborious work. If the speculum appears too flat, the larger brasa tool must be worked on the hones for some time, keeping its centre near their circumference, with a circular motion; but concluding for four or five minutes with such a motion as was before described. Then figure the metal anew on the hones, and try it again on the polisher as before. If the metal be too concave, the surface of the hones may be flatted by rubbing the smaller brasa plate, or the before-mentioned ill-cut metal, on the middle of them; with a direct but short stroke, so as but just to reach over their circumference with the edge of it. Then the larger brasa is to be worked on them in the same manner; and last of all the metal to be polished. When you find the brasa tool and hones, &c. answer the curvature of the polisher, you may then examine the truth of the figure of the speculum more strictly, to avoid the loss of time and labour in finishing its polish while the figure is imperfect.

Method of  
examining  
the true fi-  
gure of the  
speculum.

"Place the speculum in a vertical posture on a table about  $3\frac{1}{2}$  or 4 feet from the floor. On another table set a candle whose flame should be about the level of the middle of the speculum, and very near the centre of its concavity. About  $\frac{1}{2}$  an inch before the flame, place a flat tin, or thin brass, plate about 3 inches broad, but 4 or 5 high, having several holes about the middle, of different shapes and sizes; some of them as small as the point of the sharpest needle will make them, the biggest about the size of a large mullard-seed: darken the room, and move this candle and plate about on the table, till the light from the brightest part of the flame, passing through some of the larger holes to the speculum, is reflected back so as to form the images of those holes close without one of the side-edges of that thin plate. Those largest images in this case will be visible, (although the speculum have no other polish than what the hones give it), when received on a thick white card held close to that edge of the plate, if the back of the card be either blacked or so shaded that the candle may not shine through it, and the eye be also screened from the candle's direct light. If any difficulty happens in discerning them, the plate may be removed, and the image of the whole flame will be easily seen. Have ready an eye-glass whose focal distance may be something greater than the double of that of the eye-glass you intend for the instrument when finished: you may try several at your discretion. Let this be supported by a small stand moveable on the table, and capable of raising and sinking it as the height of the flame requires, and of turning it into any direction. By means of this stand, bring the eye-glass into such a position, that the light from some of the holes, after its reflection from the speculum, may be received perpendicularly on its surface; and that its distance from the speculum be such, that the reflected images of the holes may be seen distinctly through it, near the edge of the thin plate, by the light coming immediately from the speculum: guide the candle and thin plate with one hand, and the stand carrying the eye-glass with the other, till you have got them into such a situation, that you see distinctly at the same time, through the eye-glass, the edge of the thin plate, and the image of one of the holes close to it. Measure the exact distance of the middle of the speculum from the thin plate directly against the flame, and also from the edge close to which you see the image of the hole. If these measures are the same, set it down as the exact radius of concavity of your speculum, and proper curvature for any that are to be polished on your polishers, though that will allow some latitude: if the measures aforesaid differ, take the mean between them.

"You will now also judge of the perfection of the spherical figure of your metal by the distinctness with which you see the representations of the holes, with their raggedness, dusts, and small hairs sticking in them; and you will be able to judge of this more exactly, and likewise to discover the particular defects of your speculum, by placing the eye-glass so as to see one of the smallest holes in or near its axis; and then by moving the eye-glass a very little forward towards the speculum, and pulling it away, by turns, letting the candle and plate stand still in the mean time. By this means you will observe in what manner the light from the metal comes to a point, to form the

images, and opens again after it has past it. If the area of the light, just as it comes to or parts from the point, appears not round, but oval, squarish, or triangular, &c. it is a sign that the sections of the specular surface, through several diameters of it, have not the same curvature. If the light, just before it comes to a point, have a brighter circle round the circumference, and a greater darkless near the centre, than after it has crossed and is parting again; the surface is more curve towards the circumference, and flatter about the centre, like that of a prolate spheroid round the extremities of its axis; and the ill effects of this figure will be more sensible when it comes to be used in the telescope. But if the light appears more hazy and undefined near the edges, and brighter in the middle before its meeting than afterwards, the metal is then more curve at its centre and less towards the circumference; and if it be in a proper degree, may probably come near the true parabolic figure. But the skill to judge well of this, must be acquired by observation.

"In performing the foregoing examination, the image must be reflected back as near the hole itself as the eye's approach to the candle will admit of, that the obliquity of the reflection may not occasion any sensible errors: in order to which, the eye should be screened from the candle; and the glaring light, which may disturb the observation, may be still more effectually shut out, by placing a plate, with a small hole in it, in that focus of the eye-glass which is next the eye. *A* is the speculum, *B* the candle and plate with the small holes, *C* the cell with the eye-glass and plate be- hind it. Fig. 10.

"Instead of the flame of the candle and plate with small holes, I sometimes made use of a piece of glass thick stuck with globules of quicksilver, strained thro' a leather, and allowed to fall on it in a dew; placing this glass near a window, and the speculum at a distance on the side of the room, being itself and every thing about it as much in the dark as can be. The light of the window reflected from the globules of mercury, appearing as so many stars, serves instead of the small holes, with this advantage, that the reflection from the metal may be very near at right angles.

"If the figure of the metal appears not satisfactory, the hones must be worked with the brasts tool and water for 2 or 3 minutes with the motion, &c. first directed; then work the metal on them with the like motion, and such length of the stroke as may carry the edge of it about  $\frac{1}{2}$  or  $\frac{2}{3}$  of its diameter beyond that of the hone pavement each way; carry it likewise by turns to the right and left, to about the same distance. Continue this about 5 minutes, not pressing the metal down to the hones with any more than its own weight, and observe that the oftener the mud is washed away, the more truly spherical the figure of the speculum will generally be: but the leaving a little more of this mud on the stones has sometimes seemed to give the metal a parabolic figure. I have likewise given it the same, by concluding with a kind of spiral motion of the centre of the metal, near the circumference of the hones, in the manner represented in fig. 11. for about half a minute.

"If after several trials the metal appears to have always the same kind of defect, and answering to the same

 fame particular part of the metal, it is a sign of a different hardness in its several parts, which will make it very difficult to bring that speculum to perfection. In working the tools or metals on the hones, there will often appear little spots in them, much blacker and harder than the rest; these must be dug out as fast as they appear.

“When the figure is to your mind, you may proceed to finish the polish on the facenet with very little putty, and that diluted with a great deal of water. Before you put the putty and water on it, observe, by holding it very obliquely between your eyes and the light, if it have any lifts or stripes across it, which appear more glossy than the rest. If it be so, let the motion of the metal in polishing be directly athwart these lifts, and not along with them, nor even circular. In other respects you may observe the same directions as were before given for its motion on the hones; not forgetting, after every 15 or 20 strokes, to turn it on its axis about  $\frac{1}{2}$  or  $\frac{1}{4}$  of a revolution. As the polisher grows dry, you will find the metal stick to it more and more stiff; at which time it both polishes faster and with a better gloss: only take care that it grows not so dry as for the metal to take hold of the facenet and cut it up, or for the pitch and putty to fix in little knobs here and there on it; which, if it happen, will presently spoil the figure. As fast therefore as the facenet appears to be growing dry at any of its edges, touch the place with the end of a feather dipped in clean water: you may use the same putty at least half an hour. As often as you change it, wash the old clean away, and rub the new about first with your bruiser, to see if there be any gritty or gross particles in it, and rub them away for fear of scratching the metal; then laying down the edge of the speculum a little way on the edge of the polisher, where it is well covered with water, slide it on the middle, and then proceed. The less putty you use at a time, the slower the work will advance; but if you use too much, it will spoil a little of the figure round the edges. It will not want any considerable force to press it down; but if it be of 5 or 6 inches diameter or more, it will be very laborious to go through the polish without some kind of machine.”

Mr Mudge is of opinion that all this troublesome method is entirely unnecessary, and of the same opinion is an anonymous French author who wrote on this subject in the year 1738. The latter tells us what is certainly agreeable to reason and experience, that the more complicated the machines are by which we attempt to accomplish any purpose, the more liable we are to error by reason of their perpetual tendency to go wrong, and the necessary multiplication of inaccuracy is a complicated motion. Four tools, according to Mr Mudge, are all that are necessary; viz. the rough grinder to work off the rough face of the metal; a brass convex grinder, on which the metal is to receive its spherical figure; a bed of hones, which is to perfect that figure, and to give the metal its smooth fine face; and a concave tool or bruiser, with which both the brass grinder and the hones are to be formed. A polisher may be considered as an additional tool; but as the brass grinder is used for this purpose, and its pithy surface is expeditiously and without difficulty formed by the bruiser, the ap-

paratus is therefore not enlarged.

The tool by which the rough surface of the metal is rendered smooth and fit for the hones, is best made of lead stiffened with about a sixth part of tin. This tool should be at least a third more in diameter than the metal which is to be ground; and for one of any size, not less than an inch thick. It may be cemented upon a block of wool, in order to raise it higher from the bench. This leaden tool being cast, it being fixed in the lathe, and turned as true as possible by the gauge to the figure of the intended speculum, making a hole or pit in the middle for a lodgement to the emery, of four inches; when this is done, deep grooves must be cut across its surface with a graver, as is represented fig. 7. These grooves will serve to lodge the emery, and by their means the tool will cut a great deal faster. There is no reason to fear any alteration in the convexity of this tool by working the metal upon it; for the emery will bed itself in the lead, and so far arm the surface of it, that it will preserve its figure, and cut the metal very fast. Any kind of low handle, fixed on the back of the metal, with soft cement, will be sufficient; but it should cover two thirds of its back, to prevent its bending. “This way of working (says Mr Mudge) will cut the metal faster, and with more truth, than the method described by Dr Smith; for should the surface and rough parts be attempted to be ground off by a common grindstone by hand, though you did it as near the gauge as possible, yet the metal would be so much out of truth when applied to the succeeding tool, that no time would be saved by it.” For this purpose Mr Mudge used to employ a common labourer, who soon acquired such dexterity at working upon the tool, that in two hours time he would give a metal of four inches diameter so good a face and figure as even to fit it for the hones.

When all the sand-holes and irregularities on the face of the metal are ground off, and the whole surface is smooth and regularly figured, the speculum is then ready for the brass grinder, and must be laid aside for the present.

The brass grinding-tool is formed in the following manner. Procure a round stout piece of Hamburgh brass, at most a sixth part larger than the metal to be polished; and let it be well hammered, by the assistance of the gauge, into a degree of convexity suitable to the intended speculum. Having done this, scrape and clean the concave side so thoroughly, that it may be well tinned all over; then call upon it, after it has been pressed a proper depth into the sand, the composition of tin and lead above-mentioned, in such quantity, that it may, for a speculum of four inches diameter, be at least an inch and half thick, and with a base considerably broader than the top, in order that it may stand firmly upon the bench hereafter to be described. This being done, it must be fixed and turned in the lathe with great care, and of such a convexity as exactly to suit the concave gauge. More care will be necessary in forming this tool than the former, especially that no rings be left in turning; nor will the succeeding hone-tool require so much exactness, as any defects in turning will, by a method hereafter mentioned, be easily removed; but any inequality or want of truth in the brass tool will occasion

hones.

tion a great deal of trouble before it can be ground out by the emery. This tool must have a hole, somewhat less than that in the metal to be worked upon it, in the middle, quite through to the bottom. When this tool is finished off in the lathe, its diameter should be one-eighth wider than the metal.

The hones should be of the best sort of those recommended by Dr Smith. They should be cemented in small pieces (in a kind of pavement, as hath been already mentioned) upon a thick round piece of marble, or metal made of lead and tin in the proportions above directed, in such a manner, that the lines between the stones may run straight from one end to the other; so that placing the teeth of a fine saw in each of these divisions, they may be cleared from one end to the other of the cement which rises between the stones. This bed of hones should be at least one-fourth larger than the metal which is to be ground upon it; but there is no necessity for turning the metal on which the hones are cemented to the same convexity with the gauge. As soon as the hones are cemented down, and the joints cleared by the saw, this tool must be fixed in the lathe, and turned as exactly true to the gauge as possible; which done, it must be laid aside for the present. The next tool to be made is the bruiser.

201  
Manner of  
forming the  
bruiser.

The bruiser should be made of thick stout brass like the former, perfectly sound, about a quarter of an inch thick, and hammered as near to the gauge as possible. It should then be scraped, cleaned, and tinned on the convex side, as the former tool was on the concave, and the same thickness of lead and tin cast upon it. The general shape of this should differ from the former; for as that increased in diameter at the bottom for the sake of standing firmly, so this should be only as broad at bottom as at top, as it is to be used occasionally in both those positions. When this tool is fixed in the lathe, and turned off concave to the convex gauge with great truth likewise, its diameter ought to be the middle size between the hones and the polisher.

Having with the lathe roughly formed the convex brass grinder, the bed of hones, and the concave bruisers, the convex and concave brass tools and the metal must be wrought alternately and reciprocally upon each other with fine emery and water, so as to keep them as nearly to the same figure as possible; in order to which, some washed emery must be procured. This is best done by putting it into a vial, which must be half filled with water and well shaken up, so that, as it subsides, the coarsest may fall to the bottom first, and the finest remain at the top; and whenever fresh emery is laid upon the tools, the best method (which we should also observe with the putty in polishing) will be, to shake gently the bottle, and pour out a small quantity of the turbid mixture.

202  
Of grinding  
the specu-  
lum, the  
brass tool,  
and the  
bruiser, to-  
gether.

The tools being now all ready, upon a firm post in the middle of a room, you are to begin to grind the brass convex tool with the bruiser upon it, working the latter crosswise, with strokes sometimes across its diameter, at others a little to the right and left, and always so short, that the bruisers may not pass above half an inch within the surface of the brass tool either way, shifting the bruiser round its axis every half dozen strokes or thereabout. You must likewise,

every now and then, shift your own position, by walking round, and working at different sides of the brass tool: at times the stroke should be carried round and round, but not much over the tool: in short, they must be directed in such a manner, and with such equality, that every part of both tools may wear equally. This habit of grinding, as well as the future one of polishing, will soon be acquired. When you have wrought in this manner about a quarter of an hour with the bruiser upon the tool, it will be then necessary to change them, and, placing the bruiser upon its bottom, to work the convex tool upon that in the same manner.

When, by working in this equable manner alternately with the bruiser and tool, and occasionally adding fresh emery, you have nearly got out all the vestiges of the turning tool, and brought them both nearly to a figure, it will then be time to give the same form to the metal. This must be done by now and then grinding it upon the brass tool with the same kind of emery; taking care, however, by working the two former tools frequently together, to keep all three exactly in the same curve. The best kind of handle for the metal is made of lead, a little more than double its thickness, and somewhat less in diameter, of about three pounds weight, with a hole in the middle, (for reasons to be afterwards shown), a little larger than that in the metal: this handle should be cemented on with pitch. The upper edge of this working should be rounded off, that the fingers may not be hurt; and a groove about the bigness of a little finger be turned round just below it, for the more conveniently holding and taking the metal off the tools.

When the bruiser, brass tool, and metal, are all brought to the same figure, and have all a true good surface, the next part of the process is to give a correct spherical figure and a fine face to the metal upon the hones. It is necessary to observe, however, that the hones should be placed in a vessel of water, with which they should be quite covered for at least an hour before they are used; otherwise they will be continually altering their figure when the metal comes to be ground upon them. The same precaution is also necessary if you are called off from the work while you are grinding the metal; for, if they be suffered to grow dry, the same inconvenience will ensue.

In order to give a proper figure to the hones, and exactly suitable to that of the brass tool, bruiser, and metal, when the hones are fixed down to the block, some common flour emery (unwashed), with a good deal of water, must be put upon them, and the bruiser being placed upon the hones and rubbed thereon with a few strokes and a light hand, the inequalities of the stone will be quickly worn off; but, as a great deal of mud will be suddenly generated, it must be washed off every quarter of a minute with plenty of water. By a repetition of this two or three times, the hones (being of a very soft and friable nature) will be cut down to the figure without wearing or altering the bruiser at all. Tho' this business may be quickly done, and can be continued but for a few strokes at a time, it is absolutely necessary that those strokes be carried in the same direction, and with the same care, which was observed in grinding the former tools together.

As soon as the hones have received the general figure of the bruiser, and all the turning strokes are worn out from them, the emery must be carefully washed off; in order to which, it will be necessary to clear it from the joints with a brush, under a stream of water. The bruiser and metal must likewise be cleared in the same manner, and with equal care, from any lurking particles of emery.

The hones being fixed down upon the block, you now begin to work the bruiser upon them with very cautious, regular, short strokes, forward and backward, to the right and left, turning the axis of the bruiser in the hand, while you move round the hones by shifting your position, and walking round the block. The whole now depends upon a knack in working, which should be conducted nearly in the following manner. Having placed the bruiser on the centre of the hones, slide it in an equable manner forward and backward, with a stroke or two directly across the diameter, a little on one side, and so on the other. Then, shifting your position an eighth part round the block, and having turned the bruiser in your hand about as much, give it a stroke or two round and round, but not far over the edges of the hones, and then repeat the cross-strokes as before: those round strokes, which ought not to be above two or three at most, are given every time you shift your own position and that of the metals previous to the cross ones, in order to take out any stripes, either in the hones or bruiser, which may be supposed to be occasioned by the straight cross strokes. During the time of working, no mud must be suffered to collect upon the hones, so as to destroy the perfect contact between the two tools; and therefore they must every now and then be washed clean by throwing some water upon them. When, by working in this manner, all the emery strokes are ground off from the bruiser, and it has acquired a good figure and clean surface, you may then begin with the metal upon the hones, in the same cautious manner, washing off the mud as fast as it collects; though that will be much less now than when the bruiser was ground upon them. Every now and then, however, the bruiser must be rubbed gently and lightly upon the hones, which will, as it were, by sharpening them, and preventing too great smoothness, occasion them to cut the metal faster.

After having, by working in this manner, taken out all the emery strokes, and given a fine face and true figure to the metal, which will be pretty well known by the great equality there is in the feel while you are working, and by which an experienced workman will form a pretty certain judgement, you may then try your metal, and judge of its figure by the following more certain method.

Wash the hone pavement quite clean; then put the metal upon the centre of it, and give two or three strokes round and round only, not carrying, however, the edges of the metal much over the hones; this will take out the order of straight strokes: then, having again washed the hones, and placed the speculum upon their centre, with gentle pressure, slide it towards you, till its edge be brought a little over that of the hones; then carry it quite across the diameter as far on the other side, and having given the metal a light stroke or two in this direction, take it off the

tool. The metal being wiped quite dry, place it upon a table at a little distance from a window; stand yourself as near the window, at some distance from the metal, and looking obliquely on its surface, turn it round its axis, and you will see at every half turn the grain given by the last cross strokes flash upon your eye at once over the whole surface of the metal. This, says Mr Mudge, is as certain a proof of a true spherical figure, as the operose and difficult method described by Dr Smith: for as there is nothing soft or elastic either in the metal, or in the hones, this glare is a certain proof of a perfect contact in every part of the two surfaces; which there could not be, if the spheres were not both perfect and precisely the same. Indeed there is one accidental circumstance which affords its aid in this and other similar cases; namely, that a concave and convex surface ground together, though ever so irregular at first, (will, if the working be uniform and proper, consisting, especially at last, of cross strokes in every possible direction across the diameter) be formed into portions of true and equal spheres. Had it not been for this lucky necessity, it would have been impossible to have produced that correctness which is essential in the speculum of a good reflecting telescope by any mechanical contrivance whatever. For when it is considered, that the errors in reflection are four times as great as in refraction, and that the least defect in figure is magnified by the powers of the instrument, any thing short of perfection in the figure of the speculum would be evidently perceived by the want of distinctness in the performance.

Here, however, Mr Mudge observes, that he all along supposes, both in forming the tools, and at last in figuring the metal (and the same is to be observed in the future process of polishing), that no kind of pressure is used that may endanger the bending or irregularly grinding them; they should therefore be held with a light hand, and loosely between the fingers; and the motion given should be in a horizontal direction, with no other pressure than their own dead weight.

Having now finished the metal on the hones, and rendered it both in point of figure and surface fit for the last and most essential part of the process, viz. that of polishing, we shall now proceed to describe it as minutely as possible, though many little circumstances must necessarily be omitted, and can only be supplied by experience.

The polishing of the speculum is the most difficult and essential part of the process; and every experienced workman knows, to his vexation, that the most trifling error here will be sufficient to spoil the figure of his metal, and render all his preceding caution useless. On this occasion also Mr Mudge makes the following remarks on the method of polishing used by Hadley and Molyneux, and already described from Dr Smith's Optics. "First then, says he, the tool itself used by them in polishing the metal is formed with infinite difficulty. The first described polisher is directed to be made by covering the tool with farcenet, which is to be saturated with a solution of pitch in spirit of wine, by successive applications of it with a brush, till it is covered, and by the evaporation of the spirit of wine filled with this extract of pitch; the surface is then to be worked down and finished with

the bruifer. This is all very easy in imagination; but whoever has used this method (which I have myself, unsuccessfully, several times) must have found it attended with infinite labour, and at last the business done in a very unsatisfactory manner; for the pitch by this process will be deprived of an essential part of its composition. The spirit of wine dissolves none but the resinous parts of its substance, which is hard and untractable; and if you use soap or spirit of wine to soften or dissolve it, it will equally affect the whole surface, the lower as well as the higher parts of it. And suppose that, with infinite labour with the bruifer, it is at last reduced to a fine uniform surface, it is nevertheless too hard ever to give a good polish with that lustre which is always seen in good metals. Nor will it give a good spherical figure: for a perfect sphere is formed, as I observed before, by that intimate accommodation arising from the wear and yielding of both tool and metal; whereas, in this method there is such a stubbornness in the polisher, that the figure of the metal, whether good or bad, must depend upon the truth of the former, which is very seldom perfect.

"If the polisher be made in the second manner proposed, viz. by straining the pitch through an outer covering, which is afterwards to be stripped off, the superficies of pitch and sarcenet is so very thin, that the putty working into them forms a surface hard and untractable, so that it is impossible to give the speculum a fine polish. Accordingly all those metals which are wrought in this way have an order of scratches instead of polish, discovering itself by a greyish visible surface. Besides, supposing this tool perfectly finished, and answering its purpose ever so well, it is impossible that it can produce in the speculum any other than a spherical figure; and indeed nothing else is expected from this method, as is evident from the experiment recommended to ascertain the truth of it. You are directed to place a small luminous object in the centre of the sphere of which the metal is a segment; and then having adjusted an eye-glass at the distance of its own focal length from the object, and so situated that the image of the object formed by the speculum may be visible to the eye, you are to judge of the perfect figure of the metal by the sharpness and distinctness with which the image appears. From hence it is very evident, that as the object and image are both distant from the metal by exactly its radius, nothing but a true spherical figure of the speculum can produce a sharp and distinct image; and that the image could not be distinct if the figure of the speculum were parabolic. Consequently, if the same speculum used in a telescope were to receive parallel rays, there would necessarily be a considerable aberration produced, and a consequent imperfection in the image. Accordingly, there never was a good telescope made in this manner; for if the number of degrees, or the portion of the sphere of which the great metal is a part, were as considerable as it ought to be, the instrument would bear but a very low charge, unless a great part of the circumference of the metal were cut off by an aperture, and the ill effects of the aberration by that means in some measure prevented.

"If ever a finished metal turned out without this defect, and has been found perfectly sharp and distinct, it must have been owing to an accidental parabolic

tendency, noways the natural result of the process, and therefore quite unexpected, and most probably unknown to the workman."

Our author next acquaints us, that, from observing the high polish of some of the metals made by Mr Short, and concluding that the high lustre of the polish could never have been produced in the manner above described, but by some more soft and tender substance, he was directed to make use of pitch itself, especially as Sir Isaac Newton mentions his having used that substance in his operations. Accordingly, shortening Dr Smith's process, he made a set of tools in the manner above-mentioned, except that he was obliged to make some subsequent alteration in the polisher. Having given a good spherical figure to the brass tool and the bruifer, and likewise to the metal upon the hones, and made the brass convex tool so hot as just not to hurt the finger, he tied a lump of common pitch, which should neither be too hard nor too soft, in a rag, and holding it in a pair of tongs over a still fire where there was no rising dust, till it was ready to strain through the linen, he caused it to drop on the several parts of the convex tool, till he supposed it would cover the whole surface to about twice the thickness of a shilling; then spreading the pitch as equally as he could, he suffered the polisher (the name he gives to the tool so prepared) to grow quite cold. He then made the bruifer so hot as almost to burn his fingers; and having fixed it to the bench with its face upwards, he suddenly placed the polisher upon it, and quickly slid it off; by this means rendering the surface of the pitch somewhat more equal. The pitch is then to be wiped off from the bruifer with a little tow; and by touching the surface with a tallow candle, and wiping it a second time, it will then be perfectly clean, and fit for a second process of the same sort, which must again be performed as quickly as possible; and this is ordinarily sufficient to give a general figure to the surface of the pitch. The bruifer and the polisher are then suffered to grow perfectly cold; when the pitch, considering what has been taken off, will be about the thickness of a shilling.

Here, however, it is necessary to observe, that the pitch should neither be very hard and resinous, nor too soft: if the former, it will be so untractable as not to work kindly; and if too soft, it will in working alter its figure faster than the metal, and too readily fit itself to the irregularity of its figure, if it have any. When both tools are perfectly cold, he gave the polisher a gentle warmth, and then fixed the bruifer to the block with its face upwards; and (having, with a large camel's-hair brush, spread over the face of the polisher a little water and soap to prevent sticking, with short, straight, and round strokes, he worked it upon the bruifer, every now and then adding a little more water and soap, till the pitch upon the polisher had a fine surface and the true form of the bruifer; and this he continued till they both grew perfectly cold together: in this manner the polisher was formed in about a quarter of an hour. But here a difficulty arose. For when he began to polish the metal, he found that the edge of the hole in the speculum collected the pitch towards the middle of the polisher: hence, though in this method of working

he could give an exquisite polish, as the putty lodged itself in the pitch exceedingly well, yet the figure of the metal was injured in the middle; nor indeed did the work go on with that equability which is the inseparable attendant on a good figure. In order to obviate this difficulty, he cast some metals with a continued face, the holes not going quite through, within perhaps the thickness of a sixpence. In this way he finished two or three metals, and the work went on very well; but when he came to open the holes, even though the utmost caution was used, the metals were found to be imperfect. This he attributed to an alteration of the figure from the removal of even that small portion of metal after the speculum had been finished. This he supposes to have been the cause of his spoiling a very distinct and perfect two-foot metal, which bore a charge of 200 times, only by opening the sharp part of the edge of the hole, because he thought that it bounded the field: so essentially necessary is an exquisite correctness of figure in the speculum of a perfect reflector.

This experiment not succeeding, instead of casting the metal without a hole, he made one quite through the middle of the polisher, a little less than that in the speculum. This perfectly answered the purpose; no more inconvenience arose from the gathering of the pitch, for it had now no greater tendency to collect at the centre than the sides; and thus he finished several metals successively, excellent both in figure and polish. One of these, of 2 inches diameter and 7.5 focal length, bore a charge of 60 times and upwards.

In this method of working, the polishing goes on in an agreeable, uniform, and smooth manner; and the small degree of yielding in the pitch, which is actually not more than the wearing of the metal, produces that mutual accommodation of surfaces so necessary to a true figure. In the beginning of the polish, and indeed for some time during the progress of it, (always remembering now and then to move the metal round its axis), he worked round and round, not far from, and always equally distant from, the centre; except that every time, previous to the shifting the metal on its axis, he used a cross stroke or two; and when the polish was nearly completed, he used mostly cross strokes, giving a round stroke or two likewise every time he turned the metal on its axis. In this method of working, he always observed that the metal polished fastest in the middle; inasmuch that one half or two thirds of it would be completely polished, when the circumference was scarcely touched by the tool. Observing this in some of the first metals, and not considering that this way of polishing was in fact a species of grinding, and as perfect as that upon the hones, he went on reluctantly with the work, almost despairing of being able to produce a good figure. However, he was always agreeably disappointed; for when the polish was extended to the edge, or within a tenth of an inch of it, he almost constantly found the figure good, and the performance of the metal very distinct. But this same circumstance of apparent defect in the metals, was in fact that to which their perfection was owing; for they all, contrary to his expectation, turned out parabolic. On the other hand, when he chanced to find that a metal, when first applied to the polisher, took the polish

equally all over, and consequently the business did not take up above 10 minutes; yet the metal constantly turned out good for nothing. From frequent observations, however, he at last found a method of giving a correct parabolic figure and an exquisite polish at the same time.

In polishing the speculum, in order to avoid the intrusion of any particles of emery, it would not be right to polish in the same room where the metal and tools were ground, nor in the same cloths which were worn in the former process; at least it would be necessary to keep the bench quite wet, to prevent any dust from rising.

Having then made the polisher, by coating the brass convex tool equally with pitch, which we suppose smoothed and finished with the brass tool in the manner before described, and which is a very easy process, the whole operation is begun and finished in the following manner.

The leaden weight, or handle, upon the back of the metal, should be divided into eight parts, by so many deep strokes of a graver upon the upper surface of the lead, marking each stroke with the numbers 1, 2, 3, 4, and so on, that the turns of the metal in the hand may be known to be uniform and regular.

To prevent any mischief from coarse particles of putty, it must be washed immediately before using. In order to this, put about half an ounce of putty into an ounce phial, and fill it two-thirds with water; then having shaken the whole, let the putty subside, and stop the bottle with a cork.

In a tea-cup with a little water, there should be a full-sized camel's-hair brush, and a piece of dry clean soap in a galley-pot: a soft piece of sponge will also be necessary. These, as well as the metal brusher and polisher, should be constantly covered from dust.

The polisher being fixed down, and the camel's-hair brush being first wetted and rubbed a little over the soap, let every part of the tool be brushed over therewith; then work the brusher with short, straight, and round strokes, lightly upon the tool, and continue to do so, now and then turning it, till the polisher have a good face, and be fit for the metal. Then having shaken up the putty in the phial, and touched the polisher in five or six places with the cork wetted with that and the water, place the brusher upon the tool, and give a few strokes upon the putty to rub down any gritty particles; after which, having removed it, work the metal lightly upon the polisher round and round, carrying the edges of the speculum, however, not quite half an inch over the edge of the tool, and now and then with a cross stroke.

The first putty, and indeed all the succeeding applications of it, should be wrought with a considerable while: for if time be not given for the putty to bed itself in the pitch, and any quantity of it lie loose upon the polisher, it will accumulate into knobs, which will injure the figure of the metal; and therefore as often as ever such knobs arise, they must be carefully scraped off with the point of a penknife, and the loose stuff taken away with the brush. After the putty is well wrought into the pitch, some more may be added in the same manner, but never much at a time; and always remembering to work upon it first with the brusher, for fear any gritty particles may find their way

upon;

upon the polisher. If the bruise be apt to stick, and do not slide smoothly upon the pitch, the surface of either tool may be occasionally brushed over with the soap and water, but it must be remembered that the wet brush must be but lightly rubbed upon the soap.

In the beginning of this process little effect is produced, and the metal does not seem to polish fast, in some measure owing to its taking the polish in the middle, and perhaps because neither that nor the bruise move evenly upon the polisher: but a little perseverance will bring the whole into a good temper of working; and, when the pitch is well defended by the coating of the putty, the process will advance apace, and the former acquiring possibly some little warmth, the metal moves more agreeably over it, with an uniform and regular friction. All this while the metal must have no more pressure than that which it derives from its own weight and that of the handle; and the polisher must never be suffered to grow dry, but, as often as it has any tendency to do so, the edges of it must be moistened with the hair-pencil; and now and then, even when fresh putty is not laid on, the surface of the polisher should be touched with the brush to keep it moist.

When the polish of the metal nearly reaches the edge (for it always, as we said before, begins in the middle) you must alter your method of working; for now the round strokes must be gradually altered for the short and straight ones. Supposing then you are just beginning to alter them; after having put on fresh putty, and gently rubbed it with two or three strokes of the bruise, you place the metal on the tool, and after a stroke or two round and round, give it a few forward and backward, and from side to side, but with the edges very little over the tool; then having turned the metal one-eighth round in your hand, and having moved yourself as much round the block (which must be remembered throughout the whole process) you go on again with a stroke or two round, to lead you only to the cross strokes, which are now to be principally used, and with more boldness. After this has been done some time, the metal will begin to move stiffly as the friction now increases, and the speculum polishes very beautifully and fast; and the whole surface of the polishing tool will be equally covered with a fine metallic bronze. The tool, even now, must not be suffered to become dry; a single round stroke in each of your stations and turnings of the metal will be sufficient, and the rest must all be cross ones, for we are completing a circular figure. You must now be very diligent; for the polisher drying, and the friction increasing very fast, the business of the spherical figure is nearly at an end. As the metal wears much, its surface must be now and then cleaned, with a piece of shammy leather, from the black stuff which collects upon it; and the polisher likewise from the same matter, with a soft piece of wet sponge. You will now be able to judge of the perfect spherical figure of the metal and tool, when there is a perfect correspondence between the surfaces, by the fine equable feel there is in working, which is totally free from all jerks and inequalities. Having proceeded thus far, you may put the last finishing to this figure of the metal by bold cross strokes, only three or four in the directions of each of the eight diameters, turning the metal at the same time: this

must be done quickly; for it ought, in this part of the process particularly, to be remembered, that, if you permit the tool to grow quite dry, you will never be able, with all your force, to separate that and the metal, without destroying the polisher by heat.

The metal has now a beautiful polish and a true spherical figure, but will by no means make a sharp distinct image in the telescope: for the speculum (if it be tried in the manner hereafter recommended) will not be found to make parallel rays converge without great aberration; indeed the deviation will be so great, as to be very sensibly perceived by a great indistinctness in the image.

In order then to give the speculum the last and finishing figure, which is done by a few strokes, it must be particularly remarked, that by working the metal round and round, the sphere of the polisher by this means growing less, it wears fastest in the middle; and as a segment of a sphere may become parabolic, by opening the extremes gradually from within outwards, so it may be equally well done by increasing the curvature in the middle, in a certain ratio, from without inwards.

Supposing then the metal to be now truly spherical, stop the hole in the polisher, by forcing a cork into it underneath, about an inch, so that it do not reach quite to the surface; and having washed off any mud that may be on the surface of the tool with a wet soft piece of sponge, whilst the surface of it is a little moist, place the centre of the metal upon the middle of the polisher; then having, with the wet brush, lodged as much water round the edge of the metal as the projecting edge will hold, fill the hole of the metal and its handle with water, to prevent the evaporation of the moisture, and the consequent adhesion between the speculum and polisher, and let the whole rest in this state two or three hours: this will produce an intimate contact between the two, and by parting with any degree of warmth they may have acquired by the vicinity of the operator, they will grow perfectly cold together.

By this time you may push out the cork from the polisher, to discharge the water, and give the metal the parabolic figure in the following manner.

Move the metal, gently and slowly at first, a very little round the centre of the polisher (indeed after this rest it will move stiffly); then increasing by degrees the diameter of these strokes, and turning the metal frequently round its axis, give it a larger circular motion, and this without any pressure but its own weight, and holding it loosely between the fingers: this manner of working may safely be continued about two minutes, moving yourself as usual round the block, and carrying the round strokes in their increased and largest state, not more than will move the edge of the metal half an inch or five-eighths over the tool. The speculum must not all this while be taken off from the polisher; and consequently no fresh putty can be added. It will not be safe to continue this motion longer than the time above-mentioned; for if the parabolic tendency be carried the least too far, it will be impossible to recover a true figure of that kind but by going through the whole process for the spherical one in the manner before described, by the cross strokes upon the polisher, which takes a great deal of time. However,

when

206  
How to  
the para-  
lic figure  
to the m-  
tal.

when there is occasion, it may be done; and Mr Mudge has several times recovered the circular figure when he had inadvertently gone too far with the parabolic, and ultimately finished the metal on the polisher without the use of the hone.

It will now be proper to try the figure of the speculum; and that is always best done by placing it in the telescope it is intended for. In order to this, Mr Mudge uses the instrument as a kind of microscope; placing the object, however, at such a distance that the rays may be nearly parallel. At about 20 yards, a watch-paper, or some such object, on which there are some very fine hair-strokes of a graver, is fixed up. The lead must then be taken off from the back of the speculum; which is best done by placing the edge of a knife at the junction of the lead and metal, when, by striking the back of it with a slight blow, the pitch immediately separates, and the handle drops off; the remaining pitch may be scraped off with a knife, taking care that none of the dust stick to the polished face of the metal.

Having placed the speculum in the cell of the tube, and directed the instrument to the object, make an annular kind of diaphragm with card-paper, so as to cover a circular portion of the middle part of the metal between the hole and the circumference, equal in breadth to about one-eighth part of the diameter of the speculum: this paper ring should be fixed in the mouth of the telescope, and remain so during the whole experiment; for the part of the metal covered by it is supposed to be perfect, and therefore unemployed.

There must likewise be two other circular pieces of card-paper cut out, of such sizes, that one may cover the centre of the metal by completely filling the hole in the last described annular piece; and the other, such a round piece as shall exactly fit into the tube, and so broad as that the inner edge may just touch the outward circumference of the middle annular piece. It would be convenient to have these two last pieces so fixed to an axis that they may be put in their places, or removed from thence, so easily, as not to displace or shake the instrument. All these pieces therefore together will completely shut up the mouth of the telescope.

Let the round piece which covers the centre of the metal, or that which has no hole in it, be removed; and, by a nice adjustment of the screw, let the image (which is now formed by the centre of the mirror) be made as sharp and distinct as possible. This being done, every thing else remaining at rest, replace the central piece, and remove the outside annular one, by which means the circumference only of the speculum will be exposed, and the image now formed will be from the rays reflected from the outside of the metal. If there be no occasion to move the screw and the little metal, and the two images formed by these two portions of the metal be perfectly sharp and equally distinct, the speculum is perfect, and of the true parabolic curve; or at least the errors of the great and little speculum, if there be any, are corrected by each other.

If, on the contrary, under the last circumstance, the image from the outside of the metal should not be distinct, and it should become necessary, in order to make it so, that the little speculum be brought nearer, it is plain that the metal is not yet brought

to the parabolic figure; but if, on the other hand, in order to procure distinctness, you be obliged to move the little speculum farther off, then the figure of the great speculum has been carried beyond the parabolic, and hath assumed an hyperbolic form. When the latter is the case, the circular figure of the metal must be recovered (after having fixed on the handle with soft pitch) by bold erofs strokes upon the polisher, finishing it again in the manner above described. If the speculum be not yet brought to the parabolic form, it must cautiously have a few more round strokes upon the polisher; indeed a very few of them in the manner before described make in effect a greater difference in the speculum than would be at first imagined. If a metal of a true spherical figure were to be tried in the above-mentioned manner in the telescope (which Mr Mudge has frequently done) the difference of the foci of the two segments of the metal would be so considerable, as to require two or three turns of the screw to adjust them; so very great is the aberration of a spherical figure of the speculum, and so improper to procure that sharpness and precision so necessary to a good reflecting telescope.

This is by no means the case with the object-glasses of refractors; for besides that they are in fact never so distinct as well-finished reflectors, the apertures of them are so exceedingly small, compared to the latter, and the number of degrees employed so very small, that the inconvenience of a spherical figure is not so much perceived. Accordingly we observe in the generality of reflectors, (whose specula, unless by accident, are always spherical), that the only true rays which form the distinct image arise from the middle of the metal: and unless the defect be remedied by a considerable aperture, which destroys much light, the false reflection from the inside of the metal produces a greyish kind of haziness, which is never seen in Mr Short's, or indeed in any good telescopes.

Supposing that the two foci of the different parts of the metal perfectly coincide; and that, by the union of them when the apertures are removed, the telescope shews the objects very sharp and distinct, you are not, however, even then to conclude that the instrument is not capable of farther improvement: for you will perceive a sensible difference in the sharpness of the image, under different positions of the great speculum with respect to the little one, by turning round the great metal in its cell, and opposing different parts of it to different parts of the little metal, correcting by this means the error of one by the other. This attempt should be persevered in for some time, turning round the great speculum about one-sixteenth at a time, and carefully observing the most distinct situation each time the eyepiece is screwed on: when, by trying and turning the great metal all round, the distinctest position is discovered, the upper part of the metal should be marked with a black stroke, in order that it may always be lodged in the cell in the same position. This is the method Mr Short always used; and the caution is of so much consequence, that he thought it necessary to mention it very particularly in his printed directions for the use of the instrument.

And, farther, Mr Short frequently corrected the errors of the great by the little metal in another way. If the great speculum did not answer quite well in the

Mechanism  
of  
Optical  
Instruments

telescope, he cured that defect sometimes by trying the effect of several metals successively, by this means correcting the errors of one by the other; for in several of his telescopes which have passed thro' our author's hands, when the sizes and powers have been the same, he has found that the great metals, tho' very distinct in their proper telescopes, yet have, when taken out and changed from one to the other, spoiled both telescopes, rendering them exceedingly indistinct, which could arise from no other circumstance. For this reason he supposes it was, that Mr Short kept, ready furnished, a great many large metals of the same focal length, so that, when he wanted to mount a telescope, he might from a great choice be able to combine those metals which suited each other best. Our author is strongly inclined to believe this was the case, not only from the above observation, but because he shewed him a box of finished metals, in which he is sure there were a dozen and a half of the same focal length.

To return: A little use in working will make the whole of the process of grinding and polishing very easy and certain; for though we have endeavoured to be as particular as possible, it is yet scarcely possible to supply a want of dexterity, arising from habit only, by the most laboured and minute description. And though the above account may appear irksome to the reader, as it lies cold before the eye, it is hoped, whoever attempts to make the instrument, will not complain of it as tediously particular.

It may, however, be farther remarked, that when the metal begins to move stiffly upon the polisher, and particularly when the figure is almost brought to the parabolic form, it will be necessary to fix the elbows against the sides, in order to give momentum and equality to the motion of the hand by that of the whole body.

The same polisher will serve for several metals, if it be somewhat warmed when you begin to use it.

There is another circumstance, and a material one too, which must not be omitted; it is this. For the very same reason that the pitch should not be too hard or soft, the work will not proceed well in the heat of summer, or the cold of winter: in the latter, it may be possible to remedy the defect by having the room warmed with a stove; and in the summer, the other inconvenience may perhaps be avoided by using a harder kind of pitch; but our author much doubts in either case whether the work will go on so kindly: he has himself always wrought in spring and autumn.

The process of polishing, and indeed grinding upon the hones, will not go on so well if it be not continued uninterruptedly from beginning to end; for if the work of either kind be left but for a quarter of an hour, and you then return to it again, it will be some time before the tool and metal can get into a kindly way of working; and till they do, you are hurting what was done before.

We have all along supposed that the metal we have been working was about four inches diameter: if it be either larger or smaller, the sizes of the hones, bruiser, and polisher, must be proportionably different. Our author says he never found any ill consequence arising from the different expansion from heat and cold in any of the tools, though they be made of different metals and substances, unless the inconvenience, occa-

sioned by the interruption before hinted at, be thought to result from thence; for the alteration produced in the surface of the speculum, both by grinding and polishing, is so much quicker than any that can be supposed to arise from the former cause, that it is never attended with any practical consequence.

Magnifying very minute objects, and particularly reading at a distance, have been generally considered as the surest test of the goodness of a telescope; and indeed, when the page is placed at a great distance, so that the letters subtend but a very small angle at the eye, if then they appear with great precision and sharpness, it is most probable that the instrument is a good one. But we are, nevertheless, sometimes apt to be deceived by this method; nor is it always possible to determine upon the different merits of two instruments of equal power, by this mode of examination; for when the letters are removed to the utmost extent of the powers of the two instruments, the eye is apt to be prejudiced by the imagination. If two or three words can be here and there made out, all the rest are guessed at by the sense; inasmuch that an observer, zealous for the honour of his instrument, is very apt to deceive himself in spite of his intentions. The surer test is by figures, where you can procure no aid from this sort of deception. In order to examine reflecting telescopes, our author made upon a piece of copper, and on a black ground, six lines consisting of about 12 pieces of gold figures, and each line of figures differing in magnitude; from the smallest that could be distinctly made, to those of about two-tenths of an inch long: moreover, the figures in the several lines were differently disposed, and the sum of each line also differed. It is evident that by this method all guesses is precluded; and that of two instruments, of the same powers, that which can make out the least order of figures, which will be known by the sum, is the best telescope. Such a plate he caused to be fixed up for experiments against the top of a steeple, about 300 yards north of his house; and it will serve to give some idea of the distinctness with which very small figures could be made out at that distance, by saying, that in a clear state of the air, and with the sun behind him, with a telescope of 18 inches focal length, which count Bruhl did him the honour to accept, and now has in his possession, he has seen the legs of a small fly, and the shadows of them, with great precision and exactness.

"I cannot conclude, (says our author,) without indulging myself in an observation on the amazing sagacity of Sir Isaac Newton in every subject upon which he thought fit to employ his attention. It was he who first proposed, and indeed practised, the polishing with pitch: a substance, which at first sight, perhaps, every one but himself would have thought very improper, from its softness, to produce that correctness of figure so necessary upon these occasions; and yet I do believe, that it is the only substance in nature that is perfectly calculated for the purpose: for at the same time that it is soft enough to suffer the putty to lodge very freely on its surface, and for that reason to give a most tender and delicate polish; it is likewise totally inelastic, and therefore never, from that principle, suffers any alteration in the figure you give it. If the first makers of the instrument, therefore, had given proper credit to, or had simply followed the hint

Mechanism

Fig. 10.

OPTICS.

A Bell Sculp.

Mechanism of Optical Instruments hint Sir Isaac gave, it would have saved them infinite trouble, and they would have produced much better instruments; but the pretended refinement, of drawing a tincture from pitch with spirits of wine, affords you only the refinous, hard, and untractable part of the pitch, divested of all that part of its original substance, which is necessary to give it that accommodating pliability in which its excellence consists."

It is needless to swell this account with a detail of the process for polishing the little speculum, as it must be conducted in the same manner which has been already described in that of the large one: only observing, that as the little metal has an uninterrupted face, without a hole, so there is no occasion for one in the polisher; and likewise that, as a spherical figure is all that need here be practically attempted, so the difficulty in finishing is infinitely short of that of the other.

As it is always necessary to solder to the back of the little speculum a piece of brass, as a fixture for the screw to adjust its axis, Mr Mudge mentions a safe and neat method of doing it, which may be very useful to the optical or mathematical instrument-maker upon other occasions. Having cleaned the parts to be soldered very well, cut out a piece of tin-foil the exact size of them; then dip a feather into a pretty strong solution of *sal ammoniac* in water, and rub it over the surfaces to be soldered; after which place the tin-foil between them as fast as you can (for the air will quickly corrode their surfaces so as to prevent the solder taking), and give the whole a gradual and sufficient heat to melt the tin. If the joints to be soldered have been made very flat, they will not be thicker than a hair: though the surfaces be ever so extensive, the soldering may be conducted in the same manner; only care must be taken, by general pressure, to keep them close together. In this manner, for instance, a silver graduated plate may be soldered on to the brass limb of a quadrant, so as not to be discernible by any thing but the different colour of the metals. This method was communicated to our author by the late Mr Jackson, who during his life kept it a secret, as he used it in the construction of his quadrants.

In Plate CCXXVIII. are figured the shape of the leaden tool for rough-grinding; the hones; and the apparatus to be applied in the mouth of the telescope, to ascertain the true figure of the speculum.

Fig. 7. The grinder for working off the rough face of the metal: the black strokes represent deep grooves made with a graver.

Fig. 8. The bed of hones, which is to complete the spherical figure of the speculum, and to render its surface fit for the polisher.

Fig. 9. An apparatus for examining the parabolic figure of the speculum.

AA, The mouth of the telescope, or edge of the great tube.

BB, A thin piece of wood fastened into and flush with the end of the tube; to which is permanently fixed the annular piece of pasteboard CC, intended to cover and to prevent the action of the corresponding part of the speculum.

D, Another piece of pasteboard, fixed by a pin to the piece of wood BB, on which it turns as on a centre; so that the great annular opening HH,

may be shut up by the ring FF, or the aperture GG by the imperforate piece E, in such manner, that in the first instance the reflection may be from the centre, and in the latter from the circumference, of the great speculum.

§ 6. Description of the different parts of which Reflecting Telescopes are composed, and of fitting up an instrument of that kind; with the rectification of Telescopic sights of Quadrants, &c.

In Plate CCXXIX. all these are distinctly represented.

Fig. 1. shews the form of a pair of pincers necessary on several occasions, particularly for breaking off the corners of a piece of glass, in order to make the eye-glasses.

Fig. 2. 3. Two wooden frames for confining the sand in which the metalline specula are to be cast.

Fig. 6. 7. Two iron moulds in which are to be cast two models of lead for the specula. These models are afterwards to be turned as exactly as possible to the gauges, and then used for giving the form necessary to the sand in the frames.

Having cast the specula, and polished them according to the directions already given, you must next provide a tube of plate brass, well smoothed, for the body of your telescope; and whose length must be determined by the focal length of the large speculum. This tube must be painted black on the inside, in order to reflect as little extraneous light as possible. When the telescopes are small, brass is the usual material of the tube; but when large, the expence will be lessened by making them of wood. This tube must have a slit in one of its sides, for allowing the small mirror to slide up and down.

AB is a circle of brass, to be soldered round the mouth of the tube CD, in order to keep on the cover. Of this cover EFHI shews one piece, which is another brazen circle fitting the one AB so closely that it cannot be taken off or put on without some difficulty. G is a solid plate, which being fitted to the middle vacancy of the former, completes the cover.

LM is another circle of the same materials which contains the large speculum, and to which is soldered the piece NO, having a hole in it to receive the eye-piece of the telescope.  $xyz$  is a thin piece of copper, a little bent, on which the speculum is laid, and which by its spring keeps it stiff in its place.

The eye-piece may be composed of two tubes RPQ and YDZ, of which the latter slides upon the former. KZ is the extremity of the eye-piece; and hath a small hemisphere perforated, in order to admit the light to the eye. The various parts of this extremity are represented at  $b, c$ , and  $v$ , which will give a more perfect idea of it than any description. In this eye-piece are placed the two lenses which magnify the image from the mirrors, and which are kept in their proper places by the rings S, T, V, X.

The small mirror is now to be fixed exactly in the middle of the tube, which is best done by such a contrivance as is shewn at  $gbi, k$  and  $n$ .  $f$  is a ruler of brass, which, sliding along with the piece  $g$ , preserves, by means of its cross branches, the small mirror from falling from side to side as the telescope happens to be turned.  $l$  is a round piece of brass, fastened on the

5632

Mechanism  
of  
Optical  
Instruments

immovable piece *i*, and which holds the small speculum. By means of a dove-tail fit it can be moved up and down till we find the position of the speculum is right, after which it is to be firmly screwed on to the piece *i*. *m* is a small piece of brass, having a female screw, in which the rod *ro* is screwed, and which moves the little speculum up or down, as it shall be found necessary for procuring distinct vision.

210  
Method of  
adjusting  
the large  
mirror.Plate  
CXXXIX.

Having now got all the parts of your telescope, it is necessary in the first place to see that the tubes are perfectly straight and round; after which you may proceed to place your mirrors in the telescope, and to prove their situation by the following method.—AB CD, fig. 8. is a circle drawn on a round piece of pasteboard, having a small hole in the centre at E. FGHI (fig. 9.) is another perforated circular piece of pasteboard, having two hairs crossing each other as in the figure. The former of these is placed just behind the large mirror; the latter in the place where the nearest eye-glass should stand. If the light passing through the small hole in the large circle falls exactly on the intersection of the hairs, it shews that the large speculum is properly placed; if not, its situation must be altered till this is accomplished.

211  
Of adjust-  
ing the  
small spec-  
ulum,

AB (fig. 10.) shews the shape of another piece of pasteboard, likewise perforated in the centre at C. The small circle is to be of the diameter of the lesser speculum; and when the pasteboard is put exactly in its focus, the light will pass straight through the little hole and eye-piece, so as to be distinctly visible if the position of the speculum is exactly right; but if that is not the case, the light will fall either to one side or other, and the position of the speculum must be altered accordingly.

212  
Of adjust-  
ing the  
mirrors of  
a Newton-  
ian tele-  
scope.

Fig. 12. Shews a telescope of the Newtonian form, in which the plane speculum is somewhat nearer the large one than in those formerly described: in consequence of which this requires a small eye-piece at the side, that the magnifying glass may be placed at a sufficient distance from it. This telescope is to be adjusted in the following manner. Let there be provided two circles of pasteboard, represented fig. 13. and 14. both of which are perforated in such a manner, that the tube of the telescope may just enter the perforation. The circle fig. 13. is divided into quadrants, at each of which is pricked a hole with a pin. That represented fig. 14. is also divided into quadrants; but, instead of pin-holes, has black lines drawn upon it. The former is to be fixed on the open end of the tube, and the latter on the end where the concave speculum is placed. The telescope is then to be turned towards the sun, so that the little specks of light passing thro' the pin-holes of the circle fig. 13. fall upon the black circular lines of fig. 14. Have then ready another piece of pasteboard, fig. 15. perforated with pin-holes in five different places as there represented. This piece must exactly fit the opening of the telescope; and while the tube continues thus turned straight to the sun, look through the eye-piece. If all the specks of light coming through the holes in the pasteboard are seen distinct in the plane mirror, it is a sign that the mirrors are in a proper position with regard to each other: but if not, some of them will not be seen at all, or will appear confused and indistinct; in which case, the situation of the mirrors must be altered till the light ap-

pears bright and distinct.

In the application of telescopes to astronomical instruments and many other purposes, it is absolutely necessary to fix the plane of the cross-hairs exactly upon the plane of the picture of an object; which may easily be done from a knowledge of the following properties. First, let the interval between the two convex glasses of the telescope be adjusted to shew an object distinctly; and if the hairs appear confused, they will seem to dance upon the object, while the eye moves sideways; and in dancing, if they seem to move the same way as the eye does, they lie behind the picture of the object; but if they move the contrary way, they lie before it; and must be removed accordingly, till they appear distinct; and then they will also seem fixed upon the object, notwithstanding the motion of the eye. Secondly, let the interval between the hairs and the eye-glass be first adjusted, till the hairs appear distinct; then, if the object appears confused, it will also appear to dance while the eye moves sideways; and in dancing, if it moves the same way as the eye does, its picture is behind the hairs; if the contrary way, its picture is before them; and to bring it to the hairs, either the object-glass must be moved, or else the hairs and eye-glass both together. In both these cases, it is the confused object (for the hairs may also be called so) that seems to move, and the distinct one to stand still; as in vision with the naked eye. For, to a person in motion, suppose he be walking, any object appears fixed that he fixes his eyes upon and sees distinctly, while the rest that are nearer or farther off appear confused and in motion; the reason of it is too obvious to need an explanation. But to shew it in the telescope, let *h* be the intersection of the cross-hairs, and *hik* a pencil of rays flowing from it, which, after refraction through the eye-glass *eai*, belong to the focus *k*, either at a finite or an infinite distance. Draw *he*, the axis of this pencil, cutting the object in *Q*, and its picture in *q*; and let the emergent rays of the pencil *qab*, flowing from *q*, cut the emergent rays of the former pencil in the points *p*, and belong to the focus *b*, either at a finite or an infinite distance. Now, if the eye be placed at any point *o* in the common axis of these pencils, the points *h*, *Q* will both appear in the same direction *oe*; but if the eye be moved sideways from *o* to *p*, the point *Q* will appear in the direction *pa*, and the point *h* in the direction *pi*. And from hence the reason of the foregoing cases will be sufficiently manifest, by attending to the figures. Lastly, while the foci *h*, *q* are disjoined, the mutual inclination of the emergent rays in one pencil, must be different from the mutual inclination of the emergent rays in the other; and so the humours of the eye cannot be adapted to collect the rays in both pencils to two distinct points. If one be distinct, the other will be confused, and in a different part of the retina; (except when the eye is in the axis); but when the foci *h*, *q* are united, the foci *k*, *b*, of the emergent rays will also be united; and consequently the coinciding rays of both pencils will be united in the same point of the retina, wherever the pupil of the eye be placed; and therefore the corresponding points of the object and cross-hairs will appear fixed together without any parallax.

Mechanism  
of  
Optical  
Instruments213  
Of fixing  
cross-hairs  
in the foci  
of tele-  
scopes.

**Mechanism of Optical Instrument.** When the place of the hairs is thus determined, it may be of use to measure their distance from the object-glass; which is the exactest way of finding its focal distance, if the object be very remote. And to keep this distance always the same whenever the telescope is used, it is convenient to have marks or stops at the end of each joint of the tube. For then, whatever eye-glass be applied, the object and hairs will both appear distinct at the same time, and without parallax. Instead of hairs, the finest silver wires are now made use of, but are still called *hairs*.

**214**  
**Line of collimation defined.** A line drawn from the intersection of the hairs through the centre of refractions in the object-glass, whether it coincides with the axis of the glass or is inclined to it, is called the *line of collimation* or *line of sight*; because this line produced, falls upon the object in that point whose image falls upon the intersection of the hairs: and therefore the straight ray that describes this line, answers to the visual ray by which we take aim at an object with plain-sights. Hence, when the object-glass and hairs are firmly fixed in a strong tube, or to a straight ruler, it is manifest, that the line of sight is as immutable with respect to the tube, as if two little holes or plain-sights were substituted in the places of the intersection of the hairs, and of the centre of refractions in the object-glass.

**215**  
**How to adjust telescopic sights.** In order to set the line of sight parallel to a given line upon the plane of an instrument, the object-glass must be firmly fixed, and the ring or plate that carries the cross-hairs must have two gradual motions in its own plane by two screws at right angles to each other; for by this means the intersection of the hairs may be moved to any given point in that plane. These motions are effected by three brass plates laid over one another. The uppermost, having a circular hole in it, over which the hairs are strained, slides over the middlemost in the direction of an oblong hole cut in it, whose breadth is somewhat greater than that of the hole above it; and these two together slide sideways over the undermost plate, in which there is a larger oval hole. We shall describe these plates more particularly in a contrary order. On each side of the oval hole in the middle of the plate R last mentioned, two brass ledges *m, n*, are firmly riveted to receive the dove-tailed sides of the plate S; and the contiguous ends of both these plates are turned up square at *b* and *c*; and through a hole *b* in the middle of the part turned up in the larger plate R, there works a pretty thick screw *abc*, whose fore-end *c* being filed to a neck, goes through a hole *c* in the lip of the other plate S; and in the end of the neck *c* there is made a small screw hole to receive a screw-pin *d*; so that by turning the screw *abc* with a kind of a watch-key, the plate S is moved backwards or forwards between the ledges *m, n*. The figure T represents two more ledges *o, p*, that are to be riveted upon the plate S; these ledges are part of the plate T turned up at right angles to them, in which part there is the like contrivance of a screw *abcd* to move a third plate V between the ledges *o, p*, at right angles to the former motion. The silver wires are strained over the hole in the plate V by four small pegs, that fix them in four little holes. The other end of the plate R, opposite to the part *b* that carries the screw, is bent square the

contrary way to the part *b*; or, which answers the same purpose, one ledge *ef* of the plate X bent square, is riveted to the backside of the plate R at the end opposite to the screw *b*; and its other ledge *gh* is screwed to the side of the tube of the telescope; and the necks of the screws go through long slits in this ledge, to give liberty of placing it accurately at the due distance from the object-glass: and for the purpose of letting this brass work into the tube, two large slits must be cut in two contiguous sides of it: one of which may best be covered with a thin piece of horn, to admit the light of a candle upon the hairs in observing small stars in the night time.

To make the line of sight through a moveable telescope parallel to a given line YZ upon a fixed plane; Fig. 5. let the ends of the tube of the telescope, whether square or cylindrical, be put through two holes in two square plates *abcd*, and *efgh*, made exactly equal to each other, and so fixed to the tube that the sides of the one may be exactly parallel to the sides of the other; which is easily done by applying their corners *a, e*, to the given line YZ, and by drawing two lines *a i, e k*, perpendicular to it, upon the given plane, and by making all the corresponding sides, as *a b, e f*, coincide with these perpendiculars. Then observe what point of a remote object is covered by the intersection of the hairs when the corners *a, e*, touch the given line YZ, and likewise what other point is covered by them when the opposite corners *c, g*, touch the same line in the same places, that is, when the telescope is turned upside down or half round. Then conceiving these two points of the object to be connected by a straight line, move the cross-hairs by the two screws, till you judge their intersection bisects that line; and by repeating the same practice, you may soon bring the intersection of the hairs to cover one and the same point of the object, when the opposite corners of the squares are successively applied to the line YZ; and then the line of sight will be parallel to it.

To shew the reason of this practice, we may suppose the centre of refraction in the object-glass to be any point *l* of the square *abcd*, and the intersection of the hairs to be any point *m* of the square *efgh*. Upon the plane of the first square, and through its centre *o*, draw *loa*, and take *oa* equal to *ol*; also upon the plane of the second square, and through its centre *p*, draw *mpμ*, and take *pμ* equal to *pm*. Join *lm* and *μμ*; and supposing *lm* and *μμ* parallel to the axis *o p*, join *mn, nμ, μl*. Then because the respective sides about the equal angles *m p n, μ p n*, are made equal, the lines *m n, μ n*, opposite to them, are also equal and parallel. Now the parallel lines *n l, p o, μ μ*, produced will fall upon a remote object in three points so close together as to appear like a single point thro' the telescope; and consequently the planes of the parallel triangles *l m n, μ μ n*, produced, will cut the same object in two parallel lines so close together as to appear but one line through the telescope; and since the angles *m l n, μ μ n*, are equal, the intersection of the hairs, now at *m* and then turned half round to *μ*, will cover two points in that line equidistant from the point abovementioned, and on opposite sides of it: therefore, by removing the intersection from *m* to *n*, it will appear to bisect the interval between those two points; and then the line of sight *n l* will be parallel

to the axis  $po$ , and to the sides of the parallelopiped, and also to the given line  $YZ$ .

A telescope thus prepared, may be useful upon several occasions; as if it be required to rectify the hairs in a telescope fixed to any instrument, so as to set the line of sight parallel to a given line upon the plane of the instrument. Apply the corners of the squares of the telescope abovementioned to the given line, and observing what point of a remote object is covered by its cross hairs, move the cross hairs of the fixed telescope till they cover the same point of the object, and the business is done.

215  
Of rectifying the sights of quadrants and sextants by a plumb-line.

Plate  
CCXXIX.  
fig. 18. 19.

But the telescopic sights of quadrants and sextants, whose planes may be readily placed in any given posture, may be rectified by a plumb-line. We shall here transcribe an account of these rectifications from Mr Molyneux's Dioptrics, p. 238. "I come now to the rectification of these sights on quadrants and sextants, for taking angles. This may be done either before or after the division into degrees, &c. are made on the limb of the quadrant. If it be done before, then we suppose the telescope  $TL$  fixed to the quadrant, which we suppose continued a little farther than the fourth part of a circle. Choosing then an object pretty near the horizon; let us look thro' the telescope, in the usual posture of observation, and observe the point in the object marked by the cross-hairs; and at the same time we are to note most nicely the point  $c$ , which the plumb-line  $scg$ , hung from the centre  $f$  of the quadrant, cuts on the limb. Then we are to invert the quadrant into the posture of fig. 19. (which is easily done by the usual contrivances for managing great quadrants, by toothed semicircles and endless screws) keeping still the telescope  $TL$  nearly upon the same height from the ground as before, unless the object we look at be so far distant, that the breadth of the quadrant subtends but an insensible angle. But yet for certainty, it is better to keep the telescope, as it is said, upon the same height from the floor; then direct the telescope  $TL$ , that the cross-hairs may cover exactly the same point in the object, as before in the posture of fig. 18. And hanging now the plumb-line  $afg$  on the limb of the quadrant, let us remove it to and fro, till we find out the exact point  $a$ , from which the plumb-line being hung, shall most nicely hang over the centre of the quadrant  $f$ . Then carefully marking the point  $a$ , let us divide the arch  $ca$  into two equal parts in  $b$ ; and drawing  $bf$ , the point  $b$  is the point from which we are to begin the divisions of the quadrant: and the line of collimation through the telescopic sight, stands exactly at right angles to the line  $bf$ . So that the quadrant  $bfd$  being complicated and divided, the said line of sight thro' the telescope runs exquisitely parallel to the line  $fd$ .

"In the next place, supposing the quadrant  $bfd$  truly complicated and divided; and that we designed to fix thereto the telescopic sight  $TL$ , so that the line of sight may run exactly at right angles to the line  $bf$ , or parallel to the line  $df$ ; we are to do as in the foregoing praxis. And if, in dividing the arch  $ac$ , we find its half exactly coincident with the point  $b$ , we have our desire. But if it differs from the point  $b$ , and falls between  $b$  and  $d$ , then the line of collimation through the telescope stands at an obtuse angle with

the line  $bf$ ; and the instrument errs in excess: if this half arch fall without  $b$  and  $d$ , then the line of collimation makes an acute angle with the line  $bf$ ; and the instrument errs in defect. And by often trials, we are to remove the cross-hairs within the tube, so much as is requisite to correct this error. And when we have thus rectified them to their due place, there they are to be strongly fixed. Or else, in observations taken by this instrument, we are to make allowance for this error; by subtracting from (if it be in excess), or by adding to (if it be in defect), each observation, so much as we find the error to be.

"The reason of this rectification is most plain; for it is manifest, that  $cfd$  wants of a full quadrant, as much as  $afd$  exceeds a quadrant. So the difference of the two arches in the two postures being  $ac$ ; half this difference  $bc$  added in fig. 18. or  $ab$  subtracted in fig. 19. makes  $b$  a complete quadrant.

"If we find our instrument errs in taking angles, and we desire to know the error more nicely than perhaps the divisions of the instrument itself will shew it, we are to do thus. Supposing the quadrant  $bfd$  already accurately divided, and that the plumb-line plays over the point  $c$ ; and upon the inversion of the instrument, we find that before we can get it to play exactly over the centre  $f$ , we must hang it over the point  $e$ , so that the arch  $eb$  exceeds  $bc$  by the arch  $ea$ ; it is plain that the angle  $efa$  is the error of the instrument: for had the plumb-line hung over  $a$ , and over the centre  $f$ , in this latter posture, the instrument had been exact; because  $a$  is as much on one side  $b$ , as  $c$  is on the other side  $b$ . Wherefore  $efa$  being the angle by which our instrument errs in observation, let us turn the instrument into the usual posture of observation, as in fig. 18. and hanging the plumb-line on the centre  $f$ , let us bring it to play nicely on the point  $e$ , and observe what distant object is covered by the cross-hairs: then let us bring it to play exactly on the point  $a$ , and observe likewise what distant object is pointed at by the telescope-hairs. Lastly, by a large telescope and micrometer, let us measure the angle between these two objects, and we shall have the angle of error much more nicely than it is possible the angle  $efa$  should be given by the divisions on the limb of the quadrant  $ea$ . And thus much for adjusting a quadrant.

"A sextant is rectified in like manner; if we consider, that if from the centre  $f$  to the beginning of the divisions  $d$  there be drawn the radius  $fd$ , and it be divided equally in  $c$ , and from  $c$  there be suspended the plumb-line  $cb$ : when the plumb-line hangs over the 60th degree at  $b$ , then the line  $fd$  lies horizontal; and consequently, if the line of collimation thro' the tube be parallel to  $fd$ , this line also lies horizontal. To try which, whilst the sextant stands in this posture, observe the object marked by the cross-hairs; then invert the sextant, and over the point  $b$  hang the plumb-line; and when from the point  $b$  the plumb-line hangs over the middle point  $c$ , then again is the line  $fd$  horizontal in this posture. Mark, then, whether the cross-hairs cover the same object as before: if they do, then the line of collimation is parallel to  $fd$ ; if they do not, but the point in the object marked in this latter posture be higher than the point marked in the first posture, the instrument errs in excess; if it be lower, the instrument

instrument errs in defect. And either we are to remove the cross-hairs, till we bring all to rights, and there fix them; or by the methods before laid down in the rectification of the quadrant, we are to find the quantity of this erroneous angle, and to allow for it in observation.

"In instruments furnished with two pair of telescopic sights, one on a fixed arm, and the other on a moveable arm (by the ancients termed an *alidade*); it is easy rectifying the sights on the moveable arm, thus. After the sights on the fixed arm are rectified by what foregoes, bring the index of the moveable arm, to the beginning of the divisions on the limb of the instrument, be it quadrant or sextant, &c. it is then manifest, that the line of collimation through the moveable telescope (if it be right) should lie parallel to the line of collimation through the fixed telescope. Observe, therefore, whether the cross-hairs in both telescopes do at the same time cut the same star, or fall on the same point in an object distant three or four miles. If they do, then the moveable telescope agreeing with the fixed, and the fixed being supposed rectified to the divisions on the instrument, the moveable is right likewise. But if the hairs in the moveable telescope do not agree in marking the same point with the cross-hairs in the fixed telescope, then the hairs in this moveable telescope are to be removed (by whatever contrivance there is for that purpose) and brought to rights, and there fixed."

There are other methods propounded for rectifying telescopic sights on other sorts of instruments, by means of observations towards the zenith, as our former methods have been employed towards the horizon. But it is sufficient here to lay down only what foregoes, as being of the greatest and most frequent use: referring for the others to M. Picard's "Treatise of the measure of a degree of a great circle of the earth," published at the end of the "Memoirs of a Natural History of animals, &c." by the Royal Academy at Paris; translated into English and printed at London 1688, folio.

SECT. VII. *Of the different Merits of Microscopes and Telescopes, compared with one another; how far we may reasonably depend on the Discoveries made by them, and what hopes we may entertain of further Improvements.*

The advantages arising from the use of microscopes and telescopes depend in the first place upon their property of magnifying the minute parts of objects, so that they can by that means be more distinctly viewed by the eye; and, secondly, upon their throwing more light into the pupil of the eye than what is done without them. The advantages arising from the magnifying power would be extremely limited, if they were not also accompanied by the latter: for if the same quantity of light is spread over a large portion of surface, it becomes proportionably diminished in force; and therefore the objects, though magnified, appear proportionably dim. Thus, though any magnifying glass should enlarge the diameter of the object 10 times, and consequently magnify the surface 100 times, yet if the focal distance of the glass was about eight inches, (provided this was possible), and its diameter only about the size of the pupil of the eye, the object would appear 100

times more dim when we looked thro' the glass, than when we beheld it with our naked eyes; and this, even on a supposition that the glass transmitted all the light which fell upon it, which no glass can do. But if the focal distance of the glass was only four inches, tho' its diameter remained as before, the inconvenience would be vastly diminished, because the glass could then be placed twice as near the object as before, and consequently would receive four times as many rays as in the former case, and therefore we would see it much brighter than before. Going on thus, still diminishing the focal distance of the glass, and keeping its diameter as large as possible, we will perceive the object more and more magnified, and at the same time very distinct and bright. It is evident, however, that with regard to optical instruments of the microscopic kind, we must sooner or later arrive at a limit which cannot be passed. This limit is formed by the following particulars. 1. The quantity of light lost in passing through the glass. 2. The diminution of the glass itself, by which it receives only a small quantity of rays. 3. The extreme shortness of the focal distance of great magnifiers, whereby the free access of the light to the object which we wish to view is impeded, and consequently the reflection of the light from it is weakened. 4. The aberrations of the rays, occasioned by their different refrangibility.

To understand this more fully, as well as to see how far these obstacles can be removed, let us suppose the lens made of such a dull kind of glass that it transmits only one half of the light which falls upon it. It is evident that such a glass, of four inches focal distance, and which magnifies the diameter of an object twice, still supposing its own breadth equal to that of the pupil of the eye, will shew it four times magnified in surface, but only half as bright as if it was seen by the naked eye at the usual distance; for the light which falls upon the eye from the object at eight inches distance, and likewise the surface of the object in its natural size, being both represented by 1, the surface of the magnified object will be  $\frac{1}{4}$ , and the light which makes that magnified object visible only  $\frac{1}{2}$ ; because though the glass receives four times as much light as the naked eye does at the usual distance of distinct vision, yet one half is lost in passing through the glass. The inconvenience in this respect can therefore be removed only as far as it is possible to increase the clearness of the glass, so that it shall transmit nearly all the rays which fall upon it; and how far this can be done, hath not yet been ascertained.

The second obstacle to the perfection of microscopic glasses is the small size of great magnifiers, by which, notwithstanding their near approach to the object, they receive a smaller quantity of rays than might be expected. Thus, suppose a glass of only  $\frac{1}{100}$ th of an inch focal distance; such a glass would increase the visible diameter 80 times, and the surface 6400 times. If the breadth of the glass could at the same time be preserved as great as that of the pupil of the eye, which we shall suppose  $\frac{1}{10}$ th of an inch, the object would appear magnified 6400 times, at the same time that every part of it would be as bright as it appears to the naked eye. But if we suppose that this magnifying glass is only  $\frac{1}{2}$ th of an inch in diameter, it will then only receive  $\frac{1}{4}$ th of the light which other-

217  
Limits of  
the advan-  
tages in the  
use of mi-  
croscopes.

Mechanism  
of  
Optical  
Instruments

otherwise would have fallen upon it; and therefore, instead of communicating to the magnified object a quantity of illumination equal to 6400, it would communicate only one equal to 1600, and the magnified object would appear four times as dim as it does to the naked eye. This inconvenience however is still capable of being removed, not indeed by increasing the diameter of the lens, because this must be in proportion to its focal distance, but by throwing a greater quantity of light on the object. Thus, in the above-mentioned example, if four times the quantity of light which naturally falls upon it could be thrown upon the object, it is plain that the reflection from it would be four times as great as in the natural way; and consequently the magnified image, at the same time that it was as many times magnified as before, would be as bright as when seen by the naked eye. In transparent objects this can be done very effectually by a concave speculum, as in the reflecting microscope already described: but in opaque objects the case is somewhat more doubtful; neither do the contrivances for viewing these objects seem entirely to make up for the deficiencies of the light from the smallness of the lens and shortness of the focus. When a microscopic lens magnifies the diameter of an object 40 times, it hath then the utmost possible magnifying power, without diminishing the natural brightness of the object.

218  
Utmost  
magnifying  
power of a  
microscope,  
without di-  
minishing  
the light.

The third obstacle arises from the shortness of the focal distance in large magnifiers: but in transparent objects, where a sufficient quantity of light is thrown on the object from below, the inconvenience arises at last from straining the eye, which must be placed nearer the glass than it can well bear; and this entirely supercedes the use of magnifiers beyond a certain degree.

The fourth obstacle arises from the different refrangibility of the rays of light, and which frequently causes such a deviation from truth in the appearances of things, that many people have imagined themselves to have made surprising discoveries, and have even published them to the world; when in fact they have been only as many optical deceptions, owing to the unequal refractions of the rays. For this there seems to be no remedy, except the introduction of achromatic glasses into microscopes as well as telescopes. How far this is practicable, hath not yet been tried; but when these glasses shall be introduced, (if such introduction is practicable), microscopes will then undoubtedly have received their ultimate degree of perfection.

219  
Comparative  
good-  
ness of the  
different  
kinds of te-  
lescopes.

With regard to telescopes, those of the refracting kind have evidently the advantage of all others, where the aperture is equal, and the aberrations of the rays are corrected according to Mr Dollond's method; because the image is not only more perfect, but a much greater quantity of light is transmitted than what can be reflected from the best materials hitherto known. Unluckily, however, the imperfections of the glass set a limit to these telescopes, as hath already been observed, so that they cannot be made above three feet and an half long. On the whole, therefore, the reflecting telescopes are preferable in this respect, that they may be made of dimensions greatly superior; by which means they can both magnify to a greater degree, and at the same time throw much more light into the eye.

With regard to the powers of telescopes, however, they are all of them exceedingly less than what we would be apt to imagine from the number of times which they magnify the object. Thus, when we hear of a telescope which magnifies 200 times, we are apt to imagine, that, on looking at any distant object through it, we should perceive it as distinctly as we would with our naked eye at the 200th part of the distance. But this is by no means the case; neither is there any theory capable of directing us in this matter: we must therefore depend entirely on experience.

The best method of trying the goodness of any telescope is by observing how much farther off you are able to read with it than you can with the naked eye. But that all deception may be avoided, it is proper to choose something to be read where the imagination cannot give any assistance, such as a table of logarithms, or something which consists entirely of figures; and hence the truly useful power of the telescope is easily known. In this way Mr Short's large telescope, which magnifies the diameter of objects 1200 times, is yet unable to afford sufficient light for reading at more than 200 times the distance at which we can read with our naked eye.

With regard to the form of reflecting telescopes, it is now pretty generally agreed, that when the Gregorian ones are well constructed, they have the advantage of those of the Newtonian form. One advantage evident at first sight is, that with the Gregorian telescope an object is perceived by looking directly thro' it, and consequently is found with much greater ease than in the Newtonian telescope, where we must look into the side. The unavoidable imperfection of the specula common to both, also gives the Gregorian an advantage over the Newtonian form. Notwithstanding the utmost care and labour of the workmen, it is found impossible to give the metals either a perfectly spherical, or a perfectly parabolical form. Hence arises some indistinctness of the image formed by the great speculum, which is frequently corrected by the little one, provided they are properly matched. But if this is not done, the error will be made much worse: and hence many of the Gregorian telescopes are far inferior to the Newtonian ones; namely, when the specula have not been properly adapted to each other. There is no method by which the workman can know the specula which will fit one another, without a trial; and therefore there is a necessity for having many specula ready made of each sort, that in fitting up a telescope those many be chosen which best suit each other.

The brightness of any object seen through a telescope, in comparison with its brightness when seen by the naked eye, may in all cases be easily found by the following formula. Let  $n$  represent the natural distance of a bright visible object, at which it can be distinctly seen; and let  $d$  represent its distance from the object-glass of the instrument. Let  $m$  be the magnifying power of the instrument; that is, let the visual angle subtended at the eye by the object when at the distance  $n$ , and viewed without the instrument, be to the visual angle produced by the instrument as 1 to  $m$ . Let  $a$  be the diameter of the object-glass, and  $p$  be that of the pupil. Let the instrument be so constructed, that no parts of the pencils are intercepted for want of suffi-

or micro-  
scopes.

cient apertures of the intermediate glasses. Lastly, let the light lost in reflection or refraction be neglected. The brightness of vision through the instrument will be expressed by the fraction  $\frac{a n^2}{m p d}$ , the brightness of natural vision being 1. But although this fraction may exceed unity, the vision through the instrument will not be brighter than natural vision. For, when this is the case, the pupil does not receive all the light

transmitted through the instrument. In microscopes,  $n$  is the nearest limits of distinct vision, nearly 8 inches. But a difference in this circumstance, arising from a difference in the eye, makes no change in the formula, because  $m$  changes in the same proportion with  $n$ . In telescopes,  $n$  and  $d$  may be accounted equal, and the formula becomes  $\frac{a^2}{m p}$ .

Optimates

Oracle.

OPTIMATES, in Roman antiquity, were, according to Tully, the best citizens, who desired that their actions might be approved of by the better sort; as the *Populares* were those who, out of a thirst of vain glory, did not so much consider what was right, as what would please the populace.

OPUNTIA, INDIAN FIG, or *Prickly Pear*. This plant is by Linnaeus joined to the genus of *Cactus*; though, for reasons given under that article, we have chosen to consider it as a genus by itself. There are nine species, all natives of warm climates. The most remarkable are, 1. The vulgaris, or common Indian fig. This is found in the warm parts of Europe as well as in America, and grows wild on the sides of the roads in Sicily, Naples, and Spain; but it is probable that the seeds of it may have been brought thither from America. This has oval or roundish branches, compressed on their two sides flat, and have small leaves coming out in knots on their surface, as also on their upper edges, which fall off in a short time; and at the same knots are three or four sharp spines, which do not appear unless they are closely viewed; but, on being handled, they enter the flesh, separate from the plant, and so are very troublesome and difficult to get out. The branches spread near the ground, and frequently trail upon it, putting out new roots; so are extended to a considerable distance, and never rise in height: these are fleshy and herbaceous while young; but, as they grow old, become drier, of a tough contexture, and have ligneous fibres. The flowers come out on the upper edges of the branches, though sometimes they are produced on their sides: these sit upon the embryo of the fruit, and are composed of several roundish concave petals, which spread open. They are of pale yellow colour, and appear in July and August. They are succeeded by an oblong fruit, whose skin or cover is set with small spines in clusters; and the inside is fleshy, of a purple or red colour, in which are lodged many black seeds. 1. The cochinalifera, or cochineal fig; so called from its being the food of the cochineal insect. It hath oblong, smooth, green branches, which grow erect to the height of 8 or 10 feet, with but very few spines, and these so soft that they are not troublesome when handled. The flowers of this are of a purple colour; and sit on the embryo of the fruit, like those of the former sort, but do not expand like them. This kind grows naturally in Jamaica; where it is probable that the true cochineal might be discovered if persons of skill were to search for it. The vulgaris is the only kind which can be raised in this country without great difficulty; and may be propagated by slips, in a light mould.

OR, the French word for *gold*, by which this metal is expressed in heraldry. In engraving it is denoted by small points all over the field or bearing. It may be supposed to signify of itself, *generosity, splendour, or solidity*; according to G. Leigh, if it is compounded with

Gul.	} If signifies	Courage.
Azu.		Trust.
Vor.		Joy.
Pur.		Charity.
Sab.		Constancy.

ORACH. See *ATRIplex*.

ORACLE, among the heathens, was the answer

Oracle.

which the gods were supposed to give to those who consulted them upon any affair of importance. It is also used for the god who was thought to give the answer, and the place where it was given.

The credit of oracles was so great, that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no business of any consequence was undertaken, scarce any peace concluded, any war waged, or any new form of government instituted, without the advice and approbation of some oracle. The answers were usually given by the intervention of the priest or priestesses of the god who was consulted; and generally expressed in such dark and unintelligible phrases, as might be easily wrested to prove the truth of the oracle, whatever was the event. It is not, therefore, to be wondered at, that the priests who delivered them were in the highest credit and esteem, and that they improved this reputation greatly to their advantage. They accordingly allowed no man to consult the gods, before he had offered costly sacrifices, and made rich presents to them. And to keep up the veneration for their oracles, and to prevent their being taken unprepared, they admitted persons to consult the gods only at certain stated times; and sometimes they were so cautious, that the greatest personages could obtain no answer at all. Thus Alexander himself was peremptorily denied by the pythia, or priestess of Apollo, till she was by downright force obliged to ascend the tripod; when, being unable to resist any longer, she cried out, *Thou art invincible*: and these words were accepted instead of a farther oracle.

Of the ambiguity of oracles, the following, out of a great many examples, may be mentioned. Cræsus having received from the pythonefs this answer, That by passing the river Halys, he would destroy a great empire; he understood it to be the empire of his enemy, whereas he destroyed his own.—The oracle consulted by Pyrrhus gave him an answer, which might be equally understood of the victory of Pyrrhus, and the victory of the Romans his enemies:

*Aio te, Eacida, Romanos vincere posse.*

The equivocation lies in the construction of the Latin tongue, which cannot be rendered in English.—The pythonefs advised Cræsus to guard against the mule. The king of Lydia understood nothing of the oracle, which denoted Cyrus descended from two different nations; from the Medes, by Mandana his mother, the daughter of Astyages; and from the Persians, by his father Cambyfes, whose race was by far less grand and illustrious.—Nero had for answer, from the oracle of Delphos, that seventy-three might prove fatal to him. He believed he was safe from all danger till that age; but, finding himself deserted by every one, and hearing Galba proclaimed emperor, who was 73 years of age, he was sensible of the deceit of the oracle.

When men began to be better instructed by the lights philosophy had introduced into the world, the false oracles insensibly lost their credit. Chrypsippus filled an entire volume with false or doubtful oracles. Oenomaus, to be revenged of some oracle that had deceived him, made a compilation of oracles, to shew their ridicule and vanity. Eusebius has preserved some

some fragments of this criticism on oracles by Oenomaus. "I might (says Origen) have recourse to the authority of Aristotle and the Peripatetics, to make the Pythoness much suspected; I might extract from the writings of Epicurus and his sectators an abundance of things to discredit oracles; and I might shew that the Greeks themselves made no great account of them."

The reputation of oracles was greatly lessened when they became an artifice of politics. Themistocles, with a design of engaging the Athenians to quit Athens, and to embark, in order to be in a better condition to resist Xerxes, made the Pythoness deliver an oracle, commanding them to take refuge in wooden walls. Demosthenes said, that the Pythoness *Philippised*; to signify that she was gained over by Philip's presents.

The cessation of oracles is attested by several profane authors; as Strabo, Juvenal, Lucan, and others. Plutarch accounts for the cause of it, either that the benefits of the Gods are not eternal as themselves are; or that the genii, who presided over oracles, are subject to death; or that the exhalations of the earth had been exhausted. It appears that the last reason had been alleged in the time of Cicero, who ridicules it in his second book of Divination, as if the spirit of prophecy, supposed to be excited by subterraneous effluvia, had evaporated by length of time, as wine or pickle by being long kept.

Suidas, Nicephorus, and Cedrenus, relate, that Augustus, having consulted the oracle of Delphos, could obtain no other answer but this: "The Hebrew child whom all the Gods obey, drives me hence, and sends me back to hell: get out of this temple without speaking one word." Suidas adds, that Augustus dedicated an altar in the Capitol with this inscription, "To the eldest Son of God." Notwithstanding these testimonies, the answer of the oracle of Delphos to Augustus seems very suspicious. Cedrenus cites Eusebius for this oracle, which is not now found in his works; and Augustus's peregrination into Greece was 18 years before the birth of Christ.

Suidas and Cedrenus give an account also of an ancient oracle delivered to Thulis, a king of Egypt, which they say is well authenticated. The king having consulted the oracle of Serapis, to know if there ever was, or would be, one so great as himself, received this answer: "First, God, next the Word, and the Spirit with them. They are equally eternal, and make but one, whose power will never end. But thou, mortal, go hence, and think that the end of the life of man is uncertain."

Van Dale, in his treatise of oracles, does not believe that they ceased at the coming of Christ. He relates several examples of oracles consulted till the death of Theodosius the Great. He quotes the laws of the emperors Theodosius, Gratian, and Valentinian, against those who consulted oracles, as a certain proof that the superstition of oracles still subsisted in the time of those emperors.

According to others, the opinion of those who believe that the demons had no share in the oracles, and that the coming of the Messiah made no change in them, and the contrary opinion of those who pretend that the incarnation of the Word imposed a general

silence on all oracles, should be equally rejected. They allege, that two sorts of oracles ought to be distinguished: the one dictated by the spirits of darkness, who deceived men by their obscure and doubtful answers; the other, the pure artifice and cheat of the priests of false divinities. As to the oracles given out by demons, the reign of Satan was destroyed by the coming of the Saviour; truth shut the mouth of lies; but Satan continued his old craft among idolaters. All the devils were not forced to silence at the same time by the coming of the Messiah; it was on particular occasions that the truth of Christianity, and the virtue of Christians, imposed silence on the devils. St Athanasius tells the Pagans, that they have been witnesses themselves that the sign of the cross puts the devils to flight, silences oracles, and dissipates enchantments. This power of silencing oracles, and putting the devils to flight, is also attested by Arnobius, Lactantius, Prudentius, Minutius Felix, and several others. Their testimony is a certain proof that the coming of the Messiah had not imposed a general silence on oracles.

Plutarch relates, that the pilot Thamus heard a voice in the air, crying out, "The great Pan is dead;" whereupon Eusebius observes, that the accounts of the death of the demons were frequent in the reign of Tiberius, when Christ drove out the wicked spirits.

The same judgment, it is said, may be passed on oracles as on *possessioners*. It was on particular occasions, by the divine permission, that the Christians cast out devils, or silenced oracles, in the presence, and even by the confession, of the Pagans themselves. And thus it is we should, it seems, understand the passages of St Jerom, Eusebius, Cyril, Theodoret, Prudentius, and other authors, who said that the coming of Christ had imposed silence on the oracles.

As to the second sort of oracles, which were pure artifices and cheats of the priests of false divinities, and which probably exceeded the number of those that immediately proceeded from demons, they did not cease till idolatry was abolished, though they had lost their credit for a considerable time before the coming of Christ. It was concerning this more common and general sort of oracles that Minutius Felix said, they began to discontinue their responses, according as men began to be more polite. But, however decried oracles were, impostors always found dupes, the grossest cheats having never failed.

Daniel discovered the imposture of the priests of Bel, who had a private way of getting into the temple to take away the offered meats, and who made the king believe that the idol consumed them.—Mundus, being in love with Paulina, the eldest of the priestesses of Isis, went and told her, that the god Anubis, being passionately fond of her, commanded her to give him a meeting. She was afterwards shut up in a dark room, where her lover Mundus, whom she believed to be the god Anubis, was concealed. This imposture having been discovered, Tiberius ordered those detestable priests and priestesses to be crucified, and with them Idea, Mundus's free-woman, who had conducted the whole intrigue. He also commanded the temple of Isis to be levelled with the ground, and her statue to be thrown into the Tiber; and, as to Mundus,

dus, he contented himself with fending him into banishment.

Theophilus, bishop of Alexandria, not only destroyed the temples of the false gods, but discovered the cheats of the priests, by shewing that the statues, some of which were of brass, and others of wood, were hollow within, and led into dark passages made in the wall.

Lucian, in discovering the impostures of the false prophet Alexander, says, that the oracles were chiefly afraid of the subtilties of the Epicureans and Christians. The false prophet Alexander sometimes feigned himself seized with a divine fury, and by means of the herb fopewort, which he chewed, frothed at the mouth in so extraordinary a manner, that the ignorant people attributed it to the strength of the god he was possessed by. He had long before prepared a head of a dragon made of linen, which opened and shut its mouth by means of a horse-hair. He went by night to a place where the foundations of a temple were digging; and, having found water, either of a spring, or rain that had settled there, he hid in it a goose-egg, in which he had inclosed a little serpent that had been just hatched. The next day, very early in the morning, he came quite naked into the street, having only a scarf about his middle, holding in his hand a scythe, and tossing about his hair as the priests of Cybele; then getting a-top of a high altar, he said that the place was happy to be honoured by the birth of a god.—Afterwards, running down to the place where he had hid the goose-egg, and going into the water, he began to sing the praises of Apollo and Æsculapius, and to invite the latter to come and shew himself to men. With these words, he dips a bowl into the water, and takes out a mysterious egg, which had a god inclosed in it; and when he had it in his hand, he began to say that he held Æsculapius. Whilst all were eager to have a sight of this fine mystery, he broke the egg, and the little serpent starting out, twisted itself about his fingers.

These examples shew clearly, that both Christians and Pagans were so far agreed as to treat the *greater number* of oracles as purely human impostures.—That, in fact, ALL of them were so, will be concluded by those who give equal credit to *demoniacal inspiration*, and *demoniacal possession*. See the article POSSESSION (*Demoniacal*).

ORAL, something delivered by word of mouth, without being committed to writing; in which sense we say oral law, oral tradition, &c.

ORANGE OUTANG. See SIMIA.

ORANGE PEEL. See CITRUS and ORANGE-TREE.

ORAN, a very strong and important town of Africa, in Barbary, and in the kingdom of Tremecen, with several forts, and an excellent harbour. It is seated partly on the side of a hill, and partly on a plain, about a stone-cast from the sea, almost opposite to Carthagen in Spain. It is about a mile and an half in circumference, and well fortified, but com-

manded by the adjacent hills. It was taken by the Spaniards in 1509, and retaken by the Algerines in 1708; but in 1732 the Spaniards became masters of it, and have continued so ever since. E. Long. 6. 5. N. Lat. 37. 40.

ORANGE, a famous city, and capital of a province of the same name, united to Dauphiny, with a university and a bishop's see. It is seated in a fine large plain, watered by a vast number of little rivulets on the east side of the river Rhone. It is a very large ancient place, and was considerable in the time of the Romans, who adorned it with several buildings, of which there are still some ruins left, particularly of an amphitheatre, and a triumphal arch, which is almost entire. This town was formerly much larger than it is at present, as appears from the traces of the ancient walls. The wall was in 1682 entirely demolished by order of Lewis XIV. and the inhabitants were exposed to the fury of the soldiers. The town was restored to king William by the treaty of Ryfwick; but after his death the French took it again, and expelled the protestant inhabitants. By the treaty of Utrecht it was confirmed to the crown of France, though the title is still retained in the house of Nassau. The principality is a very small district, it being only twelve miles in length and nine in breadth, and the revenue amounted to about 5000 l. a-year. The country is pleasant, and abounds with corn and fruit, but is exposed to violent winds. E. Long. 4. 51. N. Lat. 44. 21.

ORANGE-TREE, in botany. See the article CITRUS.—Orange-flowers are justly esteemed one of the finest perfumes; and though little used in medicine, yet the water distilled from them is accounted stomachic, cordial, and carminative. The fruit is cooling, and good in feverish disorders, and particularly in diarrhoeas. Orange-peel is an agreeable aromatic, proper to repair and strengthen the stomach, and give a very grateful flavour to any infusions or tinctures into whose compositions they enter. It is particularly useful in preparations of the bark; gives an agreeable warmth to the infusion; and, according to Dr Percival, considerably increases its virtue.

ORATION, in rhetoric, a speech or harangue, composed according to the rules of oratory, but spoken in public. Orations may be reduced to three kinds, viz. the demonstrative, deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliaca, epithalamia, congratulations, &c. To the deliberative kind belong persuasion, exhortation, &c. And to the judicial kind belong accusation, consultation, &c.

ORATORIO, in the Italian music, a sort of sacred drama of dialogues; containing recitatives, duettos, trios, ritornellos, choruses, &c. The subjects of these pieces are usually taken from scripture, or the life of some saint, &c. The music for the oratorios should be in the finest taste and best chosen strains. These oratorios are greatly used at Rome in the time of lent, and of late in England.

## O R A T O R Y;

The art of speaking well upon any subject, in order to persuade.

## INTRODUCTION.

§ 1. *Of the Rise and Progress of Oratory.*

THE invention of oratory is by the Egyptians, and the fables of the poets, ascribed to Mercury. And it is well known, that the Greeks made their deities the authors likewise of other arts, and supposed that they presided over them. Hence they gave Mercury the titles of *Δεσιπότης* and *Ἑρμῆς*, both which names come words that signify "to speak." And Aristides calls eloquence *the gift of Mercury*; and for the same reason anciently the tongue was consecrated to him. He was likewise said to be the interpreter or messenger of the gods; which office very well suited him, as he excelled in eloquence. Hence we read in the Sacred Writings, that when the people of Lystra took Barnabas and Paul for gods in human shape, because of that sudden and surprising cure which was wrought upon the lame man, they called Barnabas *Jupiter*, and Paul *Mercury*; for this reason, as the inspired writer tells us, 'because he was the chief speaker,' that is (as the spectators then thought) the interpreter or spokesman of Barnabas.

But to pass over these fictions of the heathen deities, let us hear what Quintilian says of the *origin* of this art; who seems to give a very probable account of it in the following passage. 'The faculty of speech (says he) we derive from nature; but the art from observation. For as in physic, men, by seeing that some things promote health and others destroy it, formed the art upon those observations; in like manner, by perceiving that some things in discourse are said to advantage, and others not, they accordingly marked those things, in order to imitate the one, and avoid the other. They also added some things from their own reason and judgment, which being confirmed by use, they began to teach others what they knew themselves.' But no certain account can be given when, or by whom, this method of observation first began to take place. And Aristotle supposes, not without reason, that the first lineaments of the art were very rude and imperfect. Pausanias, indeed, in his *Description of Greece*, tells us, that Pittheus, the uncle of Theseus, taught it at Trezene a city of Peloponnesus, and wrote a book concerning it; which he read himself, as it was published by one of Epidaurus. But as Pittheus lived above 1000 years before Pausanias, who flourished in the time of the emperor Hadrian, some are of opinion he might be imposed upon by the Epidaurian, who published this book under the name of *Pittheus*. But be that as it will, it is very reasonable to believe, that the Greeks had the principles of this art so early as the time of Pittheus. For Theseus his nephew lived not long before the taking of Troy, which, according to Sir Isaac Newton, happened 604 years before the birth of Christ; at which time Cicero thought it was in much esteem among them. 'Homer (says he) would never have given Ulysses and Nestor in the Trojan wars so great commendations on account of their speeches

(to one of whom he attributes force, and to the other sweetness of expression) if eloquence had not in those times been in great repute.' And lest any one should imagine, that in those days they made use only of such helps as nature and practice could afford them; the same poet informs us, that Peleus sent Phenix with his son Achilles to the Trojan war, to instruct him not only in the art of war, but likewise of eloquence. But who were the professors of this art for some ages following, is not known. For Quintilian says, that afterwards Empedocles is the first upon record, who attempted any thing concerning it. And he, by Sir Isaac Newton's account, flourished about 500 years after Troy was taken. At which time, as Cicero observes, men being now sensible of the powerful charms of oratory, and the influence it had upon the mind, there immediately arose several masters of it; the chief of whom are mentioned by Quintilian, who tells us, that 'the oldest writers upon this art are Corax and Tisias, both of Sicily. After them came Gorgias of Leontium in the same island, who is said to have been the scholar of Empedocles, and by reason of his great age (for he lived to be 109 years old) had many contemporaries. Thrasyarchus of Chalcedon, Prodicus of Cea, Protagoras of Abdera, Hippas of Elis, and Alcidas of Elea, lived in his time; as likewise Antiphon, who first wrote orations, and also upon the art, and is said to have spoken admirably well in his own defence; and besides these, Polycrates, and Theodore of Byzantium.' These persons contributed different ways towards the improvement of the art. Corax and Tisias gave rules for methodizing a discourse, and adjusting its particular parts; as may be conjectured from Cicero's account of them, who says, 'Though some had spoke well before their time, yet none with order and method.' But Gorgias seems to have excelled all the rest in fame and reputation: for he was so highly applauded by all Greece, that a golden statue was erected to him at Delphos, which was a distinguishing honour conferred upon him only. And he is said to have been so great a master of oratory, that in a public assembly he would undertake to declaim immediately upon any subject proposed to him. He wrote, as Cicero informs us, in the demonstrative or laudatory way; which requires most of the sublime, and makes what Diodorus Siculus says of him the more probable, that 'he first introduced the strongest figures, members of periods opposite in sense, of an equal length, or ending with a like sound, and other ornaments of that nature.' And hence those figures, which give the greatest force and lustre to a discourse, were anciently called by his name. Cicero tells us further, that Thrasyarchus and Gorgias were the first who introduced numbers into prose, which Isocrates afterwards brought to perfection. Quintilian likewise mentions Protagoras, Gorgias, Prodicus, and Thrasyarchus, as the first who treated of common-places, and showed the use of them for the invention of arguments. Nor must we omit Plato, whose elegant dialogue upon this subject is still extant, which he entitles

Gorgias

*Gorgias.* For though he does not lay down the common rules of the art; yet he very well explains the nature of it, and maintains its true end and use against the generality of its professors, who had greatly perverted the original design of it. Thus by the study and industry of so many ingenious and great men, the art of oratory was then carried to a considerable height among the Grecians. Though many of those, who professed it in those times, employed their skill rather to promote their own reputation and applause, than to serve the real interests of truth and virtue. 'For they proposed in an arrogant manner (as Cicero says) to teach how a bad cause might be so managed, as to get the better of a good one.' That is, they would undertake to charm the ears and strike the passions of their hearers in so powerful a manner, by sophistical reasonings, turns of wit, and fine language, as to impose falsehood upon them for truth; than which nothing could be either more disingenuous in itself, or prejudicial to society.

But those who succeeded them, seem to have consulted better, both for their own honour, and that of their profession. Isocrates was the most renowned of all Gorgias's scholars, whom Cicero frequently extols with the highest commendations, as the greatest master and teacher of oratory; 'whose school (as he says) like the Trojan horse, sent forth abundance of great men.' Aristotle was chiefly induced to engage in this province from an emulation of his glory; and would often say in a verse of Sophocles, somewhat varied to his purpose,

To be silent it is a shame;

While Isocrates gets such fame.

Quintilian says they both wrote upon the art, though there is no system of the former now extant. But that of Aristotle is esteemed the best and most complete of any in the Greek language. In this age the Grecian eloquence appeared in its highest perfection. Demosthenes was an hearer both of Isocrates and Plato, as also of Læus (ten of whose orations are yet extant); and by the assistance of a surprising genius, joined with indefatigable industry, made that advantage of their precepts, that he has been always esteemed by the best judges the prince of Grecian orators. His great adversary and rival Æschines, after his banishment is said to have gone to Rhodes, and employed his time there in teaching of rhetoric. Theodectes and Theophrastus, both of them scholars of Aristotle, imitated their master in writing upon the art. And from that time the philosophers, especially the Stoics and peripatetics, applied themselves to lay down the rules of oratory; which Socrates had before separated from the province of a philosopher. And there is yet preserved a treatise upon this subject, which some have ascribed to Demetrius Phalereus the peripatetic, and scholar of Theophrastus, though others more probably to Dionysius of Halicarnassus. Quintilian mentions several other famous rhetoricians in the following ages, who were likewise writers; as Hermagoras, Athenæus, Apollonius Molon, Areus Cæcilius, Dionysius of Halicarnassus, Apollonius of Pergamus, and Theodore of Gadara. But of these nothing now remains upon the subject of oratory, except some tracts of Dionysius, who flourished in the reign of Augustus Cæsar. Nor have there been wanting some eminent

writers of this kind among the Greeks since the time of Quintilian; two of whom we cannot omit to mention, Hermogenes, and Longinus the author of the incomparable treatise *Of the Sublime*, a book which can scarce be too much commended or too often read.

It was long before Rome received this art, and not without difficulty at first. The reason was, because the Romans were for several ages wholly addicted to military affairs, and to enlarge their territories; so that they not only neglected to cultivate learning, but thought the pursuit of it a thing of ill tendency, by diverting the minds of their youth from the cares and toils of war, to a more soft and indolent kind of life. Therefore so late as the year of their city 592, when by the industry of some Grecians the liberal arts began to flourish in Italy, a decree passed the senate, by which all philosophers and rhetoricians were ordered to depart out of Rome. But in a few years after, when Carneades, Critolaus, and Diogenes, who were not only philosophers but orators, came ambassadors from Athens to Rome; the Roman youth were so charmed with the eloquence of their harangues, that they could no longer be stopt from pursuing the study of oratory. And by a further acquaintance with the Greeks, it soon gained such esteem, that persons of the first quality employed their time and pains to acquire it. And a young gentleman, who was ambitious to advance himself in the service of his country, could have little hopes of success, unless he had laid the foundation of his future prospects in that study.

Seneca tells us, that Lucius Plotius, a Gaul, was the first who taught the art of oratory at Rome in Latin; which Cicero says, was while he was a boy; and when the most studious persons went to hear him, he lamented that he could not go with them; being prevented by the regard he paid to the opinion of some of his friends, who thought that greater improvements were made by exercises in the Greek language under Grecian masters. Seneca adds, that this profession continued for some time in the hands of freedmen; and that the first Roman who engaged in it was Blandus of the equestrian order, who was succeeded by others; some of whose lives are yet extant, written by Suetonius, as many of the Grecians are by Philostratus and Eunapius. Quintilian likewise gives us the names of those among the Romans, who wrote upon the art. 'The first (says he) as far as I can learn, who composed any thing upon this argument, was M. Cato the censor. After him Anthony the orator began upon the subject, which is the only work he has left, and that imperfect. Then followed some of less note. But he who carried eloquence to its highest pitch among us, was Cicero; who has likewise by his rules given the best plan both to practise and teach the art. After whom modesty would require us to mention no more, had he not told us himself, that his books of rhetoric slipped out of his hands, while he was but a youth. And those lesser things, which many persons want, he has purposely omitted in his discourses of oratory. Cornificius wrote largely upon the same subject; Stertinius and Gallio the father, each of them something. But Celsus and Lenas were more accurate than Gallio; and in our times Virginius, Pliny, and Rutilius. And there are at this day some celebrated authors of the same kind, who, if they had

taken

taken in every thing, might have saved my pains.' Time has since deprived us of most of the writers mentioned here by Quintilian. But we have the less reason to regret this loss, since it has preserved to us Cicero's treatises upon this subject; which we may well suppose to have been chiefly owing to their own excellency, and the great esteem they have always had in the world. Besides his *Two books of Invention*, which Quintilian here calls his *Books of Rhetoric*, there are extant of his, *Three books of an Orator*; one *Of famous Orators*; and another, which is called *The Orator*; as also his *Topics*, a preface *Concerning the best sort of Orators*, and a treatise *Of the parts of Oratory*. Each of which treatises, whether we regard the justness and delicacy of the thoughts, the usefulness of the rules, or the elegance and beauty of the style, deserve to be frequently perused by all who are lovers of eloquence. For who can be thought so well qualified to give the rules of any art, as he who excelled all mankind in the practice of them? But those *Four books to Herennius*, which are published among Cicero's works, seem with good reason to be attributed to Cornificus, whom Quintilian here mentions. And Celsus is by some affirmed to have taught oratory, whom he also places among the rhetoricians, and whose *Eight books of Medicine* are yet extant, written in so beautiful a style as plainly shews him to be a master of eloquence. But Quintilian himself outdid all who went before him in diligence and accuracy as a writer. His *Institutions* are so comprehensive, and written with such great exactness and judgment, that they are generally allowed to be the most perfect work of the kind. With this excellent author we shall finish the account of the Latin rhetoricians.

There were indeed some others in the following ages, whose works are yet extant; but as they contain nothing of moment, which is not to be found in those already mentioned, we shall forbear to name them. Much less shall we defend to that numerous body of writers, who since the revival of learning have treated upon this subject, for the same reason. And a very good judge\* has not long since given it as his opinion, that the method of forming the best system of oratory, is to collect it from the finest precepts of Aristotle, Cicero, Quintilian, Longinus, and other celebrated authors; with proper examples taken from the choicest parts of the purest antiquity. And this is the method attempted to be pursued in the following treatise.

## § 2. Of the Nature of Oratory.

THE terms *rhetoric* and *oratory*, having no other difference but that one is taken from the Greek language and the other from the Latin, may be used promiscuously; but the case is not the same with respect to the words *rhetorician* and *orator*. For although the Grecians used the former, both to express those who taught the art, and those who practised it; yet the Romans afterward, when they took that word into their language, confined it to the teachers of the art, and called the rest *orators*. And there seems to have been a sufficient reason for this distinction, since the art was the same in both, and might therefore go by either name; but the different province of rhetoricians and orators made it not improper they should be called

by different names. Besides, anciently, before rhetoric was made a separate and distinct art from philosophy, the same persons taught both. And then they were called not only *rhetoricians*, but *sophists*. But because they often employed their art rather to vindicate what was false and unjust, than to support truth and virtue: this dissingenuous conduct, by which they frequently imposed upon weak minds, brought a discredit both upon themselves and their profession. And therefore the name *sophist*, or *sophist*, has been more generally used in an ill sense, to signify one skilled rather in the arts of cavilling, than qualified to speak well and accurately upon any subject.

It is not necessary to use many words, to prove that oratory is an art. For it is comprised under certain rules, agreeable to reason, delivered in a regular method, and suited to attain the end it proposes; which are characters sufficient to denominate it an art. Indeed the case is the same here, as in most other things, that a good genius is of itself more serviceable, than the most exact acquaintance with all the rules of art, where that is wanting. But it is sufficient that art help nature, and carry it farther than it can otherwise advance without it. And he who is desirous to gain the reputation of a good orator, will find the assistance of both very necessary. Some persons have thought, that many of the common systems written upon the subject of oratory have been attended with this inconvenience, that by burdening the mind with too great a number of rules about things of less importance, they have oftentimes rather discouraged than promoted the study of eloquence. This undoubtedly is extreme which should be always carefully avoided. But however, an indifferent guide in a strange road is better than none at all. It may be worth while to hear Quintilian's opinion upon this head. "I would not (says he) have young persons think they are sufficiently instructed, if they have learned one of those compends which are commonly handed about, and fancy themselves safe in the decrees, as it were, of these technical writers. The art of speaking requires much labour, constant study, a variety of exercise, many trials, the greatest prudence, and readiness of thought. However, these treatises are useful, when they set you in a plain and open way, and do not confine you to one narrow tract, from which he who thinks it a crime to depart must move as slowly as one that walks upon a rope." We see he is not for having us confine ourselves too closely to systems, though he thinks they are of service at first, till use and experience render them less necessary.

The business of oratory is to teach us to speak well; which, as Cicero explains it, is to speak *justly, methodically, floridly, and copiously*.

Now, in order to speak *justly*, or pertinently, a person must be master of his subject, that he may be able to say all that is proper, and avoid whatever may appear foreign and trifling. And he must clothe his thoughts with such words and expressions, as are most suited to the nature of the argument, and will give it the greatest force and evidence.

And as it teaches to speak *justly*, so likewise *methodically*. This requires, that all the parts of a discourse be placed in their proper order, and with such just connection, as to reflect a light upon each other, and thereby

thereby to render the whole both clear in itself, and easy to be retained. But the same method is not proper for all discourses. And very frequently a different manner is convenient in handling the same subject. For it is plain, that art, as well as nature, loves variety; and it discovers the speaker's judgment, when the disposition of his discourse is so framed, as to appear easy and natural, rather than the effect of industry and labour.

To speak *floridly*, is so peculiar a property of this art, that some have wholly confined it to the pomp and ornaments of language. But that it extends farther, and respects things as well as words, we shall have occasion to shew hereafter. It contains indeed the whole subject of elocution, but does not wholly consist in it. True and solid eloquence requires not only the beauties and flowers of language; but likewise the best sense and clearest reasoning. Besides, rhetoric gives rules for the several sorts of style, and directs the use of them agreeably to the nature of the subject.

But the force of oratory appears in nothing more, than a *copiousness* of expression, or a proper manner of enlargement, suited to the nature of the subject; which is of great use in persuasion, and forms the last property, required by Cicero, of speaking well. A short and concise account of things is often attended with obscurity, from an omission of some necessary circumstances relating to them. Or, however, where that is not the case, yet for want of proper embellishments to enliven the discourse, and thereby to excite and fix the hearers attention, it is apt to slip through their minds without leaving any impression. But where the images of things are drawn in their full proportion, painted in their proper colours, set in a clear light, and represented in different views, with all the strength and beauties of eloquence, they captivate the minds of the audience with the highest pleasure, engage their attention, and by an irresistible force move and bend them to the design of the speaker.

The principal end and design of oratory is to persuade. For which reason it is frequently called the *art of persuasion*. Indeed the orator has often other subordinate views; as when he endeavours either to delight his hearers with what is pleasant and agreeable, or to conciliate their good opinion by a smooth and

artful address: but still both these are in order to persuade and excite them to action.

And while the orator employs his art in pursuing only those ends for which it was at first designed, the persuading men to good and virtuous actions, and dissuading them from every thing that is ill and vicious; nothing can be more commendable in itself, or useful to human societies.

### § 3. Of the Division of Oratory.

ORATORY consists of four parts; *invention, disposition, elocution, and pronunciation*. This will appear by considering the nature of each of them, and what it contributes in forming an orator. Every one who aims to speak well and accurately upon any subject, does naturally in the first place inquire after and pursue such thoughts as may seem most proper to explain and illustrate the thing upon which he designs to discourse. And if the nature of it requires that he should bring reasons to confirm what he says, he not only seeks the strongest, and such as are like to be best received; but also prepares to answer any thing which may be offered to the contrary. This is *invention*. After this he deliberates with himself in what method to dispose of those things which have occurred to his mind, that they may appear in the plainest light, and not lose their force by disorder and confusion. This is the business of *disposition*. His next concern is to give his thoughts an agreeable dress; by making choice of the fittest words, clearest expressions, smooth and harmonious periods, with other ornaments of style, as may best suit the nature of his subject, brighten his discourse, and render it most entertaining to his hearers. And this is called *elocution*. The last thing he attends to, is to deliver what he has thus composed, with a just and agreeable *pronunciation*. And daily experience convinces us, how much this contributes both to engage the attention, and impress what is spoken upon the mind. This then is the method to which nature directs, in order to qualify ourselves for discoursing to the best advantage: Though by custom and habit these things become so familiar to us, that we do not always attend to them separately in their natural order. However, it is the business of art to follow nature, and to treat of things in that manner which she dictates.

## PART I. OF INVENTION.

### CHAP. I. Of Invention in general; and particularly of Common Places, and State of a Cause.

INVENTION, considered in general, is the discovery of such things as are proper to persuade. And in order to attain this end, the orator proposes to himself three things: To prove or illustrate the subject upon which he treats; to conciliate the minds of his hearers; and to engage their passions in his favour. And as these require different kinds of arguments or motives, invention furnishes him with a supply for each of them, as will be shewn in their order.

An argument, as defined by Cicero, is a reason, which induces us to believe, what before we doubted of.

And as different kinds of discourses require different arguments, rhetoricians have considered them two ways; in general, under certain heads, as a common fund for all subjects; and in a more particular manner, as they are suited to *demonstrative, deliberative, or judicial* discourses. At present we shall treat only upon the former of these. And now, that one thing may receive proof and confirmation from another, it is necessary that there be some relation between them; for all things are not equally adapted to prove one another. Thus, in measuring the quantity of two things which we would shew, to be either equal or unequal, if they are of such a nature that one cannot be applied to the other, then we take a third thing, which may be applied to them both; and that must be equal at least

Fig. 2.

least to one of the two, which if applied to the other, and found equal to that also, we presently conclude that those two things are equal; but if it be unequal to the other, we say that those two things are unequal. Because it is the certain and known property of all quantities, that whatsoever two things are equal to a third, are equal to one another; and where one of any two things is equal to a third, and the other unequal, those two things are unequal to one another. What has been said of quantities, will hold true in all other cases, that so far as any two things or ideas agree to a third, so far they agree to one another. So likewise, on the contrary, as far as one of any two things or ideas does agree to a third, and the other does not, so far they disagree with one another; in which respect, one of them cannot be truly affirmed of the other. Since, therefore, in every proposition, one thing is spoken of another, if we would find out whether the two ideas agree to each other or not, where this is not evident of itself, we must find out some third thing, the idea of which agrees to one of them; and then that being applied to the other, as it does agree or disagree with it, so we may conclude, that the two things proposed do agree or disagree with one another. This will be made more clear by an example or two. Should it be inquired, *Whether virtue is to be loved*; the agreement between virtue and love might be found by comparing them separately with happiness, as a common measure to both. For since the idea of happiness agrees to that of love, and the idea of virtue to that of happiness; it follows, that the ideas of virtue and love agree to one another: and therefore it may be affirmed, *That virtue is to be loved*. But on the contrary, because the idea of misery disagrees with that of love, but the idea of vice agrees to that of misery, the two ideas of vice and love must consequently disagree with one another; and therefore it would be false to assert, *That vice is to be loved*. Now, this third thing logicians call the *medium*, or *middle term*, because it does as it were connect two extremes; that is, both parts of a proposition. But rhetoricians call it an *argument*, because it is so applied to what was before proposed, as to become the instrument of procuring our assent to it. Thus far as to the nature and use of arguments. We shall next explain by what methods they are to be sought.

A lively imagination, and readiness of thought, are undoubtedly a very great help to invention. Some persons are naturally endued with that quickness of fancy, and penetration of mind, that they are seldom at a loss for arguments either to defend their own opinions, or to attack their adversaries. However, these things being the gift of nature, and not to be gained by art, do not properly fall under our present consideration.

It will be readily granted, that great learning and extensive knowledge are a noble fund for invention. An orator therefore should be furnished with a stock of important truths, solid maxims of reason, and a variety of knowledge, collected and treasured up both from observation, and a large acquaintance with the liberal arts; that he may not only be qualified to express himself in the most agreeable manner, but likewise to support what he says with the strongest and clearest arguments.

But because all are not born with a like happy genius, and have not the same opportunity to cultivate their minds with learning and knowledge; and because nothing is more difficult than to dwell long upon the consideration of one thing, in order to find out the strongest arguments which may be offered for and against it; upon these accounts, art has prescribed a method to lessen, in some measure, these difficulties, and help every one to a supply of arguments upon any subject. And this is done by the contrivance of *common places*, which Cicero calls the *seats* or *heads* of arguments, and by a Greek name *topics*. They are of two sorts, *internal* and *external*.

**I. Internal topics.** Though things, with regard to their nature and properties, are exceedingly various, yet they have certain common relations, by means whereof the truth of what is either affirmed or denied concerning them in any respect may be evinced. The ancient Greek rhetoricians therefore reduced these relations to some general heads, which are termed *common places*; because the reasons or arguments suited to prove any proposition, are repositied in them, as a common fund or receptacle. And they are called *internal heads*, because they arise from the subject upon which the orator treats; and are therefore distinguished from others named *external*, which he fetches from without, and applies to his present purpose, as will be shewn hereafter. Cicero and Quintilian make them 16; three of which comprehend the whole thing they are brought to prove, namely, *definition*, *enumeration*, and *notation*: of the remaining 13, some contain a part of it, and the rest its various properties and circumstances, with other considerations relating to it; and these are, *genus*, *species*, *antecedents*, *consequents*, *adjuncts*, *conjugates*, *cause*, *effect*, *contraries*, *opposites*, *similitude*, *dissimilitude*, and *comparison*.

*Definition* explains the nature of the thing defined, and shews what it is. And to whatsoever the definition agrees, the thing defined does so likewise. If therefore Socrates be a rational creature, he is a man; because it is the definition of a man, that he is a rational creature.

*Enumeration* takes in all the parts of a thing. And from this we prove, that what agrees to all the parts, agrees to the whole; and what does not agree to any one or more parts, does not agree to the whole: As when Cicero proves to Piso that all the Roman state hated him, by enumerating the several ranks and orders of Roman citizens who all did so.

*Notation*, or etymology, explains the meaning or signification of a word. From which we reason thus: "If he cannot pay his debts, he is insolvent;" for that is the meaning of the word *insolvent*.

*Genus* is what contains under it two or more sorts of things, differing in nature. From this head logicians reason thus: "Because every animal is mortal, and man is an animal, therefore man is mortal." But orators make a further use of this argument, which they call *ascending from the hypothesis to the thesis*; that is, from a particular to a general: As should a person, when speaking in praise of justice, take occasion from thence to commend and shew the excellency of virtue in general, with a view to render that particular virtue more amiable. For since every species contains in it the whole nature of the genus to which it relates, besides what is peculiar to itself, whereby it is distinguished

Invention.

guished from it; what is affirmed of the genus, must of necessity be applicable to the species.

Species is that which comprehends under it all the individuals of the same nature. From hence we may argue, "He is a man, therefore he has a rational soul." And orators sometimes take occasion from this head to defend from the theists to the hypothesis: that is, in treating upon what is more general, to introduce some particular contained under it, for the greater illustration of the general.

*Antecedents* are such things, as, being once allowed, others necessarily, or very probably, follow. From this head an inseparable property is proved from its subject; as, It is material, and therefore corruptible.

*Consequents* are such things, as being allowed, necessarily, or very probably infer their antecedents. Hence the subject is proved from an inseparable property in this manner: It is corruptible, and therefore material.

*Adjuncts* are separable properties of things, or circumstances that attend them. These are very numerous, and afford a great variety of arguments, some of which usually occur in every discourse. They do not necessarily infer their subject; but, if fitly chosen, render a thing credible, and are a sufficient ground for assent. The way of reasoning from them we shall shew presently.

*Conjugates* are words deduced from the same origin with that of our subject. By these the habit is proved from its acts: as, He who does justly is just. He does not act wisely, therefore he is not wise. But this inference will not hold, unless the actions appear continued and constant.

A *cause* is that, by the force of which a thing does exist. There are four kinds of causes, matter, form, efficient, and end, which afford a great variety of arguments. The way of reasoning from them is to infer the effect from the cause: as, Man is endued with reason, therefore he is capable of knowledge.

An *effect* is that which arises from a cause, therefore the cause is proved by it: as, He is endued with knowledge, therefore with reason.

*Contraries* are things, which under the same genus are at the utmost distance from each other. So that what we grant to the one, we utterly deny the other: as, Virtue ought to be embraced, therefore vice should be avoided.

*Opposites* are such things, which, though repugnant to each other, yet are not directly contradictory: as, To love and to injure, to hate and to commend. They differ from contraries in this, that they do not absolutely exclude one another. An argument is drawn from things repugnant, thus: He will do a man a mischief, therefore he does not love him. He loves a man, therefore he will not reproach him.

*Similitude* is an agreement of things in quality. Thus Cicero proves, that pernicious citizens ought to be taken out of the state; by the likeness they bear to corrupted members, which are cut off to prevent further damage to the body.

*Dissimilitude* is a disagreement of things in quality. From this head Cicero shews the preference of his own exile to Piso's government of Macedonia; by the difference between their conduct, and the people's esteem of them.

Invention.

*Comparison* is made three ways: for either a thing is compared with a greater, with a less, or with its equal. This place, therefore, differs from that of similitude on this account, that the quality was considered in that, but here the quantity. An argument from the greater is thus drawn: If five legions could not conquer the enemy, much less will two.

We shall just give one example of the manner of reasoning from these heads, whereby the use of them may further appear. If any one, therefore, should have endeavoured to persuade Cicero not to accept of his life upon the condition offered him by Antony, That he would burn his Philippic orations which had been spoken against him, he might be supposed to use such arguments as these; partly taken from the adjuncts of Cicero, partly from those of Antony, and partly from the thing itself. And first with regard to Cicero, it might be said, That so great a man ought not to purchase his life at so dear a price as the loss of that immortal honour which by so great pains and labour he had acquired. And this might be confirmed by another argument, That now he was grown old, and could not expect to live much longer. And from the character of Antony he might argue thus: That he was very crafty and deceitful; and only designed, by giving him hopes of life, to have the Philippics first burnt, which otherwise he knew would transmit to posterity an eternal brand of infamy upon him; and then he would take off the author. And this might be shewn by comparison. For since he would not spare others, who had not so highly exasperated him, and from whom he had not so much to fear; certainly he would not forgive Cicero, since he knew well enough, that so long as he lived, he himself could never be in safety. And, lastly, an argument might also be fetched from the nature of the thing itself in the following manner: That Cicero by this action would shamefully betray the state, and the cause of liberty, which he had through his whole life most courageously defended, with so great honour to himself, and advantage to the public. Upon such an account, a person might have used these or the like arguments with Cicero, which arise from the fore-mentioned heads.

From this account of common places, it is easy 5—(18) to conceive what a large field of discourse they open to the mind upon every subject. These different considerations furnish out a great number and variety of arguments, sufficient to supply the most barren invention. He can never be at a loss for matter, who considers well the nature of his subject, the parts of which it consists, the circumstances which attend it, the causes from whence it springs, the effects it produces, its agreement, disagreement, or repugnancy to other things; and in like manner carries it through all the remaining heads. But although this method will assist us very much to enlarge upon a subject, and place it in different views; yet a prudent man is not so desirous to say a great deal, as to speak to the purpose; and therefore will make choice of proper arguments, and such only as have a direct tendency to confirm or illustrate his subject. And for this end, it is necessary for him to gain, first a thorough knowledge of his subject, and then arguments will naturally spring up in his mind proper to support it: and if he

be

vention. be fill at a loss, and find occasion to have recourse to these heads, he will readily perceive from whence to take those which are best suited to his purpose.

19

II. *Of external topics.* When the orator reasons from such topics as do not arise from his subject, but from things of a different nature, these are called *external*. They are all taken from authorities, and are by one general name called *Testimonies*.

Now a testimony may be expressed by writing, speech, or any other sign proper to declare a person's mind. And all testimonies may be distinguished into two sorts, divine and human. A divine testimony, when certainly known to be such, is incontestable, and admits of no debate, but should be acquiesced in without hesitation. Indeed the ancient Greeks and Romans esteemed the pretended oracles of their deities, the answers of their augurs, and the like fallacies, divine testimonies: but with us no one can be ignorant of their true notion, though they do not so directly come under our present consideration. Human testimonies, considered as furnishing the orator with arguments, may be reduced to three heads; *writings, witnesses, and contradi.*

I. *By Writings*, here, are to be understood written laws, wills, or other legal instruments, expressed and conveyed in that manner. And it is not so much the force and validity of such testimonies, considered in themselves, that is here intended, as the occasion of dispute which may at any time arise concerning their true design and import, when produced in proof upon either side of a controversy. And these are five; Ambiguity, Disagreement between the words and intention, Contrariety, Reasoning, and Interpretation.

A writing is then said to be ambiguous, when it is capable of two or more senses, which makes the writer's design uncertain. Now ambiguity may arise either from single words, or the construction of sentences. From single words; as when either the sense of a word, or the application of it, is doubtful. As, should it be questioned, whether ready money ought to be included under the appellation of chattels left by a will; or, if a testator bequeath a certain legacy to his nephew Thomas, and he has two nephews of that name. But ambiguity is also sometimes occasioned from the construction of a sentence; as when several things or persons having been already mentioned, it is doubtful to which of them that which follows ought to be referred. For example, a person writes thus in his will: 'Let my heir give as a legacy to Titius, an horse out of my stable, which he pleases.' Here it may be questioned, whether the word *he* refers to the heir or to Titius; and consequently, whether the heir be allowed to give Titius which horse he please, or Titius may choose which he likes best. Now as to controversies of this kind, in the first case above-mentioned, the party who claims the chattels may plead, that all moveable goods come under that name, and therefore that he has a right to the money. This he will endeavour to prove from some instances where the word has been so used. The business of the opposite party is to refute this, by shewing that money is not there included. And if either side produce precedents in his favour, the other may endeavour to shew the cases are not parallel. As to the second case, arising from an ambiguity in the name, if any other

words or expressions in the will seem to countenance either of the claimants, he will not fail to interpret them to his advantage. So likewise, if any thing said by the testator, in his lifetime, or any regard shewn to either of these nephews more than the other, may help to determine which of them was intended, a proper use may be made of it. And the same may be said with regard to the third case. In which the legatee may reason likewise from the common use of language, and shew, that in such expressions, it is usual to make the reference to the last or next antecedent; and from thence plead, that it was the design of the testator to give him the option. But in answer to this, it may be said, that allowing it to be very often so, yet in this instance it seems more easy and natural to repeat the verb *give* after *pleases*, and so to supply the sentence, *which he pleases to give him*, referring it to the heir, than to bring in the verb *choose*, which was not in the sentence before; and so, by supplying the sense, *which he pleases to choose*, to give the option to Titius. But where controversies of this kind arise from a law, recourse may be had to other laws where the same thing has been expressed with greater clearness; which may help to determine the sense of the passage in dispute.

A second controversy from writings is, when one party adheres to the words, and the other to what he asserts was the writer's intention. Now he who opposes the literal sense, either contends, that what he himself offers is the simple and plain meaning of the writing, or that it must be so understood in the particular case in dispute. An instance of the former is this, as we find it in Cicero. A person who died without children, but left a widow, had made this provision in his will: "If I have a son born to me, he shall be my heir." And a little after; "If my son die before he comes of age, let Curius be my heir." There is no son born: Curius therefore sues for the estate, and pleads the intention of the testator, who designed him for his heir, if he should have no son who arrived at age; and says, there can be no reason to suppose he did not intend the same person for his heir if he had no son, as if he should have one who afterwards died in his minority. But the heir at law insists upon the words of the will; which, as he says, require, that first a son should be born, and afterwards die under age, before Curius can succeed to the inheritance; and there being no son, a substituted heir, as Curius was, can have no claim where the first heir does not exist, from whom he derives his pretension, and was to succeed by the appointment of the will. Of the latter case, rhetoricians give this example: "It was forbidden by a law to open the city-gates in the night. A certain person notwithstanding, in time of war, did open them in the night, and let in some auxiliary troops, to prevent their being cut off by the enemy, who was posted near the town." Afterwards, when the war was over, this person is arraigned, and tried for his life on account of this action. Now, in such a case, the prosecutor founds his charge upon the express words of the law; and pleads, that no sufficient reason can be assigned for going contrary to the letter of it, which would be to make a new law, and not to execute one already made. The defendant, on the other hand, alleges, That the

Invention.

Invention.

fact he is charged with cannot, however, come within the intention of the law; since he either could not, or ought not, to have complied with the letter of it in that particular case, which must therefore necessarily be supposed to have been excepted in the design of that law when it was made. But to this the prosecutor may reply, That all such exceptions as are intended by any law, are usually expressed in it: and instances may be brought of particular exceptions expressed in some laws; and if there be any such exception in the law under debate, it should especially be mentioned. He may further add, That to admit of exceptions not expressed in the law itself, is to enervate the force of all laws, by explaining them away, and in effect to render them useless. And this he may further corroborate, by comparing the law under debate with others, and considering its nature and importance, and how far the public interest of the state is concerned in the due and regular execution of it; from whence he may infer, that should exceptions be admitted in other laws of less consequence, yet, however, they ought not in this. Lastly, he may consider the reason alleged by the defendant, on which he founds his plea, and shew there was not that necessity of violating the law in the present case, as is pretended. And this is often the more requisite, because the party who disputes against the words of the law, always endeavours to support his allegations from the equity of the case. If, therefore, this plea can be enervated, the main support of the defendant's cause is removed. For as the former arguments are designed to prevail with the judge, to determine the matter on this side the question from the nature of the case; so the intention of this argument is to induce him to it, from the weakness of the defence made by the opposite party. But the defendant will, on the contrary, use such arguments, as may best demonstrate the equity of his cause, and endeavour to vindicate the fact from his good design and intention in doing it. He will say, That the laws have allotted punishments for the commission of such facts as are evil in themselves, or prejudicial to others; neither of which can be charged upon the action for which he is accused: That no law can be rightly executed, if more regard be had to the words and syllables of the writing, than to the intention of the legislator. To which purpose, he may allege that direction of the law itself, which says, "The law ought not to be too rigorously interpreted, nor the words of it strained; but the true intention and design of each part of it duly considered:" As also that saying of Cicero, "What law may not be weakened and destroyed, if we bend the sense to the words, and do not regard the design and view of the legislator?" Hence he may take occasion to complain of the hardship of such a procedure, that no difference should be made between an audacious and wilful crime, and an honest or necessary action, which might happen to disagree with the letter of the law, though not with the intent of it. And as it was observed before to be of considerable service to the accuser, if he could remove the defendant's plea of equity; so it will be of equal advantage to the defendant, if he can fix upon any words in the law, which may in the least seem to countenance his case, since this will take off the main force of the charge.

The third controversy of this kind is, when two writings happen to clash with each other, or at least seem to do so. Of this Hermogenes gives the following instance. One law enjoins: "He who continues alone in a ship during a tempest, shall have the property of the ship." Another law says, "A disinherited son shall enjoy no part of his father's estate." Now a son, who had been disinherited by his father, happens to be in his father's ship in a tempest, and continues there alone, when every one else had deserted it. He claims the ship by the former of these laws, and his brother tries his right with him by the latter. In such cases, therefore, it may first be considered, Whether the two laws can be reconciled, And if that cannot be done, then, Which of them appears more equitable. Also, Whether one be positive, and the other negative: because prohibitions are a sort of exceptions to positive injunctions. Or, If one be a general law, and the other more particular, and come nearer to the matter in question. Likewise, Which was last made: since former laws are often abrogated, either wholly or in part, by subsequent laws; or at least were designed to be so. Lastly, it may be observed, Whether one of the laws be not plain and express; and the other more dubious, or has any ambiguity in it. All, or any of which things, that party will not omit to improve for his advantage whose interest is concerned in it.

The fourth controversy is *reasoning*. As when something, not expressly provided for by a law, is inferred by a similitude, or parity of reason, from what is contained in it. Quintilian mentions this instance of it. "There was a law made at Tarentum, to prohibit the exportation of wool, but a certain person exports sheep." In this case, the prosecutor may first compare the thing which occasions the charge, with the words of the law, and shew their agreement, and how unnecessary it was that particular thing should have been expressly mentioned in the law, since it is plainly contained in it, or at least an evident consequence from it. He may then plead, that many things of a like nature are omitted in other laws for the same reason. And, lastly, he may urge the reasonableness and equity of the procedure. The defendant, on the other hand, will endeavour to shew the deficiency of the reasoning, and the difference between the two cases. He will insist upon the plain and express words of the law, and set forth the ill tendency of such inferences and conclusions drawn from similitudes and comparisons, since there is scarce any thing but in some respect may bear a resemblance to another.

The last controversy under this head is *interpretation*, in which the dispute turns upon the true meaning and explication of the law in reference to that particular case. We have the following instance of this in the Pandects: "A man who had two sons, both under age, substitutes Titius as heir to him who should die last, provided both of them died in their minority. They both perish together at sea before they came to age. Here arises a doubt, whether the substitution can take place, or the inheritance devolves to the heir at law." The latter pleads, That as neither of them can be said to have died last, the substitution cannot take place; which was suspended, upon

upon the condition that one died after the other. But to this it may be said, It was the intention of the testator, that if both died in their nonage, Titius should succeed to the inheritance; and therefore it makes no difference whether they died together, or one after the other: and so the law determines it.

2. The second head of external arguments are *Witnesses*. These may either give their evidence, when absent, in writing subscribed with their name; or present, by word of mouth. And what both of them testify, may either be from hearsay; or what they saw themselves, and were present at the time it was done. As the weight of the evidence may be thought greater or less on each of these accounts, either party will make such use of it as he finds for his advantage. The characters of the witnesses are also to be considered; and if any thing be found in their lives or behaviour that is justly exceptionable, to invalidate their evidence, it ought not to be omitted. And how they are affected to the contending parties, or either of them, may deserve consideration; for some allowances may be judged reasonable in case of friendship, or enmity, where there is no room for any other exception. But regard should chiefly be had to what they testify, and how far the cause is affected by it. Cicero is very large upon most of these heads in his defence of Marcus Fonteius, with a design to weaken the evidence of the Gauls against him. And where witnesses are produced on one side only, as orators sometimes attempt to lessen the credit of this kind of proof, by pleading, that witnesses are liable to be corrupted, or biased by some prevailing interest or passion, to which arguments taken from the nature and circumstances of things are not subject; it may be answered on the other hand, that sophistical arguments and false colourings are not exposed to infamy or punishment, whereas witnesses are restrained by shame and penalties, nor would the law require them if they were not necessary.

3. The third and last head of external arguments are *Contracts*; which may be either public or private. By public are meant the transactions between different states, as leagues, alliances, and the like; which depend on the laws of nations, and come more properly under deliberative discourses, to which we shall refer them. Those are called *private*, which relate to lesser bodies or societies of men, and single persons; and may be either written, or verbal. And it is not so much the true meaning and purport of them that is here considered, as their force and obligation. And, as the Roman law declares, 'Nothing can be more agreeable to human faith, than that persons should stand to their agreements.' Therefore, in controversies of this kind, the party, whose interest it is that the contract should be maintained, will plead, that such covenants have the force of private laws, and ought religiously to be observed, since the common affairs of mankind are transacted in that manner; and therefore to violate them, is to destroy all commerce and society among men. On the other side it may be said, that justice and equity are chiefly to be regarded, which are immutable; and besides, that the public laws are the common rule to determine such differences, which are designed to redress those who are aggrieved. And, indeed, where a compact has been obtained by force or fraud, it is in itself void, and

has no effect either in law or reason. But on the other hand, the Roman lawyers seem to have very rightly determined, that all such obligations as are founded in natural equity, though not binding by national laws, and are therefore called *nuda pacta*, ought, however, in honour and conscience to be performed.

III. *Of the State of a Controversy*. The ancients, observing that the principal question or point of dispute in all controversies might be referred to some particular head, reduced those heads to a certain number; that both the nature of the question might by that means be better known, and the arguments suited to it be discovered with greater ease. And these heads they call *states*.

By the state of a controversy, then, we are to understand the principal point in dispute between contending parties, upon the proof of which the whole cause or controversy depends. We find it expressed by several other names in ancient writers: as, the *constitution of the cause*, the *general head*, and the *chief question*. And as this is the principal thing to be attended to in every such discourse; so it is what first requires the consideration of the speaker, and should be well fixed and digested in his mind, before he proceeds to look for arguments proper to support it. Thus Anthony, the Roman orator, speaking of his own method in his pleading, says: "When I understand the nature of the cause, and begin to consider it, the first thing I endeavour to do is, to settle with myself what that is to which all my discourse relating to the matter in dispute ought to be referred: then I diligently attend to these other two things, How to recommend myself, or those for whom I plead, to the good esteem of my hearers; and how to influence their minds, as may best suit my design." This way of proceeding appears very agreeable to reason and prudence. For what can be more absurd, than for a person to attempt the proof of any thing, before he has well settled in his own mind a clear and distinct notion, what the thing is which he would endeavour to prove? Quintilian describes it to be, 'That kind of question which arises from the first conflict of causes.' In judicial cases, it immediately follows upon the charge of the plaintiff, and plea of the defendant. Our common law expresses it by one word, namely, the *issue*. Which interpreters explain, by describing it to be, "That point of matter depending in suit, whereupon the parties join, and put their cause to the trial." Examples will further help to illustrate this, and render it more evident. In the cause of Milo, the charge of the Clodian party is, *Milo killed Clodius*. Milo's plea or defence, *I killed him, but justly*. From hence arises this grand question, or state of the cause: *Whether it was lawful for Milo to kill Clodius?* And that Clodius was lawfully killed by Milo, is what Cicero in his defence of Milo principally endeavours to prove. This is the main subject of that fine and beautiful oration. The whole of his discourse is to be considered as centering at last in this one point. Whatever different matters are occasionally mentioned, will, if closely attended to, be found to have been introduced some way or other the better to support and carry on this design. Now in such cases, where the fact is not denied, but something is offered in its defence, the state of the cause is taken from the defendant's plea, who is obliged to make it good: As in the instance here given, the

*Invention.* the chief point in dispute was the lawfulness of Milo's action, which it was Cicero's business to demonstrate. But when the defendant denies the fact, the state of the cause arises from the accusation; the proof of which then lies upon the plaintiff, and not, as in the former case, upon the defendant. So in the cause of Roscius, the charge made against him is, *That he killed his father.* But he denies the fact. The grand question therefore to be argued is: *Whether or not he killed his father?* The proof of this lay upon his accusers. And Cicero's design in his defence of him is to shew, that they had not made good their charge. But it sometimes happens, that the defendant neither absolutely denies the fact, nor attempts to justify it; but only endeavours to qualify it, by denying that it is a crime of that nature, or deserves that name, by which it is expressed in the charge. We have an example of this proposed by Cicero: "A person is accused of sacrilege, for taking a thing, that was sacred, out of a private house. He owns the fact, but denies it to be sacrilege; since it was committed in a private house, and not in a temple." Hence this question arises: *Whether to take a sacred thing out of a private house, is to be deemed sacrilege, or only simple theft?* It lies upon the accuser to prove what the other denies; and therefore the state of the cause is here also, as well as in the preceding case, taken from the indictment.

But besides the principal question, there are other subordinate questions, which follow upon it in the course of a dispute, and should be carefully distinguished from it. Particularly that which arises from the reason, or argument, which is brought in proof of the principal question. For the principal question itself proves nothing, but is the thing to be proved, and becomes at last the conclusion of the discourse. Thus, in the cause of Milo, his argument is: *I killed Clodius justly, because he assassinated me.* Unless the Clodian party be supposed to deny this, they give up their cause. From hence therefore this subordinate question follows: *Whether Clodius assassinated Milo?* Now Cicero spends much time in the proof of this, as the hinge on which the first question, and consequently the whole cause, depended. For if this was once made to appear, the lawfulness of Milo's killing Clodius, which was the grand question or thing to be proved, might be inferred as an allowed consequence from it. This will be evident, by throwing Milo's argument, as used by Cicero, into the form of a syllogism.

*An assassinator is lawfully killed:*

*Clodius was an assassinator:*

*Therefore he was lawfully killed by Milo, whom he assassinated.*

If the minor proposition of this syllogism was granted, no one would deny the conclusion: for the Roman law allowed of self-defence. But as Cicero was very sensible this would not be admitted, so he takes much pains to bring the court into the belief of it. Now where the argument brought in defence of the second question is contested, or the orator supposes that it may be so, and therefore supports that with another argument, this occasions a third question consequent upon the former; and in like manner he may proceed to a fourth. But be they more or fewer, they are to be considered but as one chain of subordinate questions

dependent upon the first. And though each of them has its particular state, yet none of these is what rhetoricians call *The state of the Cause*, which is to be understood only of the principal question. And if, as it frequently happens, the first or principal question is itself directly proved from more than one argument; this makes no other difference, but that each of these arguments, so far as they are followed by others to support them, become a distinct series of subordinate questions, all dependent upon the first. As when Cicero endeavours to prove, that Roscius did not kill his father, from two reasons or arguments: *Because he had neither any cause to move him to such a barbarous action, nor any opportunity for it.*

Moreover, besides these subordinate questions, there are also incidental ones often introduced, which have some reference to the principal question, and contribute towards the proof it, though they are not necessarily connected with it, or dependent upon it. And each of these also has its state, though different from that of the cause. For every question, or point of controversy, must be stated, before it can be made the subject of disputation. And it is for this reason, that every new argument advanced by an orator is called a *question*, because it is considered as a fresh matter of controversy. In Cicero's defence of Milo, we meet with several of this sort of questions, occasioned by some aspersions which had been thrown out by the Clodian party to the prejudice of Milo. As, "That he was unworthy to see the light, who owned he had killed a man:" For Milo before his trial had openly confessed he killed Clodius. So likewise, "That the senate had declared the killing of Clodius was an illegal action." And further, "That Pompey, by making a new law to settle the manner of Milo's trial, had given his judgment against Milo." Now to each of these Cicero replies, before he proceeds to the principal question. And therefore, though the question, in which the state of a controversy consists, is said by Quintilian to arise from "the first conflict of causes," yet we find by this instance of Cicero, that it is not always the first question in order, upon which the orator treats.

But it sometimes happens, that the same cause or controversy contains in it more than one state. Thus in judicial causes, every distinct charge occasions a new state. All Cicero's orations against Verres relate to one cause, founded upon a law of the Romans against unjust exactions made by their governors of provinces upon the inhabitants; but as that prosecution is made up of as many charges as there are orations, every charge, or indictment, has its different state. So likewise his oration in defence of Caelius has two states, in answer to a double charge made against him by his adversaries: one, "for borrowing money of Clodia, in order to bribe certain slaves to kill a foreign ambassador;" and the other, "for an attempt afterward to poison Clodia herself." Besides which, there were several other matters of a less heinous nature, which had been thrown upon him by his accusers, with a design, very likely, to render the two principal charges more credible; to which Cicero first replies, in the same manner as in his defence of Milo.

Though all the examples we have hitherto brought to illustrate this subject, have been taken from judicial cases;

causes; yet not only these, but very frequently discourses of the deliberative kind, and sometimes those of the demonstrative, are managed in a controversial way. And all controversies have their state. And therefore Quintilian very justly observes, that "states belong both to general and particular questions; and to all sorts of causes, demonstrative, deliberative, and judicial." In Cicero's oration for the Manilian law, this is the main point in dispute between him, and those who opposed that law: "Whether Pompey was the fittest person to be intrusted with the management of the war against Mithridates?" This is a subject of the deliberative kind. And of the same nature was that debate in the senate, concerning the demolition of Carthage. For the matter in dispute between Cato, who argued for it, and those who were of the contrary opinion, seems to have been this: "Whether it was for the interest of the Romans to demolish Carthage?" And so likewise in those two fine orations of Cato and Cæsar, given us by Sallust, relating to the conspirators with Catiline, who were then in custody, the controversy turns upon this: "Whether those prisoners should be punished with death, or perpetual imprisonment?" Examples of the demonstrative kind are not so common; but Cicero's oration concerning the 'Answers of the soothsayers,' may afford us an instance of it. Several prodigies had lately happened at Rome, upon which the soothsayers being consulted, assigned this as the reason of them, Because some places consecrated to the gods had been afterwards converted to civil uses. Clodius charged this upon Cicero; whose house was rebuilt at the public expence, after it had been demolished by Clodius, and the ground consecrated to the goddess Liberty. Cicero in this oration retorts the charge; and shews, that the prodigies did not respect him, but Clodius. So that the question in dispute was: "To which of the two those prodigies related?" This oration does not appear to have been spoken in a judicial way, and must therefore belong to the demonstrative kind. His invective against Piso is likewise much of the same nature, wherein he compares his own behaviour and conduct with that of Piso.

As to the number of these states, both Cicero and Quintilian reduce them to three. "We must (says Quintilian) agree with those, whose authority Cicero follows, who tell us, that three things may be inquired into in all disputes: Whether a thing is; what it is; and how it is. And this is the method which nature prescribes. For in the first place, it is necessary the thing should exist, about which the dispute is: because no judgment can be made either of its nature, or quality, till its existence be manifest; which is therefore the first question. But though it be manifest that a thing is, it does not presently appear what it is; and when this is known, the quality yet remains: and after these three are settled, no further inquiry is necessary." Now the first of these three states is called the *conjectural state*; as if it be inquired, "Whether one person killed another?" This always follows upon the denial of a fact, by one of the parties; as was the case of Roscius. And it receives its name from hence, that the judge is left, as it were, to conjecture, whether the fact was really committed or not, from the evidence produced on the other side. The second is call-

ed the *definitive state*, when the fact is not denied; but the dispute turns upon the nature of it, and what name is proper to give it: as in that example of Cicero, "Whether to take a sacred thing out of a private house be theft, or sacrilege?" For in this case it is necessary to settle the distinct notion of those two crimes, and shew their difference. The third is called the *state of quality*; when the contending parties are agreed both as to the fact, and the nature of it; but the dispute is, "Whether it be just or unjust, profitable or unprofitable, and the like;" as in the cause of Milo.

From what has been said upon this subject, the use of it may in a good measure appear. For whoever engages in a controversy, ought in the first place to consider with himself the main question in dispute, to fix it well in his mind, and keep it constantly in his view; without which he will be very liable to ramble from the point, and bewilder both himself and his hearers. And it is no less the business of the hearers principally to attend to this; by which means they will be helped to distinguish and separate from the principal question what is only incidental, and to observe how far the principal question is affected by it; to perceive what is offered in proof, and what is only brought in for illustration; not to be misled by digressions, but to discern when the speaker goes off from his subject, and when he returns to it again; and, in a word, to accompany him through the whole discourse, and carry with them the principal chain of reasoning upon which the cause depends, so as to judge upon the whole, whether he has made out his point, and the conclusion follows from the premises.

#### CHAP. II. Of Arguments suited to Demonstrative Discourses.

THESE consist either in praise or dispraise; and, agreeably to the nature of all contraries, one of them will serve to illustrate the other.

Now we either praise *persons* or *things*.

I. In praising or dispraising *persons*, rhetoricians prescribe two methods. One is, to follow the order in which every thing happened that is mentioned in the discourse; the other is, to reduce what is said under certain general heads, without a strict regard to the order of time.

1. In pursuing the former method, the discourse may be very conveniently divided into three periods. The first of which will contain what preceded the person's birth; the second, the whole course of his life; and the third, what followed upon his death.

Under the first of these may be comprehended what is proper to be said concerning his country or family. And therefore, if these were honourable, it may be said to his advantage, that he noways disgraced them, but added suitably to such a descent. But if they were not so, they may be either wholly omitted; or it may be said, that, instead of deriving thence any advantage to his character, he has conferred a lasting honour upon them; and that it is not of so much moment where, or from whom, a person derives his birth, as how he lives.

In the second period, which is that of his life, the qualities both of his mind and body, with his circumstances in the world, may be separately considered. Though, as Quintilian rightly observes: "All external

nal advantages are not praises for themselves, but according to the use that is made of them. For riches, and power, and interest, as they have great influence, and may be applied either to good or bad purposes, are a proof of the temper of our minds; and therefore we are either made better or worse by them." But these things are a just ground for commendation, when they are the reward of virtue, or industry. Bodily endowments are health, strength, beauty, activity, and the like; which are more or less commendable, according as they are employed. And where these, or any of them, are wanting, it may be shewn, that they are abundantly compensated by the more valuable endowments of the mind. Nay, sometimes a defect in these may give an advantageous turn to a person's character; for any virtue appears greater, in proportion to the disadvantages the person laboured under in exerting it. But the chief topics of praise are taken from the virtues and qualifications of the mind. And here the orator may consider the disposition, education, learning, and several virtues, which shone through the whole course of the person's life. In doing which, the preference should always be given to virtue above knowledge or any other accomplishment. And in actions, those are most considerable, and will be heard with greatest approbation, which a person either did alone, or first, or wherein he had fewest associates; as likewise those which exceeded expectation, or were done for the advantage of others rather than his own. And further, as the last scene of a man's life generally commands the greatest regard, if any thing remarkable at that time was either said or done, it ought particularly to be mentioned. Nor should the manner of his death, or cause of it, if accompanied with any commendable circumstances, be omitted; as if he died in the service of his country, or in the pursuit of any other laudable design.

The third and last period relates to what followed after the death of the person. And here the public loss, and public honours conferred upon the deceased, are proper to be mentioned. Sepulchres, statues, and other monuments to perpetuate the memory of the dead, at the expence of the public, were in common use both among the Greeks and Romans. But in the earliest times, as these honours were more rare, so they were less costly. For as in one age it was thought a sufficient reward for him who died in the defence of his country, to have his name cut in a marble inscription, with the cause of his death; so, in others, it was very common to see the statues of gladiators, and persons of the meanest rank, erected in public places. And therefore a judgment is to be formed of these things from the time, custom, and circumstances, of different nations; since the frequency of them renders them less honourable, and takes off from their evidence as the rewards of virtue. But, as Quintilian says, "Children are an honour to their parents, cities to their founders, laws to those who compiled them, arts to their inventors, and useful customs to the authors of them."

And this may suffice for the method of praising persons, when we propose to follow the order of time, as Isocrates has done in his funeral oration upon Evagoras king of Salamis, and Pliny in his panegyric upon the emperor Trajan. But as this method is

very plain and obvious, so it requires the more agreeable dress to render it delightful; lest otherwise it seem rather like an history, than an oration: For which reason, we find, that epic poets, as Homer, Virgil, and others, begin with the middle of their story, and afterwards take a proper occasion to introduce what preceded, to diversify the subject, and give the greater pleasure and entertainment to their readers.

2. The other method above hinted was, to reduce the discourse to certain general heads, without regarding the order of time. As if any one, in praising the elder Cato, should propose to do it, by shewing, that he was a most prudent senator, an excellent orator, and most valiant general; all which commendations are given him by Pliny. In like manner, the character of a good general may be comprised under four heads; skill in military affairs, courage, authority, and success: from all which Cicero commends Pompey. And agreeably to this method Suetonius has written the lives of the first twelve Cæsars.

But in praising of persons, care should always be taken, to say nothing that may seem fictitious, or out of character, which may call the orator's judgment or integrity in question. It was not without cause, therefore, that Lyſippus the statuary, as Plutarch tells us, blamed Apelles for painting Alexander the Great with thunder in his hand; which could never suit his character as a man, however he might boast of his divine descent: for which reason Lyſippus himself made an image of him holding a spear, as the sign of a warrior. Light and trivial things in commendations are likewise to be avoided, and nothing mentioned but what may carry in it the idea of something truly valuable, and which the hearers may be supposed to wish for, and is proper to excite their emulation. These are the principal heads of praise with relation to men. In dispraise, the heads contrary to these are requisite; which being sufficiently clear from what has been said, need not particularly be insisted on.

II. We proceed therefore to the other part of the division, which respects *things*, as distinguished from persons. By which we are to understand all beings inferior to man, whether animate or inanimate; as likewise the habits and dispositions of men, either good or bad; when considered separately, and apart from their subjects, as arts and sciences, virtues and vices, with whatever else may be a proper subject for praise or dispraise. Some writers, indeed, have, for their own amusement and the diversion of others, displayed their eloquence in a jocose manner upon subjects of this kind. So Lucian has written in praise of a fly, and Synesius an elegant encomium upon baldness. Others, on the contrary, have done the like in a satirical way. Such is Seneca's apotheosis or consecration of the emperor Claudius; and the Mysopogon or beard-hater, written by Julian the emperor. Not to mention several modern authors, who have imitated them in such ludicrous compositions. But as to these things, and all of the like nature, the observation of Antony in Cicero seems very just: "That it is not necessary to reduce every subject we discourse upon to rules of art." For many are so trivial, as not to deserve it; and others so plain and evident of themselves, as not to require it. But since it frequently comes in the

*Invention.* the way both of orators and historians to describe countries, cities, and facts, we shall briefly mention the principal heads of invention proper to illustrate each of these.

Countries, then, may be celebrated from the pleasantries of their situation, the clemency and wholesomeness of the air, and goodness of the soil; to which last may be referred the springs, rivers, woods, plains, mountains, and minerals. And to all these may be added their extent, cities, the number and antiquity of the inhabitants; their policy, laws, customs, wealth, character for cultivating the arts both of peace and war; their princes, and other eminent men they have produced. Thus Pacatus has given us a very elegant description of Spain, in his panegyric upon the emperor Theodosius, who was born there.

Cities are praised from much the same topics, as countries. And here, whatever contributes either to their defence, or ornament, ought particularly to be mentioned; as the strength of the walls and fortifications, the beauty and splendor of the buildings, whether sacred or civil, public or private. We have in Herodotus a very fine description of Babylon, which was once the strongest, largest, and most regular city in the world. And Cicero has accurately described the city of Syracuse, in the island Sicily, in one of his orations against Verres.

But facts come much oftener under the cognizance of an orator. And these receive their commendation from their honour, justice, or advantage. But in describing them, all the circumstances should be related in their proper order; and that in the most lively and affecting manner, suited to their different nature. Livy has represented the demolition of Alba by the Roman army, which was sent thither to destroy it, through the whole course of that melancholy scene, in a style so moving and pathetic, that one can hardly forbear condoling with the inhabitants, upon reading his account.

But in discourses of this kind, whether of praise or dispraise, the orator should (as he ought indeed upon all occasions) well consider where, and to whom, he speaks. For the wise men often think very differently both of persons and things from the common people. And we find that learned and judicious men are frequently divided in their sentiments, from the several ways of thinking to which they have been accustomed. Besides, different opinions prevail, and gain the ascendant, at different times. While the Romans continued a free nation, love of their country, liberty, and public spirit, were principles in the highest esteem among them. And therefore, when Cato killed himself, that he might not fall into the hands of Cæsar, and sur vive the liberty of his country, it was thought an instance of the greatest heroic virtue; but afterwards, when they had been accustomed to an arbitrary government, and the spirit of liberty was now lost, the poet Martial could venture to say,

Death to avoid 'tis madness sure to die.

A prudent orator therefore will be cautious of opposing any settled and prevailing notions of those to whom he addresses; unless it be necessary, and then he will do it in the softest and most gentle manner.

### CHAP. III. Of Arguments suited to Deliberative Discourses.

22

THIS kind of discourses must certainly have been very ancient; since, doubtless, from the first beginning of mens conversing together, they deliberated upon their common interest, and offered their advice to each other. But neither those of the laudatory nor judicial kind could have been introduced, till mankind were settled in communities, and found it necessary to encourage virtue by public rewards, and bring vice under the restraint of laws. The early practice of suafory discourses appears from sacred writ, where we find, that when Moses was ordered upon an embassy into Egypt, he would have excused himself for want of eloquence. And Homer represents the Greeks at the siege of Troy, as flocking like a swarm of bees to hear their generals harangue them. Nor is this part of oratory less conspicuous for its usefulness to mankind, than its antiquity; being highly beneficial either in councils, camps, or any societies of men. How many instances have we upon record, where the fury of an enraged multitude has been checked and appealed by the prudent and artful persuasion of some particular person? The story of Agrippa Menenius, when the commons of Rome withdrew from the senators, and retired out of the city, is too well known, to need reciting. And how often have armies been animated and fired to the most dangerous exploits, or recalled to their duty, when ready to mutiny, by a moving speech of their general? many instances of which we find in history.

All deliberation respects something future, for it is in vain to consult about what is already past. The subject-matter of it is, either things public or private, sacred or civil; indeed all the valuable concerns of mankind, both present and future, come under its regard. And the end proposed by this kind of discourses is chiefly profit or interest. But since nothing is truly profitable, but what is in some respect good; and every thing, which is good in itself, may not in all circumstances be for our advantage; properly speaking, what is both good and profitable, or beneficial good, is the end here designed. And therefore, as it sometimes happens, that what appears profitable, may seem to interfere with that which is strictly just and honourable; in such cases it is certainly most advisable to determine on the safer side of honour and justice, notwithstanding some plausible things may be offered to the contrary. But where the dispute lies apparently between what is truly honest, and some external advantage proposed in opposition to it, all good men cannot but agree in favour of honesty. Such was the case of Regulus, who, being taken prisoner by the Carthaginians, was permitted to go to Rome upon giving his oath, that unless he could persuade the senate to set at liberty some young Carthaginian noblemen, then prisoners at Rome, in exchange for him, he should return again to Carthage. But Regulus, when he came to Rome, was so far from endeavouring to prevail with the senate to comply with the desire of the Carthaginians, that he used all his interest to dissuade them from hearkening to the proposal. Nor could the most earnest intreaties of his nearest

Invention.

nearest relations and friends, nor any arguments they were able to offer, engage him to continue at Rome, and not return again to Carthage. He had then plainly in his view, on the one side, ease, security, affluence, honours, and the enjoyment of his friends; and on the other, certain death, attended with cruel torments. However, thinking the former not consistent with truth and justice, he chose the latter. And he certainly acted as become an honest and brave man, in choosing death, rather than to violate his oath. Though whether he did prudently in persuading the senate not to make the exchange, or they in complying with him, we shall leave others to determine. Now, when it proves to be a matter of debate, whether a thing upon the whole be really beneficial or not; as here arise two parts, advice and dissuasion, they will each require proper heads of argument. But as they are contrary to each other, he who is acquainted with one, cannot well be ignorant of the other. We shall therefore chiefly mention those proper for advice, from whence such as are suited to dissuade will easily be perceived. Now the principal heads of this kind are these following, which are taken from the nature and properties of the thing itself under consideration.

1. *Pleasure* often affords a very cogent argument in discourses of this nature. Every one knows what an influence this has upon the generality of mankind. Though, as Quintilian remarks, pleasure ought not of itself to be proposed as a fit motive for action in serious discourses, but when it is designed to recommend something useful, which is the case here. So, would any one advise another to the pursuit of polite literature, Cicero has furnished him with a very strong inducement to it from the pleasure which attends that study, when he says: "If pleasure only was proposed by these studies, you would think them an entertainment becoming a man of sense and a gentleman. For other pursuits neither agree with all times, all ages, nor all places; but these studies improve youth, delight old age, adorn prosperity, afford a refuge and comfort in adversity, divert us at home, are no hindrance abroad, sleep, travel, and retire with us into the country."

2. *Profit*, or advantage. This has no less influence upon many persons than the former; and when it respects things truly valuable, it is a very just and laudable motive. Thus Cicero, when he sends his *Books of offices* to his son, which he wrote in Latin for his use, advises him to make the best advantage both of his tutor's instructions, and the conversation at Athens, where he then was; but withal to peruse his philosophical treatises, which would be doubly useful to him, not only upon account of the subjects, but likewise of the language, as they would enable him to express himself upon those arguments in Latin, which before had only been treated of in Greek.

3. *Honour*; than which no argument will sooner prevail with generous minds, or inspire them with greater ardour. Virgil has very beautifully described Hector's ghost appearing to Æneas the night Troy was taken, and advising him to depart from this motive of honour:

O goddess born, escape by timely flight  
The flames, and horrors of this fatal night.

The foes already have possess'd the wall,  
Troy nods from high, and totters to her fall.  
Enough is paid to Priam's royal name;  
More than enough to duty, and to fame.  
If by a mortal hand my father's throne  
Could be defended, 'twas by mine alone.

Invention.

The argument here made use of to persuade Æneas to leave Troy immediately, is, that he had done all that could be expected from him, either as a good subject or brave soldier, both for his king and country; which were sufficient to secure his honour: and now there was nothing more to be expected from him, when the city was falling, and impossible to be saved; which could it have been preserved by human power, he himself had done it.

But although a thing considered in itself appear beneficial if it could be attained, yet the expediency of undertaking it may still be questionable; in which case the following heads taken from the circumstances which attend it, will afford proper arguments to engage in it.

(1.) The *possibility* of succeeding may sometimes be argued, as one motive to this end. So Hannibal endeavoured to convince king Antiochus, that it was possible for him to conquer the Romans, if he made Italy the seat of the war; by observing to him, not only that the Gauls had formerly destroyed their city; but that he had himself defeated them, in every battle he fought with them in that country.

(2.) But an argument founded upon *probability* will be much more likely to prevail. For in many affairs of human life, men are determined either to prosecute them or not, as the prospect of success appears more or less probable. Hence Cicero, after the fatal battle at Pharsalia, dissuades those of Pompey's party, with whom he was engaged, from continuing the war any longer against Cæsar; because it was highly improbable, after such a defeat, by which their main strength was broken, that they should be able to stand their ground, or meet with better success than they had before.

(3.) But further, since probability is not a motive strong enough with many persons to engage in the prosecution of a thing which is attended with considerable difficulties, it is often necessary to represent the facility of doing it, as a further reason to induce them to it. And therefore Cicero makes use of this argument to encourage the Roman citizens in opposing Mark Anthony (who upon the death of Cæsar had assumed an arbitrary power), by representing to them, that his circumstances were then desperate, and that he might easily be vanquished.

(4.) Again, if the thing advised can be shewn to be in any respect necessary, this will render the motive still much stronger for undertaking it. And therefore Cicero joins this argument with the former, to prevail with the Roman citizens to oppose Anthony, by telling them, that "The consideration before them was, not in what circumstances they should live; but whether they should live at all, or die with ignominy and disgrace." This way of reasoning will sometimes prevail when all others prove ineffectual. For some persons are not to be moved, till things are brought to an extremity, and they find themselves reduced to the utmost danger.

(5.) To these heads may be added the consideration

invention. tion of the event, which in some cases carries great weight with it. As when we advise to the doing of a thing from this motive, That whether it succeed or not, it will yet be of service to undertake it. So after the great victory gained by Themistocles over the Persian fleet at the straits of Salamis, Mardonius advised Xerxes to return into Asia himself, lest the report of his defeat should occasion an insurrection in his absence: but to leave behind him an army of 300,000 men under his command; with which, if he should conquer Greece, the chief glory of the conquest would redound to Xerxes; but if the design miscarried, the disgrace would fall upon his generals.

These are the principal heads which furnish the orator with proper arguments in giving advice. Cicero, in his oration for the Manilian law, where he endeavours to persuade the Roman people to choose Pompey for their general in the Mithridatic war, reasons from three of these topics, into which he divides his whole discourse; namely, the necessity of the war, the greatness of it, and the choice of a proper general. Under the first of these he shews, that the war was necessary from four considerations; the honour of the Roman state, the safety of their allies, their own revenues, and the fortunes of many of their fellow citizens, which were all highly concerned in it, and called upon them to put a stop to the growing power of king Mithridates, by which they were all greatly endangered. So that this argument is taken from the head of necessity. The second, in which he treats of the greatness of the war, is founded upon the topic of possibility. For though he shews the power of Mithridates to be very great, yet not so formidable, but that he might be subdued; as was evident from the many advantages Lucullus had gained over him and his associates. In the third head, he endeavours to prevail with them to intrust the management of the war in the hands of Pompey, whom he describes as a consummate general, for his skill in military affairs, courage, authority, and success; in all which qualities he represents him as superior to any other of their generals whom they could at that time make choice of. The design of all which was, to persuade them, that they had very good reason to hope for success, and a happy event of the war, under his conduct. So that that the whole force of his reasoning under this head is drawn from probability. These are the three general topics which make up that fine discourse. Each of which is indeed supported by divers other arguments and considerations, which will be obvious in perusing the oration itself, and therefore need not be here enumerated. On the contrary, in another oration he endeavours to dissuade the senate from consenting to a peace with Mark Anthony, because it was base, dangerous, and impracticable.

But no small skill and address are required in giving advice. For since the tempers and sentiments of mankind, as well as their circumstances, are very different and various; it is often necessary to accommodate the discourse to their inclinations and opinions of things. And therefore the weightiest arguments are not always the most proper, and fittest to be used on all occasions. Cicero, who was an admirable master of this art, and knew perfectly well how to suit what he said to the taste and relish of his hearers, in treating upon

this subject, distinguishes mankind into two sorts; the ignorant and unpolished, who always prefer profit to honour; and such as are more civilized and polite, who prefer honour and reputation to all other things. Wherefore they are to be moved by these different views: Praise, glory, and virtue, influence the one; while the other is only to be engaged by a prospect of gain and pleasure. Besides, it is plain, that the generality are much more inclined to avoid evils than to pursue what is good; and to keep clear of scandal and disgrace, than to practise what is truly generous and noble. Persons likewise of a different age act from different principles; young men for the most part view things in another light, from those who are older, and have had more experience, and consequently are not to be influenced by the same motives.

#### CHAP. IV. Of Arguments suited to Judicial Discourses.

In judicial controversies there are two parties; the plaintiff or prosecutor, and the defendant or person charged. The subject of them is always something past. And the end propounded by them Cicero calls equity, or right and equity; the former of which arises from the laws of the country, and the latter from reason and the nature of things. For at Rome the prætors had a court of equity, and were empowered, in many cases relating to property, to relax the rigour of the written laws. But as this subject is very copious, and causes may arise from a great variety of things, writers have reduced them to three heads, which they call *states*, to some one of which all judicial proceedings may be referred; namely, *whether a thing is, what it is, or how it is*. By the *state* of a cause therefore is meant the principal question in dispute, upon which the whole affair depends. Which, if it stops in the first inquiry, and the defendant denies the fact, the state is called *conjectural*; but if the fact be acknowledged, and yet denied to be what the adversary calls it, it is termed *definitive*; but if there is no dispute either about the fact or its name, but only the justice of it, it is called the *state of quality*: as was shewn more largely before under n<sup>o</sup> 20. But we there considered these states only in a general view, and deferred the particular heads of argument proper for each of them, to this judicial kind of discourses; where they most frequently occur, and from which examples may easily be accommodated to other subjects.

All judicial causes are either *private* or *public*. Those are called *private*, which relate to the right of particular persons; and they are likewise called *civil* causes, as they are conversant about matters of property. *Public* causes are those which relate to public justice and the government of the state; which are also called *criminal*, because by them crimes are prosecuted, whether capital, or those of a less heinous nature. We shall take the heads of the arguments only from this latter kind, because they are more copious, and easy to be illustrated by examples; from which such as agree to the former, namely *civil* causes, will sufficiently appear.

1. The *conjectural* state. When the accused person denies the fact, there are three things which the prosecutor has to consider; whether he *would* have done it, whether he *could*, and whether he *did* it. And

hence arise three topics; from the *will*, the *power*, and the *signs* or circumstances which attended the action. The affections of the mind discover the will; as, passion, an old grudge, a desire of revenge, a resentment of an injury, and the like. Therefore Cicero argues from Clodius's hatred of Milo, that he designed his death; and from thence infers, that he was the aggressor in the combat between them, wherein Clodius was killed. This is what he principally endeavours to prove, and comes properly under this state: for Milo owned that he killed him, but alleged that he did it in his own defence. So that in regard to this point, Which of them assaulted the other, the charge was mutual. The prospect of advantage may also be alleged to the same purpose. Hence it is said of L. Cassius, that whenever he sat as judge in a case of murder, he used to advise and move the court, to examine, to whom the advantage arose from the death of the deceased. And Cicero puts this to Anthony concerning the death of Cæsar. "If any one (says he) should bring you upon trial, and that saying of Cassius, *Cui bono*? "Who got by it?" look to it, I beseech you, that you are not confounded." To these arguments may be added, hope of impunity, taken either from the circumstances of the accused person, or of him who suffered the injury. For persons, who have the advantage of interest, friends, power, or money, are apt to think they may easily escape; as likewise such, who have formerly committed other crimes with impunity. Thus Cicero represents Clodius as hardened in vice, and above all the restraint of laws, from having so often escaped punishment upon committing the highest crimes. On the contrary, such a confidence is sometimes raised from the condition of the injured party, if he is indigent, obscure, timorous, or destitute of friends; much more if he has an ill reputation, or is loaded with popular hatred and resentment. It was this presumption of the obscurity of Roscius, who lived in the country, and his want of interest at Rome, which encouraged his accusers to charge him with killing his father, as Cicero shews in his defence of him. Lastly, the temper of a person, his views, and manner of life, are considerations of great moment in this matter. For persons of bad morals, and such as are addicted to vice, are easily thought capable of committing any wickedness. Hence Sallust argues from the evil disposition and vicious life of Catiline, that he affected to raise himself upon the ruins of his country. The second head is the *power* of doing a thing; and there are three things which relate to this, the *place*, the *time*, and *opportunity*. As if a crime is said to have been committed in a private place, where no other person was present; or in the night; or when the injured person was unable to provide for his defence. Under this head, may likewise be brought in the circumstances of the persons; as if the accused person was stronger, and so able to overpower the other; or more active, and so could easily make his escape. Cicero makes great use of this topic in the case of Milo, and shews, that Clodius had all the advantages of *place*, *time*, and *opportunity*, to execute his design of killing him. The third head comprehends the *signs* and circumstances, which either preceded, accompanied, or followed, the commission of the fact. So threats, or the accused person being seen at or near the

place before the fact was committed, are circumstances that may probably precede murder; fighting, crying out, bloodshed, are such as accompany it; paleness, trembling, inconsistent answers, hesitation, or faltering of the speech, something found upon the person accused which belonged to the deceased, are such as follow it. Thus Cicero proves, that Clodius had threatened the death of Milo, and given out that he should not live above three days at the farthest. These arguments, taken from conjectures, are called *presumptions*, which, though they do not directly prove that the accused person committed the fact with which he is charged; yet when, laid together, they appeared very strong, sentence by the Roman law might sometimes be given upon them, to convict him.

These are the topics from which the prosecutor takes his arguments. Now the business of the defendant is to invalidate these. Therefore such as are brought from the *will*, he either endeavours to shew are not true, or so weak as to merit very little regard. And he refutes those taken from the *power*, by proving that he wanted either opportunity or ability: as, if he can shew, that neither the place nor time insisted on was at all proper; or that he was then in another place. In like manner he will endeavour to confute the *circumstances*, if they cannot be directly denied, by shewing that they are not such as do necessarily accompany the fact, but might have proceeded from other causes, though nothing of what is alleged had been committed; and it will be of great service to assign some other probable cause. But sometimes the defendant does not only deny that he did the fact, but charges it upon another. Thus Cicero, in his oration for Roscius, not only defends him from each of these three heads, but likewise charges the fact upon his accusers.

2. The *definitive* state, which is principally concerned in defining and fixing the name proper to the fact: though orators seldom make use of exact definitions, but commonly choose larger descriptions, taken from various properties of the subject or thing described.

The heads of argument in this state are much the same to both parties. For each of them defines the fact his own way, and endeavours to refute the other's definition. We may illustrate this by an example from Quintilian: "A person is accused of sacrilege, for stealing money out of a temple, which belonged to a private person." The fact is owned; but the question is, *Whether it be properly sacrilege?* The prosecutor calls it so, because it was taken out of a temple. But since the money belonged to a private person, the defendant denies it to be sacrilege, and says it is only simple theft. Now the reason why the defendant uses this plea, and insists upon the distinction, is, because by the Roman law the penalty of theft was only four times the value of what was stolen; whereas sacrilege was punished with death. The prosecutor then forms his definition agreeable to his charge, and says, "To steal any thing out of a sacred place is sacrilege." But the defendant excepts against this definition, as defective; and urges, that it does not amount to sacrilege, unless the thing stolen was likewise sacred. And this case might once, perhaps, have been a matter of controversy, since we find it expressly

decider-

*Invention.* determined in the Pandects, that "An action of sacrilege should not lie, but only of theft, against any one who should steal the goods of private persons deposited in a temple."

The second thing is the proof brought by each party each party to support his definition; as in the example given us by Cicero, of one "who carried his cause by bribery, and was afterwards prosecuted again upon an action of prevarication." Now, if the defendant was cast upon this action, he was, by the Roman law, subjected to the penalty of the former prosecution. Here the prosecutor defines prevarication to be, *Any bribery or corruption in the defendant, with a design to pervert justice.* The defendant therefore, on the other hand, restrains it to *bribing only the prosecutor.*

And if this latter sense agrees better with the common acceptance of the word, the prosecutor in the third place pleads the intention of the law, which was to comprehend all bribery in judicial matters under the term of *prevarication*. In answer to which the defendant endeavours to shew, either from the head of contraries, that a real prosecutor and a prevaricator are used as opposite terms in the law; or from the etymology of the word, that a prevaricator denotes one who pretends to appear in the prosecution of a cause, while in reality he favours the contrary side; and consequently, that money given for this end, only can, in the sense of the law, be called *prevarication*.

Lastly, the prosecutor pleads, that it is unreasonable, that he who does not deny the fact, should escape by a cavil about a word. But the defendant insists upon his explication as agreeable to the law; and says, the fact is misrepresented and blackened, by affixing to it a wrong name.

3. The third state is that of *quality*, in which the dispute turns upon the justice of an action. And here the defendant does not deny he did the thing he is charged with; but asserts it to be right and equitable, from the circumstances of the case, and the motives which induced him to it.

And, first, he sometimes alleges, the reason of doing it was in order to prevent some other thing of worse consequence, which would otherwise have happened. We have an instance of this in the life of Epaminondas, who, with two other generals joined in the command with him, marched the Theban army into Peloponnesus against the Lacedaemonians; but by the influence of a contrary faction at home, their commissions were superseded, and other generals sent to command the army. But Epaminondas, being sensible that, if he obeyed this order at that time, it would be attended with the loss of the whole army, and consequently the ruin of the state, refused to do it; and having persuaded the other generals to do the like, they happily finished the war in which they were engaged; and upon their return home, Epaminondas taking the whole matter upon himself, on his trial was acquitted. The arguments proper in this case are taken from the justice, usefulness, or necessity, of the action. The accuser therefore will plead, that the fact was not just, profitable, nor necessary, considered either in itself, or comparatively with that for the sake of which it is said to have been done: and he

will endeavour to shew, that what the defendant assigns for the reason of what he did, might not have happened as he pretends. Besides, he will represent of what ill consequence it must be, if such crimes go unpunished. The defendant, on the other hand, will argue from the same heads, and endeavour to prove the fact was just, useful, or necessary. And he will further urge, that no just estimate can be made of any action, but from the circumstances which attend it; as the design, occasion, and motives for doing it: which he will represent in the most favourable light to his own cause, and endeavour to fet them in such a view, as to induce others to think they could not but have done the same in the like circumstances.

Again, the cause of an action is sometimes charged by the defendant upon the party who received the damage, or some other person, who either made it necessary, or enjoined him to do it. The first of these was Milo's plea for killing Clodius, because he assaulted him with a design to take away his life. Here the fact is not denied, as in the case of Roscius above-mentioned, under the *conjectural* state; but justified from the reason of doing it. For that an assassinator might be justly killed, Cicero shews both from law and reason. The accuser, therefore, in such a case, will, if there be room for it, deny the truth of this allegation. So the friends of Clodius affirmed that Milo was the aggressor, and not Clodius; which Cicero, in his defence of Milo, principally labours to refute. In the second case, the prosecutor will say, No one ought to offend because another has offended first; which defeats the course of public justice, renders the laws useless, and destroys the authority of the magistrate. The defendant, on the other hand, will endeavour to represent the danger and necessity of the case, which required an immediate remedy, and in that manner; and urges, that it was vain and impracticable to wait for redress in the ordinary way, and therefore no ill consequence can arise to the public. Thus Cicero, in defending Sextius, who was prosecuted for a riot in bringing armed men into the forum, shews that his design was only to repel force with force; which was then necessary, there being no other means left for the people to assemble, who were excluded by a mob of the contrary party. Of the third case we have also an example in Cicero, who tells us, that, "in making a league between the Romans and Samnites, a certain young nobleman was ordered by the Roman general to hold the swine (designed for a sacrifice); but the senate afterwards disapproving the terms, and delivering up their general to the Samnites, it was moved, Whether this young man ought not likewise to be given up." Those who were for it might say, that, to allege the command of another, is not a sufficient plea for doing an ill action; and this is what the Roman law now expressly declares. But in answer to that, it might be replied, that it was his duty to obey the command of his general, who was answerable for his own orders, and not those who were obliged to execute them; and therefore, to give up this young nobleman would be to punish one person for the fault of another.

Lastly, a fact is sometimes rather excused than defended, by pleading that it was not done designedly,

or with any ill intent. This is called *concession*; and consists of two parts, *apology* and *intreaty*. The former represents the matter as the effect of inadvertency, chance, or necessity. Aristotle gives us an example of inadvertency or imprudence in a woman at Athens, who gave a young man a love-potion, which killed him; for which she was tried, but acquitted: though afterwards this was made criminal by the Roman law. The case of Adrastus, as related by Herodotus, is an instance of chance; who being intrusted by Croesus with the care of his son, as they were hunting, killed him accidentally with a javelin which he threw at a boar. It is necessity, when a person excuses his making a default, from fits of weather, sickness, or the like. Thus Cicero pleaded his illness, contracted by the fatigue of a long journey, as an excuse for not appearing in the senate upon the summons of Mark Antony, who threatened to oblige him to it by pulling his house down. But what the defendant here attributes to inadvertency, chance, or necessity, the opposite party will attribute to design, negligence, or some other culpable reason; and represent it as a matter injurious to the public to introduce such precedents; and also produce instances, if that can be done, where the like excuses have not been admitted. On the other hand, the defendant will insist on his innocence, and shew the hardship and severity of judging mens actions rather by the event, than from the intention: that such a procedure makes no difference between the innocent and the guilty; but must necessarily involve many honest men in ruin and destruction, discourage all virtuous and generous designs, and turn greatly to the prejudice of human society. He will also consider the instances alleged by the accuser, and shew the difference between them and his own case. And, lastly, he will have recourse to intreaty, or a submissive address to the equity and clemency of the court, or party offended, for pardon; as Cicero has done in his oration to Cæsar, in favour of Ligarius.

#### CHAP. V. Of the Character and Address of an Orator.

HAVING considered and explained the first part of invention, which furnishes the orator with such arguments as are necessary for the proof of his subject, we are next to shew what are the proper means to conciliate the minds of his hearers; to gain their affection; and to recommend both himself, and what he says, to their good opinion and esteem. For the parts of invention are commonly thus distinguished; that the first respects the *subject* of the discourse, the second the *speaker*, and the third the *hearers*. Now the second of these, what we have at present to explain, is by Quintilian called a *propriety of manners*. And in order to express this, it is necessary, as he tells us, "that every thing appear easy and natural, and the disposition of the speaker be discovered by his words." We may form an easy conception of this from the conduct of such persons who are most nearly concerned in each others welfare. As when relations or friends converse together upon any affairs of importance, the temper and disposition of the speaker plainly shews itself by his words and manner of address. And what nature here directs to without colouring or disguise, the ora-

tor is to endeavour to perform by his art. Though indeed, if what a person says, be inconsistent with his usual conduct and behaviour at other times; he cannot expect it should gain much credit, or make any deep impression upon his hearers: which may be one reason, why the ancient rhetoricians make it so necessary a qualification in an orator, that he be a good man; since he should always be consistent with himself, and, as we say, talk in character. And therefore it is highly requisite, that he should not only gain the skill of assuming those qualities which the nature and circumstances of his discourse require him to express; but likewise, that he should use his utmost endeavours to get the real habits implanted in his mind. For as by this means they will be always expressed with greater ease and facility; so, by appearing constantly in the course of his life, they will have more weight and influence upon particular occasions.

Now there are four qualities, more especially suited to the character of an orator, which should always appear in his discourses, in order to render what he says acceptable to his hearers; and these are, *wisdom*, *integrity*, *benevolence*, and *modesty*.

1. *Wisdom* is necessary; because we easily give into those whom we esteem wiser and more knowing than ourselves. Knowledge is very agreeable and pleasant to all, but few make very great improvements in it; either by reason they are employed in other necessary affairs, and the mind of man cannot attend to many things at once; or because the way to knowledge at first is hard and difficult, so that persons either do not care to enter upon the pursuit of it, or, if they do, they are many times soon discouraged, and drop it, for want of sufficient resolution to surmount its difficulties. Such, therefore, as either cannot, or do not care to give themselves the trouble of examining into things themselves, must take up with the representation of others; and it is an ease to them to hear the opinion of persons whom they esteem wiser than themselves. No one loves to be deceived; and those who are fearful of being misled, are pleased to meet with a person, in whose wisdom, as they think, they can safely trust. The character of wisdom therefore is of great service to an orator, since the greater part of mankind are swayed by authority rather than arguments.

2. But this of itself is not sufficient, unless the opinion of *integrity* be joined with it. Nay, so far from it, that the greater knowledge and understanding a man is supposed to have, unless he likewise have the character of an honest man, he is often the more suspected. For knowledge without honesty, is generally thought to dispose a person, as well as qualify him, to deceive.

3. And to both these qualities the appearance of kindness and *benevolence* should likewise be added. For though a person have the reputation of wisdom and honesty, yet if we apprehend he is either not well affected to us, or at least regardless of our interest; we are in many cases apt to be jealous of him. Mankind are naturally swayed by their affections, and much influenced through love or friendship; and therefore nothing has a greater tendency to induce persons to credit what is said, than intimations of affection and kindness. The best orators have been always sensible, what great influence the expressions of kindness and bene-

*Invention.* benevolence have upon the minds of others, to induce them to believe the truth of what they say; and therefore they frequently endeavour to impress them with the opinion of it. Thus Demosthenes begins his celebrated oration for Ctesiphon. "It is my hearty prayer (says he) to all the deities, that this my defence may be received by you with the same affection which I have always expressed for you and your city." And it is a very fine image of it which we have in Cicero, where, in order to influence the judges in favour of Milo, he introduces him speaking thus, as became a brave man, and a patriot, even upon the supposition he should be condemned by them: "I bid my fellow citizens adieu; may they continue flourishing and prosperous; may this famous city be preserved, my most dear country, however it has treated me; may my fellow citizens enjoy peace and tranquillity without me, since I am not to enjoy it with them, though I have procured it for them; I will withdraw, I will be gone."

4. *Modesty.* It is certain, that what is modestly spoken, is generally better received than what carries in it an air of boldness and confidence. Most persons, though ignorant of a thing, do not care to be thought so; and would have some deference paid to their understanding. But he who delivers himself in an arrogant and assuming way, seems to upbraid his hearers with ignorance, while he does not leave them to judge for themselves, but dictates to them, and as it were demands their assent to what he says; which is certainly a very improper method to win upon them. For not a few, when convinced of an error in such a way, will not own it; but will rather adhere to their former opinion, than seem forced to think right, when it gives another the opportunity of a triumph. A prudent orator therefore will behave himself with modesty, that he may not seem to insult his hearers; and will set things before them in such an engaging manner, as may remove all prejudice either from his person or what he asserts. But at the same time, firmness and resolution is as necessary as modesty, that he may appear to confide in the justice and truth of his cause. For to speak timorously, and with hesitation, destroys the credit of what is offered; and so far as the speaker seems to distrust what he says himself, he often induces others to do the like.

But, as has been said already, great care is to be taken, that these characters do not appear feigned and counterfeit. For what is fictitious can seldom be long concealed. And if this be once discovered, it makes all that is said suspected, how specious soever it may otherwise appear.

It is further necessary, that the orator should know the world, and be well acquainted with the different tempers and dispositions of mankind. Nor indeed can any one reasonably hope to succeed in this province, without well considering the circumstances of time and place, with the sentiments and dispositions of those to whom he speaks; which, according to Aristotle, may be distinguished four ways, as they discover themselves by the several *affections, habits, ages, and fortunes* of mankind. And each of these require a different conduct and manner of address.

The *affections* denote certain emotions of the mind, which, during their continuance, give a great turn to

the disposition. For love prompts to one thing, and hatred to another. The like may be said of anger, lenity, and the rest of them.

Persons differ likewise according to the various *habits* of their mind. So a just man is inclined one way, and an unjust man another; a temperate man to this, and an intemperate man to the contrary.

And as to the several *ages* of men, Aristotle has described them very accurately; and how persons are differently affected in each of them. He divides the lives of men, considered as hearers, into three stages; youth, middle age, and old age.—Young men, he says, have generally strong passions, and are very eager to obtain what they desire; but are likewise very mutable, so that the same thing does not please them long. They are ambitious of praise, and quick in their resentments. Lavish of their money, as not having experienced the want of it. Frank and open, because they have not often been deceived; and credulous for the same reason. They readily hope the best, because they have not suffered much, and are therefore not so sensible of the uncertainty of human affairs; for which reason, they are likewise more easily deceived. They are modest from their little acquaintance with the world. They love company and cheerfulness, from the briskness of their spirits. In a word, they generally exceed in what they do; love violently, hate violently, and act in the same manner through the rest of their conduct.—The disposition of old men is generally contrary to the former. They are cautious, and enter upon nothing hastily; having in the course of many years been often imposed upon; having often erred, and experienced the prevailing corruption of human affairs; for which reason they are likewise suspicious, and moderate in their affections either of love or hatred. They pursue nothing great and noble, and regard only the necessities of life. They love money; having learnt by experience the difficulty of getting it, and how easily it is lost. They are fearful, which makes them provident. Commonly full of complaints, from bodily infirmities, and a deficiency of spirits. They please themselves rather with the memory of what is past, than any future prospect; having so short a view of life before them, in comparison of what is already gone: for which reason also, they love to talk of things past; and prefer them to what is present, of which they have but little relih, and know they must shortly leave them. They are soon angry, but not to excess. Lastly, they are compassionate, from a sense of their own infirmities, which makes them think themselves of all persons most exposed.—Persons of a middle age, betwixt these two extremes, as they are freed from the rashness and temerity of youth, so they have not yet suffered the decays of old age. Hence in every thing they generally observe a better conduct. They are neither so hasty in their assent as the one, nor so minutely scrupulous as the other, but weigh the reasons of things. They regard a decency in their actions; are careful and indutious; and as they undertake what appears just and laudable upon better and more deliberate consideration than young persons, so they pursue them with more vigour and resolution than those who are older.

As to the different *fortunes* of mankind, they may be considered as noble, rich, or powerful; and the contrary

Invention.

trary to these.—Those of high birth, and noble extraction, are generally very tender of their honour, and ambitious to increase it; it being natural for all persons to desire an addition to those advantages, of which they find themselves already possessed. And they are apt to consider all others as much their inferiors, and therefore expect great regard and deference should be shewn them.—Riches, when accompanied with a generous temper, command respect from the opportunities they give of being useful to others; but they usually elate the mind, and occasion pride. For as money is commonly said to command all things, those who are possessed of a large share of it, expect others should be at their beck; since they enjoy that which all desire, and which most persons make the main pursuit of their lives to obtain.—But nothing is more apt to swell the mind than power. This is what all men naturally covet, even when perhaps they would not use it. But the views of such persons are generally more noble and generous, than of those who only pursue riches and the heaping up of money. A state contrary to these gives a contrary turn of mind; and in lower life, persons dispositions usually differ according to their station and circumstances. A citizen and a courtier, a merchant and a soldier, a scholar and a peasant, as their pursuits are different, so is generally their turn and disposition of mind.

It is the orator's business, therefore, to consider these several characters and circumstances of life, with the different bias and way of thinking they give to the mind; that he may so conduct himself in his behaviour and manner of speaking, as will render him most acceptable, and gain him the good esteem of those to whom he addresses.

#### CHAP. VI. *Of the Passions.*

25

As it is often highly necessary for the orator, so it requires his greatest skill, to engage the passions in his interest. Quintilian calls this *the soul and spirit of his art*. And, doubtless, nothing more discovers its empire over the minds of men, than this power to excite, appease, and sway their passions, agreeably to the design of the speaker. Hence we meet with the characters of *admirable, divine*, and other splendid titles, ascribed to eloquence by ancient writers. It has indeed been objected by some, that whatever high encomiums may be given of this art by the admirers of it, it is however dissingenuous to deceive and impose upon mankind, as those seem to do, who, by engaging their passions, give a bias to their minds, and take them off from the consideration of the truth; whereas every thing should be judged of from the reasons brought to support it, by the evidence of which it ought to stand or fall. But in answer to this, it may be considered, that all fallacy is not culpable. We often deceive children for their good; and physicians sometimes impose on their patients, to come at a cure. And why, therefore, when persons will not be prevailed with by reason and argument, may not an orator endeavour, by engaging their passions, to persuade them to that which is for their advantage? Besides, Quintilian makes it a necessary qualification of an orator, that he be an honest man, and one who will not abuse his art. But since those of a contrary charac-

Invention.

ter will leave no methods untried in order to carry their point, it is requisite for those who design well, to be acquainted with all their arts, without which they will not be a match for them; as in military affairs it is highly advantageous for the general of an army to get himself informed of all the designs and stratagems of the enemy, in order to counteract them. Indeed this part of oratory is not necessary at all times, nor in all places. The better prepared persons are to consider truth, and act upon the evidence of it, the less occasion there appears for it. But the greater part of mankind, either do not duly weigh the force of arguments, or refuse to act agreeably to their evidence. And where this is the case, that persons will neither be convinced by reason, nor moved by the authority of the speaker, the only way left to put them upon action, is to engage their passions. For the passions are to the mind, what the wind is to a ship: they move, and carry it forward; and he who is without them, is in a manner without action, dull and lifeless. There is nothing great or noble to be performed in life, wherein the passions are not concerned. The Stoics, therefore, who were for eradicating the passions, both maintained a thing in itself impossible, and which, if it was possible, would be of the greatest prejudice to mankind. For while they appeared such zealous assertors of the government of reason, they scarce left it any thing to govern; for the authority of reason is principally exercised in ruling and moderating the passions, which, when kept in a due regulation, are the springs and motives to virtue. Thus hope produces patience, and fear industry; and the like might be shewn of the rest. The passions therefore are not to be extirpated, as the Stoics asserted, but put under the direction and conduct of reason. Indeed where they are ungovernable, and instead of obeying command, they are, as some have fitly called them, *diseases of the mind*; and frequently hurry men into vice, and the greatest misfortunes of life: Just as the wind, when it blows moderately, carries on the ship; but if it be too boisterous and violent, may overset her. The charge therefore brought against this art, for giving rules to influence the passions, appears groundless and unjust; since the proper use of the passions is, not to hinder the exercise of reason, but to engage men to act agreeably to reason. And if an ill use be sometimes made of this, it is not the fault of the art, but of the artist.

We shall here consider the passions, as they may be separately referred, either to *demonstrative, deliberative, or judicial* discourses; though they are not wholly confined to any of them.

1. To the *demonstrative* kind, we may refer *joy and sorrow, love and hatred, emulation and contempt*.

Joy is an elation of the mind, arising from a sense of some present good. Such a reflection naturally creates a pleasant and agreeable sensation, which ends in a delightful calm and serenity. This is heightened by a description of former evils, and a comparison between them and the present felicity. Thus Cicero endeavours to excite in the minds of his fellow-citizens the highest sense of joy and delight at Catiline's departure from Rome, by representing to them the imminent danger which threatened both them and the city while he continued among them.

Sorrow, on the contrary, is an uneasiness of mind arising

Invention.

Invention.

arising from a sense of some present evil. This passion has generally a place in funeral discourses. And it may be heightened, like the former, by comparison, when any past happiness is set in opposition to a present calamity. Hence Cicero aggravates the sorrow at Rome occasioned by the death of Metellus, from his character, and great services to the public, while living.

*Love* excites us to esteem one another for some excellency, and to do him all the good in our power. It is distinguished from *Friendship*, which is mutual; and therefore love may continue where friendship is lost: that is, the affection may remain on one side. And when we assist a person from no other motive but to do him a kindness, Aristotle calls this *good-will*. Love takes its rise from a variety of causes. Generosity, benevolence, integrity, gratitude, courtesy, and other social virtues, are great incitements to love any one endued with such qualities. And persons generally love those who are of a like disposition with themselves and pursue the same views. It is therefore the chief art of a flatterer to suit himself in every thing to the inclination of the person whose good graces he courts. When the orator would excite this affection towards any person, it is proper to shew, that he is possessed of at least some, if not all, of these agreeable qualities. When the conspirators with Catiline were to be brought to justice, Cicero was very sensible of the envy he should contract on that account, and how necessary it was for him to secure the love of the Roman senate for his support and protection in that critical juncture. And this he endeavours to do in his fourth oration against Catiline, by representing to them, in the most pathetic manner, that all the labours he underwent, the difficulties he consisted with, and the dangers to which he was exposed on that account, were not for his own sake, but for their safety, quiet, and happiness.

*Hatred* is opposed to love, and produced by the contrary dispositions. And therefore persons hate those, who never did them any injury, from the ill opinion they have of their base and vicious inclinations. So that the way to excite this passion is, by shewing that any one has committed some heinous fact with an ill intent. And the more nearly affected persons are by such actions, in what they account of the greatest concern, the higher in proportion their hatred rises. Since life therefore is esteemed the most valuable good, Cicero endeavours to render Mark Anthony odious to the citizens of Rome, by describing his cruelty.

*Emulation* is a disquiet, occasioned by the felicity of another, not because he enjoys it, but because we desire the like for ourselves. So that this passion is in itself good and laudable, as it engages men to pursue those things which are so. For the proper objects of emulation are any advantages of mind, body, or fortune, acquired by study or labour.

Emulation therefore is excited by a lively representation of any desirable advantages which appear to be attainable, from the example of others who are or have been possessed of them. But where the felicity of another occasions an uneasiness, not from the want of it, but because he enjoys it, this passion is called *envy*, which the ancients describe as an hideous monster,

feeding upon itself, and being its own tormentor. Aristotle observes, that it most usually affects such persons as were once upon a level with those they envy. For most men naturally think so well of themselves, that they are uneasy to see those who were formerly their equals, advanced above them. But, as this is a base and vicious passion, the orator is not to be informed how to excite it, but how to lessen or remove it. And the method prescribed by Cicero for this purpose is, to shew that the things, which occasioned it, have not happened to the envied person undeservedly, but are the just reward of his industry or virtue; that he does not so much convert them to his own profit or pleasure, as to the benefit of others; and that the same pains and difficulties are necessary to preserve them, with which they were at first acquired.

*Contempt* is opposed to *emulation*, and arises from misconduct in things not of themselves vicious: As where a person either acts below his station and character, or affects to do that for which he is not qualified. Thus Cicero endeavours to expose Cæcilius, and bring him into contempt of the court, for pretending to rival him in the accusation of Verres, for which he was altogether unfit.

2. To *deliberative* discourses may be referred *fear*, *hope*, and *shame*.

*Fear* arises from the apprehension of some great and impending evil. For the greatest evils, while they appear at a distance, do not much affect us. Such persons occasion fear, who are possessed with power, especially if they have been injured, or apprehend so. Likewise those who are addicted to do injuries, or who bear us an ill will. And the examples of others, who have suffered in a like case, or from the same persons, help to excite fear. From the circumstances therefore either of the thing, or person, it will not be difficult for the orator to offer such arguments as may be proper to awaken this passion. So Demosthenes, when he would persuade the Athenians to put themselves in a condition of defence against king Philip, enumerates the several acts of hostility already committed by him against the neighbouring states. And because mens private concerns generally more affect them than what relates to the public; it is proper sometimes to shew the necessary connection these have with each other, and how the ruin of one draws the other after it.

The contrary passion to *fear* is *hope*; which arises, either from a prospect of some future good, or the apprehension of safety from those things which occasion our fear. Young persons are easily induced to hope the best, from the vigour of their spirits. And those who have escaped former dangers, are encouraged to hope for the like success for the future. The examples of others also, especially of wise and considerate men, have often the same good effect. To find them calm and sedate when exposed to the like dangers, naturally creates confidence and the hopes of safety. But nothing gives persons that firmness and steadiness of mind, under the apprehension of any difficulties, as a consciousness of their own integrity and innocence. Let dangers come from what quarter they will, they are best prepared to receive them. They can calmly view an impending tempest, observe the way of its approach, and prepare themselves in the best manner to avoid

avoid it. In Cicero's oration for the Manilian law, he encourages the Roman citizens to hope for success against Mithridates, if they chose Pompey for their general, from the many instances of his former successes, which he there enumerates.

*Shame* arises from the apprehension of those things that hurt a person's character. *Modesty* has been wisely implanted in mankind by the great Author of nature, as a guardian of virtue, which ought for this reason to be cherished with the greatest care; because, as Seneca has well observed, "if it be once lost, it is scarce ever to be recovered." Therefore the true cause or foundation of shame is any thing base or vicious; for this wounds the character, and will not bear reflection. And he must arrive at no small degree of insensibility, who can stand against such a charge, if he be conscious to himself that it is just. Therefore, to deter persons from vicious actions, or to expose them for the commission of them, the orator endeavours to set them in such a light as may most awaken this passion, and give them the greatest uneasiness by the reflection. And because the bare representation of the thing itself is not always sufficient for this purpose; he sometimes enforces it by enlarging the view, and introducing those persons as witnesses of the fact for whom they are supposed to have the greatest regard. Thus, when some of the Athenians, in an arbitration about certain lands which had been referred to them by the contending parties, proposed it as the shortest way of deciding the controversy, to take the possession of them into their own hands; Cydias, a member of the assembly, to dissuade them from such an unjust action, desired them to imagine themselves at that time in the general assembly of the states of Greece (who would all hear of it shortly), and then consider how it was proper to act. But where persons labour under an excess of modesty, which prevents them from exerting themselves in things fit and laudable, it may sometimes be necessary to shew, that it is faulty and ill grounded. On the other hand, *immodesty*, or impudence, which consists in a contempt of such things as affect the reputation, can never be too much discouraged and exposed. And the way of doing this is, to make use of such arguments as are most proper to excite shame. We have a very remarkable instance of it in Cicero's second Philippic, wherein he affixes this character upon Mark Anthony, through every scene of his life.

3. To judicial discourses, may be referred *anger* and *lenity*, *pity* and *indignation*.

*Anger* is a resentment, occasioned by some affront, or injury, done without any just reason. Now men are more inclined to resent such a conduct, as they think they less deserve it. Therefore persons of distinction and figure, who expect a regard should be paid to their character, can the less bear any indications of contempt. And those who are eminent in any profession or faculty, are apt to be offended, if reflections are cast either upon their reputation or art. Magistrates also, and persons in public stations, sometimes think it incumbent on them to resent indignities, for the support of their office. But nothing sooner inflames this passion, than if good services are rewarded with slights and neglect. The instance of Narfites, the Roman general, is remarkable in this

kind; who, after he had been successful in his wars with the Goths, falling under the displeasure of the emperor Justin, was removed from the government of Italy, and received by the empress with this taunt, *That he must be sent to weave among the girls; which so provoked him, that he said he would weave such a web as they should never be able to unravel.* And accordingly, he soon after brought down the Longobards, a people of Germany, into Italy; where they settled themselves in that part of the country, which from them is now called *Lombardy*. The time and place in which an injury was done, and other circumstances that attended it, may likewise contribute very much to heighten the fact. Hence Demosthenes, in his oration against Midias, endeavours to aggravate the injury of being struck by him, both as he was then a magistrate, and because it was done at a public festival. From hence it appears, that the persons, who most usually occasion this passion, are such as neglect the rules of decency, contempt and insult others, or oppose their inclinations; as likewise the ungrateful, and those who violate the ties of friendship, or requite favours with injuries. But when the orator endeavours to excite anger, he should be careful not to exceed due bounds in aggravating the charge, lest what he says, appear rather to proceed from prejudice, than a strict regard to the demerit of the action.

*Lenity* is the remission of anger. The designs of mens actions are principally to be regarded; and therefore what is done ignorantly, or through inadvertency, is sooner forgiven. Also to acknowledge a fault, submit, and ask pardon, are the ready means to take off resentment. For a generous mind is soon cooled by submission. Besides, he who repents of his fault, does really give the injured party some satisfaction, by punishing himself; as all repentance is attended with grief and uneasiness of mind, and this is apt very much to abate the desire of revenge. As, on the contrary, nothing is more provoking, than when the offender either audaciously justifies the fact, or confidently denies it. Men are likewise wont to lay aside their resentment, when their adversaries happen by some other means to suffer what they think a sufficient satisfaction. Lastly, easy circumstances, a lucky incident, or any thing which gives the mind a turn to mirth and pleasure, has a natural tendency to remove anger. For anger is accompanied with pain and uneasiness, which very ill suit joy and cheerfulness. The orator therefore, in order to assuage and pacify the minds of his auditors, will endeavour to lessen their opinion of the fault, and by that means to take off the edge of their resentment. And to this purpose, it will be proper either to represent that the thing was not designed, or that the party is sorry for it; or to mention his former services; as also to shew the credit and reputation which will be gained by a generous forgiveness. And this last topic is very artfully wrought up by Cicero, in his address to Cæsar, in favour of Ligarius.

*Pity* arises from the calamities of others, by reflecting, that we ourselves are liable to the like misfortunes. So that evils, considered as the common lot of human nature, are principally the cause of pity. And this makes the difference between *pity* and *good-will*, which

*Disposition* which arises merely from a regard to the circumstances of those who want our assistance. But considering the uncertainty of every thing about us, he must seem in a manner divested of humanity, who has no compassion for the calamities of others; since there is no affliction which happens to any man, but either that, or some other as great, may fall upon himself. But those persons are generally soonest touched with this passion, who have met with misfortunes themselves. And by how much greater the distress is, or the person appears less deserving it, the higher pity does it excite: for which reason, persons are generally most moved at the misfortunes of their relations and friends, or those of the best figure and character. The orator therefore, in order to excite the greater pity, will endeavour to heighten the idea of the calamity, from the several circumstances both of the thing itself and the person who labours under it. A fine example of this may be seen in Cicero's defence of Murena, *cap. 40. &c.*

*Indignation*, as opposed to *pity*, is an uneasiness at the felicity of another who does not seem to deserve

*Disposition* it. But this respects only external advantages, such as riches, honours, and the like; for virtues cannot be the object of this passion. Aristotle therefore says, "that pity and indignation are generally to be found in the same persons, and are both evidences of a good disposition." Now the orator excites this passion, by shewing the person to be unworthy of that felicity which he enjoys. And as, in order to move compassion, it is sometimes of use to compare the former happy state of the person with his present calamity; so here, the greater indignation is raised, by comparing his former mean circumstances with his present advancement: as Cicero does in the case of Vatinius.

These are the passions with which an orator is principally concerned. In addressing to which, not only the greatest warmth and force of expression is often necessary; but he must likewise first endeavour to impress his own mind with the same passion he would excite in others, agreeably to that of Horace:

My grief with others just proportion bears;  
To make me weep, you must be first in tears.

## PART II. OF DISPOSITION.

**A**S *Invention* supplies the orator with necessary materials, so *Disposition* directs him how to place them in the most proper and suitable order. *Disposition* therefore, considered as a part of oratory, naturally follows invention. And what is here chiefly intended by it is, the placing the several parts of a discourse in a just method and dependence upon one another.

Writers are not all agreed in determining the parts of an oration; though the difference is rather in the manner of considering them, than in the things themselves. But Cicero, whom we shall here follow, mentions six, namely, *Introduction, Narration, Proposition, Confirmation, Consolation, and Conclusion.*

### CHAP. I. Of the Introduction.

**26** THE design of this is to prepare the minds of the hearers for a suitable reception of the remaining parts that are to follow. And for this end, three things are requisite; that the orator gain the *good opinion* of his hearers, that he secure their *attention*, and give them some *general notion* of his subject.

1. *Good opinion.* When the orator introduces his discourse with his own person, he will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities, than to magnify them. And where the nature of the subject may seem to require it, he will endeavour to shew, that some just and good reason induced him to engage in it. We have a very fine example of this in Cicero's oration for the poet Aulus Licinius Archias, which begins thus: "If I have any natural genius, which I am sensible how small it is; or any ability in speaking, wherein I own I have been very conversant; or any skill acquired from the study and precepts of the best arts, to which my whole life has been devoted: this Aulus Licinius has, in a particular manner, a right to demand of me the fruit of all these things. For as far back as I can remember, and call to mind what passed in my youth,

to the present time, he has been my chief adviser and encourager both to undertake and pursue this course of studies." When the orator sets out with the persons of those to whom the discourse is made, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. Thus Cicero begins his oration of thanks for the pardon of Marcellus, with an encomium upon the mildness, clemency, and wisdom of Cæsar, to whom it was addressed. But sometimes he expresses his gratitude for past favours; as Cicero has done in his orations, both to the people and senate of Rome, after his return from banishment. And at other times he declares his concern for them and their interest; in which manner Cicero begins his fourth oration against Catiline, which was made in the senate. "I perceive (says he) that all your countenances and eyes are turned on me; I perceive that you are solicitous, not only for your own danger, and that of the state, but for mine likewise, if that should be removed. Your affection for me is pleasant in misfortunes, and grateful in sorrow; but I adjure you to lay it aside, and, forgetting my safety, consider yourselves and your children." But in judicial cases, both the character of the person whose cause he espouses, and that of the adverse party likewise, furnishes the orator with arguments for exciting the good-will of his hearers: The former, by commemorating his virtues, dignity, or merits, and sometimes his misfortunes and calamities. So Cicero in his defence of Flaccus, begins his oration in commending him on the account of his services done to the public, the dignity of his family, and his love to his country. And Demosthenes, in his oration against Midias, sets out with a recital of his vices, in order to recommend his own cause to the favourable opinion of the court.

2. *Attention.* On this head, Cicero says, "We shall be heard attentively by one of these three things; if we propose what is great, necessary, or for the in-

*Disposition* terest of those to whom the discourse is addressed." So that, according to him, the topics of attention are much the same with those of good opinion, when taken from the subject. And indeed, people are naturally led to attend either to those things or persons of which they have entertained a favourable opinion. But in order to gain this point, the orator sometimes thinks it proper to request the attention of his audience. Thus Cicero, in his defence of Cluentius, after having shewn the heinousness of the charge against him, concludes his introduction in the following manner, speaking to the judges: "Wherefore I intreat, that while I briefly and clearly reply to a charge of many years standing, you will, according to your usual custom, give me a kind and attentive hearing." And again, in his second Philippic, addressing himself to the senate: "But as I must say something for myself, and many things against Mark Anthony; one of these I beg of you, that you will hear me kindly, while I speak for myself; and the other I will undertake for, that when I speak against him, you shall hear me with attention." But though the introduction be the most usual and proper place for gaining attention, yet the orator finds it convenient sometimes to quicken and excite his hearers in other parts of his discourse, when he observes they flag, or has something of moment to offer.

3. Some general account of the subject of the discourse. This is always necessary, which the two others are not. And therefore it must be left to the prudence of the orator, when to use or omit them, as he shall judge proper, from the nature of his discourse, the circumstances of his hearers, and how he stands with them. But some account of the subject is what cannot be neglected. For every one expects to be soon informed of the design of the speaker, and what he proposes to treat of. Nor when they are all made use of, is it necessary they should always stand in the order we have here placed them. Cicero sometimes enters immediately upon his subject, and introduces the other heads afterwards. As in his third oration against Catiline, made to the body of the Roman people, which begins thus: "You see that the state, all your lives, estates, fortunes, wives and children, and this seat of the greatest empire, the most flourishing and beautiful city, having by the favour of heaven towards you, and my labours, counsels, and dangers, been this day rescued from fire and sword and the very jaws of destruction, are preserved and restored to you." And then he proceeds to recommend himself to their esteem and benevolence, from the consideration of these benefits.

These are the heads which commonly furnish matter for this part of a discourse. But orators often take occasion from the time, place, largeness of the assembly, or some other proper circumstance, to compliment their hearers, recommend themselves, or introduce the subject upon which they are about to treat. Instances of each of these may be met with in several of Cicero's orations. And sometimes they set out with some comparison, similitude, or other ornament, which they accommodate to the occasion of their discourse. Thus Isocrates enters upon his celebrated panegyric in praise of his countrymen the Athenians, with the following comparison: "I have often wondered, what could

be their design, who brought together these assemblies, and instituted the gymnical sports, to propose so great rewards for bodily strength; and to vouchsafe no honour to those, who applied their private labours to serve the public, and so cultivated their minds as to be serviceable to others, to whom they ought to have shewn greater regard. For although the strength of a champion was doubled, no benefit would from thence accrue to others; but all enjoy the prudence of one man, who will hearken to his advice." In some cases, orators have recourse to a more covert and artful way of opening their subject, endeavour to remove jealousies, apologize for what they are about to say, and seem to refer it to the candour of the hearers to judge of it as they please. Cicero appears to have been a perfect master of this art, and used it with great success. Thus his seventh Philippic, where he seems to express the greatest concern, lest what he was about to say should give any offence to the senate to whom he was speaking: "I," says he, "who always declared for peace, and to whom peace among ourselves, as it is wished for by all good men, was in a particular manner desirable; who have employed all my industry in the forum, in the senate, and in the defence of my friends, whence I have arrived to the highest honours, a moderate fortune, and what reputation I enjoy; I therefore, who owe what I am to peace, and without it could not have been the person I am, be that what it will, for I would arrogate nothing to myself; I speak with concern and fear, how you will receive what I am going to say; but I beg and intreat you, from the great regard I have always expressed for the support and advancement of your honour, that if any thing said by me should at first appear harsh or unfit to be received, you will notwithstanding please to hear it without offence, and not reject it till I have explained myself: I then, for I must repeat it again, who have always approved of peace, and promoted it, am against a peace with Mark Anthony." This is called *insinuation*; and may be necessary, where a cause is in itself doubtful, or may be thought so from the received notions of the hearers, or the impressions already made upon them by the contrary side. An honest man would not knowingly engage in a bad cause; and yet, though prevailing prejudice, that may be so esteemed which is not so in itself. In these cases, therefore, great caution and prudence are necessary to give such a turn to things, and place them in that view, as may be least liable to offence. And because it sometimes happens, that the hearers are not so much displeased at the subject as the person, Quintilian's rule seems very proper, when he says: "If the subject displeases, the character of the person should support it; and when the person gives offence, he should be helped by the cause."

#### CHAP. II. Of Narration.

THE orator having prepared his hearers to receive his discourses with candour and attention, and acquainted them with his general design in the introduction, before he proceeds directly to his subject, often finds it necessary to give some account of what preceded, accompanied, or followed upon it. And this he does in order to enlarge the view of the particular

*Disposition* *cultural point in dispute, and place it in a clearer light.* This is called *narration*; which is a recital of something done, in the order and manner in which it was done. Hence it is easy to perceive, what those things are which properly enter into a narration. And such are the cause, manner, time, place, and consequences of an action; with the temper, fortune, views, ability, associates, and other circumstances of those concerned in it. Not that each of these particulars is necessary in every narration; but so many of them at least, as are requisite to set the matter in a just light, and make it appear credible. Besides, in relating a fact, the orator does not content himself with such an account of it as is barely sufficient to render what he says intelligible to his hearers; but describes it in so strong and lively a manner, as may give the greatest evidence to his relation, and make the deepest impression upon their minds. And if any part of it appears at present less probable, he promises to clear up and remove any remaining doubts in the progress of his discourse. For the foundation of his reasoning afterwards is laid in the narration, from whence he takes his arguments for the confirmation. And therefore it is a matter of no small importance, that this part be well managed; since the success of the whole discourse so much depends upon it.

There are four properties required in a good narration; that it be short, clear, probable, and pleasant.

1. The brevity of a narration is not to be judged of barely from its length: for that may be too long, which contains but a little; and that too short, which comprehends a great deal. Wherefore this depends upon the nature of the subject, since some things require more words to give a just representation of them, and others fewer. That may properly therefore be called a *short narration*, which contains nothing that could well have been omitted, nor omits any thing which was necessary to be said. Now, in order to avoid both these extremes, care should be taken not to go further back in the account of things, nor to trace them down lower, than the subject requires; to say that only in the general, which does not need a more particular explication; not to assign the causes of things, when it is enough to shew they were done; and to omit such things as are sufficiently understood, from what either preceded, or was consequent upon them. But the orator should be careful, lest, while he endeavours to avoid prolixity, he run into obscurity. Horace was very sensible of this danger, when he said:

By striving to be short, I grow obscure.

2. *Perspicuity.* This may justly be esteemed the chief excellency of language. For as the design of speech is to communicate our thoughts to others, that must be its greatest excellence, which contributes most to this end; and that, doubtless, is perspicuity. As perspicuity therefore is requisite in all discourse, so it is particularly serviceable in a narration, which contains the substance of all that is to be said afterwards. Wherefore, if this be not sufficiently understood, much less can those things which receive their light from it. Now the following things render a narration clear and plain: Proper and significant words, whose meaning is well known and determined; short sentences, though full and explicit, whose parts are not per-

*Disposition* plexed, but placed in their just order; proper particles to join the sentences, and shew their connection and dependance on each other; a due reward to the order of time, and other circumstances necessary to be expressed; and lastly, suitable transitions.

3. *Probability.* Things appear probable, when the causes assigned for them appear natural; the manner in which they are described is easy to be conceived; the consequences are such as might be expected; the characters of the persons are justly represented; and the whole account is well attested, consistent with itself, and agreeable to the general opinion. Simplicity likewise in the manner of relating a fact, as well as in the style, without any reserve or appearance of art, contributes very much to its credibility. For truth loves to appear naked and open, stripped of all colouring or disguise. The conspiracy of Catiline was so daring and extravagant, that no one, but such a desperado, could ever have undertaken it with any hopes of success. However, Cicero's account of it to the senate was so full and exact, and so well suited to the character of the person, that it presently gained credit. And therefore, when, upon the conclusion of Cicero's speech, Catiline, who was present, immediately stood up, and desired they would not entertain such hard thoughts of his, but consider how much his family had always been attached to the public interest, and the great services they had done the state; their resentments rose so high, that he could not be heard: upon which he immediately left the city, and went to his associates.

4. The last thing required in a narration is, that it be *pleasant and entertaining*. And this is more difficult, because it does not admit of that accurate composition, and pompous dress, which delight the ear, and recommend some other parts of a discourse. For it certainly requires no small skill in the speaker, while he endeavours to express every thing in the most natural, plain, and easy manner, not to grow flat and tiresome. For Quintilian's remark is very just, that, "the most experienced orators find nothing in eloquence more difficult, than what all, who hear it, fancy they could have said themselves." And the reason of this seems very obvious. For as all art is an imitation of nature, the nearer it resembles that, the more perfect it is in its kind. Hence unexperienced persons often imagine that to be easiest, which suits best with those natural ideas to which they have been accustomed; till, upon trial, they are convinced of their mistake. Wherefore, to render this part of a discourse pleasant and agreeable, recourse must be had to variety, both in the choice of words, and turns of the expression. And therefore questions, admirations, interlocations, imagery, and other familiar figures, help very much to diversify and enliven a narration, and prevent it from becoming dull and tedious, especially when it is carried on to any considerable length.

Having given a brief account of the nature and properties of a narration, we shall now proceed to consider the uses of it.

Laudatory orations are usually as it were a sort of continued narration, set off and adorned with florid language and fine images proper to grace the subject, which is naturally so well fitted to afford pleasure and entertainment.

entertainment. Wherefore a separate narration is more suited to *deliberative* and *judicial* discourses. In Cicero's oration for the Manilian law (which is of the former kind), the design of the narration is to shew the Roman people the necessity of giving Pompey the command of the army against king Mithridates, by representing the nature of that war, which is done in the following manner. "A great and dangerous war (says he) threatens your revenues and allies from two very powerful kings, Mithridates and Tigranes; one of whom not being pursued after his defeat, and the other provoked, they think they have an opportunity to seize Asia. Letters are daily brought from those parts to worthy gentlemen of the equestrian order, who have large concerns there in farming your revenues: they acquaint me, as friends, with the state of the public affairs, and danger of their own; that many villages in Bithynia, which is now your province, are burnt down; that the kingdom of Ariobarzanes, which borders upon your revenues, is entirely in the enemy's power; that Lucullus, after several great victories, is withdrawn from the war; that he who succeeds him is not able to manage it; that all the allies and Roman citizens wish and desire the command of that war may be given to one particular person; and that he alone, and no other, is dreaded by the enemies. You see the state of the case; now consider what ought to be done." Here is an unhappy scene of affairs, which seemed to call for immediate redress. The causes and reasons of it are assigned in a very probable manner, and the account well attested by persons of character and figure. And what the consequences would be, if not timely prevented, no one could well be ignorant. The only probable remedy suggested in general is, the committing that affair to one certain person, which he afterwards shews at large could be no other than Pompey. But in Cicero's defence of Milo, (which is of the *judicial* kind), the design of the narration, which is greatly commended by Quintilian, is to prove, that, in the combat between Clodius and Milo, the former was the aggressor. And in order to make this appear, he gives a summary account of the conduct of Clodius the preceding year; and from the course of his actions and behaviour, shews the inveterate hatred he bore to Milo, who obstructed him in his wicked designs. For which cause he had often threatened to kill him, and given out that he should not live beyond such a time: and accordingly he went from Rome without any other apparent reason, but that he might have an opportunity to attack him in a convenient place near his own house, by which he knew Milo was then obliged to pass. Milo was in the senate that day, where he staid till they broke up, then went home, and afterwards set forward on his journey. When he came to the place in which he was to be assaulted, Clodius appeared every way prepared for such a design, being on horseback, and attended with a company of desperate ruffians ready to execute his commands; whereas Milo was with his wife in a chariot, wrapped up in his cloak, and attended with servants of both sexes. These were all circumstances which preceded the fact. And as to the action itself, with the event of it, the attack, as Cicero says, was begun by the attendants of Clodius from an higher

ground, who killed Milo's coachman: upon which Milo, throwing off his cloak, leaped out, and made a brave defence against Clodius's men, who were got about the chariot. But Clodius, in the heat of the skirmish, giving out that Milo was killed, was himself slain by the servants of Milo, to avenge, as they thought, the death of their master. Here seems to be all the requisites proper to make this account credible. Clodius's open and avowed hatred of Milo, which proceeded so far as to threaten his life; the time of his leaving Rome; the convenience of the place; his habit and company so different from those of Milo, joined with his known character of a most profligate and audacious wretch, could not but render it very probable that he had formed that design to kill Milo. And which of them began the attack, might very reasonably be credited from the advanced ground on which Clodius and his men were placed; the death of Milo's coachman at the beginning of the combat; the skirmish afterwards at the chariot; and the reason of Clodius's own death at last, which does not appear to have been intended, till he had given out that Milo was killed.

But a distinct and separate narration is not always necessary in any kind of discourse. For if the matter was well known before, a set and formal narrative will be tedious to the hearers. Or if one party has done it already, it is needless for the other to repeat it. But there are three occasions especially, in which it may seem very requisite: when it will bring light to the subject; when different accounts have already been given out concerning it; or when it has been misrepresented by the adverse party. If the point in controversy be of a dubious nature, or not sufficiently known to the hearers, a distinct account of the matter, with the particular circumstances attending it, must be very serviceable, in order to let them into a true state of the case, and enable them to judge of it with greater certainty.

Moreover, where the opposite party has set the matter in a false light by some artful and invidious turn, or loaded it with any odious circumstances, it seems no less necessary that endeavours should be used to remove any ill impressions, which otherwise might remain upon the minds of the hearers, by a different and more favourable representation. And if any thing can be fixed upon to make the contrary account appear absurd or incredible, it ought particularly to be remarked. Thus Cicero, in his defence of Sextus Roscius, shews that he was many miles distant from Rome at the time he was charged to have killed his father there. "Now (says he), while Sextus Roscius was at America, and this Titus Roscius [*his accuser*] at Rome, Sextus Roscius [*the father*] was killed at the baths on Mount Palatine, returning from supper. From whence I hope there can be no doubt who ought to be suspected of the murder. And, were not the thing plain of itself, there is this further suspicion to fix it upon the prosecutor; that, after the fact was committed, one Manlius Glauca, an obscure fellow, the freedman, client, and familiar of this Titus Roscius, first carried the account of it to America, not to the son of the deceased, but to the house of Titus Capito his enemy;" with more to the same purpose. But what we bring it for is, to shew the use which

*Disposition* Cicero makes of this narration for retorting the crime upon the prosecutors.

But the orator should be very careful, in conducting this part, to avoid every thing which may prejudice the cause he espouses. Falshood, and a misrepresentation of facts, are not to be justified; but no one is obliged to say those things which may hurt himself. We shall just mention one instance of this from Cicero, where he has shewn great skill in this respect, in pleading before Cæsar for the pardon of Ligarius, who had joined with Pompey in the civil war. For Ligarius, having been represented by the adverse party as an enemy to Cæsar, and so esteemed by Cæsar himself; Cicero very artfully endeavours in his narration to take off the force of this charge, by shewing, that, when the war first broke out, he refused to engage in it; which he would not have done, had he borne any personal hatred to Cæsar. "Quintus Ligarius (says he), before there was any suspicion of a war, went into Africa as a legate to the prosperous Caius Cædicius; in which he so approved himself, both to the Roman citizens and allies, that, when Cædicius left the province, the inhabitants would not be satisfied he should leave the government in the hands of any other person. Therefore Quintus Ligarius having excused himself in vain for some time, accepted of the government against his will; which he so managed during the peace, that both the citizens and allies were greatly pleased with his integrity and justice. The war broke out on a sudden, which those in Africa did not hear of till it was begun: but upon the news of it, partly through inconsiderate haste, and partly from blind fear, they looked out for a leader, first for their own safety, and then as they were affected; when Ligarius, thinking of home, and desirous to return to his friends, would not be prevailed on to engage in any affairs. In the mean time, Publius Accius Varus, the pretor, who was formerly governor of Africa, coming to Utica, recourse was immediately had to him, who very eagerly took upon himself the government; if that can be called a *government*, which was conferred on a private man by the clamour of the ignorant multitude, without any public authority. Ligarius, therefore, who endeavoured to avoid every thing of that kind, ceased to act soon after the arrival of Varus." Here Cicero ends his narrative. For, though Ligarius afterwards joined with Pompey's party, yet to have mentioned that, which was nothing more than what many others had done, whom Cæsar had already pardoned, could have served only to increase his displeasure against him. And therefore he doubtless shewed great skill in so managing his account as to take off the main force of the accusation, and by that means make way for his pardon, which he accordingly obtained.

### CHAP. III. Of the Proposition.

28 IN every just and regular discourse, the speaker's intention is to prove or illustrate something. And when he lays down the subject upon which he designs to treat, in a distinct and express manner, this is called the *proposition*.

Orators use several ways in laying down the subject of their discourses. Sometimes they do it in one general proposition. We have an instance of this in Cicero's speech to the senate, the day after Cæsar was

killed, (as it is given us by Dion Cassius), in which his design was to persuade them to peace and unanimity. "This (says he) being the state of our affairs, I think it necessary that we lay aside all the discord and enmity which have been among us, and return again to our former peace and agreement." And then he proceeds to offer his reasons for this advice.

At other times, to give a clearer and more distinct view of their discourse, they subjoin to the proposition the general heads of argument by which they endeavour to support it. This method Cicero uses in his seventh Philippic, where he says, "I who have always commended and advised to peace, am against a peace with Mark Antony. But why am I averse to peace? Because it is base, because it is dangerous, and because it is impracticable. And I beseech you to hear me with your usual candor, while I make out these three things."

But when the subject relates to several different things, which require each of them to be separately laid down in distinct propositions, it is called a *partition*; though some have made two kinds of *partition*, one of which they call *separation*, and the other *enumeration*. By the former of these, the orator shews in what he agrees with his adversary, and wherein he differs from him. So, in the case formerly mentioned, of a person accused of sacrilege for stealing private money out of a temple, he who pleads for the defendant says, "He owns the fact; but it being private money, the point in question is, Whether this be sacrilege?" And in the cause of Milo, Cicero, speaking of Clodius, says, "The point which now comes before the court, is not, Whether he was killed, or not; that we confess; but, Whether justly or unjustly." Now in reality here is no partition, since the former branch of the proposition is what is agreed upon, and given up; and consequently it is only the latter that remains to be disputed. It is called *enumeration*, when the orator acquaints his hearers with the several parts of his discourse, upon which he designs to treat. And this alone, properly speaking, is a *partition*. Thus Cicero states his plea in his defence of Muræna: "I perceive the accusation consists of three parts: the first respects the conduct of his life; the second, his dignity; and the third contains a charge of bribery."

There are three things requisite in a good partition; that it be *short*, *complete*, and consist but of a *few members*.

A partition is said to be *short*, when each proposition contains in it nothing more than what is necessary. So that the brevity here required is different from that of a narration; for that consists chiefly in things, this in words. And, as Quintilian justly observes, brevity seems very proper here, where the orator does not shew what he is then speaking of, but what he designs to discourse upon.

Again, it ought to be *complete* and perfect. And for this end, care must be taken to omit no necessary part in the enumeration.

But, however, there should be as *few heads* as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most. And we do not remember that Cicero ever exceeds that number. But it is certain, the fewer they are, the better,

Disposition

better, provided nothing necessary be omitted. For too large a number is both difficult of retention, and apt to introduce that confusion, which partition is designed to prevent.

Hitherto we have been speaking only of those heads into which the subject, or general argument of the discourse, is at first divided. For it is sometimes convenient to divide these again, or at least some of them, into several parts or members. And when this happens, it is best done, as the speaker comes to each of them in the order at first laid down; by which means the memory of the hearers will be less burdened, than by a multitude of particulars at one and the same time. Thus Cicero, in his oration for the Manilian law, comprises what he designs to say under three general heads. "First (says he) I shall speak of the nature of the war, then of its greatness, and lastly about the choice of a general." And when he comes to the first of these, he divides it again into four branches; and shews, "how much the glory of the Romans, the safety of their allies, their greatest revenues, and the fortunes of many of their citizens, were all concerned in that war." The second head, in which he considers the greatness of the war, has no division. But when he comes to the third head, concerning the choice of a general, he divides that likewise into four parts; and shews, that so many virtues are necessary in a consummate general, such an one as was proper to have the management of that war, namely, *skill in military affairs, courage, authority, and success*: all which be attributes to Pompey. And this is the scheme of that celebrated oration.

Further, some divide their subject into two parts, and propose to treat upon it *negatively and positively*; by shewing first what it is not, and then what it is. But while they are employed to prove what it is not, they are not properly treating upon that, but something else; which seems as irregular, as it is unnecessary. For he who proves what a thing is, does at the same time shew what it is not. However, in fact, there is a sort of division by affirmation and negation, which may sometimes be conveniently used. As if a person, charged with killing another, should thus state his defence: *I had done right if I had killed him, but I did not kill him*. Here indeed, if the latter can be plainly made to appear, it may seem needless to insist upon the former. But if that cannot be so fully proved, but there may be room left for suspicion, it may be proper to make use of both: for all persons do not see things in the same light, and he who believes the fact, may likewise think it just; while he who thinks it unjust, may not believe it, but rather suppose, had it really been committed by the party, he would not have denied it, since he looked upon it as defensible. And this method of proceeding, Quintilian compares to a custom often used in traffic, when persons make a large demand at first, in order to gain a reasonable price. Cicero uses this way of reasoning, in his defence of Milo; but in the contrary order: that is, he first answers the charge; and then justifies the fact, upon the supposition that the charge was true. For he proves first, that Clodius was the aggressor; and not Milo, as the contrary party had asserted; and then to give the greater advantage to his cause, he proceeds to shew, that if Milo had been the

aggressor, it would however have been a glorious action to take off such an abandoned wretch, who was not only a common enemy to mankind, but had likewise often threatened his life.

A good and just partition is attended with considerable advantages. For it gives both light and ornament to a discourse. And it is also a great relief to the hearers, who, by means of these stops and rests, are much better enabled to keep pace with the speaker without confusion, and by casting their thoughts either way, from what has been said, both know and are prepared for what is to follow. And as persons, in travelling a road with which they are acquainted, go on with greater pleasure and less fatigue, because they know how far it is to their journey's end; so to be apprised of the speaker's design, and the several parts of his discourse which he proposes to treat on, contributes very much to relieve the hearer, and keep up his attention. This must appear very evident to all who consider how difficult it is to attend long and closely to one thing, especially when we do not know how long it may be before we are like to be released. Whereas, when we are before-hand acquainted with the scheme, and the speaker proceeds regularly from one thing to another, opportunity is given to ease the mind, by relaxing the attention, and recalling it again when necessary.

#### CHAP. IV. Of Confirmation.

THE orator having acquainted his hearers, in the proposition, with the subject on which he designs to discourse, usually proceeds either to prove or illustrate what he has there laid down. For some discourses require nothing more than an enlargement or illustration, to set them in a proper light, and recommend them to the hearers; for which reason, likewise, they have often no distinct proposition. But where arguments are brought in defence of the subject, this is properly *confirmation*. For, as Cicero defines it, "confirmation is that which gives proof, authority, and support to a cause, by reasoning." And for this end, if any thing in the proposition seems obscure, or liable to be misunderstood, the orator first takes care to explain it, and then goes on to offer such arguments for the proof of it, and represent them in such a light, as may be most proper to gain the assent of his hearers.

But here it is proper to observe, that there are different ways of reasoning suited to different arts. The mathematician treats his subject after another manner than the logician, and the orator in a method different from them both. The forms of reasoning used by orators are four; *Syllogism, Enthymem, Induction, and Example*.

1. By *Syllogism*. A syllogism is a form of reasoning which consists of three propositions, the last of which is deduced from the two former. The first of these is called the *major proposition*, or, for brevity, the *major*; the second, the *minor proposition*, or *minor*; and the third, the *conclusion*. But as the last is opposed to the other two jointly, they are called the *premises*, and this the *conclusion*. So we may reduce Cicero's argument, by which he endeavours to prove, that Clodius assaulted Milo, and not Milo Clodius, to a syllogism in this manner:

*He was the aggressor, whose advantage it was to kill the other.*

*But it was the advantage of Clodius to kill Milo, and not Milo's to kill him.*

*Therefore Clodius was the aggressor, or he assaulted Milo.*

The thing to be proved was, that Clodius assaulted Milo, which therefore comes in the conclusion: and the argument, by which it is proved, is taken from the head of profit or advantage. Thus the logician would treat this argument; and if either of the premises was questioned, he would support it with another syllogism. But this short and dry way of reasoning does not at all suit the orator: who not only for variety changes the order of the parts, beginning sometimes with the minor, and at other times with the conclusion, and ending with the major; but likewise clothes each part with such ornaments of expression, as are proper to enliven the subject, and render it more agreeable and entertaining. And he frequently subjoins, either to the major proposition, or minor, and sometimes to both, one or more arguments to support them; and perhaps others to confirm or illustrate them, as he thinks it requisite. Therefore, as a logical syllogism consists of three parts or propositions, a rhetorical syllogism frequently contains four, and many times five parts. And Cicero reckons this last the most complete. But all that is said in confirmation of either of the premises, is accounted but as one part. This will appear more evident by examples. By a short syllogism Cicero thus proves, that the Carthaginians were not to be trusted: "Those who have often deceived us, by violating their engagements, ought not to be trusted. For if we receive any damage by their treachery, we can blame no body but ourselves. But the Carthaginians have often so deceived us. Therefore it is madness to trust them." Here the major proposition is supported by a reason. The minor needed none; because the treachery of the Carthaginians was well known. So that this syllogism consists of four parts. But by a syllogism of five parts he proves somewhat more largely and elegantly, that the world is under the direction of a wise governor. The major is this: "Those things are better governed which are under the direction of wisdom, than those which are not." This he proves by several instances: "A house managed with prudence has every thing in better order, and more convenient, than that which is under no regulation. An army commanded by a wise and skillful general, is in all respects better governed, than one which has a fool or a madman at the head of it. And the like is to be said of a ship, which performs her course best under the direction of a skillful pilot." Then he proceeds to the minor thus: "But nothing is better governed than the universe." Which he proves in this manner: "The rising and setting of the heavenly bodies keep a certain determined order; and the several seasons of the year do not only necessarily return in the same manner, but are suited to the advantage of the whole; nor did the vicissitudes of night and day ever yet become prejudicial, by altering their course." From all which he concludes, "That the world must be under the direction of a wise governor." In both these examples, the regular order of the parts is observed. We shall

therefore produce another, in which the order is directly contrary; for beginning with the conclusion, he proceeds next to the minor proposition, and so ends with the major. In his defence of Cælius, his design is to prove that Cælius had not led a loose and vicious life, with which his enemies had charged him. And this he does, by shewing he had closely followed his studies, and was a good orator. This may probably at first sight appear but a weak argument; though to him who considers, what Cicero every where declares necessary to gain that character, it may perhaps be thought otherwise. The sense of what he says here may be reduced to this syllogism.

*Those who have pursued the study of oratory, so as to excel in it, cannot have led a loose and vicious life.*

*But Cælius has done this.*

*Therefore his enemies charge him wrongfully.*

But let us hear Cicero himself. He begins with the conclusion, thus: "Cælius is not chargeable with profuseness, extravagancy, contracting of debts, or intemperance, a vice which age is so far from abating, that it rather increases it. Nay, he never engaged in amours, and those pleasures of youth, as they are called, which are soon thrown off, as reason prevails." Then he proceeds to the minor, and shews from the effects, that Cælius had closely applied himself to the best arts, by which he means those necessary for an orator: "You have now heard him make his own defence, and you formerly heard him engaged in a prosecution (I speak this to vindicate, not to applaud him), you could not but perceive his manner of speaking, his ability, his good sense, and command of language. Nor did he only discover a good genius, which will oftentimes do much of itself when it is not improved by industry; but what he said (if my affection for him did not bias my judgment) appeared to be the effect of learning, application, and study." And then he comes to the major: "But be assured, that those vices charged upon Cælius, and the studies upon which I am now discoursing, cannot meet in the same person. For it is not possible that a mind, disturbed by such irregular passions, should be able to go through what we orators do, I do not mean only in speaking, but even in thinking." And this he proves by an argument taken from the scarcity of good orators. "Can any other reason be imagined, why so few, both now, and at all times, have engaged in this province, when the rewards of eloquence are so magnificent, and it is attended with so great delight, applause, glory, and honour? All pleasures must be neglected; diversions, recreations, and entertainments omitted; and even the conversation of all our friends must in a manner be laid aside. This it is which detests persons from the labour and study of oratory; not their want of genius, or education."

II. By *Enthymem*. But orators do not often use complete syllogisms, but most commonly enthymems. An *enthymem* is an imperfect syllogism, consisting of two parts; the conclusion, and one of the premises. And in this kind of syllogism, that proposition is omitted, whether it be the major or minor, which is sufficiently manifest of itself, and may easily be supplied by the hearers. But the proposition that is expressed, is usually called the *antecedent*, and the

Disposition conclusion the consequent. So if the major of that syllogism be omitted, by which Cicero endeavours to prove that Clodius assaulted Milo, it will make this enthymem:

*The death of Milo would have been an advantage to Clodius.*

*Therefore Clodius was the aggressor; or, therefore he assaulted Milo.*

In like manner that other syllogism above-mentioned, by which he shews that the Carthaginians ought not to be trusted, by omitting the minor, may be reduced to the following enthymem:

*Those who have often broke their faith, ought not to be trusted.*

*For which reason the Carthaginians ought not to be trusted.*

Every one would readily supply the minor, since the perfidiousness of the Carthaginians was known to a proverb. But it is reckoned a beauty in enthymems, when they consist of contrary parts: because the turn of them is most acute and pungent. Such is that of Micipia in Sallust: "What stranger will be faithful to you, who are an enemy to your friends?" And so likewise that of Cicero for Milo, speaking of Clodius: "You sit as avengers of his death; whose life you would not restore, did you think it in your power." Orators manage enthymems in the same manner they do syllogisms; that is, they invert the order of the parts, and confirm the proposition by one or more reasons: and therefore a rhetorical enthymem frequently consists of three parts, as a syllogism does of five. Though strictly speaking, a syllogism can consist of no more than three parts, and an enthymem but of two: and the arguments brought to support either of the propositions constitute for many new enthymems, of which the part they are designed to prove is the conclusion. To illustrate this by an example:

*An honest man thinks himself under the highest obligation to his country.*

*Therefore he should shun no danger to serve it.*

In this enthymem the major is wanting, which would run thus: "He who is under the highest obligations to another, should shun no danger in order to serve him." This last proposition is founded upon the common principle of gratitude; which requires, that, to the utmost of our power, a return should be made in proportion to the kindness received. And this being a maxim generally allowed, it is omitted by the orator. But now this enthymem, consisting of the minor and conclusion, might be managed in some such manner as this, beginning with the conclusion: "An honest man ought to shun no danger, but readily expose his life for the safety and preservation of his country." Then the reason of this conduct might be added, which is the antecedent of the enthymem, or minor of the syllogism: "For he is sensible, that his obligations to his country are so many, and so great, that he can never fully requite them." And this again might be confirmed by an enumeration of particulars: "He looks upon himself as indebted to his country for every thing he enjoys; for his friends, relations, all the pleasures of life, and even for life itself." Now the orator calls this *one enthymem*, though in reality there are two: For the second reason, or argument,

added to the first, becomes the antecedent of a new enthymem, of which the first reason is the consequent. And if these two enthymems were expressed separately in the natural order of the parts, the former would stand thus: "An honest man thinks himself under the highest obligations to his country: therefore he ought to shun no danger for its preservation." The latter thus: "An honest man esteems himself indebted to his country for every thing he enjoys; therefore he thinks he is under the highest obligations to it." The same thing might be proved in the like way of reasoning, by arguments of a different kind. From comparison, thus: "As it would be thought base and ungrateful in a son not to hazard himself for the preservation of his father; an honest man must certainly esteem it so when his country is in danger." Or from an example, in this manner: "An honest man in like circumstances would propose to himself the example of Decius, who freely gave up his life for the service of his country. He gave up his life indeed, but did not lose it; for he cannot be said to have lost his life, who lives in immortal honour." And orators frequently intermix such arguments to adorn and illustrate their subject, with others taken from the nature and circumstances of things. And now, if we consider a little this method of reasoning, we shall find it the most plain and easy imaginable. For when any proposition is laid down, and one or more reasons subjoined to prove it, each reason joined with the proposition makes a distinct enthymem, of which the proposition is the conclusion. Thus Cicero, in his seventh Philippic, lays down this as the foundation of his discourse, "That he is against a peace with Mark Antony," for which he gives three reasons: "Because it is base, because it is dangerous, and because it is impracticable." These severally joined with the proposition, form three enthymems; and upon each of these he discourses separately, which make up that oration. And this method is what persons for the most part naturally fall into, who know nothing of the terms *syllogism* or *enthymem*. They advance something, and think of a reason to prove it, and another perhaps to support that; and, so far as their invention will assist them, or they are masters of language, they endeavour to set what they say in the plainest light, give it the best dress, embellish it with proper figures and different turns of expression; and, as they think convenient, illustrate it with similitudes, comparisons, and the like ornaments, to render it most agreeable, till they think what they have advanced sufficiently proved. As this method of arguing therefore is the most plain, easy, and natural; so it is what is most commonly used in oratory. Whereas a strict syllogistical way of discoursing is dry and jejune, cramps the mind, and does not admit of those embellishments of language which are a great advantage to the orator: for which reason he seldom uses complete syllogisms; and when he does, it is with great latitude. —However, syllogistical reasoning is very useful, though not in popular discourses: for every argument may be reduced to a syllogism; and if it will not hold in that form, there is certainly some flaw in it, which by that means will most easily be discovered.

III. By *induction*: That is, when one thing is inferred

ferred from several others, by reason of the similitude between them. And this way of reasoning is often very useful in popular discourses. For many persons are sooner moved by examples and similitudes, than by arguments taken from the nature of things. Every one either endeavours to think right, or at least would be esteemed so to do. But it is often no easy matter to take in the force of an argument, especially for those who have not been accustomed to examine things closely, and weigh them duly in their minds. And therefore, when this cannot be done without some pain and uneasiness to the mind, till it become habitual by practice, it is not to be wondered at if such persons are best pleased with that way of reasoning by which they imagine they can form a judgment of things with the greatest ease and facility. But though inductions are made from all kinds of similitudes, yet those usually carry the greatest force with them which are drawn from like facts. Such is that of Cicero in his oration for the Manilian law: for when some persons objected to Pompey's being entrusted with the Mithridatic war, as a thing not customary to put such an accession of power into the hands of one man; Cicero removes that objection, by producing several instances of the like nature, and particularly shews that more new honours had already been conferred on Pompey than upon any other Roman citizen before him, which had all been employed to the advantage of the state. "I will not (says he) take notice that two very great wars, the Punic and the Carthaginian, were both managed by one general; and two very powerful cities, which threatened this empire most, Carthage and Numantia, both destroyed by the same Scipio. I will not observe, that both you and your fathers thought fit to place the safety of the government alone in Caius Marius; and that the same person should carry on the war with Jugurtha, with the Cimbrians, and with the Teutones. You remember how many new powers have already been conferred on Pompey;" which he then proceeds to enumerate, and from thence infers, that the objection of novelty was no just reason against his being entrusted with the conduct of that important war. And as to other similitudes, it may thus be shewn by induction, that virtuous habits are gained and improved by practice. Bodily strength is increased and confirmed by daily exercise: All manual arts are acquired by repeated trials and experiments: The liberal sciences are also attained by constant study and application: And in like manner the mind is formed to virtue, and improved in it, by the continued practice of right actions.

But there is one particular form of induction called *Socratic*, because Socrates very frequently used that way of reasoning. It proceeds by several questions, which being separately granted, the thing designed to be inferred is afterwards put, which, by reason of its similitude with the several cases allowed before, cannot be denied. But this is a captious way of reasoning; for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued discourses, as to those which are interlocutory; and therefore we meet with it oftentimes in the Socratic dialogues.

both of Plato and Xenophon. However, it may be made use of in oratory by a figure called *subjection*, when the same person first puts the question, and then makes the answer. So in the famous cause of Epaminondas, general of the Thebans, who was accused for refusing to surrender his command to his successor appointed by the state, till after he had engaged the enemy, and given them a total defeat, Cicero thus represents his accuser pleading for the words of the law against Epaminondas, who alleged the intention of it in his defence: "Should Epaminondas add that exception to the law, which, he says, was the intention of the writer, namely, *Except any one refuse to give up his command when it is for the interest of the public he should not*; would you admit of it? I believe not. Should you yourselves, which is a thing most remote from your justice and wisdom, in order to screen him, order this exception to be added to the law, without the command of the people; would the Thebans suffer it to be done? No certainly. Can it be right then to come into that, as if it was written, which it would be a crime to write? I know it cannot be agreeable to your wisdom to think so."

IV. By *Example*. Rhetoricians use this word in a different sense from the common acceptation. For that is usually called an *example*, which is brought either to prove or illustrate some general assertion: As if any one should say, that *human bodies may be brought to sustain the greatest labours by use and exercise*; and in order to prove this should relate what is said of Milo of Croton, that "by the constant practice or carrying a calf several furlongs every day, he could carry it as far after it was to its full size." But in oratory the word *example* is used for any kind of similitude; or, as Vossius defines it, "When one thing is inferred from another, by reason of the likeness which appears between them." Hence it is called an *imperfect induction*, which infers something from several others of a like nature. But, as was observed before, in speaking of induction, so likewise in examples, those have the greatest force in reasoning, which are taken from facts. Now facts may be compared with respect to some agreement or similitude between them, which in themselves are either equal or unequal. Of the former kind this is an instance: "Cato acted as became a patriot and a lover of his country's liberty, in opposing the arms of Cæsar: and therefore so did Cicero." The reason of the inference is founded in the parity of the case, which equally concerned all good subjects of the Roman government at that time. For all were alike obliged to oppose a common enemy, who endeavoured to subvert the constitution, and subjected them to his own arbitrary power. But though an example consists in the comparison of two single facts, yet several persons may be concerned in each fact. Of this kind is that which follows: "As Pompey, Cæsar, and Crassus, acted illegally in the first triumvirate, by engrossing the sole power into their own hands, and by that means violating the public liberty; so likewise did Augustus, Mark Anthony, and Lepidus, in the second triumvirate, by pursuing the same measures." But when Cicero defends Milo for killing Clodius, from the like instances of Ahala Servilius, Scipio Nafica, Lucius Opimius, and others; that is not an example, but an induction: because one

Disposition

Disposition

thing is there inferred from its similitude to several others. But when a comparison is made between two facts that are unequal, the inference may be either from the greater to the less, or from the less to the greater. From the greater to the less in this manner: "Cæsar had no just pretensions to the Roman government, and therefore much less had Anthony." The reason lies in the difference between the two persons. Cæsar had very much enlarged the bounds of the Roman empire by his conquests, and greatly obliged the populace by his generosity; but as he had always acted by an authority from the senate and people of Rome, these things gave him no claim to a power over them. Much less then had Anthony any such pretence, who always acted under Cæsar, and had never performed any signal services himself. Cicero has described the difference between them in a very beautiful manner in his second Philippic, thus speaking to Anthony: "Are you in any thing to be compared to him? He had a genius, sagacity, memory, learning, care, thought, diligence; he had performed great things in war, though detrimental to the state; he had for many years designed to get the government into his hands, and obtained his end by much labour and many dangers; he gained over the ignorant multitude by public shows, buildings, congiaries, and feasts; obliged his friends by rewards, and his enemies by a shew of clemency. In a word, he subjected a free state to slavery, partly through fear, and partly compliance. I can liken you to him for ambition of power; but in other things you are in no respect to be compared with him." By a comparison from the less to the greater, Cicero thus argues against Catiline: "Did the brave Scipio, when a private man, kill Tiberius Gracchus, for attempting to weaken the state; and shall we consuls bear with Catiline endeavouring to destroy the world by fire and sword?" The circumstances of these two cases were very different; and the comparison runs between a private man, and a consul intrusted with the highest authority; between a design only to raise a tumult, and a plot to destroy the government: whence the orator justly infers, that what was esteemed lawful in one case, was much more so in the other. The like way of reasoning is sometimes used from other similitudes, which may be taken from things of all kinds, whether animate or inanimate. Of the former sort is that of Cicero speaking of Muræna, when candidate for the consulship, after he had himself gone through that office: "If it is usual (says he) for such persons as are safely arrived in port, to give those who are going out the best account they can with relation to the weather, pirates, and coasts; because thus nature directs us to assist those who are entering upon the same dangers which we ourselves have escaped: how ought I, who now after a great storm am brought within a near prospect of land, to be affected towards him, who, I perceive, must be exposed to the greatest tempests of the state?" He alludes to the late disturbances and tumults occasioned by the conspiracy of Catiline, which had been so happily suppressed by him in the time of his consulship. Of the latter kind is that of Quintilian: "As the ground is made better and more fruitful by culture, so is the mind by instruction." There is both a beauty and justness in this simile.

But comparisons are sometimes made between facts and other things, in order to infer some difference or opposition between them. In comparing two facts, on account of some disagreement and unlikeness, the inference is made from the difference between one and the other in that particular respect only. As thus: "Though it was not esteemed cruelty in Brutus to put his two sons to death, for endeavouring to betray their country; it might be so in Manlius, who put his son to death, only for engaging the enemy without orders, though he gained the victory." The difference between the two facts, lies in the different nature of the crime. The sons of Brutus entered into a conspiracy to betray their country; and though they miscarried in it, yet the intention and endeavours they used to accomplish it were criminal in the highest degree. But young Manlius could only be charged with rashness. His design was honourable, and intended for the interest of his country; only it was irregular, and might have proved of ill consequence to military discipline. Now in all such cases, the force of the argument is the stronger, the greater the difference appears. But the same facts which differ in one respect, may agree in many others; as in the example here mentioned. Brutus and Manlius were both magistrates as well as fathers; they both killed their sons, and that for a capital crime by the Roman law. In any of which respects they may be compared in a way of similitude: as, "If Brutus might lawfully put his son to death for a capital crime, so might Manlius." But now contrary facts do not only differ in some certain respect, but are wholly opposite to each other; so that what is affirmed of the one, must be denied of the other; and if one be a virtue, the other is a vice. Thus Cicero compares the conduct of Marcellus and Verres in a way of opposition. "Marcellus (says he), who had engaged, if he took Syracuse, to erect two temples at Rome, would not beautify them with the spoils he had taken: Verres, who had made no vows to Honour and Virtue, but to Venus and Cupid, endeavoured to plunder the temple of Minerva. The former would not adorn the gods with the spoils of other deities: the latter carried the ornaments of Minerva, a virgin, into the house of a strumpet." If therefore the conduct of Marcellus was laudable and virtuous, that of Verres must bear the contrary character. But this way of reasoning has likewise place in other respects. Thus Cicero, in the quarrel between Cæsar and Pompey, advised to peace from the difference between a foreign and domestic war: "That the former might prove beneficial to the state; but in the latter, whichever side conquered, the public must suffer." And thus the ill effects of intemperance may be shewn in a way of opposition: "That as temperance preserves the health of the body, keeps up the vigour of the mind, and prolongs life; so excess must necessarily have the contrary effects."

Thus we have given a brief account of the principal ways of reasoning commonly made use of by orators. As to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle: And such as are stronger, partly in the beginning, to gain the esteem of the hearers and render them more attentive; and partly at the end, because what is last heard is likely

to

Disposition to be retained longest: But if there are but two arguments, to place the stronger first, and then the weaker; and after that to return again to the former, and insist principally upon that. But this must be left to the prudence of the speaker, and the nature of the subject. Though to begin with the strongest, and so gradually descend to the weakest, can never be proper, for the reason last mentioned. Nor ought arguments to be crowded too close upon one another; for that takes off from their force, as it breaks in upon the attention of the hearers, and does not leave them sufficient time duly to consider them. Nor indeed should more be used than are necessary; because the fewer they are, the more easily they are remembered. And the observation of a great master of eloquence upon this subject is certainly very just, that *arguments ought rather to be weighed than numbered.*

#### CHAP. V. Of Confutation.

34 THE forms of reasoning here are the same as have been already explained under *confirmation*. *Confutation*, however, is often the more difficult task: because he who is to prove a thing, comes usually prepared; but he who is to confute it, is frequently left to a sudden answer. For which reason, in *judicial* cases, Quintilian says, "It is as much easier to accuse than defend, as it is to make a wound than to heal it." Therefore, not only a good judgment, but a readiness of thought also, seems necessary for this province. But, in all disputes, it is of the greatest consequence to observe where the stress of the controversy lies. For without attending to this, persons may cavil about different matters without understanding each other, or deciding any thing. And in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. As to the things themselves; whether they immediately relate to the matter in dispute, or are foreign to it. Those things that are foreign to the subject, may either be pass over in silence, or in a very few words shewn to be insignificant. And there ought likewise to be a distinction made between such things as relate to the subject, according to their importance. Those that appear to have no great weight, should be slightly remarked. For to insist largely upon such matters is both tiresome to the hearers, and apt to bring the judgment of the speaker into question. And therefore things of that nature are generally better turned off with an air of neglect, a pungent question, or an agreeable jest, than confuted by a serious and laboured answer. 2. But those things, which relate to the merits of the cause, may be confuted either by *contradicting* them, or by shewing some *mistake* in the reasoning, or their *invalidity* when granted.

Things may be *contradicted* several ways. What is apparently false may be expressly denied. Thus Cicero in his defence of Cluentius: "When the accuser had said, that the man fell down dead after he had drunk off his cup, denies that he died that day." And things which the adversary cannot prove, may likewise be denied. Of which we have also an instance in Cicero, who first upbraids Mark Anthony as guilty of a breach not only of good breeding, but likewise of friendship, for reading publicly a private letter he had sent him. And then adds: "But what will you say now,

if I should deny that ever I sent you that letter? How will you prove it? By the hand-writing? In which I confess you have a peculiar skill, and have found the benefit of it. But how can you make it out? For it is in my secretary's hand. I cannot but envy your master, who had so great a reward for teaching you to understand just nothing. For what can be more unbecoming not only an orator, but even a man, than for any one to offer such things, which if the adversary denies, he has nothing more to say?" It is an handsome way of contradicting a thing, by shewing, that the adversary himself maintained the contrary. So when Oppius was charged with defrauding the soldiers of their provisions, Cicero refutes it, by proving, that the same persons charged Oppius with a design to corrupt the army by his liberality. An adversary is never more effectually silenced than when you can fatten contradictions upon him; for this is stabbing him with his own weapon. Sometimes a thing is not in express terms denied, but represented to be utterly incredible. And this method exposes the adversary more than a bare denial. So when some persons reproached Cicero with cowardice, and a shameful fear of death; he recites their reasons in such a manner, that any one would be inclined to think the charge entirely false. "Was it becoming me (says he) to expect death with that composedness of mind as some have imagined? Well, and did I then avoid it? Nay, was there any thing in the world that I could apprehend more desirable: Or when I had done the greatest things in such a crowd of ill-minded persons about me, do you think banishment and death were not always in my view, and continually sounding in my ears as my certain fate, while I was so employed? Was life desirable, when all my friends were in such sorrow, and myself in so great distress, deprived of all the gifts both of nature and fortune? Was I so unexperienced, so ignorant, so void of reason and prudence? Had I never seen nor heard any thing in my whole life? Did all I had read and studied avail nothing? What! did not I know that life is short, but the glory of generous actions permanent? When death is appointed for all, does it not seem eligible, that life, which must be wrested from us, should rather be freely devoted to the service of our country, than reserved to be worn out by the decays of nature? Was not I sensible, there has been this controversy among the wisest men, that some say, the minds of men and their consciousness utterly perish at death; and others, that the minds of wise and brave men are then in their greatest strength and vigour, when they are set free from the body? The first state is not greatly to be dreaded, to be void of sense; but the other, of enjoying larger capacities, is greatly to be desired. Therefore, since I always aimed at dignity, and thought nothing was worth living for without it; how should I, who am past the consulship, and did so great things in it, be afraid to die?" Thus far Cicero. There is likewise an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverse party. Thus Cicero, in his oration against Vatinius, says: "You have objected to me, that I defended Cornelius, my old friend, and your acquaintance. But pray why should I not have defended him? Has Cornelius carried any law contrary to the omens? Has he violated any

any law? Has he assaulted the consul? Did he take possession of a temple by force of arms? Did he drive away the tribune, who opposed the passing a law? Has he thrown contempt upon religion? Has he plundered the treasury? Has he pillaged the state? No, these, all these, are your doings?" Such an unexpected return is sometimes of great service to abate the confidence of an adversary.

A second way of confutation is, by observing some *flaw* in the reasoning of the adverse party. We shall endeavour to illustrate this from the several kinds of reasoning treated of before under *confirmation*. And first, as to syllogisms; they may be refuted, either by shewing some mistake in the premises, or that the conclusion is not justly deduced from them. So when the Clodian party contended, that Milo ought to suffer death for this reason, Because he had confessed that he had killed Clodius; that argument, reduced to a syllogism, would stand thus:

*He who confesses he has killed another, ought not to be allowed to see the light.*

*But Milo confesses this.*

*Therefore he ought not to live.*

Now the force of this argument lies in the major or first proposition; which Cicero refutes, by proving, that the Roman people had already determined contrary to what is there asserted: "In what city (says he) do these men dispute after this weak manner? In that wherein the first capital trial was in the case of the brave Horatius, who, before the city enjoyed perfect freedom, was saved by the sufragances of the Roman people, though he confessed that he killed his sister with his own hand." But when Cicero accused Verres for mal-administration in his government of Sicily, Hortensius, who defended him, being sensible the allegations brought against him could not be denied, had no other way left to bring him off, but by pleading his military virtues in abatement, which at that time were much wanted, and very serviceable to the state. The form of the argument was this:

*That the Romans then wanted good generals.*

*That Verres was such.*

*And consequently, that it was for the interest of the public that he should not be condemned.*

But Cicero, who knew his design, states the argument for him in his charge; and then answers it by denying the consequence, since the crimes of Verres were of so heinous a nature, that he ought by no means to be pardoned on the account of any other qualifications: Though indeed he afterwards refutes the minor or second proposition, and shews that he had not merited the character of a good general. Enthymems may be refuted, either by shewing that the antecedent is false, or the consequent not justly inferred from it. As thus, with respect to the former case:

*A strict adherence to virtue has often proved detrimental.*

*Therefore virtue ought not constantly to be embraced.*

Here the antecedent may be denied. For virtue is always beneficial to those who strictly adhere to it, both in the present satisfaction it affords them, and the future rewards they may certainly expect from it. And as to the latter case, in this manner:

*She is a mother.*

*Therefore she loves her children.*

Now as the certainty of that inference depends upon this general assertion, That all mothers love their children, which is not true, the mistake of the reasoning may be shewn from the instance of Medea and others, who destroyed their own children. As to *induction* and *example*, by which the truth or equity of a thing is proved from its likeness to one or more other things; the reasoning in either is invalid, if the things so compared can be shewn not to have that similitude or agreement on which the inference is founded. One instance therefore may serve for both. As when Cicero, after the death of Cæsar, pleaded for the continuance of his laws, but not of those which were made afterwards by Mark Anthony: Because, though both were in themselves invalid, and impositions upon the public liberty; yet some of Cæsar's were useful, and others could not be set aside without disturbance to the state, and injuring particular persons; but those of Anthony were all detrimental to the public.

The last method of *confutation* before-mentioned was, when the orator does in some sense *grant* the adversary his argument, and at the same time shews its *invalidity*. And this is done by a variety of ways, according to the different nature of the subject. Sometimes he allows what was said may be true; but pleads, that what he contends for is necessary. This was the method by which Hortensius proposed to bring off Verres, as we have already shewn from Cicero, whose words are these, addressing himself to the judges: "What shall I do? which way shall I bring in my accusation? where shall I turn myself? for the character of a brave general is placed like a wall against all the attacks I can make. I know the place, I perceive where Hortensius intends to display himself. He will recount the hazards of war, the necessities of the state, the scarcity of commanders; and then he will intreat you, and do his utmost to persuade you, not to suffer the Roman people to be deprived of such a commander upon the testimony of the Sicilians, nor the glory of his arms to be sullied by a charge of avarice." At other times the orator pleads, that altho' the contrary opinion may seem to be attended with advantage, yet that his own is more just or honourable. Such was the case of Regulus, when his friends endeavoured to prevail with him to continue at Rome, and not return to Carthage, where he knew he must undergo a cruel death. But as this could not be done without violating his oath, he refused to hearken to their persuasions. Another way of confutation is, by retorting upon the adversary his own argument. Thus Cicero, in his defence of Ligarius, says: "You have, Tubero, that which is most desirable to an accuser, the confession of the accused party; but yet such a confession, that he was on the same side that you, Tubero, chose yourself, and your father too, a man worthy of the highest praise. Wherefore, if there was any crime in this, you ought first to confess your own before you attempt to fasten any upon Ligarius." The orator takes this advantage where an argument proves too much, that is, more than the person designed it for, who made use of it. Not much unlike this is what they call *inversion*, by which the orator shews, that the reasons offered by the opposite party make for him. So when Cæcilius urged, that the province of

*Disposition* accusing Verres ought to be granted to him, and not to Cicero, because he had been his treasurer in Sicily at the time those crimes were committed with which he was charged, and consequently knew most of that affair; Cicero turns the argument upon him, and shews, for that very reason he was the most unfit of any man to be intrusted with his prosecution; since having been concerned with him in his crimes, he would certainly do all in his power to conceal or lessen them. Again, sometimes the charge is acknowledged, but the crime shifted off to another. Thus, when Sextus was accused of sedition, because he had got together a body of gladiators, and brought them into the forum, where a warm engagement happened between them and Clodius's faction; Cicero owns the fact, but charges the crime of sedition upon Clodius's party in being the aggressors. Another method made use of for the same purpose is, to alleviate the charge, and take off the force of it, by shewing, that the thing was not done with that intention which the adversary insinuates. Thus Cicero, in his defence of king Dejotarus, owns he had raised some forces, though not to invade the Roman territories, as had been alleged, but only to defend his own borders, and send aid to the Roman generals.

We have hitherto been speaking of the methods of confutation used by orators, in answering those arguments which are brought by the contrary party. But sometimes they raise such objections themselves to what they have said, as they imagine may be made by others; which they afterwards answer, the better to induce their hearers to think, that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. Thus, when Cicero, at the request of the Sicilians, had undertaken the accusation of Verres, it came under debate, whether he, or Cæcilius, who had been Verres's quaestor in Sicily, should be admitted to that province. Cicero, therefore, in order to fet him aside, among other arguments, shews his incapacity for such an undertaking, and for that end recounts at large the qualifications necessary for an orator. Which he represents to be so many and great, that he thought it necessary to start the following objection to what he had himself said upon that subject. "But you will say perhaps, Have you all these qualifications?" To which he thus replies: "I wish I had; but it has been my constant study from my youth to gain them. And if, from their greatness and difficulty, I have not been able to attain them, who have done nothing else through my whole life; how far, do you imagine, you must be from it, who never thought of them before; and even now, when you are entering upon them, have no apprehension, what, and how great, they are?" This is an effectual way of defeating an adversary, when the objection is well founded, and clearly answered. But we shall have occasion to consider this matter more largely hereafter, under the figure *prolepsis*, to which it properly relates.

#### CHAP. VI. Of the Conclusion.

RHETORICIANS make this conclusion of a discourse to consist of two parts; recapitulation; and an address to the passion.

1. *Recapitulation* is a summary account of what the

speaker has before offered in maintenance of his subject; and is designed both to refresh the memory of the hearers, and to bring the principal arguments together into a narrow compass, that they may appear in a stronger light. Now there are several things necessary to a good repetition.

And first, it must be short and concise; since it is designed to refresh the memory, and not to burden it. For this end, therefore, the chief things only are to be touched upon; those on which the cause principally depends, and which the orator is most desirous should be regarded by his hearers. Now these are, The general heads of the discourse, with the main arguments brought to support them. But either to insist particularly upon every minute circumstance, or to enlarge upon those heads which it may be thought proper to mention, carries in it not so much the appearance of a repetition, as of a new discourse.

Again, it is convenient in a repetition to recite things in the same order in which they were at first laid down. By this means the hearers will be enabled much better to keep pace with the speaker as he goes along; and if they happen to have forgot any thing, they will the more readily readily recal it. And besides, this method appears most simple and open, when the speaker reviews what he has said in the same manner it was before delivered, and sets it in the clearest light for others to judge of it. But though a repetition contains only the same things which had been more largely treated of before; yet it is not necessary they should be expressed in the same words. Nay, this would many times be tiresome and unpleasant to the hearers; whereas a variety of expression is grateful, provided the sense be the same. Besides, every thing ought now to be represented in the strongest terms, and in so lively manner, as may at the same time both entertain the audience, and make the deepest impression upon their minds. We have a very exact and accurate example of repetition in Cicero's oration for Quintius. Cicero was then a young man, and seems to have kept more closely to the rules of art, than afterwards, when by use and practice he had gained a greater freedom of speaking. We formerly cited the partition of this speech, upon another occasion, which runs thus: "We deny, Sextus Nevius, that you was pnt into the possession of the estate of P. Quintius, by the prætor's edict. This is the dispute between us. I will therefore show, first, that you had no just cause to apply to the prætor for possession of the estate of P. Quintius; then, that you could not possess it by the edict; and lastly, that you did not possess it. When I have proved these three things, I will conclude. Now Cicero begins his conclusion with a repetition of those three heads, and a summary account of the several arguments he made use of under each of them. But they are too long to be here exhibited. In his oration for the Manilian law, his repetition is very short. He proposed in the partition to speak to three things: The nature of the war against king Mithridates, the greatness of it, and what sort of general was proper to be intrusted with it. And when he has gone thro' each of these heads, and treated upon them very largely, he reduces the substance of what he has said to this general and short account: "Since therefore the war is so necessary, that it cannot be neglected; and so great,

Disposition

great, that it requires a very careful management; and you can intrust it with a general of admirable skill in military affairs, of singular courage, the greatest authority, and eminent success: do you doubt to make use of this so great a blessing, conferred and bestowed upon you by heaven, for the preservation and enlargement of the Roman state?" Indeed this repetition is made by Cicero, before he proceeds to the confutation; and not at the end of his discourse, where it is usually longer and more particular: however, this may serve to shew the nature of such a recital.

But sometimes a repetition is made, by running a comparison between the speaker's own arguments, and those of the adverse party; and placing them in opposition to each other. And this method Cicero takes in the conclusion of his third oration upon the Agrarian law. And here sometimes the orator takes occasion to find fault with his adversary's management, in these and such like expressions: "This part he has entirely dropt. To that he has given an invidious turn, or a false colouring. He leaves arguments, and flies to intreaties; and not without good reason, if we consider the weakness of his cause."

But when the discourse is very long, and the arguments insisted on have been many, to prevent the hearers growing out of patience by a more particular recital, the orator sometimes only just mentions such things, which he thinks of least consequence, by saying, that he omits or passes over them, till he comes to what is of greater moment, which he represents more fully. This method Cicero has taken in his defence of Cluentius; where, having run over several lesser heads in the manner now described, he then alters his expression, and introduces what was of more importance, by saying: "What I first complain of, is that wickedness, which is now discovered." And so he proceeds more particularly to recite those things which immediately related to Cluentius. And this is what the writers upon this art call *preterition*. But thus much may serve for repetition or recapitulation.

2. We now proceed to the other part of the conclusion, which consists in an *address to the passions*. Indeed the orator sometimes endeavours occasionally to work upon the passions of his hearers in other parts of his discourse, but more especially in the conclusion, where he is warmest himself, and labours to make them so. For the main design of the introduction is to conciliate the hearers, and gain their attention; of the narration, proposition, and confirmation, to inform them; and of the conclusion, to move them. And therefore, to use Quintilian's words, "Here all the springs of eloquence are to be opened. It is here we secure the minds of the hearers, if what went before was well managed. Now we are pelt the rocks and shallows, all the fails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here." Now the passions, to which the orator more particularly addresses, differ according to the nature of the discourse. In demonstrative orations, when laudatory,—love, admiration, and emulation, are usually excited; but in invectives,—hated, envy, and contempt. In deliberative subjects, either the hope of gratifying some desire is set in view, or the fear of some impending evil. And in judicial dis-

courses, almost all the passions have place, but more especially resentment and pity; inasmuch that most of the ancient rhetoricians mention only these two. But having treated upon the nature of the passions, and the methods suited both to excite and allay them, in a former chapter, we shall at present only add a few general observations, which may not be improper in this place, where the skill of the orator in addressing to them is more especially required.

The orator will observe what circumstances either of things, or persons, or both, will furnish him with motives proper to apply to those passions he desires to excite in the minds of his hearers. Thus Cicero, in his orations for Plancus and Sylla, moves his hearers from the circumstances of the men; but in his accusation of Verres, very frequently from the barbarity and horrid nature of his crimes; and from both, in his defence of Quintus.

But the same passion may be excited by very different methods. This is plain from the writings of those Roman satyrists which are yet extant; for they have all the same design, and that is to engage men to a love of virtue, and hatred of vice: but their manner is very different, suited to the genius of each writer. Horace endeavours to recommend virtue, by laughing vice out of countenance; Persius moves us to an abhorrence and detestation of vice, with the gravity and severity of a philosopher; and Juvenal, by open and vehement invectives. So orators make use of all these methods in exciting the passions; as may be seen by their discourses, and particularly those of Cicero. But it is not convenient to dwell long upon the same passion. For the image thus wrought up in the minds of the hearers, does not last a great while, but they soon return to reflection. When the emotion therefore is once carried as high as it well can be, they should be left under its influence, and the speaker proceed to some new matter, before it declines again.

Moreover, orators sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator express the same passion himself with which he endeavours to affect others; and that not only in his action and voice, but likewise in his language: and and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind which he designs to represent. However, a decency and propriety of character is always carefully to be observed; for, as Cicero very well remarks, "A neglect of this is not only very culpable in life, but likewise in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who, designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Calchas the priest with a sad countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate; but

Disposition

Disposition

but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his defence of Milo; for as Milo was always known to be a man of the greatest resolution, and most undaunted courage, it was very improper to introduce him (as the usual method then was in capital cases) moving pity, and begging for mercy. Cicero therefore takes this part upon himself; and what he could not do with any propriety in the person of Milo, he performs in his own, and thus addresses the judges: "What remains, but that I intreat and beseech you, that you would shew that compassion to this brave man, for which he himself does not solicit, but I, against his inclination, earnestly implore and request. Do not be less inclined to acquit him, if in this our common sorrow you see no tear fall from Milo's eyes; but perceive in him the same countenance, voice, and language, as at other times, steady and unmoved. Nay, I know not whether for this reason you ought not much sooner to favour him: For if, in the contests of gladiators, (persons of the lowest condition and fortune in life), we are wont to be displeased with the timorous and suppliant, and those who beg for their life; but interpose in favour of the brave and courageous, and such as expose themselves to death; and we shew more compassion to those who do not sue for it, than to those who do: with how much greater reason ought we to act in the same manner towards the bravest of our fellow-citizens?" And as these words were agreeable to his own character, while soliciting in behalf of another; so, immediately after, he introduces Milo speaking like himself, with a generous and undaunted air: "These words of Milo (says he) quite sink and dispirit me, which I daily hear from him. Farewel, farewel, my fellow-citizens, farewell may you be happy, flourish, and prosper; with this renowned city be preferred, my most dear country, however it has treated me; may it continue in peace, though I cannot continue in it, to whom it owes its peace. I will retire; I will be gone."

But as persons are commonly more affected with what they see than what they hear, orators sometimes call in the assistance of that sense in moving the passions. For this reason it was usual among the Romans, in judicial cases, for accused persons to appear with a dejected air and a sordid garb, attended by their parents, children, or other relations and friends, with the like dress and aspect; as likewise to shew their fears, wounds, bloody garments, and other things of the like nature, in open court. So when, upon the death of Cæsar, Mark Antony harangued the populace, he at the same time exposed to their view the garment in which he was stabbed, fixed upon a pole; at which sight they were so enraged, that immediately they ran with lighted torches to set fire to the houses of the conspirators. But this custom at last became so common, and was sometimes so ill conducted, that the force of it was greatly abated, as we learn from Quintilian. However, if the Romans proceeded to an excess on the one hand, the strictness of the Areopagites at Athens may perhaps be thought too rigid on the other; for in that court, if the orator began to

say any thing which was moving, an officer immediately stood up, and bade him be silent. There is certainly a medium between these two extremes, which is sometimes not only useful, but even necessary: for, as Quintilian very justly says, "It is necessary to apply to the passions, when those things which are true, just, and of common benefit, cannot be come at any other way."

#### CHAP. VII. Of Digression, Transition, and Amplification.

THE number, order, and nature of the parts which constitute a complete and regular oration, we have endeavoured to explain in several preceding chapters. But there are two or three things yet remaining, very necessary to be known by an orator, which seem most properly to come under the second branch of his art.—And these are, *Digression*, *Transition*, and *Amplification*.

I. *Digression*, as defined by Quintilian, is, "A going off from the subject we are upon to some different thing, which may however be of service to it." We have a very beautiful instance of this in Cicero's defence of Cælius, who was accused of having first borrowed money of Clodia, and then engaging her servants to poison her. Now, as the proof of the fact depended upon several circumstances, the orator examines them separately; and shews them to be all highly improbable. "How," says he, "was the design of this poison laid? Whence came it? how did they get it? by whose assistance, to whom, or where, was it delivered?" Now to the first of these queries he makes the accuser give this answer: "They say Cælius had it at home, and tried the force of it upon a slave provided on purpose, whose sudden death proved the strength of the poison." Now as Cicero represents the whole charge against Cælius as a fiction of Clodia, invented out of revenge for some slights he had put upon her; to make this the more probable, he insinuates that she had poisoned her husband, and takes this opportunity to hint it, that he might shew how easy it was for her to charge another with poisoning a servant, who had done the same to her own husband. But not contented with this, he steps out of his way, and introduces some of the last words of her husband Metellus, to render the fact more barbarous and shocking, from the admirable character of the man. "O immortal gods! why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity? For I saw, I myself saw (and it was the most doleful scene of my whole life) when Q. Metellus was taken from the bosom of his country; and when he, who thought himself born to be serviceable to this state, within three days after he had appeared with such advantage in the senate, in the forum, and every where in public, was snatched from us in the flower of his age, and prime of his strength and vigour. At which time, when he was about to expire, and his mind had lost the sense of other things, still retaining a concern for the public, he looked upon me, as I was all in tears, and intimated in broken and dying words, how great a storm hung over the city and threatened the whole state; often striking the wall which separated his house from that of Quintus Catulus, and frequently

37

Disposition

calling both upon him and me, and seeming to grieve not so much at the approach of his own death, as that both his country and I should be deprived of his assistance. Had he not been wickedly taken off on a sudden, how would he after his consulship have withstood the fury of his kinsman Publius Clodius, who, while in that office, threatened, in the hearing of the senate, to kill him with his own hand, when he first began to break out. And will this woman dare to come out of those doors, and talk of the force of poison? will not the fear, left the house itself should speak the villainy? will not the dread the conscious walls, nor that sad and mournful night? But I return to the accusation." And then he proceeds to consider and refute the several circumstances of the accusation. All this was no part of his argument; but having mentioned the charge of poison, he immediately takes occasion to introduce it, in order to excite the indignation of the hearers against Clodia, and invalidate the prosecution as coming from a person of her character. Digression cannot properly be said to be a necessary part of a discourse; but it may sometimes be very convenient, and that upon several accounts.

As first, where a subject is of itself flat and dry, or requires close attention, it is of use to relieve and unbend the mind by something agreeable and entertaining. For which reason Quintilian observes, that the orators of his time generally made an excursion in their harangues upon some pleasing topic, between the narration and the proof. But he condemns the practice, as too general; for while they seemed to think it necessary, it obliged them sometimes to bring in things trifling and foreign to the purpose. Besides, a digression is confined to no one part of a discourse, but may come in any where, as occasion offers; provided it fall in naturally with the subject, and be made some way subservient to it. We never meet with it in Cicero, without some evident and good reason. So in his prosecution of Verres for his barbarous and inhuman outrages against the Sicilians, he takes an occasion to launch out in a beautiful description of the island, and to recount the advantages which accrued from it to the Romans. His subject did not necessarily lead him to this, but his view in it was to heighten and aggravate the charge against Verres.

Again, as a digression ought not to be made without sufficient reason, so neither should it be too frequent. And he who never does it but where it is proper and useful, will not often see occasion for it. Frequently to leave the subject, and go off to other things, breaks the thread of the discourse, and is apt to introduce confusion. Indeed some kinds of writing admit of a more frequent use of digressions than others. In history they are often very serviceable. For as that consists of a series of facts, and a long continued narrative without variety is apt to grow dull and tedious; it is necessary at proper distances to throw in something entertaining, in order to enliven it, and keep up the attention. And accordingly we find the best historians often embellish their writings with descriptions of cities, rivers, and countries, as likewise with the speeches of eminent persons upon important occasions, and other ornaments, to render them the more pleasing and delightful. Poets take a still greater liberty in this respect: for as their principal

view is most commonly to please, they do not attend so closely to connection; but as an image offers itself, which may be agreeably wrought up, they bring it in, and go off more frequently to different things, than others writers.

Another property of a digression is, that it ought not to be too long, lest the hearers forget what preceded, before the speaker returns again to his subject.

For a digression being no principal part of a discourse, nor of any further use than as it serves some way or other to enforce or illustrate the main subject; it cannot answer this end, if it be carried to such a length, as to cause that either to be forgotten, or neglected. And every one's memory will not serve him to connect together two parts of a discourse, which lie at a wide distance from each other. The better therefore to guard against this, it is not unusual with orators, before they enter upon a digression of any considerable length, to prepare their hearers, by giving them notice of it, and sometimes desiring leave to divert a little from the subject. And so likewise at the conclusion they introduce the subject again by a short transition. Thus Cicero in the example cited above, when he has finished his digression concerning the death of Metellus, proceeds to his subject again with these words: "But I return to the accusation."

Indeed we find orators sometimes, when fore pressed, and the cause will not bear a close scrutiny, artfully run into digressions with a design to divert the attention of the hearers from the subject, and turn them to a different view. And in such cases, as they endeavour to be unobserved, so they do it tacitly without any transition or intimation of their design; their business being only to get clear of a difficulty, till they have an opportunity of entering upon some fresh topic.

II. *Transitions* are often used not only after a digression, but likewise upon other occasions. A transition is, "A form of speech, by which the speaker in a few words tells his hearers both what he has said already, and what he next designs to say." Where a discourse consists of several parts, this is often very proper in passing from one to another, especially when the parts are of a considerable length; for it assists the hearers to carry on the series of the discourse in their mind, which is a great advantage to the memory. It is likewise a great relief to the attention, to be told when an argument is finished, and what is to be expected next. And therefore we meet with it very frequently in history. But we consider it at present only as made use of by orators. Cicero, in his second oration against Catiline, who had then left Rome, having at large described his conduct and designs, he adds: "But why do I talk so long concerning one enemy, and such an one; who owns himself an enemy, and whom I do not fear, since, what I always desired, there is now a wall between us; and says nothing of those, who conceal themselves, who remain at Rome, and among us." And then he proceeds to give an account of the other conspirators.

But sometimes, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow. Thus Cicero in his second Philippic says: "But those things are old,

Disposition

Disposition

this is yet fresh." And again: "But I have insisted too long upon trifles, let us come to things of greater moment." And at other times, for greater brevity, the transition is imperfect, and mention made only of the following head, without any intimation of what has been said already. As in Cicero's defence of Muræna, where he says: "I must now proceed to the third part of my oration concerning the charge of bribery." And soon after: "I come now to Cato, who is the support and strength of this charge."

39

III. The third and last head is, *Amplification*. Now by amplification is meant, not barely a method of enlarging upon a thing, but so to represent it in the fullest and most comprehensive view, as that it may in the liveliest manner strike the mind, and influence the passions. Cicero speaking of this, calls it *the greatest commendation of eloquence*; and observes, "that it consists not only in magnifying and heightening a thing, but likewise in extenuating and lessening it." But though it consists of these two parts, and may be applied either way; yet to amplify, is not to set things in a false light, but to paint them in their just proportion and proper colours, suitable to their nature and qualities. Rhetoricians have observed several ways of doing this.

One is to ascend from a particular thing to a general. Thus Cicero, in his defence of Archias, having commended him as an excellent poet, and likewise observed, that all the liberal arts have a connection with each other, and a mutual relation between them, in order to raise a just esteem of him in the minds of his hearers, takes occasion to say many things in praise of polite literature in general, and the great advantages that may be received from it. "You will ask me," says he, "why we are so delighted with this man? Because he supplies us with those things, which both refresh our minds after the noise of the forum, and delight our ears when wearied with contention. Do you think we could either be furnished with matter for such a variety of subjects, if we did not cultivate our minds with learning; or bear such a constant fatigue, without affording them that refreshment? I own I have always pursued these studies; let those be ashamed, who have so given up themselves to learning, as neither to be able to convert it to any common benefit, nor discover it in public. But why should it shame me, who have so lived for many years, that no advantage or ease has ever diverted me, no pleasure allured me, nor sleep retarded me, from this pursuit. Who then can blame me, or who can justly be displeased with me, if I have employed that time in reviewing these studies, which has been spent by others in managing their affairs, in the celebration of festivals, or other diversions, in refreshments of mind and body, in unseasonable banquets, in dice, or tennis? And this ought the rather to be allowed me, because my ability as an orator has been improved by those pursuits, which, such as it is, was never wanting to assist my friends. And if it be esteemed but small, yet I am sensible from what spring I must draw those things, which are of the greatest importance." With more to the same purpose; from which he draws this inference: "Shall I not therefore love this man? shall I not admire him? shall I not by all means defend him?"

i

A contrary method to the former is, to descend from a general to a particular. As if any one, while speaking in commendation of eloquence, should illustrate what he says from the example of Cicero, and shew the great services he did his country, and the honours he gained to himself, by his admirable skill in oratory. Our common way of judging of the nature of things is from what we observe in particular instances, by which we form general notions concerning them. When therefore we consider the character of Cicero, and the figure he made in the world, it leads us to conclude, there must be something very admirable in that art by which he became so celebrated. And this method he has taken himself in his oration for the Manilian law, where having first intimated the scarcity of good generals at that time among the Romans, he then describes the virtues of a complete commander as a proof of it, and shews how many and great qualifications are necessary to form such a character, as courage, prudence, experience, and success; all which he afterwards applies to Pompey.

A third method is by an enumeration of parts. So when Cicero, upon the defeat of Mark Antony before Mutina, proposed that a funeral monument should be erected in honour of the soldiers who were killed in that battle, as a comfort to their surviving relations; he does it in this way, to give it the greater weight: "Since (says he) the tribute of glory is paid to the best and most valiant citizens by the honour of a monument, let us thus comfort their relations, who will receive the greatest consolation in this manner: their parents, who produced such brave defenders of the state; their children, who will enjoy these domestic examples of fortitude; their wives, for the loss of such husbands, whom it will be more fitting to extol than lament; their brethren, who will hope to resemble them no less in their virtues, than their aspect. And I wish we may be able to remove the grief of all these by our resolutions." Such representations greatly enlarge the image of a thing, and afford the mind a much clearer view of it than if it were contracted into one single proposition.

Again, another method not much unlike the former is, when any thing is illustrated from a variety of causes. Thus Cicero justifies his behaviour in retiring, and not opposing his enemies, when they spirited up the mob in order to banish him, from the following reasons, which at that time determined him to such a conduct: "When (says he) unless I was given up, so many armed fleets seemed ready to attack this single ship of the state, tossed with the tempests of seditions and discords, and the senate was now removed from the helm; when banishment, murder, and outrage, were threatened; when some, from an apprehension of their own danger, would not defend me; others were incited by an inveterate hatred to all good men, others thought I stood in their way, others took this opportunity to express their resentment, others envied the peace and tranquillity of the state; and upon all these accounts I was particularly struck at: should I have chosen rather to oppose them, (I will not say to my own certain destruction, but to the greatest danger both of you and your children), than alone to submit to and undergo what threatened us all in common?" Such a number of reasons brought together, must set a

32 C 2

thing

Disposition

thing in a very strong and clear light.

The like may be said of a number and variety of effects. Thus Cicero describes the force and excellence of oratory from its great and surprising effects, when he says, "Nothing seems to me more excellent, than by discourse to draw the attention of a whole assembly, delight them, and sway their inclinations different ways at pleasure. This, in every free state, and especially in times of peace and tranquillity, has been always in the highest esteem and reputation. For what is either so admirable, as for one only, or a very few, out of a vast multitude, to be able to do that which all have a natural power of doing? or so delightful to hear, as a judicious and solid discourse in florid and polite language? or so powerful and grand, as to influence the populace, the judges, the senate, by the charms of eloquence? Nay, what is so noble, so generous, so munificent, as to afford aid to supplicants, to support the afflicted, give safety, deliver from dangers, and preserve from exile? Or what is so necessary as to be always furnished with arms to guard yourself, assert your right, or repel injuries? And, not to confine our thoughts wholly to the courts of justice or the senate, what is there in the arts of peace more agreeable and entertaining than good language and a fine way of speaking? For it is this especially wherein we excel other animals, that we can discourse together, and convey our thoughts to each other by words. Who therefore would not esteem, and in a particular manner endeavour to surpass others in that wherein mankind principally excels brute beasts? But to proceed to its chief advantages: What else would have drawn men into societies, or taken them off from a wild and savage life, and soften them into a polite and civilized behaviour; or, when settled in communities, have restrained them by laws?" Who but, after such a description, must conceive the strongest passion for an art attended with so many great and good effects?

A thing may likewise be illustrated by its opposite. So the blessings and advantages of peace may be recommended from the miseries and calamities of war; and thus Cicero endeavours to throw contempt upon Catiline and his party, by comparing them with the contrary side: "But if, omitting all these things with which we abound, and they want, the senate, the knights, the populace, the city, treasury, revenues, all Italy, the provinces, and foreign nations; if, I say,

omitting these things, we compare the causes themselves in which each side is engaged, we may learn from thence how despicable they are.—For on this side modestly is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that fraud; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion: In a word, equity, temperance, fortitude, prudence, and all virtues, contend with injustice, luxury, cowardice, rashness, and all vices; plenty with want; reason with folly; sobriety with madness; and, lastly, good hope with despair. In such a contest, did men desert us, would not heaven ordain that so many and so great virtues should be defeated by these most excellent virtues?"

Gradation is another beautiful way of doing this. So when Cicero would aggravate the cruelty and barbarity of Verres for crucifying a Roman citizen, which was a sort of punishment only inflicted upon slaves, he chooses this way of doing it. "It is a crime (says he) to bind a Roman citizen, wickedness to whip him, and a sort of parricide to kill him; what then must I call it to crucify him? No name can sufficiently express such a villany." And the images of things may be thus heightened, either by ascending, as in this instance; or descending, as in that which follows, relating to the same action of Verres: "Was I not to complain of or bewail these things to Roman citizens, nor the friends of our state, nor those who had heard of the Roman name; nay, if not to men, but beasts; or, to go yet further, if in the most desert wilderness to stones and rocks; even all mute and inanimate creatures would be moved by so great and heinous cruelty."

And, to name no more, facts may be amplified from their circumstances; as time, place, manner, event, and the like. But instances of this would carry us too far; and therefore we shall only add, that, as the design of *amplification* is not barely to prove or evince the truth of things, but also to adorn and illustrate them, it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures. But the consideration of these things come under the third part of oratory, upon which we are now to enter.

### PART III. OF ELOCUTION.

**E**LOCUTION directs us to suit both the words and expressions of a discourse to the nature of the subject, or to speak with propriety and decency. This faculty is in one word called *eloquence*; and those persons who are possessed of it are therefore styled *eloquent*.

*Elocution* is twofold; general, and particular. The former treats of the several properties and ornaments of language in common; the latter considers them as they are made use of to form different sorts of style.

#### I. GENERAL ELOCUTION.

THIS, according to rhetoricians, consists of three

parts; *Elegance, Composition, and Dignity*. A discourse which has all these properties suitably adjusted, must, with respect to the language, be perfect in its kind, and delightful to the hearers.

#### CHAP. I. Of Elegance.

ELEGANCE consists in two things; *Purity, and Perspicuity*: And both these, as well with respect to single words, as their construction in sentences. These properties in language give it the name of *elegant*, for a like reason that we call other things so which are clean and neat in their kind. But in the common use of our tongue, we are apt to confound *elegance* with *eloquence*; and say, a discourse is *elegant*, when we mean by

location. by the expression, that it has all the properties of fine language.

§ 1. Purity.

41

By this we are to understand the choice of such words and phrases as are suited and agreeable to the use of the language in which we speak: And so grammarians reduce the faults they oppose to it to two sorts, which they call *barbarism* and *solecism*; the former of which respects single words, and the latter their construction. But we shall consider them jointly, and in a manner different from grammarians; for with them all words are esteemed pure, which are once adopted into a language, and authorized by use. And as to phrases, or forms of expression, they allow them all the same claim, which are agreeable to the analogy of the tongue. But in oratory, neither all words nor all expressions are so called, which occur in language; but such only as come recommended by the authority of those who speak or write with accuracy and politeness. Indeed it is a common saying, *that we should think with the learned, and speak with the vulgar*. But the meaning of that expression is no more than that we should speak agreeably to the common usage of the tongue, that every one may understand us; and not choose such words or expressions as are either difficult to be understood, or may carry in them an appearance of affectation and singularity. But in order to set this matter in a clearer light, we shall here recount the principal things which vitiate the purity of language.

And first, it often happens, that such words and forms of speaking as were introduced by the learned, are afterwards dropped by them as mean and sordid, from a seeming baseness contracted by vulgar use. For polite and elegant speakers distinguish themselves by their discourse, as persons of figure do by their garb; one being the dress of the mind, as the other is of the body. And hence it comes to pass, that both have their different fashions, which are often changed; and as the vulgar affect to imitate those above them in both, this frequently occasions an alteration when either becomes too trite and common. But beside these sordid words and expressions, which are rendered so by the use of the vulgar; there is another sort first introduced by them, which is carefully to be avoided by all those who are desirous to speak well. For the vulgar have their peculiar words and phrases, suited to their circumstances, and taken from such things as usually occur in their way of life. Thus in the old comedians, many things are spoken by servants, agreeable to their character, which would be very unbecoming from the mouth of a gentleman. And we cannot but daily observe the like instances among ourselves.

Again, this is common to language with all other human productions, that it is in its own nature liable to a constant change and alteration. For, as Horace has justly observed,

All human works shall waste,  
Then how can feeble words pretend to last?

Nothing could ever please all persons, or at least for any length of time. And there is nothing from which this can less be expected than language. For as the thoughts of men are exceedingly various, and words

are the signs of their thoughts; they will be constantly inventing new signs to express them by, in order to convey their ideas with more clearness, or greater beauty. If we look into the different ages of the Latin writers, what great alterations and changes do we find in their language? How few now understand the remaining fragments of the *twelve tables*? Nay, how many words do we meet with even in Plautus, the meaning of which has not yet been fixed with certainty by the skill of the best critics? And if we consider our own language, it will appear to have been in a manner entirely changed from what it was a few ages since. To mention no others, our celebrated Chaucer is to most persons now almost unintelligible, and wants an expositor. And even since our own memory, we cannot but have observed, that many words and expressions, which a few years ago were in common use, are now in a manner laid aside and antiquated; and that others have constantly succeeded, and daily do succeed, in their room. So true is that observation of the same poet:

Some words that have or else will feel decay,  
Shall be rector'd, and come again in play;  
And words now fam'd, shall not be fancied long,  
They shall not please the ear, nor move the tongue:  
As use shall these approve, and those condemn;  
Use, the sole rule of speech, and judge supreme.

We must therefore no less abstain from antiquated or obsolete words and phrases, than from sordid ones. Though all old words are not to be thought antiquated. By the former we mean such as, though of an ancient standing, are not yet entirely disused, nor their signification lost. And from the use of these we are not to be wholly debarred, especially when they appear more significant than any others we can fix upon. But as to phrases or expressions, greater caution seems still necessary; and such as are old, should doubtless, if at all, be used more sparingly. The Latin tongue was brought to its greatest perfection in the reign of Augustus, or somewhat sooner; and he himself studied it very carefully. For, as Suetonius tells us, "He applied himself to eloquence, and the study of the liberal arts, from his childhood, with great diligence and labour. He chose a manner of speaking which was smooth and elegant: he avoided the ill favour, as he used to call it, of antiquated words; and he was wont to blame Tiberius for his affectation of them." In our own language, such words are to be esteemed antiquated, which the most polite persons have dropped, both in their discourse and writings; whose example we should follow, unless we would be thought to converse rather with the dead than the living.

But further: As on the one hand we must avoid obsolete words and phrases; so on the other, we should refrain from new ones, or such whose use has not been yet been sufficiently established, at least among those of the best taste. Words may be considered as new in two respects; either when they are first brought into a language, or when they are used in a new sense. As the former of these may sometimes leave us in the dark by not being understood, so the latter are most apt to mislead us; for when we hear a word that has been familiar to us, we are presently led to fix that idea to it with which it has usually been attended.

And

And therefore, in both cases, some previous intimation may be necessary. Cicero, who perhaps enlarged the furniture of the Roman tongue more than any one person besides, appears always very cautious how he introduces any thing new, and generally gives notice of it when he attempts it, as appears in many instances scattered through his works. What bounds we are now to fix to the purity of the Latin tongue in the use of it, the learned are not well agreed. It is certain, our furniture is much less than when it was a living language, and therefore the greater liberty must of necessity be sometimes taken. So that their opinion seems not unadvisable, who direct us to make choice principally of what we are furnished with from the writers of the Augustan age; and, where we cannot be supplied from them, to make use of such authors as lived nearest to them, either before or since. And as to our own tongue, it is certainly prudent to be as careful how we admit any thing into it that is uncouth or disagreeable to its genius, as the ancient Romans were into theirs; for the perfection of a language does in a great measure consist in a certain analogy, and harmony running through the whole, by which it may be capable of being brought to a standard.

But besides those things already mentioned, any mistake in the sense of words, or their construction, is opposed to purity. For to speak purely, is to speak correctly. And such is the nature of these faults in elocution, that they are often not so easy to be observed by hearing as by reading. Whence it is, that many persons are thought to speak better than they write; for while they are speaking, many slips and inaccuracies escape disregarded, which in reading would presently appear. And this is more especially the case of persons unacquainted with arts and literature; who, by the assistance of a lively fancy and flow of words, often speak with great ease and freedom, and by that means please the ear; when, at the same time, what they say, would not so well bear reading.

We shall only add, that a distinction ought likewise to be made between a poetic diction, and that of prose writers. For poets in all languages have a sort of peculiar dialect, and take greater liberties, not only in their figures, but also in their choice and disposition of words; so that what is a beauty in them would often appear unnatural and affected in prose.

### § 2. Of Perspicuity.

PERSPICUITY, as well as purity, consists partly in single words, and partly in their construction.

1. As to single words, those are generally clearest and best understood which are used in their proper sense. But it requires no small attention and skill to be well acquainted with the force and propriety of words; which ought to be duly regarded, since the perspicuity of a discourse depends so much upon it. Cæsar seems plainly to have been of this mind, when he tells us, "The foundation of eloquence consists in the choice of words." It may not be amiss, therefore, to lay down some few observations, by which the distinct notions of words and their peculiar force may more easily be perceived. All words may be divided into *proper words* and *tropes*. Those are called *proper words*, which are expressed in their proper and usual

sense. And *tropes* are such words as are applied to some other thing than what they properly denote, by reason of some similitude, relation, or contrariety between the two things. So, when a subtle artful man is called a *fox*, the reason of the name is founded in a similitude of qualities. If we say, *Cicero will always live*, meaning *his works*, the cause is transferred to the effect. And when we are told, *Cæsar conquered the Gauls*, we understand that he did it with the assistance of his army; where a part is put for the whole, from the relation between them. And when Cicero calls Anthony a *fine guardian of the state*, every one perceives he means the contrary. But the nature and use of tropes will be explained more fully hereafter in their proper place. All words must at first have had one original and primary signification, which, strictly speaking, may be called their *proper sense*. But it sometimes happens through length of time, that words lose their original signification, and assume a new one, which then becomes their proper sense. So *hostis* in the Latin tongue at first signified a *stranger*; but afterwards that sense of the word was entirely laid aside, and it was used to denote a *public enemy*. And in our language, it is well known, that the word *knave* anciently signified a *servant*. The reason of the change seems to be much the same, as in that of the Latin word *latro*; which first signified a *soldier*, but afterwards a *robber*. Besides, in all languages it has frequently happened, that many words have gradually varied from their first sense to others somewhat different; which may, notwithstanding, all of them, when rightly applied, be looked upon as proper. Nay, in process of time, it is often difficult to say which is the original, or most proper sense. Again, sometimes two or more words may appear to have the same signification with each other, and may therefore be used indifferently; unless the beauty of the period, or some other particular reason, determine to the choice of one rather than another. Of this kind are the words *ensis* and *gladius* in the Latin tongue; and in ours, *pity* and *compassion*. And there are other words of so near an affinity to each other, or at least appear so from vulgar use, that they are commonly thought to be synonymous. Such are the words *mercy* and *pity*; though mercy in its strict sense is exercised towards an offender, and pity respects one in distress. As this peculiar force and distinction of words is carefully to be attended to, so it may be known several ways. Thus the proper signification of substantives may be seen by their application to other substantives. As in the instance just now given, a person is said to shew *mercy to a criminal*, and *pity to one in distress*. And in the like manner verbs are distinguished, by being joined to some certain nouns, and not to others. So a person is said to *command an inferior*, to *intreat a superior*, and to *desire an equal*. Adjectives also, which denote the properties of things, have their signification determined by those subjects to which they most properly relate. Thus we say, an *honest mind*, and a *healthful body*; a *wise man*, and a *fine house*. Another way of distinguishing the propriety of words, is by their use in gradations. As if one should say, *Hated, grudges, quarrels, tumults, seditions, wars, spring from unbridled passions*. The proper sense of words may likewise be known by observing to what other words

words they are either opposed, or used as equivalent. So in that passage of Cicero, where he says, "I cannot perceive why you should be angry with me: If it be because I defend him whom you accuse, why may not I be displeased with you for accusing him whom I defend? You say, I accuse my enemy; and I say, I defend my friend." Here the words *accuse* and *defend*, *friend* and *enemy*, are opposed; and *to be angry* and *displeased*, are used as terms equivalent. Lastly, the derivation of words, contributes very much to determine their true meaning. Thus because the word *manners* comes from the word *man*, it may properly be applied either to that, or any other put for it. And therefore we say, *the manners of men*, and *the manners of the age*; because the word *age* is there used for *the men of the age*. But if we apply the word *manners* to any other animal, it is a trope. By these, and such like observations, we may perceive the proper sense and peculiar force of words, either by their connection with other words, distinction from them, opposition to them, equivalency with them, or derivation. And by thus fixing their true and genuine signification we shall easily see when they become tropes. But though words, when taken in their proper signification, generally convey the plainest and clearest sense; yet some are more forcible, sonorous, or beautiful than others. And by these considerations we must often be determined in our choice of them. So whether we say, *he got*, or *he obtained*, the victory, the sense is the same; but the latter is more full and sonorous. In Latin, *timeo* signifies *I fear*; *pertimeo* is more full and significant, and *pertimesco* more sonorous than either of the former. The Latin and Greek languages have much the advantage of ours in this respect, by reason of their compositions; by the help of which they can often express that in one word, for which we are obliged to put two words, and sometimes more. So *pertimeo* cannot be fully expressed in our language by one word; but we are forced to join one or two particles to the verb, to convey its just idea, and say, *I greatly*, or *very much fear*: and yet even then, we scarce seem to reach its full force. As to tropes, tho' generally speaking they are not to be chosen where plainness and perspicuity of expression is only designed, and proper words may be found; yet through the penury of all languages, the use of them is often made necessary. And some of them, especially metaphors, which are taken from the similitude of things, may, when custom has rendered them familiar, be considered as proper words, and used in their stead. Thus, whether we say, *I see your meaning*, or, *I understand your meaning*, the sense is equally clear, tho' the latter expression is proper, and the former metaphorical, by which the action of seeing is transferred from the eyes to the mind.

11. But *perspicuity* arises not only from a choice of single words, but likewise from the construction of them in sentences. For the meaning of all the words in a sentence, considered by themselves, may be very plain and evident; and yet, by reason of a disorderly placing them, or confusion of the parts, the sense of the whole may be very dark and obscure. Now it is certain, that the most natural order is the plainest; that is, when both the words and parts of a sentence are so disposed, as best agrees with their mu-

tual relation and dependence upon each other. And where this is changed, as is usually done, especially in the ancient languages, for the greater beauty and harmony of the periods; yet due regard is had by the best writers to the evidence and perspicuity of the expression.

But to set this subject in a clearer light, on which the perfection of language so much depends, we shall mention some few things which chiefly occasion obscurity; and this either with respect to single words, or their construction.

And first, all ambiguity of expression is one cause of obscurity. This sometimes arises from the different senses in which a word is capable of being taken. So we are told, that upon Cicero's addressing himself to Octavius Cæsar, when he thought himself in danger from his resentment, and reminding him of the many services he had done him, Octavius replied, *He came the last of his friends*. But there was a designed ambiguity in the word *last*, as it might either respect the time of his coming, or the opinion he had of his friendship. And this use of ambiguous words we sometimes meet with, not only in poetry, where the turn and wit of an epigram often rests upon it; but likewise in prose, either for pleasantry or ridicule. Thus Cicero calls Sextus Clodius, *the light of the senate*; which is a compliment he pays to several great men, who had distinguished themselves by their public services to their country. But Sextus, who had a contrary character, was a relation of P. Clodius, whose dead body, after he had been killed by Milo, he carried in a tumultuous manner into the senate-house, and there burnt it with the senators benches, in order to inflame the populace against Milo. And it is in allusion to that riotous action, that Cicero, using this ambiguous expression, calls him *the light of the senate*. In such instances, therefore, it is a beauty, and not the fault we are cautioning against; as the same thing may be either good or bad, as it is differently applied. Tho' even in such designed ambiguities, where one sense is aimed at, it ought to be sufficiently plain, otherwise they lose their intention. And in all serious discourses they ought carefully to be avoided. But obscurity more frequently arises from the ambiguous construction of words, which renders it difficult to determine in what sense they are to be taken. Quintilian gives us this example of it: "A certain man ordered in his will, that his heir should erect for him a statue holding a spear made of gold." A question arises here, of great consequence to the heir from the ambiguity of the expression, whether the words *made of gold*, are to be applied to the *statue* or the *spear*; that is, whether it was the design of the testator by this appointment, that the whole statue, or only the spear, should be made of gold. A small note of distinction, differently placed between the parts of this sentence, would clear up the doubt, and determine the sense either way. For if one comma be put after the word *statue*, and another after *spear*, the words *made of gold* must be referred to the statue, as if it had been said, *a statue, made of gold, holding a spear*. But if there be only the first comma placed after *statue*, it will limit the words *made of gold* to the *spear* only; in the same sense as if it had been said, *A statue holding a golden spear*. And either of these ways of expression would

in this case have been preferable, for avoiding the ambiguity, according to the intention of the testator. The ancient heathen oracles were generally delivered in such ambiguous terms. Which, without doubt, were so contrived on purpose, that those who gave out the answers might have room left for an evasion.

Again, obscurity is occasioned either by too short and concise a manner of speaking, or by sentences too long and prolix; either of these extremes have sometimes this bad consequence. We find an instance of the former in Pliny the elder, where, speaking of heliobore, he says, "They forbid it to be given to aged persons and children, and less to women than men." The verb is wanting in the latter part of the sentence, and *less to women than men*: which in such cases being usually supplied from what went before, would here stand thus; and they forbid it to be given *less to women than men*. But this is directly contrary to the sense of the writer, whose meaning is, either that it is ordered to given in a less quantity to women than men, or not so frequently to women as men. And therefore the word *order* is here to be supplied, which being of a contrary signification to *forbid*, expressed in the former part of the sentence, occasions the obscurity. That long periods are often attended with the same ill effect, must be so obvious to every one's experience, that it would be entirely needless to produce any examples in order to evince the truth of it. And therefore we shall only observe, that the best way of preventing this seems to be by dividing such sentences as exceed a proper length, into two or more; which may generally be done without much trouble.

Another cause of obscurity, not inferior to any yet mentioned, is *parenthesis*, when it is either too long or too frequent. This of Cicero, in his oration for Sylla, is longer than we usually find in him: "O immortal gods! (for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state), you inflamed my mind with a desire to save my country." But where any obscurity arises from such sentences, they may frequently be remedied by much the same means as was just now hinted concerning long and prolix periods; that is, by separating the parenthesis from the rest of the sentence, and placing it either before or after. So in this sentence of Cicero, the parenthesis may stand last, in the following manner: "O immortal gods! you inflamed my mind with a desire to save my country: for I must attribute to you what is your own; nor indeed can I claim so much to my own abilities, as to have been able of myself to go through so many, so great, such different affairs, with that expedition, in that boisterous tempest of the state." This order of the sentence is very plain, and less involved than the former.

#### CHAP. II. Of Composition.

COMPOSITION, in the sense it is here used, gives rules for the structure of sentences, with the several members, words, and syllables, of which they consist, in such a manner as may best contribute to the force, beauty, and evidence of the whole.

Composition consists of four parts, which rhetori-

cians call *period*, *order*, *juncture*, and *number*. The first of these treats on the structure of sentences; the second, of the parts of sentences, which are words and members; and the two last, of the parts of words, which are letters and syllables. For all articulate sounds, and even the most minute parts of language, come under the cognizance of oratory.

##### § 1. Of Period.

In every sentence or proposition, something is said of something. That of which something is said, logicians call the *subject*; and that which is said of it, the *predicate*: but in grammatical terms, the former is a *noun substantive of the nominative case*, and the latter a *finite verb*. These two parts may of themselves constitute a sentence: As when we say, *The sun shines*, or *The clock strikes*, the words *sun* and *clock* are the subject in these expressions, *shines* and *strikes* the predicate. But most commonly they are accompanied with other words, which in grammatical construction are said either to be connected with or to depend upon them; but in a logical consideration they denote some property or circumstance relating to them. As in the following sentence: *A good man loves virtue for itself*. The subject of this sentence is a *good man*; and the predicate, or thing affirmed of him, that he *loves virtue for itself*. But the two principal or necessary words, on which all the rest depend, are, *man* and *loves*. Now a simple sentence consists of one such noun and verb, with whatever else is joined to either or both of them. And a compound sentence contains two or more of them; and may be divided into so many distinct propositions, as there are such nouns and verbs, either expressed or understood. So in the following sentence, *Compliance gains friends, but truth procures hatred*, there are two members, each of which contains in it an entire proposition. For, *Compliance gains friends*, is one complete sentence; and, *Truth procures hatred*, is another; which are connected into one compound sentence by the particle *but*. Moreover, it frequently happens, that compound sentences are made up of such parts or members, some if not all of which are themselves compounded, and contain in them two or more simple members. Such is that of Sallust: "Ambition has betrayed many persons into deceit; to say one thing, and to mean another; to found friendship and enmity, not upon reason, but interest; and to be more careful to appear honest, than really to be so." This sentence consists of four members; the last of which three, consisting of opposite parts, are all compounded, as will appear by expressing them at length in the following manner: *Ambition has betrayed many persons into deceit; [that is, ambition] has betrayed them to say one thing, it and to mean another; it has betrayed them to found friendship and enmity, not upon reason, but interest; and it has betrayed them to be more careful to appear honest, than really to be so*. The three last of these members, beginning with the words *it betrays*, are all of them compounded, and consist of two opposite members; which might each of them be expressed at length in the same manner, by supplying the ellipsis. As, *Ambition has betrayed many persons to say one thing, and it has betrayed them to mean another*. And so of the rest. From this instance we see how much is

Elocution. left to be supplied by the mind in all discourse, which if expressed would both destroy its harmony and render it exceedingly tedious. But still regard must be had to that which is omitted, so as to render what is said consistent with it; otherwise there can be no propriety in what is spoken. Nor can the members of a sentence be distinguished and duly ranged in their proper order, without this. But to proceed: Some sentences consist either wholly, or in part, of such members as contain in them two or more compound ones, which may therefore, for distinction's sake, be called *decompound members*. Of this kind is that of Cicero in his defence of Milo: "Great is the force of conscience, great either way: that those persons are not afraid who have committed no offence; and those who have offended, always think punishment present before their eyes." The latter member of this sentence, which begins with the word *that*, contains in it two compound members, which represent the different state of mind between innocent and guilty persons. And it is in the proper distinction, and separation of the members in such complex sentences, that the art of pointing chiefly consists. For the principal use of a comma is to divide the simple members, a semicolon the compound ones, a colon such as are decompounded, and a period the whole from the following sentence. We mention this the rather, to shew the different acceptance of these terms by grammarians, from that of the ancient writers upon oratory. For these latter apply them to the sense, and not to any points of distinction. A very short member, whether simple or compound, with them is a comma, and a longer a colon; for they have no such term as a semicolon. Besides, they call a very short sentence, whether simple or compound, a *comma*; and one of somewhat a greater length, a *colon*. And therefore, if a person expressed himself either of these ways in any considerable number of sentences together, he was to speak by commas or colons. But a sentence containing more words than will consist with either of these terms, they call a simple period; the least compound period with them requiring the length of two colons. However, this way of denominating sentences, and the parts of them, rather from their length than the nature of them, appearing not so suitable, we have chosen rather to make use of the terms *simple* and *compound members*; and to call all those *compound periods*, which contain two or more members, whether simple or compounded.

But to proceed: Sentences with respect to their form or composition, are distinguished into two sorts, called by Cicero *tractas*, "straight or direct;" and *contortas*, "bent or winding." By the former are meant those whose members follow each other in a direct order, without any inflexion; and by the latter, those which strictly speaking are called *periods*. For *περίοδος* in Greek signifies a *circuit* or *circle*. And so the Latins call it *circuitus* and *ambitus*. By which both of them mean a sentence consisting of correspondent parts, so framed, that the voice in pronouncing them may have a proper elevation and cadency, and distinguish them by its inflexion; and as the latter part returns back, and unites with the former, the period, like a circle, surrounds and incloses the whole sense. This elevation of the voice in the former part of the

period, is by the Greeks called *ὑψωτική*, and by the Latins *propositio*; and the depression of it in the latter part, by the one *ἀνωστική*, and by the other *reductio*.

Now as simple sentences have not these correspondent parts, which require any inflexion of the voice; nor a circular form, by reason of their brevity; they are not properly periods, in the strict sense of the word: though in common speech, the words *sentence* and *period* are often used as equivalent terms. Thus, if we say, *Generous minds are incited to the performance of noble exploits from motives of glory*; here is no distinction of parts, nor inflexion of the voice in this sentence. And indeed there is not any thing which relates to the structure of these sentences, but what will more properly be taken notice of in the second part of *composition*, which is *order*.

And as to those compound sentences, whose members follow each other in a direct order, without any inflexion, there is little art required in their composition. We shall produce one example of this kind from Cicero: "Natural reason inclines men to mutual converse and society; and implants in them a strong affection for those who spring from them; and excites them to form communities, and join in public assemblies; and, for these ends, to endeavour to procure both the necessities and conveniences of life; and that not for themselves only, but likewise their wives, children, and others who are dear to them, and have a right to their assistance." Here are five short members in this sentence, placed in a series, without any inflexion of the parts, or orbit of the whole. And as such sentences have no other boundary but the conclusion of the sense, suited to the breath of the speaker, he may either contract or lengthen them at pleasure, without offending the ear. So, should the sentence last mentioned conclude with the first member in this manner, *Natural reason inclines men to mutual converse and society*; the sense would be perfect, and the ear satisfied. The case would be the same at the end of the second member, thus: *Natural reason inclines men to mutual converse and society, and implants in them a strong affection for those who spring from them*. And the like may be said of the rest. Since such sentences therefore may be thus limited at pleasure, it seems more convenient both for the speaker and hearers to confine them to a moderate length.

But because the principal art relating to this part of composition lies in the frame and structure of such compound sentences as are properly called *periods*, we shall treat upon these somewhat more largely. In the formation of these periods, two things are chiefly to be regarded; their *length*, and *cadency*. As the length ought to be suited to the breath of the speaker, the ancient rhetoricians scarce admit of more than four colons; by which we may here understand compound members of a moderate size, which will be generally found a suitable and proportionate length. For to extend them farther than the voice can well manage must be painful to the speaker, and of consequence unpleasant to the hearers. As to the cadency, what Cicero has observed, is found true by experience, that the ears judge what is full and what is deficient; and direct us to fill up our periods, that nothing be wanting, of what they expect. When the voice is raised

Elocution.

Elocution.

at the beginning of a sentence, they are in suspense till it be finished; and are pleased with a full and just cadency, but are sensible of any defect, and are displeased with redundancy. Therefore care must be taken that periods be neither deficient, and as it were maimed, that is, that they do not drop before their time, and defraud the ears of what seemed to be promised them; nor, on the other hand, offend them by too long and immoderate excursions. This rise and cadency of the voice in pronunciation, depend on the nature and situation of the members, as we shall endeavour to shew by particular instances; in the explanation of which, by the words *members*, are to be understood such as are compounded. In a period of two members, the turn of the voice begins with the latter member. Of this kind is the following sentence of Cicero: "If impudence prevailed as much in the forum and courts of justice, as insolence does in the country and places of less resort; Aulus Cæcina would submit as much to the impudence of Sextus Ebutius in this cause, as he did before to his insolence when assaulted by him." Here the cadency begins at the words *Aulus Cæcina*. If a sentence consist of three members, the inflection is best made at the end of the second member: for if it begin immediately after the first, the voice will either be apt to sink too low, and not be heard, before it reach the end; or else be precipitated, in order to prevent it. Cicero begins his oration for Milo with a sentence of this form: "Although I fear, it may be a shame to be dismayed at the entrance of my discourse in defence of a most valiant man; and that it noways becomes me, while Milo is more concerned for the safety of the state than for himself, not to shew the same greatness of mind in his behalf: yet this new form of prosecution terrifies my eyes, which, whatever way they turn, want the ancient custom of the forum, and former manner of trials." Here the cadency beginning at the third member with the word *yet*, makes a proper division of the sentence, and easy for the speaker. But a period of four members is reckoned the most complete and perfect, where the inflection begins at the middle, that is, with the third member. Nor is it the same case here, as if, in a sentence of three members, the cadency be made at the second. For in proportion to the time of raising the voice, may the space be allowed for its sinking. The following sentence of Cicero gives us an instance of this, where he speaks to his son: "Although, son Mark, having now been an hearer of Cratippus for a year, and this at Athens, you ought to abound in the precepts and doctrines of philosophy, by reason of the great character both of your instructor and the city; one of which can furnish you with knowledge, and the other with examples: yet, as I always to my advantage joined the Latin tongue with the Greek, and have done it not only in oratory, but likewise in philosophy; I think you ought to do the same, that you may be equally conversant in both languages." The turn in this period begins at the word *yet*; which standing near the middle, the voice is raised to that pitch in pronouncing the former part, as to admit of a gradual cadency, without being lost before the conclusion of the sentence. But where the sense does not suit with this division at the entrance upon the third member, it is

best made at the fourth. Such is the following sentence of Cicero: "If I have any genius, which I am sensible how small it is; or any readiness in speaking, wherein I do not deny but I have been much conversant; or any skill in oratory, from an acquaintance with the best arts, to which I confess I have been always inclined: *no one* has a better right to demand of me the fruit of all these things, than this Aulus Læcinius." The cadency of this sentence does not begin till the words *no one*; yet it ends handsomely, and without disappointing the ear. Though indeed the three first members having each of them an inflection, check the elevation of the voice, and by that variety in the pronunciation add to the harmony of the sentence. An equality of the members should likewise be attended to in the composition of a period, the better to adjust their rise and cadency. And for this reason, in sentences of three members, where the cadency begins with the third; or in those of four members, where it begins at the fourth; it promotes the harmony to make the last member longest. This is properly the nature of rhetorical periods, which when rightly formed have both an equal beauty and dignity in their composition.

But as all discourse is made up of distinct sentences, and whenever we express our thoughts it is in some of the forms above-mentioned; so the use of them is not promiscuous, but suited to answer different designs in speaking. And in this view they are considered and made use of by the orator, as will be shewn hereafter.

#### § 2. Of Order.

By *order*, rhetoricians mean the placing each word and member of a sentence in such a manner as will most contribute to the force, beauty, or evidence of the whole.

Order is of two kinds, *natural* and *artificial*. And each of these may be considered with respect to the parts either of simple or compound sentences.

As to simple sentences, we may call that order *natural*, when all the words in a sentence are so placed, as they are connected with or follow each other in a grammatical construction. And it may properly enough admit of this name, as it is founded in the nature of a proposition, and the relation of the several words of which it consists to each other. This we explained in the last chapter, and illustrated by proper examples; and shall therefore only give one instance of it here, to introduce the subject we are now upon. And it is this: *The fame of Isocrates excited Aristotle to the profession of oratory*. Here these words, *the fame of Isocrates*, contain the subject of this sentence, with what relates to it; and all those which follow, *excited Aristotle to the profession of oratory*, make up the predicate and its dependants. And in both parts each word grammatically considered stands in its proper order of construction. And this seems agreeable to the natural way of conveying our thoughts, which leads us first to express the subject or thing of which some other thing is said, before the predicate or that which is said concerning it; and with respect to both, as every idea succeeds another in the order of our conceptions, to range it in the same order when we communicate them to others. Our language in the general keeps pretty

[45]

pretty much to this method. But in one thing particularly it recedes from it; and that is, in placing adjectives, which denote the properties of things, before their substantives or subjects, whose properties they are: As when it is said, *Evil communication corrupts good manners*. And this we always do, except something follows which depends upon the adjective. So we say, *He was a man eminent for his virtue*; not, *an eminent man*.

*Artificial order*, as it respects simple sentences, has little or no regard to the natural construction of words; but disposes them in such a manner, as will be most agreeable to the ear, and best answer the design of the speaker. The Latins take a much greater liberty in this respect than we do, or than the nature of our language will permit. Quintilian says, it is best for the verb to stand last, when there is no particular reason to the contrary. And he gives this reason for it, *because the force of the sentence lies in the verb*. So that, according to him, they seem to have had this view in putting the verb at the end; that as the whole sentence is imperfect without the verb, the mind being thus held in suspense might receive the deeper impression from it at last. They likewise separate such words as have an immediate relation between them or dependence one upon another, and place any of them first or last as they please. In short, their order seems in a manner arbitrary, if it does not break in upon perspicuity, to which they usually attend. But most of these things are unfuitable to the genius of our language. One might say indeed, *Convince him you cannot*; instead of saying, *You cannot convince him*: Or, *With my own eyes I saw it*; for, *I saw it with my own eyes*. And again: *In proportion to the increase of luxury the Roman state declined*; for, *The Roman state declined in proportion to the increase of luxury*. But the inversion of the words in the former order of these expressions, doth not sound so kindly to an English ear, which is not accustomed to such a manner of speaking.

As to compound sentences, that is, such as consist of two or more members, either simple or compounded; what relates to the words in each member separately, is the same as in simple sentences. But with regard to the disposition of the several members, that may be called the *natural order*, which so places them as they mutually depend on each other. Thus the antecedent member naturally precedes the relative; as in this expression, *Men are apt to forgive themselves, what they blame in others*. In hypothetical sentences the conditional member naturally stands first. Thus: *If Socrates be a rational creature, he is a man*. That member which expresses the effect of an action naturally comes last; as, *Though you offer ever so good reasons, you will not prevail with him*. The like may be said of time, with regard to things done in it; as, *The Roman eloquence soon declined, when Cicero was dead*. And to name no more, the reason of a thing naturally follows that of which it is the reason; as thus: *All the pleasures of life must be uncertain, since life itself is not secure*.

When this order is inverted, it may be styled *artificial*. So to keep to the instances already given, the two members in the first sentence may be thus inverted: *What they blame in others, men are apt to forgive*

*themselves*. In the second, in this manner: *Socrates is a man, if he be a rational creature*. In the third, thus: *You will not prevail with him, though you offer ever so good reasons*. And so in the rest: As, *When Cicero was dead, the Roman eloquence soon declined*; and, *Since life itself is not secure, all the pleasures of life must be uncertain*. The variety of inversions in a sentence may generally be greater or less in proportion to the number of its members. In the following sentence of Cicero, the natural order seems to be this: *If that greatness of mind be void of justice, which shews itself in dangers and labours, it is blameable*. Which may be varied by changing the place of the first and third member, in the following manner: *That greatness of mind is blameable which shews itself in dangers and labours, if it want justice*. Or by altering the place of all the three members thus: *That greatness of mind is blameable, if it be void of justice, which shews itself in dangers and labours*. But oftentimes one member may be included in another, as in the instance here given: *If that greatness of mind, which shews itself in dangers and labours, be void of justice, it is blameable*. Here the relative member is included in the conditional, which is placed first, and the antecedent member follows both. But in Cicero it stands thus: *That greatness of mind, which shews itself in dangers and labours, if it want justice, is blameable*; where the relative and conditional members are both included in the antecedent member. The Latin tongue commonly admits of a much greater variety in the transposition of members, as well as in that of single words, than suits with our idiom. In the following sentence the natural order is much preferable, as it best suits with the proper elevation and cadency of the voice in its pronunciation: *I am willing to remit all that is past, provided it may be done with safety*. But should we invert the members, and say, *Provided it may be done with safety, I am willing to remit all that is past*: the harmony of the cadency would be lost. And if the latter member be included in the former, the alteration will still be worse; as, *I am willing, provided it may be done with safety, to forgive all that is past*. Here the inflection of the voice falls upon the same member as before, and destroys the beauty of the period by its elevation afterwards. Some sentences admit of no involution of their members. Such are those whose members are connected by conjunctive or disjunctive particles. As: *Virtue furnishes the mind with the truest pleasure in prosperity, and affords it the greatest comfort in adversity*. And: *A wise man is neither elated by prosperity, nor depressed by adversity*. And the like may be said of those where the latter member begins with some illative or redditive particle. As in these instances: *The chief thing to be regarded in life is virtue, for all other things are vain and uncertain*. And: *Though fortune is always inconstant, yet she has many votaries*. Neither of the members in any of these ways of expression, and some others which might be named, can be included one in the other. In all the examples hitherto given, the sentences consist only of simple members; and indeed compound members are not so often inverted, nor included one in another, by reason of their length. However, we shall here produce one instance of each: *Whoever considers the uncertainty of human*

*affairs, and how frequently the greatest hopes are frustrated; he will see just reason to be always on his guard, and not place too much dependence upon things so precarious.* This sentence consists of two compound members, which here stand in their natural order, but may be thus inverted: *He will see just reason to be always on his guard, and not place too much dependence on things so precarious; whoever considers the uncertainty of human affairs, and how often the greatest hopes are frustrated.* In the following sentence one compound member is included in another: *Let us not conclude, while dangers are at a distance, and do not immediately approach us, that we are secure; unless we use all necessary precaution to prevent them.* Here the natural order would be: *While dangers are at a distance, and do not immediately approach us; let us not conclude, that we are secure, unless we use all necessary precaution to prevent them.*

But there are some other considerations relating to order, which, being taken from the nature of things, equally suit all languages. So in amplifying, there should be a constant gradation from a less to a greater; as when Cicero says, *Ambition creates hatred, slyness, discords, seditions, and wars.* On the contrary, in extenuating, we should descend from a greater to a less; as if, speaking of the ancient laws of Rome, one should say, *They were so far from suffering a Roman citizen to be put to death, that they would not allow him to be whipped, or even to be bound.* In constituting any whole, we put the parts first; as, *Invention, disposition, elocution, and pronunciation, make up the art of oratory.* But in separating any whole, the parts follow; as, *The art of oratory may be divided into these four parts; invention, disposition, elocution, and pronunciation.* In every enumeration care must be taken not to mix the whole with the parts; but if it be mentioned at all, it must either be put first or last. So it would be wrong to say, *He was a man of the greatest prudence, virtue, justice, and modesty:* for the word *virtue* here contains in it the other three, and therefore should not be inserted among them.

### § 3. Of Juncture and Number.

\* **QUINTILIAN**, speaking of composition, represents a discourse as very happy in that respect, when the *order, juncture, and number*, are all just and proper. The first of these, which gives rules for the due placing of the words and members of a sentence, has been already explained. We now proceed to the other two, which relate to letters and syllables; the former treating of their connection, and the latter of their quantity.

46 1. *As to juncture.* A due attendance is to be given to the nature of the vowels, consonants, and syllables in the connection of words, with regard to the sound.

As to the *first*, when a word ends with a vowel, and the next begins either with a different vowel, or the same repeated, it usually renders the pronunciation hollow and unpleasant. For, as Quintilian has justly observed, "This makes a chasm in the sentence, and stops the course of it." For there must be some pause, in order to pronounce them both, or otherwise the sound of one will be lost. So, for instance, in pronouncing these words, *the other day*, unless you

stop a little after the word *the*, the sound of *e* will not be heard; and if it is dropt, it will occasion a rougher sound, from the aspiration of *th* twice repeated so near together, as *th' other day*. Therefore to prevent both these inconveniences, we usually say, *i' other day*. But the different consonants, which together with the vowels make up those syllables, often cause a considerable difference in the pronunciation, so as to render it more or less agreeable. As, if we say, *he overdid it*, the words *he over* have not so harsh a sound, as *the other*; though still they require some pause to keep them distinct. Besides, some vowels meet more amicably, and admit of a softer pronunciation, than others. Those which have the weakest and smallest sound, follow best; because they occasion the least alteration of the organ in forming the two sounds. Such are *e* and *i*; and therefore, without any chasm in the sound, or hesitation of the voice, we say, *he is*. But where the action of the organs is greater, and the sound stronger, the pronunciation is more difficult: as when we say, *tho' all*. For here is a contrary motion of the lips, which are first put forward in founding the *o*, and then drawn backward to pronounce the *a*; and therefore the sound is much softer to say, *tho' every*, where their action is less. And the like ill effect commonly happens from the repetition of the same vowel: as if we say, *go on; or, you usually act thus*. There is a considerable difference between these two expressions, in repeating the sound of the vowel, and where either of them is doubled in a single word. For then the same sound only is protracted by one continued motion of the organ; as in the words *good, and deem*. But here the sound is repeated again by a new action of the organ; which, if precipitated, obscures the sound of one of the vowels; and, if too much retarded, makes a chasm in the pronunciation; either of which is unpleasant to the ear.

But as the coalition of two vowels occasions an hollow and obscure sound, so the meeting of some consonants renders it very harsh and rough. Thus the words *king Xerxes, and public good*, when so placed, have not only a roughness, but likewise a difficulty in their pronunciation, from the contrary action of the lips; which in the former are first drawn back and then forward, but in the latter the contrary way, and in both of them with some considerable force. But this may very easily be avoided, by saying, with a little alteration in the words, *Xerxes the king, and the good of the public*. So likewise the words *ill company*, have a softer sound, than *bad company*, for the same reason. To multiply instances of this kind seems unnecessary, which is frequently used in all discourse.

The repetition of the same syllable, at the end and beginning of words, is the last thing to be considered. And a little observation will convince us, that where this happens, it generally renders the sound either confused, or unpleasant. Cicero was often rallied on account of this verse:

*O fortunatam natam me consule Roman.*

Every one will easily perceive a disagreeable sound in the following expression: "A man many times does that unadvisedly, of which he afterwards repents." The chime of the words *man many* both seems affected, and displeases the ear. But this will soon be remedied, if we separate those two words, and say, "A man

man

Elocution. man does that many times unadvisedly."

From the short account here given of this part of composition, it is easy to perceive what things are necessary to render it most complete and accurate; which are these following. If a word end with a vowel, the next ought to begin with a consonant, or such a vowel whose sound may agree well with the former. But if a word conclude with a consonant, either a vowel should follow, or such a consonant whose pronunciation will suit with it. And lastly, the same syllable ought not to be repeated at the end of one word, and the beginning of the next. It has been observed by some critics, that the following verse at the beginning of Virgil's *Æneid*, has all these properties:

*Arma virumque cano, Trojæ qui primus ab oris.*

Where any word in this verse ends with a vowel, the next begins with a consonant; and where any one ends with a consonant, the next begins with a vowel; and there is no repetition of the same sound throughout the whole. But this is what rarely happens, especially in our language, which abounds with consonants. And what Quintilian says of the coalition of vowels, in treating upon this subject, seems applicable to the whole. "This" says he, "is a thing not much to be dreaded; and I know not whether the neglect of it, or too great a concern about it, be worse. It necessarily checks the vigour of the mind, and diverts it from matters of great importance. And therefore, as it shews negligence to permit it, so to be in constant fear of it discovers a low genius." This was the opinion of that judicious writer. And as these things cannot always be attended to, it may be sufficient to avoid them, where they prove very offensive to the ear, and it may be done without some greater inconvenience. So in this sentence, *Honesty is the best policy*, the coalition of *y* and *p* in the two last words *best policy* produces a roughness in their pronunciation; but as the expression is strong, and cannot perhaps be well altered for the better, the sound here ought to give way to the sense.

47 II. *Number*. This respects the quantity of syllables, as *Juncture* does their quality. In the Greek and Roman languages every syllable has its distinct quantity; and is either long, short, or common: two or more of which joined together in a certain order make a foot, and a determinate number of these in a different order constitute their several sorts of metre. This variety of sounds gives a much greater harmony to their poetry, than what can arise only from the seat of the accent, and the similitude of sound at the end of two verses, which chiefly regulate our metre. And although their prose was not so confined with regard to the feet, either as to the kind or place of them, as their metrical compositions; yet it had a sort of measure, more especially in the rise and cadency of their periods. This they call *rhetorical number*. And accordingly the ancient writers upon this art acquaint us, what feet are best suited to the beginning, middle, or conclusion of a sentence. Such rules are not applicable to our language, which has not that accurate distinction of quantity in its syllables. For we are apt to confound accent with quantity, and pronounce those syllables longest, on which we lay the accent, though in their nature they are not so. As in the

word *admirable*, where none but the first syllable *ad* is pronounced long; though that is only rendered so by position, and the two following are so by nature. And again, in the word *avarice*, we found the first *a* long for the same reason, and the second short; contrary to the nature of both those vowels. However, we shall offer a few things that may be of some use to modulate our periods and adjust their cadency.

A great number of monosyllables do not stand well together. For as there ought to be a greater distance in the pronunciation between one word and another, than between the syllables of the same word; such pauses, though short, yet, when too frequent, make the sound rough and uneven, and by that means spoil its harmony. And this may seem more necessary to be attended to, because the English language abounds so much with monosyllables. On the contrary, a continuation of many long words makes a sentence move too slow and heavily. And therefore such periods generally run best, which have a proper mixture of words of a different length. Besides, as every word has its accent, which with us stands for quantity; a number either of monosyllables, or long words, coming together, so far abates the harmony, as it lessens the variety.

Again, several words of the same ending do not stand well together, especially where the accent falls upon the same syllable in each of them. For this creates too great a jingle by the similitude of sound; and is apt to displease, from an appearance of affectation. Of this kind is the following sentence: *Nothing is more welcome, delightful, or wholesome, than rest to a wearied man*. In such expressions therefore, if the order of the words cannot well be altered, some other word should be substituted in the room of one of them at least, to diversify the sound. So in the example here given, the sound might be varied by saying: *Nothing is more welcome, pleasant, or wholesome*.

But to add no more, if a sentence end with a monosyllable, it is apt to hurt the cadency, and disappoint the ear; whereas words of a moderate length carry a greater force with them, by the fullness of their sound, and afford the ear what it expected. And there is one sort of monosyllables more especially, which never stand well at the conclusion of a period, tho' we frequently find them there; and these are the signs of cases. Thus we say: *Avarice is a crime, which wise men are too often guilty of*. But the cadency would doubtless be more agreeable if it was altered thus: *Avarice is a crime, of which wise men are too often guilty*. Every one must perceive, when the accent falls upon the last syllable in the sentence, as it does if it end with *of*, the sound is not so pleasant, as when it rests upon the preceding syllable in the word *guilty*. Nor are very long words well suited either to the beginning or conclusion of a period; for they retard the pronunciation at first, and fall too heavy at the end.

### CHAP. III. Of Dignity.

DIGNITY, consists in the right use of tropes and figures. It is not sufficient for an orator to express himself with propriety and clearness, or in smooth and harmonious periods; but his language must likewise be

be suited to the nature and importance of the subject. And therefore, as *elegance* gives rules for the first of these, and *composition* for the second; so does *dignity* for the last of them. It is very evident, that different subjects require a different style and manner of expression; since, as Quintilian says, "What is magnificent in one discourse, would be turgid in another; and those expressions, which appear low upon a sublime subject, would suit lesser matters: and as in a florid harangue a mean word is remarkable, and like a blemish; so any thing lofty and bright upon a trivial argument is disproportionate, and like a tumour upon an even surface." Now this variety in the manner of expression arises in a great measure from *tropes* and *figures*, which not only enliven and beautify a discourse, but give it likewise force and grandeur; for which reason this part of elocution seems to have been called *dignity*.

Tropes and figures are distinguished from each other in several respects. Tropes mostly affect single words, but figures whole sentences. A trope conveys two ideas to the mind by means of one word; but a figure throws the sentence into a different form from the common and usual manner of expression. Besides, tropes are chiefly designed to represent our thoughts, but figures our passions.

#### § 1. Tropes.

- 49 A *trope* as it has been usually defined, is, the change of a word from its proper signification to some other with advantage. The words, with advantage, are added in the definition, because a trope ought not to be chosen, unless there is some good reason for using it rather than the proper word. But in what manner, or how far, it can be said of all tropes in general, that they change the proper signification of words, will best appear by considering the nature of each kind of them separately. Now in every trope a reference is had to two things, which occasions two ideas, one of the thing expressed, and another of that thing to which it has a respect, and is supplied by the mind. For all tropes are taken either from things internally related, as the whole and a part; or externally, as cause and effect, subject and adjunct; or from some similitude that is found between them; or from a contrariety. The first of these is called *synecdoche*, the second *metonymy*, the third *metaphor*, and the last *irony*. We shall endeavour to illustrate this by examples. When we say, *Hannibal beat the Romans*; the meaning is, that Hannibal and his army did this. So that altho' in some sense a part may here be said to stand for the whole, which makes it a *synecdoche*; yet strictly speaking, the word *Hannibal* does not alter its sense, but there is an ellipsis in the expression, Hannibal being put for himself and his army. But if we say, *Cicero should be read by all lovers of eloquence*; here indeed the word *Cicero* appears to be changed from its proper sense, and to signify the books of Cicero; which is a *metonymy*, the author being put for his works; and therefore such expressions need not be deemed elliptical. Again, if any one speaking of a subtle and crafty man, should say *he is a fox*; the meaning is, he is like a fox; which is a *metaphor*, where the word *fox* retains its proper sense, and denotes that animal, to which the man is compared on account of his craft. Lastly, if a person say to another, *Well done*; meaning that the

thing was ill done, the word *well* keeps its own sense; but from the manner of its pronunciation, or some other circumstance attending the expression, it will be evident that the contrary is intended: which is called an *irony*. From these instances it may appear in what latitude we must understand the common definition of a trope, which makes it to consist in the change of a word from its proper sense into some other. But tho' in reality there are but four kinds of tropes, which are distinguished by so many different respects which things bear one to another; yet as these several respects are found in a variety of subjects, and attended with different circumstances, the names of *tropes* have from hence been greatly multiplied; which, however, may all be referred to some or other of those already mentioned, as will be shewn when we come to treat of them in their order. And for distinction sake we shall call the former *primary*, and the latter *secondary*, *tropes*.

We now proceed to consider the reasons which have occasioned the introduction of tropes. And these, as Quintilian observes, are three; *necessity*, *emphasis*, and *beauty*.

1. Tropes were first introduced from *necessity*, because no language contains a sufficient number of proper words to express all the different conceptions of our minds. The mind considers the same thing various ways; views it in different lights; compares it with other things; and observes their several relations and affections; wherein they agree, and in what they differ. From all which reflections, it is furnished with almost an infinite number of ideas; which cannot all of them be distinguished and expressed by proper words, since new ones occur daily. And were this possible, yet would it be impracticable; because the multitude of words must be so vastly great, that the memory could not retain them, and be able to recall them as occasion required. Tropes have in a good measure redressed both these inconveniences; for by means of them the mind is not burdened with a numberless stock of different words, and yet nothing seems to want a name. Thus sometimes, where a word is wanting to express any particular thing, it is clearly enough represented by the name of some other thing, by reason of the similitude between them. At other times, the cause is signified by the effect; the subject by the adjunct; or the contrary. And the whole is often understood by a part, or a part by the whole. And thus by the use of tropes, the mind is helped to conceive of something not expressed, from that which is expressed. It is much the same case, as when we have occasion to speak of a person, whose name we are either unacquainted with, or have forgot; for by describing his person, abode, or some other circumstances relating to him, those we converse with as well understand whom we mean, as if we mentioned his name. So the shepherd in Virgil, when he could not think of the name of Archimedes, describes him by his works:

And what's his name who form'd the sphere,  
And heav'd the seasons of the sliding year?

Besides, it sometimes happens in a discourse, that those things are necessary to be said, which, if expressed in their proper terms, would be offensive; but being clothed with metaphors, may be conveyed to the mind with decency.

2. A second reason above-mentioned for the use of tropes

tropes was, *emphasis*. Tropes do many times express things with greater force and evidence, than can be done by proper words. We receive much the greater part of our knowledge by our senses. And similitudes taken from sensible things, as in metaphors, very much assist the mind in its reflections upon those things which do not come under the cognizance of the senses. For it is certain, that we are sooner and more strongly affected with sensible objects, than with things of which we can have no ideas but from the internal operations of our own minds. Nay, sometimes one bright and lively trope shall convey a fuller and more just idea of a thing, than a large periphrasis. So when Virgil calls the Scipios *two thunderbolts of war*, he gives a more lively image of the rapid force and speedy success of their arms, than could have been conveyed by a long description in plain words. And in many cases the tropical use of words is so emphatical, and suited to the idea we design to excite; that in this respect it may be justly esteemed the most proper. So, *incensed with anger, inflamed with desire, fallen into an error*, are all metaphorical expressions, used in a way of similitude; and yet perhaps no proper words can be made use of, which will convey a more lively image of the thing we design to represent by them.

But *beauty* and ornament, as was observed before, have been another cause of the use of tropes. Some subjects require a more florid and elegant dress than others. When we describe or applaud, ornaments of speech and a gaiety of expression are requisite. And it is the business of an orator to entertain his hearers at the same time that he instructs them. Now Cicero, who was an admirable judge of the force and power of eloquence, has observed, that tropical expressions give the mind the greatest delight and entertainment. "I have often wondered (says he) why tropes should give greater pleasure than proper words. I imagine the reason must be, either that there is an appearance of wit in neglecting what is at hand, and making choice of something at a distance; or that the hearer is furnished with a different thought, without being led into a mistake, which affords a very agreeable pleasure; or that a whole similitude is conveyed to the mind by a single word; or that, particularly in the best and most lively metaphor, the image is presented to our sight, which is the quickest of our senses." And therefore he supposes, that "as garments were first invented from necessity, to secure us from the injuries of the weather, but improved afterwards for ornament and distinction; so the poverty of language first introduced tropes, which were afterwards increased for delight." Besides, a variety of expression is pleasing in a discourse. It is many times necessary that the same things should be repeated; and if this be done in the same words, it will grow tiresome to the hearers, and sink their esteem of the speaker's ability. Therefore, to prevent this, it is proper the expression should be varied, that although the sense be the same, it may give the mind a new pleasure by its different dress.

We come now, in the last place, to lay down some directions proper to be observed in the choice of tropes.

And first, as every trope gives us two ideas; one, of the word expressed; and another, which, by means of that, the mind connects with it; it is necessary, that the relation between these two appear very plain and

evident. For an obscure trope is always faulty, unless where some particular reason makes it necessary. And therefore tropes ought not to be too far-fetched, lest that should render them dark. For which reason Cicero says, he should not choose to call any thing destructive to a person's fortune, *the Syrtis of his patrimony*, but rather *the rock of it*; nor the *Charybdis of his estate*, but *the gulph of it*. For those, who either did not know that the Syrtis were two quicksands upon the coast of Africa, or that Charybdis was a gulph in the streight of Sicily, both of them very destructive to mariners, would be at a loss to understand the meaning of the metaphor. Besides, metaphors taken from things we have seen, affect the mind more forcibly than those which are taken from such things as we have only heard. Now there is scarce any one who has not seen a rock or a gulph; but there are very few persons, comparatively, who have been either at Charybdis or the Syrtis. It is necessary therefore in a good trope, not only that there be a near affinity between the two ideas, but likewise, that this affinity be very obvious and generally known, so that the word be no sooner pronounced, but both images do immediately present themselves to the mind.

Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, so as neither to heighten nor diminish the just idea of it. Indeed, sometimes, when we speak of things indefinitely, we say too much, lest we should seem to say too little. And this manner of speaking is called an *hyperbole*; which is not uncommon in the sacred writings. So, for instance, Saul and Jonathan are said to be *swifter than eagles, and stronger than lions*. But even in this way of expression a proportion is to be observed. For some very considerable and unusual excess of the thing in its kind is at least designed by it; which perhaps cannot, or however is not necessary to be defined. And therefore Quintilian blames Cato for calling the top of an hill a *quart*; because the proportion between the two ideas is no ways adequate. And so, on the contrary, Aristotle censures Euripides for calling rowing, *the empire of the oar*. Poets indeed are allowed a greater liberty in this respect. But an orator should be modest in his expressions, and take care that he neither so heighten nor diminish the natural ideas of things by tropes, as to lead his hearers into mistakes.

But further: As a moderate use of tropes, justly applied, beautifies and enlivens a discourse; so an excess of them causes obscurity, by running it into abstruse allegories and riddles. Tropes are not the common and ordinary dress of our thoughts, but a foreign habit: And therefore he who fills his discourse with a continued series of them, seems to act like one who appears in public in a strange dress; which no man of character would choose to do.

Moreover, as one use of tropes is pleasure and entertainment, we should endeavour to make choice of such as are smooth and easy. But if at any time we think in necessary to use a harsh trope, it is proper to soften it by some precaution. For, as Cicero very handsomely says, *a trope should be modest, since it stands in a place which does not belong to it; for which reason it should seem to come thither by permission, and not by force*. And therefore, when he thought it harsh to say,

say,

say, *The death of Cato made the senate an orphan*; he guards the expression by saying, *The death of Cato has (if I may be allowed to say so) rendered the senate an orphan*.

And, to add no more, care should be taken how we transfer tropes from one language into another. For as they are frequently taken not only from natural things, or such notions as are common to the generality of mankind, but likewise from the manners, customs, and occurrences of particular nations; so they may be very plain and obvious to those among whom they took their rise, but altogether unintelligible to others who are unacquainted with the reason of them. It was customary for the Roman soldiers to carry their money in their girdles; hence it was the same thing with them to say, *a person had left his girdle*, as that *he had left his money*. And because the Romans wore the *toga*, which was a long gown, in time of peace, and a different garb when engaged in war, their writers sometimes use the word *toga* to signify peace. But as neither of these customs is in use among us, so neither would the tropes suit our language, or be generally understood by us. And even in such tropes as are taken from the common nature of things, languages very much differ. There is a very beautiful trope in the account of St Paul's shipwreck, where it is said, *The ship was caught, and could not bear up into the wind*. The original word, that we translate *bear up*, is *αντιβαλμεν*; and properly signifies, *to look, or keep its eyes against it*; which is a very strong and lively image, taken from animate beings, and when applied to men often signifies *to withstand or resist*: as, *αντιβαλμεν πολεμικη, to resist an enemy*; and Plutarch says of Demosthenes, that he could not *αντιβαλμεν τα αερριμα, look against or resist the power of money*. Nothing is more common with Latin writers, than to call men of a public spirit and true patriots, *lumina et ornamenta republicae*, that is, *the lights and ornaments of the state*: And we have borrowed from them the use of both these metaphors. But because tropes and figures illustrate and heighten the style, they call them also, *lumina orationis*, or, *the lights of a discourse*. It sometimes happens, that only the tropical sense of a word is taken from one language into another, and not the proper signification of the same word. So *scrupulus* in Latin properly signifies *a little stone, which getting into the shoe hurts a person as he walks*; hence it is applied to the mind, and used to express *a doubt, or uneasy thought that gives it pain*. We have borrowed this latter sense of the word, but not the former.

#### ART. I. PRIMARY TROPES.

50

I. *Metaphor*. A metaphor, as usually defined, is: *A trope, which changes words from their proper signification to another different from it, by reason of some similitude between them*. But that a word, when used metaphorically, does not alter its signification, but retains its proper sense, was shewn above. However, it may not be amiss to explain this matter more fully, and set it in a clearer light. Every *metaphor*, then, is nothing else but a short similitude. Cicero calls it, *a similitudo reduced to a single word*. And Quintilian to the same purpose says, that, "A metaphor is a short similitude, and differs from it only in this; that the former is compared to the thing we de-

sign to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion." Thus far Quintilian. Now in every similitude three things are requisite: two things that are compared together; and a third, in which the similitude or likeness between them consists. And therefore, to keep to this example, when Horace calls a Roman soldier *a lion*, if the word *lion* did not retain its proper sense, there could be no similitude; because there would not be two things to be compared together with respect to a third, which is necessary in every similitude, and was designed by this expression. The sense of which is plainly this: *That as a lion seizes his prey with the greatest fierceness, so a Roman soldier with like rage and fury attacked his enemies*. In the same manner, when Cicero calls Piso *the vulture of the province*, his meaning is, that he was like a vulture, or acted in such a manner as a vulture acts, that is, rapaciously. So that the real difference between a metaphor and a similitude consists in this; that a metaphor has not those signs of comparison which are expressed in a similitude. But some persons have run into mistakes in reasoning from tropes of this kind. For they have so argued from metaphorical words, as if all the affections and properties of the things expressed by them might be attributed to those other things to which they are applied, and by that means have strained the comparison (which has usually but one particular view), in order to make it tally in other respects, where there is not that similitude of ideas. We will endeavour to make this evident by another example from Cicero, where he calls M. Anthony *the torch of the state*. The similitude between Anthony and a torch lay in this: *That as a torch burns and destroys every thing within its reach, so Anthony brought devastation and ruin wherever he came*. Now a torch has not only a property to burn, but also to give light; but the similitude would not hold in this respect, nor was it at all designed. For Cicero never calls a wicked profligate man, as Anthony was, *the light of the state*; though he often gives that character to good and virtuous men, who by their examples do as it were enlighten others, and shew them the way to be happy themselves and useful to others. But though metaphors are usually taken from a similitude between two things, as in the instances here mentioned; yet sometimes they are founded in the similitude which two things bear to two others in some particular respect, by means whereof what properly belongs to one of them is transferred to the other: the former of which are called *simple metaphors*, and the latter *analogous*. Hence the rudder of a ship may be called *its reins*; for what the reins are to a horse, that the rudder is to a ship in guiding and directing it. So that here is a double similitude, one between a ship and an horse, and another between the rudder of the former and the reins of the latter; and from the analogy-between the use of the rudder to the one and reins to the other, the reins, which belong properly to the horse, are applied to the ship. Again, some metaphors are reciprocal, in which the similitude holds either way. Thus to steer and to govern are used reciprocally both of a ship and a state: the proper expressions being, *to steer a ship, and govern a state*; and the contrary metaphorical.

cal. But though we say, *the foot of a mountain*, borrowing the similitude from animals; yet we do not say, on the contrary, *the bottom of an animal*, meaning his feet; and therefore that metaphor is not reciprocal. From this account therefore of the nature of a metaphor, it may be said to be: *The application of a word by way of similitude to some other thing than what it properly signifies.* And the plainer this similitude appears, the greater beauty there is in the trope.

The use of metaphors is very extensive, as large as universal nature. For there are scarce any two things which have not some similitude between them. However, they may all be reduced to four kinds; which was the second thing proposed to be considered.

The first kind of metaphors therefore may be taken from similitudes between animate beings. As where those things, which properly relate to brutes, are accommodated to men; or those which belong to men are applied to brutes. Of the former sort is that joke of Cicero: *My brother being asked by Philip, why he barked so; answered, Because he saw a thief.* Here *barking*, the property of a dog, is applied to a man: And the reply does not seem to carry more severity, or harshness with it, than the question. By the latter sort we say, *a crafty fox*, and *a generous horse*; which are affections that properly relate to men. And to this kind of metaphors may those likewise be referred, when that which properly belongs to the senses is applied to the mind. Thus we often say *that we see a thing*, when we mean *that we understand or apprehend it.* And in the same sense we say, *that we hear such a thing*, or *person.* And by the like manner of expression, a person is said to *smell out a thing.* And those who have a genius or disposition for any art or science, are said to *have a taste for it*; and such as have entered upon the study of it, are said to *have a touch of it.* These are common ways of speaking in most languages, and very expressive of what is intended by them. And we may also bring those metaphors under this head, by which the properties and affections of men are attributed to the Deity: as, when God is said to *hear, see, be angry, repent*, and the like; which are forms of expressions very frequent in the sacred writings.

A second kind of metaphors lies between inanimate things, whether natural or artificial, which bear some similitude to each other. And this head is very extensive. Thus we say, *floods of fire*, and *clouds of smoke*, for large quantities. And so likewise, to *inflame an account*, that is, to heighten or increase it; with innumerable others of the like sort. In the two first of these instances, the terms proper to one element are applied to another; and as those elements of fire and water are opposite to each other, they shew the extensiveness of this trope, that there are no things in nature so contrary, but may come within the limits of it, and be accommodated to each other in a way of similitude. In the last example, a natural action is applied to what is artificial.

A third sort of metaphors is, when inanimate things are applied to animals, on account of some like properties between them. Thus Homer calls Ajax, *the bulwark of the Greeks*, on account of his valour, which like a wall defended them from the Trojans. And nothing is more common with Cicero, than to brand ill

men with the character of being *the pest of the state*, by reason of the mischief which they bring to the public. So likewise he calls Zeno the philosopher *an acute man*, for his great discernment and quick perception of things; fetching the allusion from metals when brought to an edge or a point. As on the contrary, old Chremes in Terence calls himself *a stone*, for want of apprehension. And we say, *a gay person*, and *a bright genius*, by this kind of metaphor.

The fourth and last kind of metaphors is that by which the actions and other attributes of animals are accommodated to inanimate things. Thus Cicero, speaking of Clodius, says: "The very altars, when they saw that monster fall, seemed to move themselves and assert their right against him." Here the words *saw*, *move*, and *assert*, are all metaphors taken from the properties of animals. And Virgil, when he would represent the impetuous force and rapidity of the river Araxes, says, *it dislained a bridge.* And it is a very useful epithet, which Homer gives to words, to call them *steep*, or *winged*, to intimate the swiftness of speech.

Lastly, as to the choice of metaphors, those are esteemed the finest and strongest, which *give life and action to inanimate things.* The reason of which is, because they do as it were invigorate all nature, introduce new forms of beings, and represent their images to the sight, which of all the senses is the quickest, most active, and yet most unwearied. What can be more moving, or in stronger terms express the villany of Clodius, than when Cicero says, "The very altars of the gods seemed to exult at his death." And the same great orator particularly commends those metaphors, for their sprightliness and vivacity, which are taken from the sense of seeing; as when we say *a bright thought*, or *a gay expression.*

However, care must be taken not to venture upon too bold and daring metaphors. Poets indeed claim greater liberty in this respect, whose view is often to amuse, terrify, or delight, by heightening the just and natural images of things. But it is expected the orator should reason coolly, though strongly and forcibly: and not by theatrical representations so transport the mind, as to take it off from reflection, unless perhaps on some particular occasion. And yet on the other hand, metaphors ought not to sink below the dignity of what they are designed to express; but the idea they convey should at least be equal to the proper word in the place of which they are substituted.

But there is a very great difference in the choice of metaphors, as they are designed either to praise or dispraise. One thing may be compared to another in a great variety of respects. And the same thing may be made to appear either noble or base, virtuous or vicious, by considering it in a different light. Such metaphors, therefore, as are chosen to commend, must be taken from great and laudable things; and on the contrary, those which are designed to discommend, from things vile and contemptible. Aristotle gives us a very pleasant example of this in the poet Simonides. A certain person, who had carried the prize at a race of mules, offered him a reward to write a poem in honour of that action. Simonides thought he did not

Elocution.

bid high enough; and therefore put him off with saying, the subject was too mean to write in praise of mules which were the offspring of asses. But upon his being offered a larger, sum he undertook the task; and, as Aristotle observes, when he has occasion to speak of the mules in that poem, he does not mention them by that name, but calls them the *daughters of fleet and generous horses*, though he might with as much propriety have called them the *daughters of dull asses*. But it was the poet's business, in praising, to take the most advantageous part of the character. Where things are capable of such different turns, metaphorical expressions are generally most beautiful. And sometimes the same metaphor may be applied contrary ways, both in praise and dispraise, as it will suit different properties of the thing to which it refers. So a *dove*, in a metaphorical sense, may represent either *innocence or fear*; and an *iron heart* may denote either *courage or cruelty*; as an *hard head*, *strength or weakness of thought*. And this ambiguity in the application of metaphorical words, often affords occasion for jests and concise wit. We observed before, that Cicero never calls ill men, *lights of the state*. But he once in this manner calls Sextius Clodius, *the light of the senate*. For, when his kinsman Publius Clodius had been killed by Milo, and his corpse was brought to Rome, Sextius raised the mob, and in a tumultuous manner carried it into the senate-house, where they burnt it, and by that means set the building on fire: For which seditious action Cicero passes that joke upon him, under the metaphor of light, which elsewhere he always uses in a good sense.

But to proceed: All forced and harsh metaphors should be avoided, the one being no less disagreeable to the mind than the other to the ear. Nor should they come too thick in a discourse. In a word, they ought not to be used, but either where a proper word is wanting, or they are more significant or beautiful than the proper word.

§1

II. *Metonymy*. This, as defined by Quintilian, is, *the putting one word for another*. But Vossius describes it more fully, when he calls it, "A trope, which changes the name of things that are naturally united, but in such a manner as that one is not of the essence of the other." That a metonymy is thus distinguished from the other tropes, has been sufficiently shewn already in the two last chapters. When it is said, to *put one word for another*, or, to *change the names of things*, the meaning is, that the word so used changes its sense, and denotes something different from its proper signification. Thus, when *Mars* is put for *war*, and *Ceres* for *corn*, they lose their personal sense, and stand for the effects of which those deities were said to be the cause. So likewise, when Virgil says,

He drank the frothing bowl,

the word *bowl* must necessarily signify the liquor in the bowl. And when in another place, describing the temple of Juno at Carthage, in which the actions of the Trojan war were represented, and the images of the heroes, he makes *Aeneas*, upon discovering that of Priam among the rest, cry out,

Lo here is Priam;

it is plain the word *Priam* there must stand not for his person, but his *image or figure*. And this property

of changing the sense of the word appears peculiar to *Elocution* metonymy. In treating upon a metaphor, we observed the mistake of those who teach, that a word used metaphorically loses its proper signification; whereas it only changes its place, but not its sense; being applied to a thing to which it does not naturally belong, by way of similitude. And as the not attending to this has run some persons into very great absurdities, in treating upon metaphorical expressions, and reasoning from them in the tropical sense; so the like has happened to others in some instances of a metonymy, where, by misapprehending their true nature, they have reasoned from them in the literal sense, as we shall shew presently. A metonymy is not so extensive as a metaphor, nor altogether so necessary: because nothing is said by a metonymy, which cannot be expressed in proper words; whereas metaphors are often used for want of proper words to express some ideas. However, metonymies are very useful in language; for they enrich a discourse with an agreeable variety, and give both force and beauty to an expression. And what we observed with relation to a metaphor, is true also of this trope; that some metonymies, even in common discourse, are more frequently made use of than the proper words in whose room they are put. So, *pale death*, *a blind way*, and *a happy state*, are very common expressions with us. And it is more usual to say, *This is such a person's hand*, or *I know his hand*, than his writing, when we intend this latter sense of the word.

We now proceed to the division of metonymies; which are commonly distinguished into four kinds, from the different manner in which things are naturally, but externally, united to one another. Now things are thus united, or one thing depends upon another, either with respect to its production, or in the manner of its existence when produced. In the former way the effect depends upon its cause, and in the latter the adjunct upon its subjects. And hence arise four sorts of metonymies, which receive their names from the *cause and effect*, the *subject and the adjunct*.

It is called a *metonymy of the cause*, when the external cause is put for the effect. The external cause is twofold, the agent and end, which are usually called the *efficient and final cause*. Of the former kind are such metonymies, where the inventor or author is put for what was invented or effected by him. Thus, as we said before, *Ceres* is sometimes put for *corn*, the use of which she was said first to have introduced; and *Mars* for *war*, over which he was thought to preside. And by this way of speaking, any artist or writer is put for his work. So Juvenal, blaming the luxury and profuseness of the Romans, says: *There are few tables without Mentor*; that is, which were not made by him, or after his manner. And our Saviour says in the parable of the rich man and Lazarus, *They have Moses and the prophets*; meaning, the books of Moses and the prophets. But under this sort of metonymy is included not only the agent, strictly so called, but also any means or instruments made use of in the doing of a thing, when put for the thing done. Thus, *polite literature* is called *humanity*, because it cultivates and improves the human mind. And in that expression of Cicero, *Words move nobody but him who*

*understands the tongue*; the word *tongue*, which is the instrument of speech, is put for *speech*, or *language*. And in the like sense, *arms* are sometimes put for *war*, and the *sword* for *slaughter*. By the same kind of metonymy, likewise, any affection or quality is put for its effect. As when it is said, *the end of government is to maintain justice*; that is, *such mutual offices among men, as are the effects of justice*. And so likewise in that of Cicero, *It is the business of magistrates to check the levity of the multitude*; by which he means tumults occasioned by their levity. Moreover, as human affections are attributed to the Deity in a metaphorical sense, so several parts of the human body are likewise ascribed to him by this kind of metonymy. Thus, his *hand* and his *arm* are used to express his *power*; as his *ear* and *eye*, his *care* and *providence*; these being the instruments of such effects in mankind. Metonymies of the final cause are those, by which the end in doing a thing is put for the thing done. As when we say, *The watch is set*, meaning the *watchmen*, who are appointed for that purpose. And so likewise that expression, *to make an example*, as it signifies to *punish*, in order to deter others from the like crimes by such an example. As also that of Virgil,

Phyllis should garlands crop,

by which are meant *flowers* to make garlands.

The second kind of metonymy puts the effect for the efficient cause, whether the agent, or only the means and instrument. So Virgil calls the two Scipios *the destruction of Libya*, because they were the agents who effected it. And Horace compliments his patron Mæcenas with the titles of being *his guard and honour*; that is, his guardian, and the author of his honour. But when Cicero tells the citizens of Rome, that *the death of Clodius was their safety*, he means the occasion only of their safety. And elsewhere he calls that *a dark hope and blind expectation*; the effect of which was dubious and uncertain to those who entertained it. And in like manner, the sons of the prophets, when they were eating the pottage which Elisha had ordered to be set before them, cried out, *There is death in the pot*; that is, *some deadly thing*, as is presently after explained. And thus sweat, which is the effect of labour, is sometimes put for labour. As in the threat denounced against Adam, *In the sweat of thy face shalt thou eat bread*; that is, by labour in cultivating the ground. And, in allusion to this way of speaking, Anthony the orator tells Crassus, “the improvement of the style by constant exercise, as he prescribed, was a thing of much sweat.” And *virtue is said to be gained by sweat*, that is, continued care and exercise in subduing the passions, and bringing them to a proper regulation. But in these two expressions there is likewise a metaphor, the effect of bodily labour being applied to that of the mind. In all these instances, the effect is put for the efficient cause.

The third kind of metonymy is, when the subject is put for the adjunct. By subject here, in a large sense of the word, may be understood that wherein some other thing is contained, or about which it is conversant; as likewise the possessor with respect to the thing he possesses; and the thing signified, when put for the sign of it. Now, by the first of these ways of speaking, the seat of any faculty or affection, is used for the faculty or affection itself. So it is usual to

say, *a man of a clear head*, when we mean a clear mind or understanding; the seat of the mind being in the head. And a person is said to have *a warm heart*, because the heart has been thought the seat of the affections. In like manner, the place where any actions are performed, is put for the actions done in it. As when Cicero says, “Do not always think of the forum, the benches, the rostra, and the senate;” meaning the discourses which were usually made in those places. So likewise the contrary, or place of residence, is put for the inhabitants, as in that passage of Cicero: “And to omit Greece, which always claimed the preeminence for eloquence, and Athens, the inventress of all sciences, where the art of speaking was invented and perfected; in this city of ours, (meaning Rome), no studies have prevailed more than that of eloquence.” Where the words *Greece* and *Athens* stand to denote the inhabitants of those places. And hither may also be referred those expressions in which the time is put for the persons living in it; as, *the degeneracy of the present age*, *the virtue of former times*. In the second way above-mentioned, the object is used for the person, or thing employed about it: As when Cicero says, “In time of battle the laws are silent;” where by *laws* he intends the *judges*, who pronounce sentence according to law. By the third of these ways, in which the possessor is put for the thing he possesses, we say, *to devour, destroy, or ruin a man*; meaning, not his *person*, but his *estate*. And mythologists explain the fable of Acteon by this trope, who is said to have been devoured by his dogs: for by dogs they understand flatterers and parasites, who consumed his estate, and brought him to beggary. By the last way before recited, which puts the thing signified for the sign, statues and pictures are called by the names of the persons which they represent; as in that jest of Cicero upon his brother Quintus, when, as Macrobius relates, “being in the province which his brother had governed, and seeing a large portrait of part of his body, holding a shield, though Quintus was but a little man, he said, My half brother is bigger than my whole brother.” The Popish doctrine of transubstantiation is founded upon an abuse of this trope. For when our Saviour, speaking of the bread and wine at that time before him, says, “This is my body; and this is my blood;” his plain meaning is, they were the signs of his body and blood, the thing signified being put for the sign by this sort of metonymy. But the Papists take the expression literally, which must doubtless be very absurd; since the words relate to the time then present, while Christ was yet living, and spoke them; when it was impossible for the bread and wine to be converted into his body and blood, it being evident to all who were present, that those elements, and his body, existed separately at the same time. But if the words are explained by this trope, the sense is plain and easy, and the way of speaking familiar to all writers. Whereas they who plead for the literal sense might with equal reason assert, that those expressions above-mentioned are to be taken literally, in which several parts of the human body, as the hand, the arm, the ear, and the eye, are ascribed to the Deity; or that, when our Saviour in a metaphorical sense calls himself *a vine*, and *a door*, these words were designed to be applied to him strictly and properly, and not by way of limitation.

litude only, as is the case in all metaphors.

The fourth kind of metonymy is that wherein the adjunct is put for the subject, which is done in the same variety of ways as the former. It is therefore a metonymy of the adjunct, when the thing contained is put for that which contains it. As when Virgil says, "They lie down upon purple;" that is, upon couches dyed with purple. And again, "They crown the wine;" meaning the bowl which contained the wine, it being the custom of the ancients to deck their bowls with garlands at their entertainments. By these tropes likewise virtues and vices are put for the persons in whom they are found. As in that beautiful passage of Cicero, where, comparing the profligate army of Catiline with the forces of the state, he says, "On this side modesty is engaged, on that impudence; on this chastity, on that lewdness; on this integrity, on that deceit; on this piety, on that profaneness; on this constancy, on that fury; on this honour, on that baseness; on this moderation, on that unbridled passion: in a word, equity, temperance, fortitude, prudence, and all virtues, engage with injustice, luxury, cowardice, rashness, and all vices." And to this trope those expressions are to be referred, in which any thing is put for the object about which it is conversant. As in that saying of the wife man, "Hope deferred makes the heart sick;" where hope is put for the thing hoped for. And thus Suetonius calls the emperor Titus *the love and delight of mankind*, whose mild and obliging temper rendered him the object of those agreeable affections to all persons under his government. A third use of this trope is by putting a thing for the time in which it was done. Thus we say of a person, *he has served so many campaigns*; meaning for many summers, that being the usual time in which armies are drawn out into the field. Lastly, by this metonymy, the sign is put for the thing it signifies; as, *the sceptre for the regal dignity, and the sword for the authority of the magistrate*.

III. *Synecdoche*. This is a trope by which either the whole of a thing is put for a part of it, or a part for the whole; so that the two things, whose ideas are presented to the mind in this trope, are internally related to each other: by which, as has been shewn already, it is distinguished from all the other tropes. In a *synecdoche* the word retains its proper sense, and the expression is elliptical, as will appear by the several species of it, wherein the ellipsis in most of the examples is very obvious, and may with no great difficulty be supplied. Now a thing may be considered as an whole in three different respects, which logicians call an *universal, essential, and integral whole*. An universal whole is any genus with regard to its several species: as, an *animal* with respect to *mankind and brutes*; or *philosophy*, with respect to the *several arts and sciences* comprised under it. An essential whole consists of matter and form; as, a *man of body and soul*. And an integral whole is any body or quantity, with respect to the several parts of which the matter of it is composed, and into which it may be divided: as, a *human body* with respect to its *several members*; or a *year*, as divisible into *months, weeks, and days*. And thus rhetoric is an integral whole in respect to the four parts that compose it, namely, invention, disposition, elocution, and pronunciation. So likewise

any aggregate body, as a civil community, which is Elocution, divisible into those who govern and are governed; or any army, consisting of the general, and his soldiers. As an whole therefore, in each of these acceptations of the word, is frequently put for a part, and a part for the whole; hence arise six species or sorts of *synecdoche*.

The first of these puts the genus for the species. Thus, virtue in general is sometimes used to denote some particular sort of virtue. As when Cicero mentions virtue as one of the four qualifications necessary in a general, he means greatness of mind. And so persons are often commended for instances of virtue shewn in their conduct, which respect only some single virtue, as justice, temperance, or the like: And in this sense Cicero calls Clodius *a deadly animal*. So when our Saviour commissions his apostles to *preach the gospel to every creature*, the meaning is, *every rational creature*. And thus likewise, to *talk to a person*, sometimes denotes the same thing as to *blame him*, which is one way of talking.

The second kind of *synecdoche* puts the species for the genus. Thus *bread* denotes any kind of food; as when a person is said to *get his bread by his labour*. In the same way of speaking, *money* is put for any kind of wealth in general. And it is an usual expression to say, that *wine destroys more than the sword*; that is, than any *hostile arms*. And the legal form of banishment among the Romans was, to prohibit persons the *use of fire and water*; that is, the *most common and ordinary necessities of life*, in which all others were included.

The third species of this trope is, when the essential whole is put for one of its parts; that is, either for the matter or form. Thus, in the evangelist, Mary Magdalen says, *They have taken away my Lord, and I know not where they have laid him*; meaning his *body*. So it is usual to say of a deceased person, *He was buried at such a time*. And in the inscriptions of sepulchral monuments we frequently meet with this expression, *Here lies such an one*; that is, his *corpse*. Nor are instances uncommon in which the whole being is put for the form. Thus when Cicero says, *Those persons live, who have fled from the confinement of the body, as from a prison*; by persons must necessarily be understood their *souls*, which are here distinguished from and set in opposition to their *bodies*. And so Virgil represents *Æneas* as meeting with *Dido* and some of his Trojan friends in the infernal regions; by which are meant their *ghosts*.

The fourth kind of *synecdoche* is, when either the matter or form is put for the whole being. Thus *silver and gold* are used to signify money made of those metals; as when we say, *I have so much silver, or so much gold*. And the word *soul*, both in our own and other languages, is put for the *whole person*. So with us, a  *merry soul, and a dull soul*; in Cicero, *dear souls*; and in Horace, *candid souls*, are all used in this tropical sense. But this way of speaking occurs nowhere more frequently than in the sacred writings. Thus, for instance, it is said, *All the souls which came with Jacob into Egypt*, meaning the *persons*. And again, *The soul that sinneth it shall die*: from which expression, and others of the like import, some persons, by not attending to the nature of this trope, have been erroneously led to infer that the soul is naturally mortal. But sometimes only part of the matter

matter stands to expresse the whole essence or being. So we imitate the Latins in using the word *caput* or *head* to denote either a *person* or *thing*. For, as with them *lepidum caput*, so with us a *witty head*, signifies the same as a *man of wit*. And in the same sense, *so many head of cattle* means *so many entire cattle*.

By the fifth sort of synecdoche, the whole of any material thing or quantity, whether continued or discrete, is put for a part of it. So when Cicero says, *A war is kindled through the whole world*; in compliment to his country, he calls the Roman empire *the world*. And this expression is also used by historians. Thus Cornelius Nepos, speaking of the quarrel between Mark Anthony and Augustus, tells us, that each of them desired to be lord of the world. And in like manner St Luke says, *There went out a decree from Caesar Augustus, that all the world should be taxed*. So in St Paul's shipwreck, it is said, *They ran the ship aground, that is, the head of her*; for it is plain by what follows, that the stern was loose. And as to discrete quantity, our Saviour, using this trope, said he should be *three days and three nights in the heart of the earth*. Though he did not continue three whole days and nights in the grave, but only part of the first and third day, and the whole second day, with the two whole nights between the first and third day, according to our way of reckoning. For he was buried on Friday in the afternoon, and rested in the grave that night, with the following day, which was the Jewish Sabbath, and was risen on the morning of the next day. So that we must necessarily have recourse to this synecdoche, which puts the whole for the part, to clear up that event.

By this kind of synecdoche, also, the plural number is sometimes put for the singular. Thus St Matthew says, *The thieves who were crucified with our Saviour reviled him*: though it is plain from St Luke, that only one of them did so. It may also be referred to this trope, when a certain number is put for an uncertain one. So it is an usual way of expression to say, *I have seen or done such a thing an hundred or a thousand times*; when perhaps so many are not really intended, but only in general some considerable number.

The sixth and last kind of synecdoche puts a part of any material thing or quantity for the whole of it. So we say of a man, *He shelters himself under such an one's roof*; that is, *in his house*. And of a fleet, that it *consists of so many sail*; meaning, *so many ships*. And by this trope, that is ascribed to a single person, which was done by the assistance of others, and in conjunction with them. As when it is said, that *Hannibal killed forty thousand Romans at the battle of Cannæ*: For an army is an aggregate body, of which the general is the head, and consequently the chief part of it. And to this kind of synecdoche may also be referred such expressions in which the singular number is put for the plural: as if one should say, *A man is liable to be misled by the influence of irregular passions*; meaning *all men, or mankind in general*. Or when less than the real number is put for any round number. Thus some ancient writers, when they speak of the Grecian armada that came against Troy, call it a *fleet of a thousand ships*; though, according to Homer's list, it contained 1186. And so likewise the Greek

interpreters of the Old Testament are usually called *the Seventy*; whereas, in reality, they were seventy-two.

IV. Irony. This is a trope in which one contrary is signified by another: As if any one should say, *Well done*; when at the same time his design is to intimate that the thing was *ill done*. So that, by this manner of expression, the speaker appears to mean something contrary to the sense of the word he makes use of. Not that the word is changed from its usual signification; but by the circumstances attending the expression, we perceive the contrary to what is spoken is intended. Quintilian observes, that an irony may be known one of these three ways: "By the manner of pronunciation, or from the nature of the person or the thing. For (as he adds) where any of these do not suit with the words, it is plain the speaker intends the contrary." The irony is very plain from the manner of pronunciation in that passage of Terence, where Simo speaking to his servant by way of reproach, says, "You have taken great care indeed." From the circumstances of the person, when Cicero, addressing to Catiline, says, "He went to your companion, that excellent man, Marcus Marcellus." When he calls him an *excellent man*, it is evident he means the contrary; because no good man would be a companion of Catiline. And when he begins his oration for Ligarius with saying, "Caesar, this is a new crime, and never heard of till now," the thing he is speaking of shews it to be an irony; for it was not new, as all who were present very well understood.

The subjects of irony are vices and follies of all kinds. And this way of exposing them is often more effectual than serious reasoning: For many persons, who, either from temper or want of reflection, cannot be moved by the force of an argument, are not proof against the poignancy of wit and railery. And therefore we find the most grave and serious persons have not declined the use of this trope upon proper occasions. Socrates, whom the oracle pronounced the wisest man of his age, gave so much into it, that he got the name of *ωῦρ*, that is, the *droll*. In the sacred writings we have a remarkable instance of it in the prophet Elijah, where he challenges the priests of Baal to prove the truth of his deity: For it is said expressly, "He mocked them, and said, Cry aloud, for he is a god; either he is talking, or he is pursuing, or he is on a journey, or peradventure he sleepeth, and must be waked." And Solomon takes the like method to expose the follies of youth by this ironical apostrophe, "Rejoice, O young man, in thy youth," with what follows, which is all ironical. Nay, our Saviour himself thought fit thus to reprove the Jewish doctors, when he says, "Full well ye reject the commandment of God, that ye may keep your own tradition." Where, by the words *full well*, or, as it is in the original, *καλως*, it is very evident that a severe reprimand was intended.

An irony is used on a variety of occasions, as we shall shew from some instances in Cicero. Sometimes he applies it in a way of jest and banter: As when he says, "We have much reason to believe the modest man would not ask him for his debt, when he pursues his life." At other times by way of insult and derision:

tion: Thus when he would represent the forces of Catiline as mean and contemptible, "O terrible war, (says he) in which this band of rakes are to march under Catiline! Draw out all your garriſons againſt this formidable body." Again, at other times, to give the greater force to his argument, he would ſeem as it were by this trope to recall and correct what he had ſaid before; as in his oration for Milo: "But it is fooliſh in us to compare Drufus, Africanus, Pompey, and ourſelves, with Clodius; all our calamities were tolerable, but no one can patiently bear the death of Clodius." Now the character of Clodius was ſo well known, that all who were preſent muſt be ſenſible he meant the contrary. And, to name no more, an irony is never uſed to greater advantage, than when it is followed immediately by ſomething very ſtinging. Thus, ſpeaking of Pifo, he ſays, "You have heard this philoſopher: he denies that he was ever deſirous of a triumph." And then addreſſing himſelf to him, he immediately adds, "O wretch! when you deſtroyed the ſenate, ſold its authority, ſubjected your conſulate to the tribune, overturned the ſtate, betrayed my life and ſafety for the reward of a province; if you did not deſire a triumph, what can you pretend you did not deſire?" This muſt effectually confound the falſe gravity at that time aſſumed by Pifo.

#### ART. II. SECONDARY TROPES.

SECONDARY TROPES are ſo called, becauſe they are all of the ſame nature with the former, and may be referred to ſome or other of them, though they have received different names.

They are chiefly eight in number; *Antonomafia*, *Communication*, *Litotes*, *Eupheuiſm*, *Catachreſis*, *Hyperbole*, *Metalepſis*, and *Allegory*. The three firſt of theſe are ſimple tropes, and may all be referred to a *Synecdoche*. But the five laſt are of a mixed or complex nature, and not confined to any one of the primary tropes; as will appear in treating upon them in order.

I. A common or general word is ſometimes uſed for the proper name of ſome particular thing or perſon which upon any account is eminent and remarkable. So we ſay, *He is gone to the city*, or *he came from the city*, that is, *London*. And by the *Scriptures* we mean the *Bible*. So likewiſe in ſpeaking of perſons, the orator is uſed for Cicero, the poet for Homer or Virgil, and the philoſopher for Ariſtotle: and it is not unuſual to ſay *the apoſtle*, when we mean St Paul. On the contrary, the proper names of things or perſons are ſometimes applied to any other of the ſame character. Thus we uſe the word *goſpel* for any certain and undoubted truth. And *Carthaginian faith* proverbially ſtood for the greateſt falſhood and deceit among the Romans. With the Greeks, *Hercules* ſignified a *ſtrong man*, *Nefor* a *wiſe man*, and *Irus* a *beggar*; and the names of *Samſon*, *Solomon*, and *Job*, now answer the like characters. Both theſe ways of expreſſion are often very emphatical, and heighten the idea more than where things are expreſſed by their own name. To call a good orator *Cicero*, or an excellent poet a *ſecond Virgil*, includes not only an encomium from the arts themſelves, but leads the mind to what is moſt perfect in them, and was peculiar to thoſe

perſons. Theſe forms of ſpeech are called *antonomafia*, and come properly under a ſynecdoche; for in the former the whole is put for a part, and in the latter a part for the whole.

II. Nothing is more common with orators, than a change of perſons. Sometimes, to avoid envy, and prevent the imputation of pride, in aſſuming to themſelves the praiſe of any laudable action, they aſcribe it to their hearers, and do not ſay, *we*, but *ye did ſo* and *ſo*. At other times, when it is neceſſary to remind them of ſomething which they have done amiſs, or to caution them againſt ſome wrong ſtep for the future; to prevent giving offence, they take it upon themſelves, or at leaſt join themſelves with them, and do not ſay, *you have done this*, or *do not you do this*; but, *we have done it*, or *let us not do it*. And again, at other times, in compliment to their hearers, they join them as partners in the commendable actions or virtues of other perſons; as when the whole body of the people is brought in to ſhare the praiſe ariſing from the ſuccesſ of wiſe counſels or victorious arms. Such ways of ſpeaking often occur both in Demoiſthenes and Cicero. They are called *communication*, and come properly under a ſynecdoche of the whole.

III. On the contrary, there is a mode of ſpeech, in which, by denying the contrary, more is intended than the words expreſs. This way of ſpeaking is called *litotes*; and is often uſed for modeſty ſake where a perſon is led to ſay any thing in his own praiſe, or to ſoften an expreſſion which in direct terms might found harſh or give offence. As if one ſhould ſay, *I do not commend you for that*; meaning, *I greatly diſcommend or blame you for it*. Where more being underſtood than the words expreſsly denote, it is properly a ſynecdoche of the part. Not that this manner of ſpeaking is always to be ſo interpreted; but where it is not, there is no trope; which muſt be judged of by the circumſtances of the diſcourſe. But that it frequently is ſo uſed, might be eaſily ſhewn from many inſtances; though it will be ſufficient to mention two or three. Cicero ſpeaking of Cotta, calls him *no mean orator*, whom he had juſt called a *very great orator*. And he ſays of Varro, that, "he purſued his ſtudies not without induſtry;" and afterwards gives him the character "of a man of the greateſt application." Which paſſages, compared together, plainly ſhew the import of thoſe negative expreſſions. And a friend of Cicero, writing to him, begins his letter thus: "Al- though I am ſenſible the news I ſend you will not be very pleaſant." This news was concerning the death of another friend of Cicero's; and there by the words *not very pleaſant*, muſt to be ſure be meant *very unpleaſant and melancholy*; but he choſe that expreſſion in the beginning of his letter, as the ſoſteſt and leaſt ſhocking, the better to prepare him for the following account of what that news was. And this way interpreters explain that paſſage in St Matthew: *And thou Bethlehem in the land of Juda are not the leaſt among the princes of Juda*; where, by *not the leaſt*, they underſtand the *greateſt*, or *very great*, upon account of the honour it received by the birth of our Saviour, as the words immediately following plainly intimate.

IV. When any diſpleaſing or ungrateful thing is expreſſed by a more ſoft and agreeable word, it is called *eupheuiſm*. And as the word made uſe of is either con-

Elocution.

Elocution.

contrary to the proper word, or only different from it, it may be referred to different tropes. The Latins have a soft way of expressing their disregard to a person, by saying *valet*; which we have borrowed from them, and say, *fare him well*. When the contrary being intended to what is expressed, it comes properly under an *irony*. And as the word *death* carries in it an idea that is disagreeable to human nature, instead of saying a person is dead, we often say *he is deceased*, or *departed*; which we have also taken from the Latins, who use the words *decessit* and *obit*, in the same sense. So that in both languages it comes under a *synecdoche* of the whole; to depart out of life being one sort of departure. But when the evangelist speaking of Stephen, who was stoned to death, expresses it by saying that *he fell asleep*; this is a beautiful metaphor, taken from the similitude between the death of a good man and sleep.

53 V. *Catachresis* signifies in general any harsh trope, though it is most commonly found in metaphors. It is principally used by poets, who make choice of it for novelty, or to enforce an expression, where the proper word does not seem strong enough. As when Milton, in describing the angel Raphael's descent from heaven, says, he

Sails between worlds and worlds;

where the novelty of the word enlivens the image more than if he had said *flies*. But it is sometimes found in the gravest authors, and even in the sacred writings. So we read of the *blood of the grape*. And Solomon says, *the horse-leech hath two daughters*. In all these instances the trope is a metaphor. But when St John says in the Revelations, *I turned to see the voice that spake to me*, it is here a metonymy of the adjunct; the word *voice* being put for the person who uttered it. In St Matthew we read of *Simon the leper*; not that he was then a leper, but had been so, and was cured; which is a *synecdoche* of the part. And when a criminal is said to have had his reward, that is, his punishment, it is an *Irony*.

59 VI. *Hyperbole* is the boldest of all tropes; for it exceeds the strict bounds of truth, and represents things either greater or less, better or worse, than they really are. But the representation is made in such a manner as not to impose on the hearers. For an *hyperbole* is not used to define or describe any thing accurately, but only to magnify or deprecate it in a considerable degree, when we either cannot or do not choose to represent it exactly. The excess in this trope is called *auxesis*; as when we say of any thing that is very high, *it reaches to the skies*. The defect, or contrary extreme, is termed *meiosis*: So we say of a very lean person, *he is nothing but skin and bones*, or a mere *skeleton*. It is principally metaphorical, but sometimes taken from other tropes. When Saul and Jonathan are said to have been *swifter than eagles*, and *stronger than lions*, the expression is founded in similitude, and is therefore a metaphor. When, instead of saying Cato was a very virtuous man, the historian calls him *the image of virtue*; it is an hyperbolical metonymy of the adjunct for the subject. And when we read in the Mosaic history of *cities fenced up to heaven*, there is a *synecdoche*. But if a man of weak sight be said to be *eagle-eyed*, it is an *irony*. Those hyperboles which are expressed comparatively, are commonly most em-

phatical, because they shew a peculiarity in the excess. To say a thing is *as light as a feather*, carries the idea very far; but to say it is *lighter*, not only carries it still farther, but also heightens it, by leaving the mind at an uncertainty where to fix the limits.

VII. Sometimes two or more tropes, and those of a different kind, are contained under one word; so that several gradations, or intervening senses, come between the word that is expressed, and the thing designed by it. And this is called a *metalepsis*. The contests between Sylla and Marius proved very fatal to the Roman state. Julius Cæsar was then a young man. But Sylla observing his aspiring genius, said of him, "In one Cæsar there are many Mariuses." Now in this expression there is a *metalepsis*. For the word *Marius*, by a *synecdoche*, or *antonomasia*, is put for any ambitious and turbulent person; and this again, by a *metonymy* of the cause, for the ill effects of such a temper to the public. So that Sylla's meaning, divested of these tropes was, that Cæsar would prove the most dangerous person to the Roman state that ever was bred in it: Which afterwards proved true in the event. So when Virgil, describing that part of the African coast where Æneas arrived with his ships, says, *A dark wood hung over it*; the word *dark*, by a metonymy of the effect, is put for *shady*, and that again by the same trope for *thick*; for his meaning is, a *thick wood*. But the words of Dido, in the same poet, contain a larger gradation, when she says,

Happy, ah truly happy had I been,  
If Trojan ships our coasts had never seen.

In which expression, first by a metonymy of the adjunct, the ships are put for the Trojans in the ships; and these, by a *synecdoche* of the whole, for Æneas, who was one of them; and again, his arriving on the coast, by a metonymy of the cause, for her seeing him; and lastly, her seeing him, by the same trope, for the passion she had for him. So that her meaning is, she had been happy, if she had never entertained a passion for Æneas. This trope is more frequently to be met with in poets than in orators, as they take greater liberty in using distant allusions than is suited to that perspicuity of expression which is required in oratory. But as Quintilian has well observed, all the intermediate links of the chain in this trope are of no further use than to lead the mind gradually from the first to the last, the better to perceive their connection. As in the example last mentioned, relating to Dido, if we drop all the intervening steps, and connect the words expressed with what is directly intended, they will be found to contain a very remote cause put for the effect, which comes under a *metonymy*. On the contrary, in the second example, where *dark* stands for *thick*, the effect is put for a remote cause. And the first, which is founded in a similitude of temper between Cæsar and Marius, belongs to a *metaphor*.

VIII. *Allegory*. As a *metalepsis* comprises several tropes in one word, so this is a continuation of several tropes in one or more sentences. Thus Cicero says, "Fortune provided you no field, in which your virtue could run and display itself." Where the words *field* and *run* are metaphors taken from corporeal things, and applied to the mind. And in another passage, speaking of himself, he says, "Nor was I so timorous, that after I had steered the ship of the state through.

60

61

through the greatest storms and waves, and brought her safe into port, I should fear the cloud of your forehead, or your colleague's pestilent breath. I saw other winds, I perceived other storms, I did not withdraw from other impending tempests; but exposed myself singly to them for the common safety." Here the state is compared to a ship, and all the things said of it under that image are expressed in metaphors made use of to signify the dangers with which it had been threatened. And indeed allegories generally consist of metaphors; which being the most beautiful trope, a number of them well chosen and put together is one of the finest and brightest ornaments in language, and exceeds a single metaphor in lustre, as a constellation does a separate star. It is true, that allegories are sometimes found in other tropes; but this is very rare. In that known expression of Terence, the tropes are all metonymies: *Without Ceres and Bacchus Venus grows cold*; that is, divelled of the tropes, *Without meat and drink, love dies*. And Samson's riddle is made up of synecdoches: "Out of the eater came forth meat, and out of the strong came forth sweetness." But there is no small skill required in the right management of allegories. For care should be taken, that the same kind of trope be carried through the whole, so as to compose one uniform and consistent set of ideas: otherwise they dress up a chimera, a thing that has no existence, and of which the mind can form no perception. And, as Quintilian says very justly, "to begin with a tempest and end with a fire, would be very ridiculous and unnatural." It is likewise very necessary that the allusions be all plain and evident, especially where the name of the thing alluded to is not expressed. These are called *pure allegories*. As that of Cicero: "So it happens, that I, whose business it is to repel the darts, and heal the wounds, am obliged to appear before the adversaries have thrown any dart; and they are allowed a time to attack us, when it will not be in our power to avoid the assault; and if they throw a poisonous dart, which they seem prepared to do, we shall have no opportunity to apply a remedy." The tropes here are all taken from military affairs, without any intimation what they are applied to. But that is plain from the context of the discourse. For he is speaking of the disadvantages he laboured under in defending his client against those of the opposite side, and so applies to the bar those terms which were proper to the field. But where the reference is not evident, it becomes a riddle; which is nothing else but an obscure allegory. To avoid this, therefore, the best writers generally use what they call *mixed allegories*; that is, such wherein the proper name of the thing is expressed, which the whole similitude respects. Of this kind is that in the speech of king Philip of Macedon, given us by Justin, where he says, "I perceive that cloud of a dreadful and bloody war arising in Italy, and a thunder-storm from the west, which will fill all places with a large shower of blood, wherever the tempest of victory shall carry it." The proper words *war, blood, and victory*, being joined to the tropes *cloud, shower, and tempest*, in this sentence, render the several parts of the similitude plain and evident. Quintilian thinks those allegories most beautiful, where the whole similitude is expressed, and those words, which in their proper sense relate to one

of the two things between which the comparison is made, are allegorically applied to the other: As when Cornelius Nepos says of Atticus, "If that pilot gains the greatest reputation who preserves his ship in a boisterous and rocky sea; ought not he to be thought a man of singular prudence, who arrived in safety through so many and so great civil tempests?" These are the allegories with which orators are chiefly concerned.

## § 2. Of Figures.

This term seems to have been borrowed from the stage, where the different habits and gestures of the actors, suitable to the several characters they sustained, were by the Greeks called *σκηνατα*, and by the Latins *figuree*: And it is not unusual with us to say of a person, both with respect to his dress and action, that he makes a *very bad*, or a *very graceful*, figure. And as language is the dress, as it were, of our thoughts, in which they appear and are represented to others; so any particular manner of speaking, may in a large sense of the word be called its *figure*, in which latitudes writers sometimes use it. But rhetoricians have restrained the sense of the word to such forms of speech as differ from the more common and ordinary ways of expression; as the theatrical habits of actors, and their deporement on the stage, are different from their usual garb and behaviour at other times. A figure therefore, in the sense it is used by rhetoricians, is, *A mode of speaking different from, and more beautiful and emphatical than, the ordinary and usual way of expressing the same sense*. Now as the habits and gestures of our bodies are in a manner infinitely variable, so it is plain that the different forms of speech are almost innumerable. But every alteration from the common manner ought not to be esteemed a figure, nor deserves that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

The subject of figures seems to have been one of the last things which was brought into the art of oratory in order to complete it. Aristotle, who treats so accurately upon other parts, says very little of this. But the Greek writers who came after him have abundantly supplied that deficiency. It is to them we owe the chief observations, that have been made on this subject. They took notice of the several modes and turns of expression, observed their force and beauty, and gave them particular names by which they might be known and distinguished from each other. And indeed they have treated the matter with that minuteness and subtilty, that Quintilian seems, not without reason, to think they have multiplied figures to an excess. But though it was so late before they were taken notice of, and introduced into the art of speaking; yet the use of them in discourse was doubtless very ancient. The author of Homer's life, which some have ascribed to Plutarch, has shewn, by examples taken out of him, that there is scarce a figure mentioned by rhetoricians, but is to be met with in that most ancient poet. And, if we consider the nature of speech, we shall easily perceive that mankind must have been under a necessity very early to introduce the use of tropes for supplying the want of proper words to express their simple ideas: so the like necessity must have

have put them upon the use of figures to represent their different passions. Tho' both of them were afterwards increased, and improved in such a manner as to become the chief ornaments of language. The passions of men have been always the same; they are implanted in us by nature, and we are all taught to discover them by the same ways. When the mind is disturbed, we shew it by our countenance, by our actions, and by our words. Fear, joy, anger, alter the countenance, and occasion different emotions and gestures of the whole body. And we know with what passion a man is affected, by hearing his words, though we do not see him. He does not express himself as he usually does at other times when cool and sedate. Objects appear to him in a different view, and therefore he cannot but speak of them in a different way. He interrogates, he exclaims, he admires, he appeals, he invokes, he threatens, he recalls his words, repeats them, and by many other different turns of expression varies his speech, no less than his countenance, from his common and ordinary manner. Now as nature seems to teach us by these figurative expressions how to represent the different commotions of our minds, hence some have thought fit to call figures *the language of the passions*. And as these are given us, among other wise ends, to excite us the better to provide for our preservation and safety, this is done sometimes by force of arms, and at other times by discourse. And therefore Cicero very handsomely compares the conduct of an orator to the exercises of the palestra: in which, as each combatant endeavours not only to defend himself, and attack his adversary, but likewise to do both with decency; so the principal weapons of an orator, as he represents them, are figures, which being no less the ornaments of language than images of our passions, answer all these purposes. Besides, figures chiefly distinguish the different kinds of style, furnish it with an agreeable variety, and often serve to represent things in a clear and forcible manner.

From this short account of the nature of figures, the advantage of them to an orator is very evident. They are a sort of natural eloquence, which every one falls into without attending to it, suitably to that temper of mind, with which he is affected himself, and is desirous to affect others. In a cool and sedate discourse, such figures as convey our sentiments with the greatest strength and evidence are most proper. And there are others, which are suited to brighten and enliven more gay and sprightly subjects. Others again are more peculiarly adapted to express the disorders and perturbations of the mind. To repeat the same thing again would many times be deemed a tautology and impertinent; but to do this when the mind is ruffled, is not only allowable, but the repetition renders it more strong and affecting. So likewise to interrogate, exclaim, or admire, under the influence of a passion, impresses the hearers, and disposes them to attention; whereas at another time perhaps such ways of speaking would scarce be consistent with prudence. There is a natural sympathy in mens minds, which disposes them to receive impressions from those with whom they converse. Thus one gay and pleasant companion gives a cheerfulness and vivacity to a whole company; whereas on the contrary, one who is dull and slegmatic damps the spirits of all about

him, and affects them with the same gloomy temper. Figures are peculiarly serviceable to an orator for answering these different intentions. And as he finds them in life, from thence he must copy them; as a painter does the features of the countenance, and the several parts of the body; figures being to the one what lines and colours are to the other. The design of Catiline to destroy the Roman state and burn the city, is a story well known. There was an army drawn together at a proper distance to favour the undertaking; and others were left in Rome, who had their parts assigned them for burning the city, and destroying those who should escape the flames. And in a word, every thing was ready for putting in execution this horrid and barbarous scheme. So that nothing retarded it but the taking off Cicero, who was then counsel, which was thought necessary to be done first. Cicero, upon information of the design against his life, finds means to prevent it, and the same day calls together the senate. And Catiline, who was a man of consummate boldness, had the confidence to appear in that assembly. Upon their meeting, Cicero opens to them the whole affair of the conspiracy, and the design against himself, in a most warm and pathetic harangue. In which he had two things in view; to raise the indignation of the senate against the conspirators, and particularly against Catiline; and, either by terrifying or exasperating him, to oblige him to leave the city. Now he does not begin this speech in his usual manner at other times, by addressing to his audience, bespeaking their favour and attention, or letting them gradually into the design of what he was about to say; but as Catiline was present, he immediately falls upon him with vehemence, in the following manner: "How far, Catiline, will you abuse our patience? How long will your fury insult us? What bounds will you set to your unbridled rage? Does neither the night guard of the palace, nor the city watch, nor the peoples fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you? Do not you perceive your designs are discovered, and that all who are present know of your conspiracy? Who of us do you think is ignorant of what you did the last night, and the night before, where you was, who were with you, and what you resolved on? O times, O manners! The senate knows this, the consul sees it; and yet this man lives!—lives? nay, comes into the senate, joins in the public counsels, observes and marks out each of us for destruction!" And in the same impetuous strain he proceeds through his whole speech, interpersing a great variety of the like strong and moving figures. And the discourse had its desired effect: for when Catiline stood up afterwards to make his defence, the whole senate was so inflamed, and their resentments against him rose so high, from what Cicero had said, that they had not patience to hear him speak; upon which he left both them and the city. Had Cicero, instead of venting his just indignation against the author of so barbarous and inhuman a design, in the manner he did, by figures suited to strike the passions of his hearers; had he, instead of this, attempted to reason with him, and told the story in a cold and lifeless manner, he would have

exposed himself to the contempt of Catiline; and by leaving the senate little or nothing moved at what he said, prevented perhaps their coming to those speedy and vigorous resolutions which were necessary at so critical a juncture. Let us suppose him to have expostulated with Catiline in much the same words as before, but thrown into a different form, and divested of those pathetic figures. As thus: "Catiline, you have really abused our patience to a great degree. You have insulted us with your furious proceedings a long while. You seem to have fixed no bounds to your unbridled rage. Neither the night-guard of the palace, nor the city-watch, nor the peoples fear, nor the agreement among good men, nor the calling together of the senate in this fortified place, nor the countenances and looks of this assembly, appear to move you in the least. I assure you we are all of us apprised of what you did the last night, and the night before, where you was, and who were with you, and what resolutions you came to. These are sad times, the age is very degenerate; that the senate should know all this, the consul see it; and yet that this man should live, come into the senate, hear all our debates, and mark us out to destroy us." You see the sense is entirely the same, and the words too in a great measure; so that there is little more than an alteration in the form of them. And yet who does not perceive how flat and languid such a way of talking must have appeared at that time? and how much it loses of that spirit and energy, which shews itself in Cicero's manner of expression? Had he delivered himself thus, it might indeed have made the senate look upon Catiline as an abandoned wretch, lost to all virtue and goodness, and perhaps have moved some to pity him on that account; as we are easily induced to compassionate persons in such circumstances, especially when descended from noble and virtuous ancestors, which was his case. But sure it would have been ill suited to fire their minds with that generous regard for their country, and the necessary precautions for its security, which the circumstances of the state then required. Nor would Catiline have been at all deterred by it, but rather encouraged in the prosecution of his designs, from the little effect a speech so managed must probably have had upon the minds of the senators. But Cicero knew very well, that the passions of mankind are the springs of action: that it is many times not sufficient for an orator to convince their minds, by setting the truth in a clear light; but he must also raise their hopes, alarm their fears, inflame their anger, or excite some other suitable passion, before they will be brought to act with that zeal and fervour, which the case may require. And as he was admirably well skilled in this art of touching the passions, he seldom fails to fix upon the proper methods of doing it, and makes choice of such figures and modes of speaking as in the strongest manner represent the emotions of his own mind. For every passion is not to be expressed by the same figures, any more than it is drawn by the same lines, or painted with the same colours. When Dido finds that Æneas is about to leave her, she uses all her arts to detain him. And as persons in great distress are seldom at a loss to express their condition in the most affecting way; she discovers her fear, anger, revenge, with the whole crowd of disorders

which then possessed her mind, in a variety of moving figures, suited to raise the counter passions in his breast, as is finely represented by Virgil in that artful speech he has made for her, which we forbear to recite for no other reason but the length of it. But what particular figures are most accommodated to answer the several ends proposed by them, will best appear when we come to treat of them separately.

We shall therefore now proceed to lay down a few directions for the proper use of figures. And first they should always be accommodated to the sentiments, and rise in proportion to the images designed to be conveyed by them. So far as they are founded in reason, they are suited to impress the mind; but where the language outstrips the thought, though it may please the ear, and some weak persons may be carried away with a pomp of words, yet an intelligent hearer will soon see through the thin and airy dress. It is the sense which gives weight to the figure, as that by striking the imagination awakens the mind, and excites it to act in conformity to reason. Again, in the use of pathetic figures, it is generally better to be nervous than copious, that the images, by their closer union, may impress the mind with greater force and energy; though in such figures as are designed for ornament or illustration, a more diffusive way of painting is sometimes agreeable. But farther, the too frequent use of figures ought to be avoided. For what was observed in relation to tropes, is also true with respect to these; that a great number of them is apt to darken and obscure the style. And besides, Cicero's reflection in this case is very just, That "it is hard to say, what should be the reason, that those things, which most affect us with a sensible pleasure, and at first sight soonest move us, do likewise soonest cloy and satiate us." But that it is so, we find by common experience. Lastly, figures should be so interwoven in a discourse, as not to render the style rough and uneven, sometimes high and at other times low; now dry and jejune, then pompous and florid. In a word, they should rather seem to arise from nature than art; to offer themselves, than to be the effect of study; and to appear not like patches upon a face, but the agreeable beauty of a sound and healthful complexion. But of this we shall have occasion to speak more at large hereafter, in treating upon the different kinds or characters of style.

As to the division of figures, which is what remains to be considered, they are usually divided into two sorts, figures of words, and figures of sentences. The difference between them consists in this; that in the former, if you alter the words, or sometimes only the situation of them, you destroy the figure; but in the latter the figure remains, whatever words are made use of, or in what manner soever the order of them is changed. Thus when the name of a person or thing is repeated, to intimate some known property or quality belonging thereto, it is a verbal figure called *place*. Cicero was a true patriot and hearty lover of his country. And therefore we shall use this figure in saying, that *at the time of Catiline's conspiracy Cicero appeared like Cicero*. The sense would remain the same, but the figure would be lost, if we should alter the words, and say, *at that time Cicero appeared like himself*. So when two or more sentences,

Elocution. or members of a sentence, end with the same word, it is called *epistrophe*; as when we say, *To lose all relish of life, is in effect to lose life*. But if only the order of the words be changed in the latter clause thus, *To lose all relish of life, is to lose life in effect*; the figure vanishes. And this is the nature of the verbal figures. But it is not so in figures of sentences; they continue the same, whatever alterations are made in the words. An orator sometimes thinks it proper to change the form of his discourse, and address himself to his audience, or an absent person, or else perhaps to introduce some other person as speaking to them. whose words may be supposed to carry greater weight and authority with them than his own. The former of these is called *apostrophe*, and the latter *propositio* or *imagery*; which require no certain words, or order of expression.

#### ART. I. VERBAL FIGURES.

THESE may be distinguished into three sorts, as they consist in a deficiency of words, a redundancy, or a repetition.

I. Of the first sort are *ellipsis* and *asyndeton*.

*Ellipsis*, is when one or more words are wanting in a sentence, to complete the construction, and fully express the sense. This figure is often used in proverbial speeches: as when we say, *Many men, many minds*: that is, *have many minds*; and, *The more danger, the more honour*, that is, *gains more honour*. But where more is intended by such expressions than mere brevity, and especially when they are the effect of some passion, the figure receives another name, and is called *apostrophe*, which is placed among the figures of sentences, where we shall consider it.

*Asyndeton*, is when the particles that connect the members of a sentence one with another are left out, to represent either the celerity of an action, or the haste and eagerness of the speaker. Thus Cæsar expresses his speedy conquest of Pharnaces: *I came, I saw, I conquered*. If he had inserted the copulatives, and said, *I came, and I saw, and I conquered*: it would have retarded the expression, and not given so full and just an idea of the swiftness of the action. In the last article we took notice of the vehement and impetuous manner in which Cicero attacked Catiline in his first oration, where his design was to fire the minds of the senate against him, and oblige him to leave the city; both which points he gained by that speech. The next day therefore, when Catiline was gone, he calls together the body of the citizens, and makes a speech to them, which in a sort of rapture or transport of mind he thus begins, by acquainting them with the departure of Catiline, *He is gone, departed, escaped, broke out*; intimating at the same time both the excessive rage in which Catiline left Rome, and the great pleasure with which he was himself affected on that account. This concise way of speaking adds likewise a considerable emphasis to an expression, and by bringing the several parts of a thing nearer together affects the mind with greater force. Thus Cicero sets Cato's character in a very strong and beautiful light by the use of this figure. "Nature itself (says he) has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtues."

II. The second sort of verbal figures is contrary Elocution. to these, and consists in a redundancy or multiplicity of words; which are likewise two, *pleonasmus* and *polyndeton*.

When we use more words than are necessary to express a thing, it is called *pleonasmus*. This is done sometimes for greater emphasis, as when we say, *Where in the world is he?* At other times it is designed to ascertain the truth of what is said: So the servant in Terence, when the truth of what he had related was called in question, replies, *It is certainly so, I saw it with these very eyes*.

When the several parts of a sentence are united by proper particles, it is called *polyndeton*. This adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by retarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits with the gravity of his style. So he encourages the Athenians to prosecute the war against king Philip of Macedon, from this consideration, that now "they had ships, and men, and money, and stores, and all other things which might contribute to the strength of the city, in greater number and plenty than in former times. Every article here has its weight, and carries in it a proper motive to animate them to the war. And if you remove the copulatives, the sentence will lose much of its force.

III. The third kind of verbal figures consist in a repetition. And either the same word in sound or sense, is repeated; or one of a like sound, or signification, or both.

Of the former sort there are ten, called *antanaclasis*, *place*, *epizeuxis*, *climax*, *anaphora*, *epistrophe*, *symplace*, *epanalepsis*, *anadiplosis*, and *epanodos*. The two first of these agree in sound, but differ in sense; the eight following agree in both.

When the same word in sound but not in sense is repeated, it is called *antanaclasis*. This figure sometimes carries a poignancy in it; and when it appears natural and easy, discovers a ready turn of thought. As when a son, to clear himself of suspicion, assured his father *he did not wait for his death*; his father replied, *But I desire you would wait for it*. Here the word *wait* is taken in two different senses. It is likewise used on serious occasions, as in grave and moral precepts, which are apt to affect the mind with greater pleasure when delivered in an agreeable dress. As this; *Care for those things in your youth, which in old age may free you from care*: Where the word *care* in the former place signifies to *provide*, and in the latter *anxiety of mind*. And even our Saviour himself once uses this figure, when he says to one of his disciples, who desired to be dismissed from attending him that he might go and bury his father; *Follow me, and let the dead bury their dead*: Where dead in one place denotes a *natural death*, and in the other a *moral or spiritual death*.

Sometimes the name of some person or thing is repeated again, to denote some particular character or property designed to be expressed by it; and then it is called *place*. Thus Cicero says, *Young Cato wants experience, but yet he is Cato*; meaning he had the

Elocution. steady temper of the family. And so in the proverbial expression: *An ape is an ape, dress him ever so fine.*

and your ancestors have undergone the greatest Elocution. labours?"

*Epistrophe*, is contrary to the former, and makes the repetition at the end of each member or sentence. As thus: *Since concord was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost.* And Cicero, in the charge which he brings against Mark Anthony before the senate, makes use of this figure, when he says, "Do you lament the destruction of three Roman armies? The author of that destruction was Anthony. Do you bewail the loss of most eminent citizens? They have been taken from you by Anthony. Is the authority of this order weakened? It is weakened by Anthony."

*Symplese* takes in both these last figures. As in that of Cicero: "You would pardon and acquit him, whom the senate hath condemned, whom the people of Rome have condemned; whom all mankind have condemned." Here the several members both begin and end with the same word. We have a beautiful instance of it in St Paul, when he says: "Are they Hebrews? so am I. Are they Israelites? so am I. Are they the seed of Abraham? so am I."

When a sentence concludes with the word with which it began, it is called *epanalepsis*. As in that expression of Plautus, "Virtue contains all things, he wants no good thing who has virtue." The figure is the same, but the principle not so honest, in the advice which we find given by the miser in Horace, when he says, "Get money if you can, honestly; but however, get money." This figure adds a force to an expression, when the principal thing designed to be conveyed is thus repeated, by leaving it last upon the mind. And it heightens the beauty of it, when the sentence has an agreeable turn arising from two opposite parts. As in Cicero's compliment to Cæsar: "We have seen your victory terminated by the war; your drawn sword in the city we have not seen." Herodotus calls this a *circle*, because the sentence returns again to the same word, as that geometrical figure is formed by the orbicular motion of a line to the same point.

When the following sentence begins with the same word with which the former concluded, it is termed *anadiplosis*. As in the following instance: *Let us think no price too great for truth; truth cannot be bought too dear.* So in that passage of St John: *He came to his own, and his own received him not.* This figure generally suits best with grave and solemn discourses.

*Epanodos*, is the inversion of a sentence, or repeating it backwards, so that it takes in the two last figures; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shews a readiness of thought. We have the following example of it in Minutius Felix, where he is exposing the folly of the Egyptian superstition. "Isis (says he) with Cynocephalus and her priests, laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother; in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous

When a word is repeated again with vehemence in the same sense, it is called *epizeuxis*. This figure shews the earnestness of the speaker, and his great concern of mind about what he says; and therefore has a natural tendency to excite the attention of the audience. It is suited to express anger, surprize, sorrow, and several other passions. As when Cicero would express his indignation against Anthony for having been the chief instrument in bringing on the civil war, he says to him: *You, you, Anthony, pushed Cæsar upon the civil war.* And thus he tells Catiline in his first invective against him: *You live; and live, not to lay aside, but to pursue, your wicked design.* And when our Saviour would express his great concern and sorrow for the wickedness of the Jews, he does it in this pathetic manner: *O Jerusalem, Jerusalem, who killest the prophets!*

*Climax*, is a beautiful kind of repetition, when the word, which ends the first member of a period, begins the second, and so through each member, till the whole is finished. There is a great deal of strength as well as beauty in this figure, where the several steps rise naturally, and are closely connected with each other. As in this example: *There is no enjoyment of property without government, no government without a magistrate, no magistrate without obedience, and no obedience where every one acts as he pleases.* But, as Quintilian observes, this figure lies so open, that it is apt to look too much like art; for which reason he advises not to use it often. To prevent this, therefore, orators sometimes disguise it, by not repeating the same word which stood in the former member, but some other equivalent to it. As in the following instance of Cicero for Milo: "Nor did he commit himself only to the people, but also to the senate; nor to the senate only, but likewise to the public forces; nor to these only, but also to his power with whom the senate had entrusted the whole commonwealth."

When several sentences, or members of a sentence, begin with the same word, it is called *anaphora*. This is a lively and elegant figure, and serves very much to engage the attention. For by the frequent return of the same word the mind of the hearer is held in an agreeable suspense, till the whole is finished. "You do nothing, (says Cicero to Catiline,) you attempt nothing, you think nothing, but what I not only hear, but also see, and plainly perceive." It is frequently used by way of question; which renders it not only beautiful, but likewise strong and nervous. As at the beginning of the same speech: "Does neither the night-guard of the palace, nor the city-watch, nor the peoples fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you?" And in another of his orations: "What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you

Elocution.

Elocution.

dulous to lament what you worship, or to worship what you lament?" It serves likewise to illustrate and enforce the sense, by setting it in two opposite views. As in that expression of the prophet: "Wo unto them who call good evil, and evil good; who put darkness for light, and light for darkness!"

Those figures which consist in a repetition of words of a like sound or signification, or both, are four; *paronomasia*, *homoiototon*, *synonymia*, and *derivatio*; the two first of which respect words that are similar in sound only, the third in sense, and the last in both.

When two words very near in sound, but different in sense, respect each other in the same sentence, it is called *paronomasia*. As when we say, *After a feast comes a fast*; and, *A friend in need is a friend indeed*. We usually call it a *pun*; which when new, and appositely used, passes for wit, and serves to enliven conversation. Nor is it wholly to be excluded from grave and serious discourses: for a witty jest has many times had a better effect than a solid argument, and prevailed with those who could not be moved by close reasoning. And therefore Cicero and the best speakers have sometimes recourse to it upon weighty and solemn occasions, as will be shewn hereafter in its proper place.

When the several parts of a sentence end with the same case, or sense of a like sound, this also is considered as a figure, and named *homoiototon*. As thus: *No marvel though wisdom complains that she is either wisely despised, or carelessly neglected; either openly scorned, or secretly abhorred*. This figure is esteemed most beautiful when the parts are all of the same length, or pretty near it; as it adds to the harmony of the period, and renders the cadency of the several members more musical from the just proportion between them. The Greek rhetoricians were much addicted to this figure, and Isocrates is particularly celebrated for it. But some of the best orators seem to have industriously avoided it, as carrying in it too much the appearance of art. And it is remarkable, that this figure appears nowhere so much in all the works of Demosthenes, as in an oration, which he did not speak himself, but wrote for his friend Diodorus, a man of that taste, who was to pronounce it as his own.

The next figure above-mentioned is *synonymia*. Now strictly speaking, synonymous words are those which have exactly the same sense. But there being few such, the use of the term is so far extended as to comprehend words of a near affinity in their signification, which in discourse are frequently put for one another. So, *to desire*, and *to treat*, are sometimes used as equivalent terms; whereas *to desire* is no more than to wish for a thing, and *to treat* is to express that inclination in words. In like manner, *esteem* and *honour*, are often taken for synonymous words, though they have not precisely the same sense, but one is the usual consequence of the other; for esteem is the good opinion we entertain of a person in our mind, and honour the outward expression of that opinion. When two or more such words come together, they constitute this figure. As when Cicero speaking of Piso says, "His whole countenance, which is the tacit language of the mind, has drawn men into a mistake, and deceived, cheated, imposed on those who did not

know him." This figure sometimes adds force to an expression, by enlivening the idea; and it often promotes the harmony and just cadency of a sentence, which otherwise would drop too soon, and disappoint the ear.

When such words as spring from the same root, as *justice*, *just*, *injustice*, *unjust*, and the like, come together in the same sentence, they make the figure called *derivatio*. Cicero observing the vanity of the philosophers, who affected praise at the same time that they derided it, uses this figure, when he says of them, "The philosophers set their names to those very books which they write for the contempt of glory; and are desirous to be honoured and applauded, even for what they say in contempt of honour and applause." This figure receives an additional beauty when repeated, especially in two opposite members; as, *He wished rather to die a present death, than to live a miserable life*.

## ART. II. FIGURES of SENTENCES.

Of these, some are principally adapted for reasoning, and others to move the passions.

1. *Those suited for proof*. Which are six: *Prolepsis*, *hypobole*, *anacoinosis*, *epitrape*, *parabole*, and *antithefis*.

*Prolepsis*, or *anticipation*, is so called, when the orator first starts an objection, which he foresees may be made either against his conduct or cause, and then answers it. Its use is to foretell an adversary, and prevent his exceptions, which cannot afterwards be introduced with so good a grace. Though it has likewise a farther advantage, as it serves to conciliate the audience, while the speaker appears desirous to represent matters fairly, and not to conceal any objection which may be made against him. The occasions of this figure are various; and the manner of introducing it very different. Sometimes the orator thinks it necessary to begin with it, in order to justify his conduct, and remove any exceptions which may be made against his design. Cicero for several years together, after he first began to plead, had always been for the defendant in criminal cases. And therefore, when he was prevailed with to undertake the accusation of Verres, he begins his oration with this apology for himself: "If any one present should wonder, that when for several years past I have so conducted myself as to defend many and accuse none, I now on a sudden alter my custom, and undertake an accusation; when he shall have heard the occasion and reason of my design, he will both approve of it, and think no person so proper to manage this affair as myself." And then he proceeds to give an account of the reasons which moved him to engage in it. At other times the objection is admitted as an exception to what has been said, but not so as to affect it in general. Thus, when Cicero has represented the advantages of literature and the polite arts, he starts this objection to what himself had said, "But some one will ask, whether those great men, the memory of whose glorious actions is delivered down to posterity, were acquainted with that sort of learning I so applaud?" To which he replies, "Indeed this can scarce be said of them all. However, the answer is easy. I have known several persons of excellent abilities, who, without learning, by the force of an extraordinary ge-

nus, have been men of great virtue and solidity. Nay I will add, that nature without learning, has oftener produced these qualifications, than learning without a genius. But yet it must still be owned, that where both these meet, they form something very excellent and singular." Again, at other times, the orator artfully represents the objection as something considerable and important, to give the greater weight to his answer when he has confuted it. Cicero, in his celebrated oration for the Manilian law, could not omit to take notice, that Lucullus had already gained several very considerable advantages over Mithridates. And therefore, having before described the war as very great and dangerous, apprehending these two accounts might appear somewhat inconsistent, and be liable to an objection; he puts it thus artfully himself: "But now, after what I have said of Lucullus, it may probably be asked, How then can the war be so great? Be pleased to hear, for there seems to be very just reason for this question." And then he proceeds to shew, from the power of king Mithridates at that time, his great abilities, long experience in military affairs, and fresh alliances, that the war was yet very great and dangerous. But sometimes, when the orator is sensible that what he has advanced lies open to an objection, he omits to make it in express terms; and yet proceeds to vindicate what he had said, as if it had been made. Thus, when Cicero had charged Verres with having plundered the inhabitants of Sicily of all their plate, jewels, and other valuable moveables, which he thought worth while to carry away; as the audience might imagine this to be scarce credible, he takes it for granted they thought so; and therefore immediately adds, "As strange as this is, I affirm it positively, without any intention to aggravate the crime." And so he goes on to the proof of his assertion. But this figure is likewise made use of to guard against some objection, which the speaker apprehends may be made against what he designs to say. And thus Cicero uses it in his oration for Sextius. "My province, (says he) as I speak last, seems to call for affection to my friend, rather than his defence; complaint, rather than eloquence; expressions of grief, rather than art. And therefore, if I shall express myself with more warmth, or greater freedom, than those who have spoke before me, I hope you will grant me all that liberty of speech which you judge reasonable to be allowed to an affectionate sorrow, and just resentment." This figure requires great prudence and discretion in the management of it. The speaker must consider well the temper, bias, and other circumstances of his hearers, in order to form a right judgment what parts of his discourse may be most liable to exception. For to object such things, which the hearers would never have thought of themselves, is to give himself a needless trouble; and to start such difficulties, which he cannot afterwards fairly remove, will expose both himself and his cause. But as nothing gives an audience greater pleasure and satisfaction, than to have their scruples fully answered as they rise in their thoughts; so on the contrary, be a discourse otherwise ever so entertaining and agreeable, if there be any doubt left upon the minds of the hearers, it gives them a pain that continues with them till it be removed.

The figure *hypocrite* or *subjection*, is not much un-

like the former; and is, when several things are mentioned that seem to make for the contrary side, and each of them refuted in order. It consists of three parts, when complete; a proposition, an enumeration of particulars with their answers, and a conclusion. Thus, Cicero upon his return from banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. "My departure (says he) is objected to me, which charge I cannot answer without commending myself. For what must I say? That I fled from a consciousness of guilt? But what is charged upon me as a crime, was so far from being a fault, that it is the most glorious action since the memory of man, (he means his punishing the associates of Cataline.) That I feared being called to an account by the people? That was never talked of; and if it had been done, I should have come off with double honour. That I wanted the support of good and honest men? That is false. That I was afraid of death? That is a calumny. I must therefore say, what I would not, unless compelled to it, that I withdrew to preserve the city." When the objections are put by way of question, as in the example here given, they add a briskness and poignancy to the figure. All the parts of it are not continually expressed. For thus Cicero in his defence of Plancius introduces his adversary objecting, and himself answering, "The people judged ill, but they did judge; they should not have done it, but they had a power; I cannot submit to it, but many very great and wise men have." Both the proposition and conclusion are here omitted.

The next figure in order is *anacoinosis*, or *communication*; by which the speaker deliberates either with the judges, the hearers, or the adversary himself. Thus Cicero addresses the judges in his accusation of Verres: "Now I desire your opinion, what you think I ought to do. And I know your advice will be, though you do not declare it, what appears to me necessary to be done." In another place we find him reasoning in this manner with the adverse party: "What could you have done in such a case, and at such a time; when to have sat still, or withdrawn, would have been cowardice? When the wickedness and fury of Saturninus the tribune had called you into the capitol; and the consuls, to defend the safety and liberty of your country; whose authority, whose voice, which party would you have followed, and whose command would you have chosen to obey?" This figure carries in it an air of modesty and condescension, when the speaker seems unwilling to determine in his own cause, but refers it to the opinion of others. It likewise shews a persuasion of the equity of his cause, that he can leave it to their arbitration; and serves very much to conciliate their minds, while he joins them, as it were, with himself, and makes them of his party. And when the appeal is made to the adverse party, it is of considerable advantage, either to extort a confession, or at least to silence him. And therefore the sacred writers sometimes very beautifully introduce God himself thus expostulating with mankind; as the prophet Malachi, *A son honoureth his father, and a servant his master. If then I be a father, where is mine honour? and if I be a master, where is my fear?*

Another figure that comes under this head, is

*epitrope* or *concession*; which grants one thing, to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or a part only, is granted. We shall consider each of these separately, and illustrate them with proper examples. Nothing more confounds an adversary, than to grant him his whole argument; and at the same time either to shew that it is nothing to the purpose, or to offer something else which may invalidate it. *I allow*, says the claimant by will against the heir at law, *that no body was more nearly related to the deceased than you; that he was under some obligations to you; that you were in the army together: but what is all this to the will?* And thus Cicero in his defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Cæsar: "You have, Tubero, what an accuser would most desire, the accused person confessing the charge; but so as to affirm, that he was of the same party with you and your excellent father. Therefore own first that it was a crime in yourself, before you charge it as such upon Ligarius." Sometimes the orator gives up some particular point that would well admit of a dispute, to gain something more considerable, which he thinks cannot fairly be denied him. In the affair of Roscius, where the proof depended upon circumstances, Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father. And after he has shewn there was no probable reason to be assigned for it, he adds, "Well, since you can offer no reason, although this might be sufficient for me, yet I will recede from my right; and upon the assurance I have of his innocence, I will grant you in this cause what I would not in another. I do not therefore insist upon your telling me why he killed his father, but ask how he did it?" This appearance of candour and ingenuity in such concessions removes the suspicion of art, and gives greater credit to what is denied. We have an example of a feigned or ironical concession, in Cicero's defence of Flaccus; where, interceding for him on the account of his former good services in the time of Cataline's conspiracy, he says in a way of irony, If such things are to be overlooked, "let us appease the ghosts of Lentulus and Cethegus; let us recall those who are in exile; and let us be punished for our too great affection and love for our country." By this artful insinuation the orator, after he has used all his arguments to persuade his hearers, does as it were set them at liberty, and leave them to their own election; it being the nature of man to adhere more steadfastly to what is not violently imposed, but referred to their own free and deliberative choice. And to these feigned concessions may be referred such ways of reasoning, by which the orator both justifies a charge brought against him upon the supposition of its being true, and also proves that the charge itself is false. Thus Cicero, in his defence of Milo, represents the taking off Clodius, with which Milo was accused, as a glorious action; after he has shewn that Milo's servants did it without the knowledge of their master.

*Parabole* or *similitude*, illustrates a thing by comparing it with some other, to which it bears a resemblance. Similitudes are indeed generally but weak

arguments, though often beautiful and fine ornaments. And where the design of them is not so much to prove what is doubtful, as to set things in a clear and agreeable light, they come properly under the notion of figures. They are of two sorts; simple and compound. Those are called *simple*, in which one thing only is likened or compared to another, in this manner: *As swallows appear in summer, but in winter retreat; so false friends show themselves in prosperity, but all fly away when adversity approaches.* Compound similitudes are such, wherein one thing is likened or compared to several others; as thus: *What light is to the world, physic to the sick, water to the thirsty, and rest to the weary; that is knowledge to the mind.* The more exact the agreement is between the things thus compared, they give the greater beauty and grace to the figure.

*Antithesis* or *opposition*, by which things contrary or different are compared, to render them more evident. Thus Cicero says, "The Roman people hate private luxury, but love public grandeur." This is a very florid figure; and suited no less for amplification than proof. As in the following instance of Cicero, where, speaking of Pompey, he says, "He waged more wars than others had read; conquered more provinces than others had governed; and had been trained up from his youth to the art of war, not by the precepts of others, but by his own commands; not by miscarriages in the field, but by victories; not by campaigns, but triumphs." It is esteemed a beauty in this figure when any of the members are inverted, which some call *antimetathesis*. As where Cicero, opposing the conduct of Verres when governor of Sicily, to that of Marcellus who took Syracuse the capital city of that island, says, "Compare this peace with that war, the arrival of this governor with the victory of that general, his profligate troops with the invincible army of the other, the luxury of the former with the temperance of the latter; you will say, that Syracuse was founded by him who took it, and taken by him who held it when founded." To this figure may also be referred *oxymoron*, or *seeming contradiction*; that is, when the parts of a sentence disagree in sound, but are consistent in sense. As when Ovid says of Althea, *that she was piously pious.* And so Cato used to say of Scipio Africanus, that "he was never less at leisure, than when he was at leisure; nor less alone, than when alone." By which he meant, as Cicero tells us, that "Scipio was wont to think of business in his retirement, and in his solitude to converse with himself." This is a strong and bold figure, which awakens the mind, and affords it an agreeable pleasure to find upon reflection, that what at first seemed contradictory, is not only consistent with good sense, but very beautiful.

II. *Those suited to move the passions.* Which are 13; namely, *epanorthosis*, *paralepsis*, *parrhesia*, *aparthneusis*, *exergasia*, *hypotyposis*, *aporia*, *pepsepsis*, *erotesis*, *ecphonesis*, *epiphonema*, *apostrophe*, and *prospecia*.

*Epanorthosis*, or *correction*, is a figure, by which the speaker either recalls or amends what he had last said. It is used different ways. For sometimes one or more words are recalled by him, and others subjoined in their room; at other times, without recalling what has been said, something else is substituted as more suitable. This is a very extensive figure, and

Elocution.

Elocution.

made use of in addressing to different passions. We have an instance of it in Terence's *Self-tormentor*, where the old man, whose extraordinary concern for the absence of his son gave occasion to the name of the play, thus bewails his condition to his neighbour, "I have an only son, Chremes. Alas! did I say that I have? I had indeed; but it is now uncertain whether I have or not." Here, to aggravate his misfortune, he recalls a pleasing word, and substitutes another more affecting in its place. And Cicero, in his defence of Milo, speaking to the judges concerning Clodius, says, "Are you only ignorant, what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius he says, "What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who, when prætor, freed the republic from a neighbouring war, and when consul, from a civil one?" He is speaking there of Opimius. But in commending the moderation of Lucius Mummus, who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole expression, and by giving it a new turn heightens the compliment he designed him: "He chose rather (says he) to adorn Italy, than his own house; though by adorning Italy, his house seems to have received the greatest ornament." And sometimes the correction is made by substituting something contrary to what had been said before; as in the following passage of Cicero: "Cæsar, (meaning Augustus) though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged, and we dreaded his cruel and pernicious return from Brundisium, at a time when we neither asked, nor expected, nor desired it, (because it was thought impossible), raised a very powerful army of invincible veterans; to effect which, he threw away his whole estate: Tho' I have used an improper word; for he did not throw it away, but employed it for the safety of the government." At other times, as has been said, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres, breaks out into this pathetic exclamation; *O the clemency, or rather wonder ful and singular patience, of the Roman people!* He did not think the word *clemency* strong enough, and therefore adds *patience*, as better answering his design. The sudden and unexpected turn of this figure gives a surprize to the mind, and by that means renders it the more pathetic.

*Paralepsis*, or omission, is another of these figures, when the speaker pretends to omit, or pass by, what at the same time he declares. It is used either in praise or dispraise. Thus Cicero, in his defence of Sextius, introduces his character in this manner, with a design to recommend him to the favour of the court: "I might say many things of his liberality, kindness to his domestics, his command in the army, and moderation during his office in the province: but the honour of the state presents itself to my view; and calling me to it, advises me to omit these lesser matters." But in his oration to the senate against Rullus the tribune, who had proposed a law to sell the public

lands, he makes use of this figure to represent the pernicious effects of such a law, particularly with respect to the lands in Italy. "I do not complain (says he) of the diminution of our revenues, and the woful effects of this loss and damage. I omit what may give every one occasion for a very grievous and just complaint, that we could not preserve the principal estate of the public, the finest possession of the Roman people, the fund of our provisions, the granary of our wants, a revenue entrusted with the state; but that we must give up those lands to Rullus, which, after the power of Sylla, and the largesses of the Gracchi, are yet left us. I do not say, this is now the only revenue of the state, which continues when others cease, is an ornament in peace, fails us not in war, supports the army, and does not fear an enemy. I pass over all these things, and reserve them for my discourse to the people, and only speak at present of the danger of our peace and liberties." His view here was to raise the indignation of the senate against Rullus, and excite them to oppose the law. There is a beautiful instance of this figure in St Paul's epistle to Philemon, where, after he has earnestly intreated him to receive again Onesimus his servant, who had run from him, and promised that if he had wronged him, or owed him any thing, he would repay it, he adds, *That I may not say, you owe even yourself to me.* Nothing could be a stronger motive to soften his displeasure against his servant, from a sense of gratitude to the apostle. Hermogenes has observed, that the design of this figure is to possess the minds of the audience with more than the words express, and that it is principally made use of on three occasions: either when things are small, but yet necessary to be mentioned; or well known, and need not be enlarged on; or ungrateful, and therefore should be introduced with caution, and not set in too strong a light.

The next figure abovementioned was *Parrhesia*, or reprehension: Not that whenever a person admonishes or reproves another, it is to be esteemed a figure; but when it is done with art and address, and in such circumstances as render it difficult not to displease. The Orator therefore sometimes prepares his hearers for this by commending them first, urging the necessity of it, representing his great concern for them as his motive, or joining himself with them. Thus Cicero charges the senate with the death of Servius Sulpicius, for sending him to Mark Antony under a very ill state of health. And his design in it was to bring them more readily into a motion he was about to make, that both a statue and a sepulchral monument might be erected to his memory at the public expence. "You (says he), it is a very severe expression, but I cannot help saying it; you, I say, have deprived Servius Sulpicius of his life. It was not from cruelty indeed, (for what is there with which this assembly is less chargeable?) but when his disemper pleaded his excuse more than his words, from the hopes you conceived, that there was nothing which his authority and wisdom might not be able to effect, you vehemently opposed his excuse, and obliged him, who always had the greatest regard for your commands, to recede from his resolution." Sometimes, indeed, the orator assumes an air of reproof, with a

view

view only to pass a compliment with a better grace. As Cicero in his address to Cæsar, when he says, "I hear that excellent and wise saying from you with concern, That you have lived long enough, either for the purposes of nature, or glory: for nature perhaps, if you think so; and, if you please, for glory; but, what is principally to be regarded, not for your country." It adds both a beauty and force to this figure, when it is expressed in a way of comparison. As in the following instance of Cicero: "But since my discourse leads me to this, consider how you ought to be affected for the dignity and glory of your empire. Your ancestors often engaged in war to redress the injuries of their merchants or sailors: how ought you then to resent it, that so many thousand Roman citizens were murdered by one message, and at one time? Your forefathers destroyed Corinth, the principal city in Greece, for the haughty treatment of their ambassadors; and will you suffer that king to go unpunished who has put to death a Roman legate, of consular dignity, in the most ignominious as well as most cruel manner? See, lest, as it was their honour to leave you the glory of so great an empire, it should prove your disgrace not to be able to maintain and defend what you have received from them." By this figure an address is made to the more tender passions, modesty, shame, and emulation, the attendants of an ingenuous temper, which is soonest touched, and most affected, by a just reproof.

89

Another of these pathetic figures is *Aparithmestis*, or *enumeration*, when that which might be expressed in general by a few words, is branched out into several particulars, to enlarge the idea, and render it the more affecting. Cicero in pleading for the Manilian law, where his design is to conciliate the love and esteem of the people to Pompey, thus enlarges upon his character: "Now, what language can equal the virtue of Cneius Pompey? What can be said either worthy of him, or new to you, or which every one has not heard? For those are not the only virtues of a general which are commonly thought so; labour in affairs, courage in dangers, industry in acting, dispatch in performing, design in contriving; which are greater in him than in all other generals we have ever seen or heard of." And so likewise, when he endeavours to dispossess Pompey of the apprehension that Milo designed to assassinate him: "If (says he) you fear Milo; if you imagine that either formerly, or at present, any ill design has been formed by him against your life; if the soldiers raised through Italy, (as some of your officers give out), if these arms, if these cohorts in the Capitol, if the centries, if the watch, if the guards which defend your person and house, are armed to prevent any attempt of Milo, and all of them appointed, prepared, and stationed on his account; he must be thought a person of great power, and incredible resolution, above the reach and capacity of a single man, that the most consummate general, and the whole republic are in arms against him only. But who does not perceive, that all the disordered and sinking parts of the state are committed to you, to rectify and support them by these forces?" This might have been said in a few words, that such vast preparations could never be intended for so low a purpose. But the orator's view was to expose that

Vol. VIII.

1

groundless report, and shame it out of countenance. And soon after he endeavours to raise compassion for Milo under those prejudices, by the same figure: "See how various and changeable is the state of human life, how unsteady and voluble is fortune, what infidelity in friends, what disguises suited to the times, what flights, what fears, even of the nearest acquaintance, at the approach of dangers." Had no address to the passions been designed here, fewer of these reflections might have been sufficient. The use of this figure in amplification is very evident from the nature of it, which consists in unfolding of things, and by that means enlarging the conception of them.

*Exergasia*, or *exposition*, has an affinity with the former figure: but it differs from it in this, that it consists of several equivalent expressions, or nearly such, in order to represent the same thing in a stronger manner; whereas the other enlarges the idea by an enumeration of different particulars. So that this figure has a near relation to synonymia, of which we have treated before under *Verbal figures*. We have an instance of it in Cicero's defence of Sextius, where he says, "Those who at any time have incited the populace to sedition, or blinded the minds of the ignorant by corruption, or traduced brave and excellent men, and such as deserved well of the public, have with us always been esteemed vain, bold, bad, and pernicious citizens. But those who repressed the attempts and endeavours of such as, by their authority, integrity, constancy, resolution, and prudence, withstood their insolence, have been always accounted men of solidity, the chiefs, the leaders, and supporters of our dignity and government." Nothing more is intended by this passage, but to set the opposite characters of seditious persons and true patriots in the strongest light, with a view to recommend the one, and create a just hatred and detestation of the other. So elsewhere he represents the justice of self-defence in no less different terms: "If reason (says he) prescribes this to the learned, and necessity to barbarians, custom to nations, and nature itself to brutes, always to ward off all manner of violence, by all possible ways, from their body, from their head, from their life; you cannot judge this to be a criminal and wicked action, without judging at the same time that all persons who fall among robbers and assassins must either perish by their weapons, or your sentence."—He is addressing here to the judges in favour of Milo. The warmth and vehemence of the speaker often runs him into this figure, when he is affected with his subject, and thinks no words, no expressions, forcible enough to convey his sentiments; and therefore repeats one after another, as his fancy suggests them. This flow of expression, under the conduct of a good judgment, is often attended with advantage; as it warms the hearers, and impresses their minds, excites their passions, and helps them to see things in a stronger light.

*Hypotyposis*, or *imagery*, is a description of things painted in such strong and bright colours, as may help the imagination of the hearers to conceive of them rather as present to their view, than described in words. It is peculiarly suited for drawing characters; and often affords the finest ornaments in poetry and history, as well as oratory. Nor is it less moving,

90

32 G

but

but suited to strike different passions, according to the nature of the subject, and artful management of the speaker. Cicero has thus drawn the picture of Catiline, consisting of an unaccountable mixture of contrary qualities. "He had (says he) the appearance of the greatest virtues: he made use of many ill men to carry on his designs, and pretended to be in the interest of the best men; he had a very engaging behaviour, and did not want industry nor application; he gave into the greatest looseness, but was a good soldier. Nor do I believe there was ever the like monster in the world, made of such jarring and repugnant qualities and inclinations. Who at one time was more acceptable to the best men, and who more intimate with the worst? Who was once a better patriot, and who a greater enemy to this state? Who more devoted to pleasures, who more patient in labours? Who more rapacious, and yet more profuse? He suited himself to the humours of all he conversed with: was serious with the reserved, and pleasant with the jocular; grave with the aged, and facetious with the young; bold with the daring, and extravagant with the profligate."—Such a character of a man, when accompanied with power and interest, must render him no less the object of fear, than detestation; which was the design of Cicero in this description. And elsewhere, in order to prevail with the senate to direct the execution of those conspirators with Catiline who were then in prison, he paints the most dismal scene of that horrid design in the strongest colours. "Methinks (says he) I see this city, the light of the world, and citadel of all nations, suddenly falling into one fire; I perceive heaps of miserable citizens unhuried in their ruined country; the countenance and fury of Cethegus raging in your slaughter, presents itself to my view." This figure is very serviceable in amplification, as we have formerly shewn in treating upon that subject. But no small judgment is required in the management of descriptions. Lesser circumstances should either be wholly omitted, or but slightly touched; and those which are more material drawn in their due proportion. Nature is as much the rule of the orator as of the painter, and what they both propose to imitate. And therefore, let a thought be ever so pleasing and beautiful in itself, it must not be introduced when foreign to the purpose, or out of its place; any more than a painter should attempt to alter nature, when he proposes to copy it. This figure requires likewise a vigorous and lively genius. For the images in description can rise no higher than the conception of the speaker, since the idea must first be formed in his own mind before he can convey it to others; and agreeably to the clearness with which he conceives it himself, he will be able to express it in words.

92 *Aporia*, or *doubt*, expresses the debate of the mind with itself upon a pressing difficulty. A person in such a state is apt to hesitate, or start several things successively, without coming to any fixed resolution. The uneasiness arising from such a disorder of thought is naturally very moving. Of this kind is that of Cicero for Cluentius, when he says, "I know not which way to turn myself. Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked

of in the court? mentioned in the senate? Can I re-  
move an opinion so deeply and long rooted in the  
minds of men? It is not in my power. You, judges,  
must support his innocence, and rescue him from this  
calamity." Orators sometimes choose to begin their  
discourse with this figure. A diffidence of mind at  
first is not unbecoming, but graceful. It carries in it  
an air of modesty, and tends very much to conciliate  
the affections of the hearers. Livy gives us a very  
elegant example of this, in a speech of Scipio Africanus  
to his soldiers, when, calling them together after a  
sedition, he thus bespeaks them: "I never thought  
I should have been at a loss, in what manner to address  
my army. Not that I have applied myself more  
to words, than things; but because I have been accustomed  
to the genius of soldiers, having been trained up  
in the camp almost from my childhood. But I am  
in doubt what or how to speak to you, not knowing  
what name to give you. Shall I call you *citizens*, who  
have revolted from your country? *Soldiers*, who have  
disowned the authority of your general, and broke your  
military oath? *Enemies*? I perceive the mien, the  
aspect, and habit of citizens; but discern the actions,  
words, designs, and dispositions of enemies."

Sometimes a passion has that effect, not so much to  
render a person doubtful what to say, as to stop him  
in the midst of a sentence, and prevent his expressing  
the whole of what he designed; and then it is called  
*Aposiopesis*, or *concealment*. It denotes different passions;  
as anger, which, by reason of its heat and vehemence,  
causes persons to break off abruptly in their  
discourse. So the old man in Terence, when he was  
jealous that his servant obstructed his designs, uses  
this imperfect, but threatening expression; *Whom, if I  
find.* And Neptune, when described by Virgil as  
very angry that the winds should presume to disturb  
the sea without his permission, after he has called them  
to him to know the reason of it, threatens them in this  
abrupt manner:

"Whom I—but first I'll lay the storm."

But Cicero, in writing to Atticus, applies it to express  
grief, where he says, "I know nothing of Pompey,  
and believe he must be taken, if he is not got on  
shipboard. O incredible swiftness! But of our friend.—  
Though I cannot accuse him without grief, for whom  
I am in so much concern and trouble." And in a  
letter to Cassius he uses it to express fear, when he  
says to him, "Brutus could scarce support himself at  
Mutina; if he is safe, we have carried the day. But  
if—heaven avert the omen! all must have recourse to  
you." His meaning is, "If Brutus should be defeated."

The next figure is *erotesis*, or *interrogation*. But every  
interrogation or question is not figurative. When we  
inquire about a thing that is doubtful, in order to be  
informed, this is no figure, but the natural form of  
such expressions. As if I ask a person, *Where he is  
going?* or *What he is doing?* But then it becomes  
figurative when the same thing may be expressed in a  
direct manner; but the putting it by way of question  
gives it a much greater life and spirit. As when  
Cicero says, "Catiline, how long will you abuse our  
patience? do not you perceive your designs are discovered?"  
He might indeed have said, *You abuse our  
patience a long while. You must be sensible your designs*  
are

Elocution.

Elocution.

are discovered. But it is easy to perceive how much this latter way of expression falls short of the force and vehemence of the former. And so when Medea says, *I could save; and do you ask, if I can destroy?* Had she said, *I could save, and I can destroy*, the sentence had been flat, and very unfit to express the rage and fury in which the poet there represents her. This figure is suited to express most passions and emotions of the mind, as anger, disdain, fear, desire, and others. It serves also to press and bear down an adversary. Cicero frequently makes this use of it. As in his defence of Plancius: "I will make you this offer (says he) choose any tribe you please, and shew, as you ought, by whom it was bribed; and if you cannot, as I believe you will not undertake it, I will prove how he gained it. Is this a fair contest? Will you engage on this foot? I cannot give you fairer play. Why are you silent? Why do you dissemble? Why do you hesitate? I insist upon it, urge you to it, press it, require, and even demand it of you." Such a way of pushing an antagonist shews the speaker has great confidence in his cause; otherwise he would never lay himself so open, if he was not assured the other party had nothing to reply. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression; provided it be neither too frequent, nor continued too long at once. And besides the warmth and eager manner in which it is expressed, enlivens the hearers, and quickens their attention.

95

*Epiphonema, or exclamation*, is a vehement extension of the voice, occasioned by a commotion of mind, naturally venting itself by this figure, which is used by Cicero to express a variety of passions. It often denotes resentment or indignation. Thus, after his return from banishment, reflecting on those who had occasioned it, he breaks out into this moving exclamation: "O mournful day to the senate, and all good men, calamitous to the state, afflictive to me and my family, but glorious in the view of posterity!" His design was to excite an odium against the authors of his exile, when recalled in so honourable a manner. And again in his defence of Cælius: "O the great force of truth; which easily supports itself against the wit, craft, subtilty, and artful designs of men!" He had been just shewing the absurdity of the charge against Cælius, and now endeavours to expose his accusers to the indignation of the court. At other times it is used to express disdain or contempt. As when speaking of Pompey's house, which was bought by Mark Anthony, he says: "O consummate impudence! dare you go within that house! dare you enter that venerable threshold, and show your audacious countenance to the tutelar deities, which reside there?" Nor is it less suited to indicate grief, as when he says of Milo: "O that happy country, which shall receive this man! ungrateful this, if it banish him! miserable, if it lose him!" And sometimes it serves to express admiration; as when, in compliment to Cæsar, he says, "O admirable clemency! worthy of the greatest praise, the highest encomiums, and most lasting monuments!" It has its use also in ridicule and irony. As in his oration for Balbus, where he derides his accuser, by saying, "O excellent interpreter of the law! master of antiquity! corrector

and amender of our constitution!" The sacred writers sometimes use it by way of intreaty or with. As the royal Psalmist: "O that I had the wings of a dove, that I might flee away, and be at rest!" And at other times in triumph and exultation, as in that of St Paul: "O death, where is thy sting! O grave, where is thy victory!" It is frequently joined with the preceding figure, *interrogation*; as appears in some of the instances here brought from Cicero. And it generally follows the representation of the thing which occasions it. Though sometimes it is made use of to introduce it, and then it serves to prepare the mind by exciting its attention. Thus Cicero, in his defence of Cælius, to render the character of Clodia more odious, at whose instigation he was accused, insinuates that she had before poisoned her husband; and to heighten the barbarity of the fact, and make it appear the more shocking, he introduces the account of it, with this moving exclamation: "O heavens, why do you sometimes wink at the greatest crimes of mankind, or delay the punishment of them to futurity!"

96

*Epiphonema, or acclamation*, has a great affinity with the former figure. And it is so called, when the speaker, at the conclusion of his argument, makes some lively and just remark upon what he has been saying, to give it the greater force, and render it the more affecting to his hearers. It is not so vehement and impetuous as exclamation, being usually expressive of the milder and more gentle passions. And the reflection ought not only to contain some plain and obvious truth, but likewise to arise naturally from the discourse which occasioned it, otherwise it loses its end. When Cicero has shewn, that recourse is never to be had to force and violence, but in cases of the utmost necessity, he concludes with the following remark: "Thus to think, is prudence; to act, fortitude; both to think and act, perfect and consummate virtue." And elsewhere, after he has described a singular instance of cruelty and breach of friendship: "Hence (says he) we may learn, that no duties are so sacred and solemn, which covenantness will not violate." This figure is frequently expressed in a way of admiration. As when Cicero has observed, that all men are desirous to live to an advanced age, but uneasy under it when attained, he makes this just reflection upon such a conduct: "So great is their inconstancy, folly, and perverseness!"

97

The next figure in order is *apostrophe, or address*, when the speaker breaks off from the series of his discourse, and addresses himself to some particular person present or absent, living or dead; or to inanimate nature, as endowed with sense and reason. By this means he has an opportunity of saying many things with greater freedom than perhaps would be consistent with decency if immediately directed to the persons themselves. He can admonish, chide, or censure, without giving offence. Nor is there any passion, but may be very advantageously expressed by this figure. When an orator has been speaking of any particular person, on a sudden to turn upon him, and apply the discourse to that person himself, is very moving; it is like attacking an adversary by surprise, when he is off his guard, and where he least expects it. Thus Cicero: "I desire, senators, to be merciful, but not to appear negligent in so great dangers of the state; tho'

at present I cannot but condemn myself of remissness. There is a camp formed in Italy, at the entrance of Etruria, against the state; our enemies increase daily; but we see the commander of the camp, and general of the enemies, within our walls, in the very senate, contriving more intestine ruin to the state. If now, Catiline, I should order you to be seized and put to death, I have reason to fear, that all good men would rather think I had deferred it too long, than charge me with cruelty. But I am prevailed with for a certain reason not to do that yet, which ought to have been done long since." This sudden turn of the discourse to Catiline himself, and the address to him in that unexpected manner, must have touched him very sensibly. So in his defence of Milo, expressing his concern if he should not succeed in it, he says: "And how shall I answer it to you, my brother Quintus, the partner of my misfortunes, who art now absent." And elsewhere addressing to the soldiers of the Martian legion, who had been killed in an engagement with Mark Anthony, he thus bespeaks them: "O happy death, which due to nature, was paid to your country! I may esteem you truly born for your country, who likewise received your name from Mars; so that the same deity seems to have produced this city for the world, and you for this city." And in his oration for Balbus he thus calls upon dumb nature to witness to Pompey's virtues: "I invoke you, mute regions; you, most distant countries; you seas, havens, islands, and shores. For what coast, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant?" An appeal to heaven, or any part of inanimate nature, has something very sublime and solemn in it, which we often meet with in sacred writ. So the divine prophet: "Hear, O heavens! and give ear, O earth! for the Lord hath spoken." And in like manner, the prophet Jeremy: "Be astonished, O ye heavens, at this."

98

*Prosopoeia, or the fiction of a person:* by which, either an absent person is introduced speaking; or one who is dead, as if he was alive and present; or speech is attributed to some inanimate being. There is no figure, perhaps, which serves more or better purposes to an orator than this. For by this means he is enabled to call in all nature to his assistance, and can assign to every thing such parts as he thinks convenient. There is scarce any thing fit to be said, but may be introduced this way. When he thinks his own character is not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence as coming from himself; he avoids this, by putting them into the mouth of some other person from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he sometimes chooses to secure himself from a suspicion of flattery, in carrying a compliment too high. We meet with several very beautiful instances of this figure in Cicero; but an example of each sort may here suffice, beginning with that of an absent person, from his defence of Milo, whom he thus introduces as speaking to the citizens of Rome: "Should he, holding the bloody sword, cry out, At-

tend, I pray, hearken, O citizens, I have killed Publius Clodius; by this sword, and by this right hand, I have kept off his rage from your necks, which no laws, no courts of judicature, could restrain; it is by my means, that justice, equity, laws, liberty, shame, and modesty, remain in the city. Is it to be feared how the city would bear this action? Is there any one now, who would not approve and commend it." And in his oration for Balbus, he introduces Marius, who was then dead, to plead in his defence: "Can Balbus (says he) be condemned, without condemning Marius for a like fact? Let him be present a little to your thoughts, since he cannot be so in person; that you may view him in your minds, though you cannot with your eyes. Let him tell you, he was not unacquainted with leagues, void of examples, or ignorant of war." And again, in his first invective against Catiline, he represents his country as thus expostulating with himself, and upbraiding him for suffering such a criminal as Catiline to live. "Should my country (says he), which is much dearer to me than my life, should all Italy, all the state, thus address me, Mark Tully, what do you do? Do you suffer him, whom you have found to be an enemy, who you see is to be at the head of the war, whom you perceive your enemies wait for in their camp as their general, who has been the contriver of this wickedness, the chief of the conspiracy, the exciter of slaves and profligate citizens, to leave the city, which is rather to bring him in, than let him out? Will not you order him to be imprisoned, condemned, and executed? What prevents you? The custom of our ancestors? But private persons have often punished pernicious citizens in this state. The laws relating to the punishment of Roman citizens? But traitors never had the rights of citizens. Do you fear the censure of posterity? Truly you make a very handsome return to the people of Rome, who have advanced you from an obscure condition so early to the highest dignity; if you neglect their safety to avoid envy, or from the apprehension of any danger. And if you fear censure; which is most to be dreaded, that which may arise from justice and fortitude, or from cowardice and treachery? When Italy shall be wasted by a war, cities plundered, and houses burnt, do you think then to escape the severest censure." In the management of this figure, care should be taken, that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

In treating upon figures, we have hitherto considered them separately; but it may not be amiss to observe, that some expressions consist of a complication of them, and may come under the denomination of several figures, as well verbal as those of sentences, differently considered. Thus when Cicero says: "What, Tubero, did your drawn sword do in the Pharalian battle? at whose side was its point directed? what was the intention of your arms?" As he speaks to Tubero, it is an apostrophe; as the expressions have much the same import, and are designed to heighten and aggravate the fact, it is *exergasia*; and as they are put by question, it is *interrogation*. So likewise in his second Philippic, where he says, "What can I think? that I am contented? I see nothing in my life, interest, actions, or abilities, as moderate

derate as they are, which Anthony can despise. Did he think he could easily lessen me in the senate? But they, who have commended many famous citizens for their good government of the state, never thanked any but me for preserving it. Would he contend with me for eloquence? This would be a favour indeed. For what could be a larger and more copious subject, than for me to speak for myself against Anthony? His design was really this: he thought he could nor convince his associates, that he was truly an enemy to his country, unless he was to first to me." There are three figures in this passage; *doubt, interrogation, and subjection*. And again, when he introduces Sicily thus addressing to Verres in a way of complaint: "Whatever gold, whatever silver, whatever ornaments in my cities, dwellings, temples, whatever right of any kind I possessed by the favour of the senate and people of Rome; you, Verres, have plundered and taken from me." Here is a *prolepsis*, joined with the verbal figure *anaphora*, as several members of the sentence begin with the same word. The like instances of complex figures frequently occur, and therefore we need not multiply examples of them here.

### PARTICULAR ELOCUTION,

Or that part of Elocution which considers the several Properties and Ornaments of Language, as they are made use of to form different sorts of Style.

#### CHAP. IV. Of Style, and its different Characters.

99

THE word *style*, properly signifies the instrument which the ancients used in writing. For as they commonly wrote upon thin boards covered over with wax, and sometimes upon the barks of trees, they made use of a long instrument like a bodkin, pointed at one end, with which they cut their letters; and broad at the other, to erase any thing they chose to alter. And this the Latins called *stilus*. But tho' this be the first sense of the word, yet afterwards it came to denote the manner of expression. In which sense we likewise use it, by the same kind of trope that we call any one's writing his *hand*. But as to the reasons which occasion a variety of style, they are principally these.

Since both speech and writing are only sensible expressions of our thoughts, by which we communicate them to others; as all men think more or less differently, so consequently they in some measure differ in their style. No two persons, who were to write upon one subject, would make use of all the same words. And were this possible, yet they would as certainly differ in their order and connection, as two painters, who used the same colours in painting the same picture, would necessarily vary their mixtures and disposition of them, in the several gradations of lights and shades. As every painter therefore has something peculiar in his manner, so has every writer in his style. It is from these internal characters, in a good measure, that critics undertake to discover the true authors of anonymous writings; and to shew that others are spurious, and not the genuine productions of those whose names they bear; as they judge of the age of such

writings from the words and manner of expression which have been in use at different times. And we may often observe in persons a fondness for some particular words or phrases; and a peculiarity in the turn or connection of their sentences, or in their transitions from one thing to another; by which their style may be known, even when they design to conceal it. For these things, thro' custom and habit, will sometimes drop from them, notwithstanding the greatest caution to prevent it.

There is likewise very often a considerable difference in the style of the same person, in several parts of his life. Young persons, whose invention is quick and lively, commonly run into a pompous and luxuriant style. Their fancy represents the images of things to their mind in a gay and spritely manner, clothed with a variety of circumstances; and while they endeavour to set off each of these in the brightest and most glittering colours, this renders their style verbose and florid, but weakens the force and strength of it. And therefore, as their imagination gradually cools, and comes under the conduct of a more mature judgment, they find it proper to cut off many superfluities; so that by omitting unnecessary words and circumstances, and by a closer connection of things placed in a stronger light, if their style becomes less swelling and pompous, it is, however, more correct and nervous. But as old age sinks the powers of the mind, chills the imagination, and weakens the judgment; the style, too, in proportion usually grows dry and languid. Critics have observed something of this difference in the writings even of Cicero himself. To be master of a good style, therefore, it seems necessary that a person should be endued with a vigorous mind and lively fancy, a strong memory, and a good judgment. It is by the imagination that the mind conceives the images of things. If the impressions of those images be clear and distinct, the style will be so too; since language is nothing but a copy of those images first conceived by the mind. But if the images are faint and imperfect, the style will accordingly be flat and languid. This is evident from the difference between such objects as are represented to our sight, and things of which we have only read or heard. For as the former generally make a deeper impression upon our minds, so we can describe them in a more strong and lively manner. And we commonly find, that according as persons are affected themselves when they speak, they are able to affect others with what they say. Now persons are more or less affected with things in proportion to the impressions which the images of those things make upon the mind. For the same reason also, if the imagination be dull, and indisposed to receive the ideas of things, the style will be stiff and heavy; or if the images are irregular and disordered, the style will likewise be perplexed and confused. When things lie straight (as we say) in the mind, we express them with ease, and in their just connection and dependence; but when they are warped and crooked, we deliver them with pain and difficulty, as well as disorder. A good fancy should likewise be accompanied with a happy memory. This helps us to retain the names of those things the ideas whereof are presented to the mind by the imagination, together

together with proper and suitable phrases to express them in their several connections and relations to each other. When the images of things offer themselves to the mind, unless the names of them present themselves at the same time, we are at a loss to express them, or at least are in danger of doing it by wrong and improper terms. Besides, variety is necessary in discourse to render it agreeable; and therefore, without a large furniture of words and phrases, the style will necessarily become insipid and jejune, by the frequent return of the same terms and manner of expression. But to both these a solid judgment is highly requisite to form a just and accurate style. A fruitful imagination will furnish the mind with plenty of ideas, and a good memory will help to clothe them in proper language; but unless they are both under the conduct of reason, they are apt to hurry persons into many inconveniences. Such are generally great talkers, but far from good orators. Fresh images continually crowd in upon them, faster than the tongue can well express them. This runs them into long and tedious discourses, abounding with words, but empty of sense. Many impertinencies, if not improprieties, necessarily mix themselves with what they say; and they are frequently carried off from their point, by not having their fancies under a proper regulation. So that such discourses, though composed perhaps of pretty expressions, rhetorical flowers, and sprightly fallacies of wit, yet fall very much short of a strong and manly eloquence. But where reason presides and holds the reins, every thing is weighed before it is spoken. The properest words are made choice of, which best suit the ideas they are designed to convey; rather than the most gay and pompous. All things are not said, which offer themselves to the mind, and fancy dictates; but such only as are fit and proper, and the rest are dropped. Some things are but slightly mentioned, and others discoursed on more largely and fully, according to their different importance. And every thing is placed in that order, and clothed in such a dress, as may represent it to the greatest advantage. So that, in a word, the foundation of a good style is chiefly good sense. Where these qualities all meet in a considerable degree, such persons have the happiness to excel, either in speaking or writing. But this is not generally the case. Many persons of a vigorous and sprightly imagination, have but a weak judgment; and others much more judicious can think but slowly. And it is this, in a great measure, which makes the difference between speaking and writing well, as one or the other of these qualities is predominant. A person of a lively fancy, ready wit, and voluble tongue, will deliver himself off hand much better and more acceptably, than one who is capable, upon due premeditation, to discern farther into the subject, but cannot command his thoughts with the same ease and freedom. And this latter would have the same advantage of the other, were they both coolly to offer their sentiments in writing. Many things appear well in speaking, which will not bear a strict scrutiny. While the hearer's attention is obliged to keep pace with the speaker, he is not at leisure to observe every impropriety or incoherence, but many slips easily escape him, which in reading are

presently discovered. Hence it is often found, that discourses, which were thought very fine when heard, appear to have much less beauty, as well as strength, when they come to be read. And therefore it is not without reason, that Cicero recommends to all those who are candidates for eloquence, and desirous to become masters of a good style, to write much. This affords them an opportunity to digest their thoughts, weigh their words and expressions, and give every thing its proper force and evidence; as likewise, by reviewing a discourse when composed, to correct its errors, or supply its defects; till by practice they gain a readiness both to think justly, and to speak with propriety and eloquence. But it is time to proceed to some other causes of the diversity of style.

Different countries have not only a different language, but likewise a peculiarity of style suited to their temper and genius. The eastern nations had a lofty and majestic way of speaking. Their words are full and sonorous, their expressions strong and forcible, and warmed with the most lively and moving figures. This is very evident from the Jewish writings in the Old Testament, in which we find a most agreeable mixture of simplicity and dignity. On the contrary, the style of the more northern languages generally partakes of the chills of their climate. "There is," says Mr Addison\*, "a certain coldness and indifference in the phrases of our European languages, when they are compared with the oriental forms of speech. And it happens very luckily, that the Hebrew idioms run into the English tongue with a peculiar grace and beauty. Our language has received innumerable elegancies and improvements from that infusion of Hebrewisms, which are derived to it out of the poetical passages in holy writ. They give a force and energy to our expressions, warm and animate our language, and convey our thoughts in more ardent and intense phrases than any that are to be met with in our own tongue. There is something so pathetic in this kind of diction, that it often sets the mind in a flame, and makes our hearts burn within us."

Again, people of different nations vary in their customs and manners, which occasions a diversity in their style. This was very remarkable in the Attics, Asiatics, and Rhodians, and is often taken notice of by ancient writers. The Athenians, while they continued a free state, were an active, industrious, and frugal people; very polite indeed, and cultivated arts and sciences beyond any other nation; but as they had powerful enemies, and were exceeding jealous of their liberties, this preserved them from wantonness and luxury. And their way of speaking was agreeable to their conduct; accurate and close, but very full and expressive. The Asiatics, on the other hand, were more gay, and loose in their manners, devoted to luxury and pleasure; and accordingly they affected a florid and swelling style, filled with redundancies and superfluities of expression. Indeed, some of the ancients have attributed this looseness of style to their way of pursuing eloquence at first. For as they were put upon it by conversing with the Greek colonies who settled among them, they suppose, that in imitating them, before they were masters of the language, they were often obliged to make use of circumlocutions,

tions, which afterwards became habitual, and very much weakened the force of their expressions, as it naturally would do. But one would think, if they were put to this necessity at first, when they found its ill effect, they might easily have amended it afterwards, as they grew better acquainted with the Greek language, had they been inclined so to do. The Rhodian style was a medium between the other two; not so concise and expressive as the Attic, nor yet so loose and redundant as the Asiatic. Quintilian says, it had a mixture of its author, and the humour of the people; and, like plants set in a foreign soil, degenerated from the Attic purity, but not so wholly as to lose it. They first received it from Æschines, who being worsted in his famous contest with Demosthenes, retired thither, and taught rhetoric, which put them upon the study of eloquence.

The style of the same country likewise very much alters in different ages. Cicero tells us, that the first Latin historians aimed at nothing more than barely to make themselves intelligible, and that with as much brevity as they could. Those who succeeded them advanced a step further; and gave somewhat a better turn and cadency to their sentences, though still without any dress or ornament. But afterwards, when the Greek language became fashionable at Rome, by copying after their writers, such as Herodotus, Thucydides, Xenophon, and others, they endeavoured to introduce all their beauties into their own tongue, which in Cicero's time was brought to its highest perfection. But it did not long continue in that state. A degeneracy of manners soon altered their taste, and corrupted their language, which Quintilian very much complains of in his time. The case was the same with respect to the Greek tongue; though that had the good fortune to continue its purity much longer than the Latin. Nor can any language be exempt from the common fate of all human productions; which have their beginning, perfection, and decay. Besides, there is a sort of fashion in language, as well as other things, and the generality of people are always fond of running into the mode. Perhaps some one, or a few persons, fall into a manner which happens to please. This gives them a reputation; and others immediately copy after them, till it generally prevail. Cicero tells us, that the most ancient Greek orators, whose writings were extant in his time, such as Pericles, Alcibiades, and others, were subtle, acute, concise, and abounded in sense rather than words. But another set that followed them, of which were Critias, Theramenes, and Lyfias, retained the good sense of the former, and at the same time took more care of their style; not leaving it so bare as the former had done, but furnishing it with a better dress. After these came Isocrates, who added all the flowers and beauties of eloquence. And as he had abundance of followers, they applied these ornaments and decorations according to their different genius; some for pomp and splendour; and others to invigorate their style, and give it the greater force and energy. And in this latter way Demosthenes principally excelled. Now as each of these manners had its peculiar beauties, and generally prevailed in different ages; Cicero thinks this could not have happened otherwise than

from imitation. And he attributes it to the same cause, that afterwards they sunk into a softer and smoother manner, not less exact and florid, but more cold and lifeless. If we take a view of our own tongue, Chaucer seems to have been the first who made any considerable attempts to cultivate it. And whoever looks into him, will perceive the difference to be so great from what it is at present, that it scarcely appears to be the same language. The gradual improvements it has since received, are very evident in the writers almost of every succeeding age since that time; and how much farther it may still be carried, time only can discover. See LANGUAGE.

Another cause of the variety of style arises from the different nature and properties of language. A difference in the letters, the make of the words, and the order of them, do all affect the style. So Quintilian observes, that the Latin tongue cannot equal the Greek in pronunciation, because it is harsher. The Latins want two of the softest Greek letters, *v* and *z*; and use others of a very hard sound, which the Greeks have not, as *f* and *g*. Again, many Latin words end in *m*; a letter of a broad and hollow sound, which never terminates any Greek word; but *v* does frequently, whose sound is much softer and sweeter. Besides, in the combination of syllables, the letters *b* and *d* are often so situated, as to require too strong and unequal a force to be laid upon them, as in the words *obversus* and *adjuugo*. Another advantage of the Greek tongue arises from the variety and different feat of the accents: for the Greeks often accent the last syllable, which both enlivens the pronunciation, and renders it more musical; whereas the Latins never do this. But the greatest advantage of the Greeks lies in their plenty and variety of words; for which reason they have less occasion for tropes or circumlocutions, which, when used from necessity, have generally less force, and weaken the style. But under these disadvantages, Quintilian seems to give his countrymen the best advice the case will admit of: That what they cannot do in words, they should make up in sense. If their expressions are not so soft and tender, they should exceed in strength; if they are less subtle, they should be more sublime; and if they have fewer proper words, they should excel in the beauty as well as number of their figures. If this account of Quintilian be just, that the Greek tongue does surpass the Latin in all these instances, it is certain that both of them have much greater advantages over some modern languages. The varying all their declinable words, both nouns and verbs, by terminations, and not by signs, contributes very much to the smoothness and harmony of their periods. Whereas in the modern languages, those small particles and pronouns, which distinguish the cases of nouns, and the tenses and persons of verbs, hinder the run of a period, and render the sound much more rough and uneven. Besides, the ancient languages seem to have a better and more equal mixture of vowels and consonants, which makes their pronunciation more easy and musical.

But the chief distinction of style arises from the different subjects, or matter of discourse. The same way of speaking no more suits all subjects, than the same garment would all persons. A prince and a peasant ought

Elocution.

ought not to have the same dress; and another different from both becomes those of a middle station in life. The style therefore should always be adapted to the nature of the subject, which rhetoricians have reduced to three ranks or degrees; the *low* or *plain* style, the *middle* or *temperate*, and the *lofty* or *sublime*: Which are likewise called *characters*, because they denote the quality of the subject upon which they treat. This division of style into three characters, was taken notice of very early by ancient writers. Some have observed it even in Homer, who seems to assign the *sublime* or magnificent to Ulysses, when he represents him so copious and vehement an orator, that his words came from him like a winter snow. On the contrary, he describes Menelaus as a *polite* speaker, but *concise* and *moderate*. And when he mentions Nestor, he represents his manner as between these two, not so high and lofty as the one, nor yet so low and dressed as the other; but *smooth*, even, and pleasant, or, as he expresses it, *more sweet than honey*. Quintilian observes, that although accuracy and politeness were general characters of the Attic writers; yet among their orators, Lyfias excelled in the *low* and *familiar* way; Isocrates for his *elegancy*, *smoothness*, and the *fine turn* of his periods; and Demosthenes for his *force* and *rapidity*, by which he carried all before him. And Gellius tells us, that the like difference was found in the three philosophers who were sent from the Athenians to Rome (before the Romans had any relish for the polite arts) to solicit the remittance of a fine laid upon them for an injury done to a neighbouring state. Carneades, one of those ambassadors, was *vehement* and *rapid* in his harangues; Critolaus, *neat* and *smooth*; and Diogenes, *modest* and *slow*. The eloquence of these orators, and the agreeable variety of their different manner, so captivated the Roman youth, and inflamed them with a love of the Grecian arts, that old Cato, who did all he could to check it by hurrying away the ambassadors, could not prevent their vigorous pursuit of them, till the study became in a manner universal. And the old gentleman afterwards learned the Greek language himself, when it became more fashionable. Which a noble writer of ours \* represents as a punishment upon him for his former crime. It seldom happens that the same person excels in each of these characters. They seem to require a different genius, and most people are naturally led to one of them more than another; though all of them are requisite for an orator upon different occasions, as we shall hereafter.

#### CHAP. V. Of the Low Style.

THIS we shall consider under two heads, *thoughts* and *language*; in each of which these several characters are distinguished from one another.

I. And with respect to the former, as the subjects proper for this style are either common things, or such as should be treated in a plain and familiar way; so plain thoughts are most suitable to it, and distinguish it from the other characters.

Now, by plain thoughts, are meant such as are simple and obvious, and seem to rise naturally from the subject, when duly considered; so that any one, upon first hearing them, would be apt to imagine they

must have occurred to himself. Not that this is really the case, but because the more natural a thing is, the more easy it seems to be; though in reality it is often otherwise; and the perfection of art lies in its nearest resemblance to nature. And therefore, in order to speak plainly and clearly upon any subject, it must first be duly considered, well understood, and thoroughly digested in the mind; which, though it require labour and study, yet the more a person is master of what he says, the less that labour will appear in his discourse. This natural plainness and simplicity, without any disguise or affectation, very much contributes to give credit to what is said. Nor is any thing more apt to impose on us, than the appearance of this, when artfully assumed. Cicero's account of the fight between Milo and Clodius, in which Clodius was killed, is a remarkable instance of this. "When Clodius knew (says he) that Milo was obliged to go to Lanuvium upon a solemn and necessary occasion, he immediately hastened from Rome, the day before, to assassinate him before Clodius's own house, as appeared afterwards by the event. And this he did at a time, when his turbulent mob in the city wanted his assistance; whom he would not have left, but for the advantage of that place and season to execute his wicked design. But the next day Milo was in the senate, where he continued till they broke up; then went home; changed his dress; staid there some time till his wife was ready; and afterwards set forward so late, that if Clodius had designed to return to Rome that day, he might have been here by that time. Clodius, prepared for his design, met him on horseback, having no chariot, no equipage, no Greek attendants as usual; and without his wife, which was scarce ever known: whereas Milo was in a chariot with his wife, wrapt up in a cloak, and attended by a large retinue of maid servants, pages, and other persons unfit for an engagement. He met with Clodius before his house, about five o'clock in the evening; and was presently assaulted from an higher ground by many armed men, who killed the coachman. Upon which, Milo, throwing off his cloak, leaped out of the chariot, and bravely defended himself: and those who were with Clodius, having their swords drawn, some made up to the chariot to attack Milo; and others, who now thought he had been killed, began to fall upon his servants who were behind. And of these, such as had courage, and were faithful to their master, some were killed; and others, when they saw the skirmish at the chariot, and could do their master no service (for they heard Clodius himself say that Milo was killed, and really thought it was so), did that, not by their master's order, not with his knowledge, nor when he was present, which every one would have his own servants to do in the like circumstances. I do not say this to fix any crime upon them, but only to relate what happened." His meaning is, they killed Clodius; which he avoids mentioning, to render what he says less offensive. Can any thing be told in a more plain and simple manner than this? Here is nothing said, but what in itself seems highly probable, and what one would imagine the fact might easily suggest to any ordinary spectator. But in this, both the art and skill of it consist. For in the whole account, as, on the one hand, Milo

\* Lord Bacon.  
con.

Elocution.

Elocution.

is so described as to render it highly improbable he could have any design at that time against Clodius; so on the other, no one circumstance is omitted which might seem proper to persuade the hearers that Clodius was the aggressor in that engagement. And yet, if we may believe Asconius, the quarrel was begun by some of Milo's retinue, and Clodius was afterwards killed by his express order. But as things are sometimes best illustrated by their opposites, we shall here produce a contrary instance of a very affected and unnatural way of relating a fact. Val. Maximus tells us of a learned man at Athens, who, by a blow which he received by a stone upon his head, entirely forgot all his learning, though he continued to remember every thing else. And therefore, as he says, since this misfortune deprived him of the greatest enjoyment of his life, it had been happier for him never to have been learned, than afterwards to lose that pleasure. This is the plain sense of the story. But now let us hear him relate it. "A man (says he) of great learning at Athens, having received a blow upon his head by a stone, retained the memory of all other things very perfectly, and only forgot his learning, to which he had chiefly devoted himself. The dreadful and malignant wound invading his mind, and as it were designedly surveying the knowledge deposited there, cruelly seized on that part of it in particular from which he received the greatest pleasure, and buried the singular learning of the man with an invidious funeral. Who since he was not permitted to enjoy his studies, had better never have obtained access to them, than afterwards to have been deprived of the delight they afforded him." What an unnatural way is this of relating such an accident, to talk of a wound invading the mind, and surveying the knowledge deposited there, and cruelly seizing a particular part of it, and burying it with an invidious funeral? There is nothing in the story could lead him to this, but an over-sensitiveness to refine upon it in a very affected manner. But there are two properties of plain thoughts, one of which ought constantly to attend them in common with all thoughts, and the other is often necessary to animate and enliven this character.

The former of these is justness and propriety, which is what reason dictates in all cases. What Cicero says of the death of Crassus the orator, seems very just, as well as natural. "It was (says he) an affliction to his friends, a loss to his country, and a concern to all good men; but such public calamities followed upon it, that heaven seemed rather to have favoured him with death, than to have deprived him of life." This thought seems very just, and agreeable to the sentiments of a good man, as Crassus was, to choose death rather than to outlive the happiness of his country, to which he himself had so much contributed. Quintilian has a reflection upon a like occasion, which is not so just and becoming. It is upon the death of his only son, a youth of very uncommon parts, as he represents him; and for whose use he had designed his *Institutions of Oratory*; but he died before they were finished. The passage is this: "I have lost him of whom I had formed the greatest hopes, and in whom I had deposited the greatest comfort of my old age. What can I do now? or of what farther use can I think myself to be, thus disappointed by heaven? What good

parent will pardon me, if I can any longer study? and not condemn such resolution, if, thus surviving all my family, I can make any other use of my voice, than to accuse the gods, and declare that providence does not govern the world?" Allowance may be made for the sallies of passion, even in wise men, upon some shocking occasions; but when it proceeds to such a degree as to become impious, it is very indecent, as well as unjust. And all indecency is unnatural, as it is disagreeable to reason, which always directs to a decorum. That seems to be a very natural as well as just thought of Pliny the Younger, when he says, "The death of those persons always appear to me too hasty and unseasonable, who are preparing some lasting work. For persons wholly devoted to pleasures, live, as it were, from day to day, and daily finish the end for which they live; but those who have a view to posterity, and preserve their memory by their labours, always die untimely, because they leave something unfinished. We shall mention but one more instance; and that in a comparative view, to make it the more evident. The two sons of Junius Brutus, the first Roman consul, having been convicted of treason in associating with Tarquin's party, were ordered, among others, to be put to death; and their father not only pronounced the sentence, but presided at the execution. This fact is mentioned by several of the Roman historians; and, as it carries in it not only the appearance of rigorous justice, but likewise of cruelty in Brutus, to have been present at the execution of his sons, they endeavour to vindicate him different ways. What Florus says, seems rather an affectation of wit, than a just defence of the fact. "He beheaded them (says he), that, being a public parent, he might appear to have adopted the whole body of the people." Nor does Val. Maximus come up to the case, who says, "He put off the father to act the consul; and chose rather to lose his sons, than be wanting to public justice." This might be a reason for condemning them; and would have been equally true, had he not been present at their execution. But Livy, whose thoughts are generally very just and natural, assigns the best reason which perhaps can be given for his vindication, when he says, "Fortune made him the executioner of the sentence, who ought not to have been a spectator." By saying *fortune made him so*, he represents it not as a matter of choice, like the other historians, but of necessity, from the nature of his office, which then obliged him to see the execution of that sentence he had himself before pronounced; as is the custom at present, in some popular governments.

The other property, which should often accompany plain and simple thoughts, is, that they be gay and sprightly. This, as has been said, is necessary to animate and enliven such discourses as require the low style. The fewer ornaments it admits of, the greater spirit and vivacity is requisite to prevent its being dry and jejune. A thought may be very brisk and lively, and at the same time appear very natural, as the effect of a ready and flowing wit. Such thoughts, attended with agreeable turns, are very suitable to this style; but care should be taken, lest, while fancy is too much indulged, the justness of them be overlooked. We shall give one instance, in which this seems to have been the case, from a celebrated English work, where

the ingenious writer endeavours to shew the disadvantages of persons not attending to their natural genius, but affecting to imitate others in those things for which they were not formed. "The great misfortune (says he) of this affectation is, that men not only lose a good quality, but also contract a bad one; they not only are unfit for what they are designed, but they assign themselves to what they are unfit for; and instead of making a very good figure one way, make a very ridiculous one another. Could the world be reformed to the obedience of that famed dictate, *follow nature*, which the oracle of Delphos pronounced to Cicero when he consulted what course of studies he should pursue, we should see almost every man as eminent in his proper sphere as Tully was in his. For my part, I could never consider this preposterous repugnancy to nature any otherwise, than not only as the greatest folly, but also one of the most heinous crimes; since it is a direct opposition to the disposition of Providence, and (as Tully expresses it) like the sin of the giants, an actual rebellion against heaven." The advantages that arise from persons attending to their own genius, and pursuing its dictates, are here represented in a very lively and agreeable manner. But there is one thing asserted, which we fear will not hold; which is, that, *Could the world be reformed to that dictate*, "Follow nature," *we should see almost every man as eminent in his proper sphere, as Tully was in his*. For though doubtless persons would generally succeed best, if they kept to this rule; yet different degrees of ability are often found, where the bias and inclination is the same, and that accompanied with equal labour and diligence. If this was not so, how happened it that no one came up to Tully in the art of oratory; especially in his own age, when there were the greatest opportunities for that study, and the highest encouragements were given to it, as it paved the way to riches, honours, and all the grand offices of the state? It cannot well be questioned, but that there were other gentlemen, who had all the same advantages, accompanied with as strong a passion for this art, as Tully had, who yet fell much short of him in point of success. And experience shews, that the case has been the same in all other pursuits.

102 III. But it is time to proceed to the other head, the *language* proper for this style. And here it may be observed in general, that the dress ought to be agreeable to the thoughts, plain, simple, and unaffected.

But the first thing that comes under consideration is elegance, or a proper choice of words and expressions; which ought always to suit the idea they are designed to convey. And therefore when an ancient writer, speaking of *cruelty*, calls it *nevus crudelitatis*, the *blemish of cruelty*; and another, applying the same word to *ingratitude*, says *nevus ingratitudinis*, the *blemish of ingratitude*; that term does not sufficiently convey to us the odious nature of either of those vices, as indeed it was not their design it should. But otherwise, where the speaker has not some particular view in doing it, to link too low is as much a fault, as to rise too high. So to call ancient Rome *the mistress of Italy*, would as much lessen the just notion of the extent of her power, as the Roman writers aggrandise it when they style her *mistress of the world*. But pu-

ry, both in the choice of words and expressions, is *Elocution*, never more necessary than it is here. This may be called *neatness in language*. And to be plain and neat at the same time, is not only very consistent but the former can no other way recommend itself, than as joined with the latter. Besides, the fewer advantages any thing has to set it off, the more carefully they ought to be observed. Periphrasis is always to be regarded; and serves very much to keep up the attention, where other ornaments are wanting. Epithets should be sparingly used, since they enlarge the images of things, and contribute very much to heighten the style. Indeed they are sometimes necessary to set a thing in its just light; and then they should not be dropped. Thus, in speaking of Xerxes, it would be too low and flat to say, *He descended with his army into Greece*. Here is no intimation given of their vast and unparalleled numbers, which ought to be done. Herodotus says, his whole army, of sea and land forces, amounted to 2,317,000 and upwards. Therefore, unless the number be mentioned, the least that can be said is, that *he descended with a vast army*.

The next thing to be regarded is composition, which here does not require the greatest accuracy and exactness. A seeming negligence is sometimes a beauty in this style, as it appears more natural. Short sentences, or those of a moderate length, are likewise upon the whole best suited to this character. Long and accurate periods, finely wrought up with a gradual rise, harmonious numbers, a due proportion of the several parts, and a just cadency, are therefore improper, as they are plainly the effect of art. But yet some proportion should be observed in the members, that neither the ears be too much defrauded, nor the sense obscured. Of this kind is that expression of a Greek orator, blamed by Demetrius: *Ceres came readily to our assistance, but Arisides not*. The latter member of this sentence is too short; and by dropping so suddenly, both disappoints the ears, and is somewhat obscure. It would have been plainer, and more agreeable thus, *but Arisides did not come*. As to order, the plainest and clearest disposition, both of the words and members of sentences, and what is most agreeable to the natural construction, best suits with this character. For one of its principal beauties is perspicuity. And a proper connection likewise of sentences, with a regular order in the dependence of things one upon another, very much contribute to this end. With regard to the collision of syllables in different words, for preventing either an hollowness or asperity of sound, greater liberty may be taken in this style than in the other characters. Here it may be allowed to say, *Virtue is amiable to all, though all do not pursue it*. But in an higher character, perhaps, in order to prevent the hollow sound of the words *though all*, a person would chuse to vary the expression a little, and say, *though few pursue it*. So, *Xerxes' expedition*, may be tolerable here; but in the florid style, *the expedition of Xerxes* would sound much better.

The last thing thing to be considered, with respect to the language, is dignity, or the use of tropes and figures. And as to tropes, they ought to be used cautiously; unless such as are very common, and by time have either come into the place of proper words, or at least

Elocution.

least equally plain and clear. So in the instance mentioned above, Diodorus Siculus, speaking of the forces of Xerxes, calls them an *innumerable company*. Where, by a *synecdoche*, he has chose to make use of an uncertain number for a certain, as less liable perhaps to exception. Other examples might be given if necessary. And with regard to figures, as most of those which consist in words, and are therefore called *verbal figures*, serve chiefly to enliven an expression, and give an agreeable turn, they are often not improper for this character. Nor are figures of sentences wholly to be excluded, especially such as are chiefly used in reasoning or demonstration. But those which are more peculiarly adapted to touch the passions, or paint things in the strongest colours, are the more proper ornaments of the higher styles, as will be shewn hereafter.

Upon the whole, therefore, pure nature, without any colouring, or appearance of art, is the distinguishing mark of the low style. The design of it is to make things plain and intelligible, and set them in an easy light. And therefore the proper subjects of it are epistles, dialogues, philosophical dissertations, or any other discourses, that ought to be treated in a plain and familiar manner, without much ornament, or address to the passions. A freedom and ease both of thought and expression, attended with an agreeable humour and pleasantry, are its peculiar beauties that engage us. As we see persons of fashion and good breeding, though in the plainest habit, have yet something in their air and manner of behaviour that is very taking and amiable. Somewhat of the like nature attends this style. It has its difficulties, which are not so easily discerned, but from experience. For it requires no small skill, to treat a common subject in such a manner as to make it entertaining. The fewer ornaments it admits of, the greater art is necessary to attain this end. Lofty subjects often engage and captivate the mind by the sublimity of the ideas. And the florid style calls in all the assistance of language and eloquence. But the plain style is in a great measure stripped of those advantages; and has little more to recommend it, than its own native beauty and simplicity.

#### CHAP. VI. Of the Middle Style.

103 THIS we shall treat in the same manner as we did the former, by considering first the *matter*, and then the *language* proper for it.

104 I. And as the subjects proper for this style are things of weight and importance, which require both a gravity and accuracy of expression; so fine thoughts are its distinguishing-mark, as plain thoughts are of the low character, and lofty thoughts of the sublime. Now a fine thought may deserve that character from some or other of the following properties.

And the first property we shall mention is gravity and dignity. Thus Cicero in a speech to Cæsar says, "It has been often told me, that you have frequently said, you have lived long enough for yourself. I believe it, if you either lived, or was born for yourself only." Nothing could either be more fit and proper, than this was, when it was spoken; or at the same time a finer compliment upon Cæsar. For the civil

war was now over, and the whole power of the Roman government in the hands of Cæsar; so that he might venture to say, he had lived long enough for himself, there being no higher pitch of glory to which his ambition could aspire. But then there were many things in the state that wanted redressing, after those times of disorder and confusion, which he had not yet been able to effect, and of which Cicero here takes an opportunity to remind him. We shall produce another example from Curtius. Philotas, one of Alexander's captains, having formed a conspiracy against him, was convicted of it, and put to death. Amintas, who was suspected of the same crime, by reason of his great intimacy with Philotas, when he comes to make his defence, among other things speaks thus: "I am so far from denying my intimacy with Philotas, that I own I courted his friendship. Do you wonder that we shewed a regard to the son of Parmenio, whom you would have to be next to yourself, giving him the preference to all your other friends? You, Sir, if I may be allowed to speak the truth, have brought me into this danger. For to whom else is it owing, that those who endeavoured to please you, addressed themselves to Philotas? By his recommendation we have been raised to this share of your friendship. Such was his interest with you, that we courted his favour, and feared his displeasure. Did we not all in a manner engage ourselves by oath, to have the same friends, and the same enemies, which you had? Should we have refused to take this, which you as it were propoed to us? Therefore, if this be a crime, you have few innocent persons about you; nay, indeed none. For all desired to be the friends of Philotas; though all could not be so, who desired it. Therefore, if you make no difference between his friends and accomplices, neither ought you to make any between those who desired to be his friends, and those who really were so." Could any thing be finer spoken, more proper, and becoming the character of a soldier, than this defence; especially to a prince of so great and generous a spirit as Alexander? There is something which appears like this in Tacitus with relation to the emperor Tiberius, but falls vastly short of it in the justness and dignity of the sentiment. Sejanus, his great favourite, and partner in his crimes, falling under his displeasure, was, like Philotas, put to death for a conspiracy. Now a Roman knight, who apprehended himself in danger on account of his friendship with Sejanus, thus apologizes for himself to the emperor, in the manner of Amintas: "It is not for us to examine the merit of a person whom you raise above others, nor your reasons for doing it. The gods have given you the sovereign power of all things, to us the glory of obeying. Let conspiracies formed against the state, or the life of the emperor, be punished; but as to friendships and private regards, the same reason that justifies you, Cæsar, renders us innocent." The turn of the expressions is not much different from that in the case of Amintas; but the beauty of the thought is spoiled, by the flattery of complimenting Tiberius upon an excess of power, which he employed to the destruction of many excellent men. There is not that impropriety in the defence of Amintas, which is equally brave and just.

Another property of a fine thought is *beauty* and *elegance*.

Elocution.

*Elocution.* *elegance.* It is a fine compliment which Pliny pays to the emperor Trajan, when he says: "It has happened to you alone, that you was father of your country, before you was made so." Some of the Roman emperors had been complimented with the title of *father of their country*, who little deserved it. But Trajan had a long time refused it, though he was really so, both by his good government, and in the esteem of his subjects, before he thought fit to accept of it. And Pliny, among other instances of the generosity of that prince, which he mentions in the same discourse, speaking of the liberty that he gave the Romans to purchase estates which had belonged to the emperors, and the peaceable possession they had of them, does it by a turn of thought no less beautiful than the former. "Such (says he) is the prince's bounty, such the security of the times, that he thinks us worthy to enjoy what has been possessed by emperors; and we are not afraid to be thought so." There is a spriteliness in this image, which gives it a beauty; as there is likewise in the following passage of the same discourse, where he says to Trajan, "Your life is displeasing to you, if it be not joined with the public safety; and you suffer us to wish you nothing but what is for the good of those who wish it." And of the same kind is that of Cicero to Cæsar, when he says: "You, Cæsar, are wont to forget nothing but injuries." It is a very handsome, as well as just reflection, made by Tacitus upon Galba's government, that, "He seemed too great for a private man, while he was but a private man; and all would have thought him worthy of the empire, had he never been emperor." The beauty of a thought may give us delight, though the subject be sorrowful; and the images of things in themselves unpleasant, may be so represented as to become agreeable. Sissigambis, the mother of Darius, after the death of her son, had been treated by Alexander with the greatest regard and tenderness, in whose power she then was. So soon as she heard therefore that he was dead, she grew weary of life, and could not bear to outlive him. Upon which Q. Curtius makes this fine reflection: "Though she had courage to survive Darius, yet she was ashamed to outlive Alexander."

The next property of a fine thought, which we shall mention, is *delicacy*. As, in the objects of our senses, those things are said to be delicate which affect us gradually in a soft and agreeable manner; so a delicate thought is that which is not wholly discovered at once, but by degrees opening and unfolding itself to the mind, discloses more than was at first perceived. Quintilian seems to refer to this, when he says, "Those things are grateful to the hearers, which when they apprehend, they are delighted with their own sagacity; and please themselves, as though they had not heard, but discovered them." Such thoughts are not unlike the sketches of some pictures, which let us into the design of the artist, and help us to discern more than the lines themselves express. Of this kind is that of Sallust: "In the greatest fortunes, there is the least liberty." This is not often so in fact, but ought to be; both to guard against an abuse of power, and to prevent the effects of a bad example to inferiors. Pliny, speaking of the emperor Trajan's

entry into Rome, says: "Some declared, upon seeing you, they had lived long enough; others, that now they were more desirous to live." The compliment is fine either way, since both must esteem the sight of him the greatest happiness in life; and in that consistency lies the delicacy of the thought. It was a fine character given of Grotius, when very young, on the account of his surprising genius and uncommon proficiency in learning, that *he was born a man*: As if nature, at his coming into the world, had at once furnished him with those endowments which others gradually acquire by study and application.

The last property of a fine thought, which we shall take notice of, is *novelty*. Mankind is naturally pleased with new things; and when at the same time they are set in an agreeable light, this very much heightens the pleasure. Indeed there are few subjects, but what have been so often considered, that it is not to be expected they should afford many thoughts entirely new; but the same thought set in a different light, or applied to a different occasion, has in some degree a claim of novelty. And even where a thing hath been so well said already, that it cannot easily be mended, the revival of a fine thought often affords a pleasure and entertainment to the mind, though it can have no longer the claim of novelty. Cicero, in his treatise of an orator, among several other encomiums which he there gives to Crassus, says of him: "Crassus always excelled every other person, but that day he excelled himself." He means as an orator. But elsewhere he applies the same thought to Cæsar, upon another account; and with some addition to it. "You had (says he) before conquered all other conquerors by your equity and clemency, but to-day you have conquered yourself; you seem to have vanquished even victory herself, therefore you alone are truly invincible." This thought, with a little variation of the phrase, has since appeared in several later writers; and it is now grown common to say of a person, who excels in any way, upon his doing better than he did before, that he has outdone himself. The like has happened to another thought, which, with a little alteration, has been variously applied. It was said by Varro, *That if the Muses were to talk Latin, they would talk like Plantus*. The younger Pliny, applying this compliment to a friend of his, says, *His letters are so finely written, that you would think the Muses themselves talked Latin*. And Cicero tells us, *It was said of Xenophon, that the Muses themselves seemed to speak Greek with his voice*. And elsewhere, *that Philosophers speak, if Jupiter speaks Greek, he must speak like Plato*. The thought is much the same in all these instances, and has been since revived by some modern writers.

II. We shall now consider the *language* proper for the middle style. And in general it may be observed, that as the proper subjects of it are things of weight and importance, though not of that exalted nature as wholly to captivate the mind and divert it from attending to the diction; so all the ornaments of speech, and beauties of eloquence, have place here.

And first with regard to elegance, it is plain that a different choice of words makes a very great difference in the style, where the sense is the same. Sometimes

Elocution.

one single word adds a grace and weight to an expression, which, if removed, the sense becomes flat and lifeless. Now such words as are most full and expressive, suit best with this character. Epithets also, which are proper and well chosen, serve very much to beautify and enliven it, as they enlarge the ideas of things, and set them in a fuller light.

The most accurate composition, in all the parts of it, has place here. Periods, the most beautiful and harmonious, of a due length, and wrought up with the most exact order, just cadency, easy and smooth connection of the words, and flowing numbers, are the genuine ornaments, which greatly contribute to form this character.

But the principal distinction of style arises from tropes and figures. By these it is chiefly animated and raised to its different degrees or characters, as it receives a lesser or greater number of them; and those either more mild, or strong and powerful.

As to tropes, those which afford the most lively and pleasing ideas, especially metaphors, suit the middle character. It is a pretty remark, which has been made by some critics upon two verses of Virgil; one in his Eclogues, and the other in his Georgics. The former of these works is for the most part written in the low style, as the language of shepherds ought to be; but the latter in the middle style, suitable to the nature of the subject, and the persons for whom it was designed, the greatest men in Rome not thinking it below them to entertain themselves with rural affairs. Now in the Eclogue, as some copies read the verse, the shepherd, complaining of the barrenness of his land, says:

*Infelix lolium et steriles nascuntur avenæ.*

In English thus:

Wild oats and darnel grow instead of corn.

But in the Georgic, where the same sense is intended, instead of the proper word *nascuntur*, grow, the author substitutes a metaphor, *dominantur*, command, and says:

*Infelix lolium et steriles dominantur avenæ.*

That is in English:

Where corn is sown, darnel and oats command.

It was fit and natural for the shepherd to express his sense in the plaiest terms; and it would have been wrong to represent him going so far out of his way, as to fetch a metaphor from government, in talking upon his own affairs. But in the Georgic, where the poet speaks in his own person, the metaphor is much more beautiful, and agreeable to the dignity of the work. This instance may shew in some measure how the style is heightened by tropes, and the same thought may be accommodated to the several characters of style by the different manner of expression.

The like may also be said of figures either of words or sentences, in reference to this character; which admits of the finest descriptions, most lively images, and brightest figures, that serve either for delight, or to influence the passions without transport or ecstacy, which is the property of the sublime. This is indeed the proper seat of such embellishments, which support and make up a principal part of the middle or florid style. Having treated largely upon these in several

preceding chapters, we shall here only briefly mention some of the most considerable.

*Descriptions* are not only a great ornament to a discourse, but represent things in a very lively and agreeable manner. In what a beautiful light has Cicero placed the polite arts and sciences, when, describing them from their effects, he thus represents to us the great advantages, as well as pleasure, which they afford to the mind? "Other studies neither suit with all times, nor all ages, nor all places: but these improve youth, delight old age, adorn prosperity, afford a refuge and solace in adversity; please at home, are no hindrance abroad; sleep, travel, and retire with us." And they often affect us very powerfully, when they are addressed to the senses. Quintilian has painted the calamities of a city taken by storm in the brightest and strongest colours, which he represents by "Flames spreading themselves over the houses and temples, the cracking of falling buildings, and a confused noise from a variety of cries and shouts; some running they know not where, others in the last embraces of their friends, the shrieks of children, women, and old men unhappily reserved to such distress; the plundering of all places civil and sacred, the hurry and confusion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarrels among the conquerors where the plunder is largest." This seems to be a very natural, as well as moving, image of so dreadful a calamity.

*Prosopopæia* is another very strong and beautiful figure, very proper for this character. Seneca has a fine instance of it in his *Consolatory letter to Marcia*, upon the death of her son. After many arguments he had made use of to alleviate her grief, he at last introduces her father, Cremutius Cordus, as thus addressing to her: "Imagine your father (says he) from the celestial regions, speaking to you in this manner: Daughter, why do you so long indulge your grief? why are you so ignorant, as to think it unhappy for your son, that, weary of life, he has withdrawn himself to his ancestors? Are you not sensible what disorders fortune occasions every where? and that she is kindest to those who have least concern with her? Need I mention to you princes who had been extremely happy had a more timely death secured them from impending evils? or Roman generals, who wanted nothing to consummate their glory, but that they lived too long? Why then is he bewailed longest in our family, who died most happily? There is nothing, as you imagine, desirable among you, nothing great, nothing noble; but, on the contrary, all things are mean, full of trouble and anxiety, and partake very little of the light which we enjoy." This advice was very suitable for a philosopher; and he seems to have chosen this way of introducing it, to enforce the argument drawn from the happiness of good men in a future state, from the testimony of a person who was actually in the possession of it.

*Similitudes* and comparisons are another great ornament of this style, and oftenest found here. Nothing can be finer than the comparison between those two great orators, Demosthenes and Cicero, made by Quintilian, when he says: "Demosthenes and Cicero differ in their elocution; one is more close, and the other more copious; the former concludes more concisely."

107

108

cisely, and the latter takes a larger compass; the one always with pungency, and the other generally with weight; one can have nothing taken from him, and the other nothing added to him; the latter has more of art, and the former more of nature. But this must be allowed to Demosthenes, that he made Cicero in a great measure what he was. For as Tully gave himself wholly to an imitation of the Greeks, he seems to me to have expressed the force of Demosthenes, the fluency of Plato, and the pleasantry of Isocrates." Similitudes, taken from natural things, serve very much to enliven the style, and give it a cheerfulness; which is a thing so common and well known, that we need not stay to give any instances of it.

109 *Antithesis*, or opposition, both in the words and sense, has often the like beautiful effect. There is an agreeable contrast in that passage of Seneca: "Cæsar does not allow himself many things, because he can do all things: his watching defends all others sleep, his labour their quiet, his industry their pleasure, his business their ease; since he has governed the world, he has deprived himself of it." Had he said no more than only in general, that, *Cæsar does not allow himself many things, because he can do all things*, it might have passed for a fine thought; but, by adding so many particulars, all in the same form of expression, and beginning each member with the same word, he has both enlarged the idea, and beautified the antithesis, by a bright verbal figure.

These, and such like florid figures, are sometimes found in historians, but oftener in orators; and indeed this middle character, in the whole of it, is best accommodated to the subjects of history and oratory.

#### CHAP. VII. *Of the Sublime Style.*

110 THE *sublime* is the most noble, as well as the most difficult part of an orator's province. It is this principally which Cicero requires in his perfect orator, whom he could not describe in words, but only conceive of in his mind. And indeed, the noblest genius and greatest art are both requisite to form this character. For where nature has been most liberal in furnishing the mind with lofty thoughts, bright images, and strong expressions; yet without the assistance of art there will sometimes be found a mixture of what is low, improper, or misplaced. And a great genius, like a too rich soil, must produce flowers and weeds promiscuously, without cultivation. But the justest propriety, joined with the greatest strength and highest elevation of thought, are required to complete the true sublime. Art therefore is necessary to regulate and perfect the taste of those who are desirous to excel in this character.

In explaining the nature and properties of this character, we shall, as in the two former, consider first the *thoughts*, and then the *language*, in each of which it is distinguished from them.

##### § 1. *Sublime, as it relates to Thoughts.*

111 Lofty and grand sentiments are the basis and foundation of the true sublime. Longinus therefore advises those who aspire at this excellence, to accustom themselves to think upon the noblest subjects. A mind that always dwells upon low and common subjects,

can never raise itself sufficiently to represent things great and magnificent in their full extent and proper light. But he who inures himself to conceive the highest and most exalted ideas, and renders them familiar to his thoughts, will not often be at a loss how to express them; for where proper words are wanting, by metaphors and images taken from other things he will be able to convey them in a just and adequate manner. What is more common than for two persons to conceive very differently of the same thing from the different manner of thinking to which they have been accustomed? After the great battle in Cilicia, between Alexander and Darius, in which the latter was routed, he sent ambassadors to Alexander with proposals of peace, offering him half his kingdom with his daughter in marriage. Parmenio, one of Alexander's chief captains, says to him upon this occasion: "For my part, was I Alexander, I would accept of these conditions." "And so would I," replies that aspiring monarch, "was I Parmenio." The half of so vast a kingdom at present, and a right of succession to the whole by marriage, was the highest ambition to which the thoughts of Parmenio could rise. But Alexander had vastly higher views, he aimed at nothing less than universal monarchy; and therefore such a proposal seemed much beneath his regard. Noble and lofty thoughts are principally those which either relate to divine objects, or such things as among men are generally esteemed the greatest and most illustrious.

Of the former sort is that of Homer, when describing the goddesses Discord, he says, that she

Walks on the ground, and hides her head in clouds.

This stretch of thought, says Longinus, as great as the distance between heaven and earth, does not more represent the stature of the goddesses, than the measure of the poet's genius and capacity. But such images, however beautiful in poetry, are not so proper for an orator, whose business it is to make choice of those which are suited to the nature of things and the common reason of mankind. When Numa the second king of Rome was settled in his government, and at peace with his neighbours, in order to soften the fierce and martial temper of his subjects, who had been always accustomed to wars during the reign of his predecessor Romulus, he endeavoured to impress their minds with an awe of the Deity; and for that end introduced a number of religious ceremonies, which he pretended to have received from the goddess Egeria. This must be esteemed an artful piece of policy at that time. But that sentiment is far more just and noble, with which Cicero endeavours to inspire the members of a community, in his treatise Of Laws, when he says, that "Citizens ought first to be persuaded, that all things are under the rule and government of the gods; that every affair is directed by their wisdom and power; that the highest regard is due to them from men, since they observe every one's conduct, how he acts and behaves himself, and with what temper and devotion he worships them; and that they make a difference between the pious and impious." Persons under the influence of such a persuasion, could not fail of behaving well in society. And what he says to Cæsar is no less in this style, when, interceding for Ligarius, he tells him, that

"men

"men in nothing approach nearer to deity, than in giving life to men." And Velleius Paterculus, speaking of Cato, gives him this sublime character, "That he was more like the gods than men; who never did a good thing, that he might seem to do it."

The other kind of lofty thoughts mentioned above, are those which relate to power, wisdom, courage, beneficence, and such other things as are of the highest esteem among mankind. "Your fortune (says Tully to Cæsar) has nothing greater than a power, nor your nature than a will, to save many." He subjoins this compliment to what we just now cited from him; and applies that to Cæsar, which was before only expressed in general, leaving him to draw the inference of his similitude to deity from the clemency of his nature. And elsewhere, as in a sort of transport for his success in defeating the conspiracy of Catiline, he thus bespeaks the Roman senate: "You have always decreed public thanks to others for their good government of the state, but to me alone for its preservation. Let that Scipio shine, by whose conduct and valour Hannibal was forced to leave Italy, and retire to Africa; let the other Scipio be greatly honoured, who destroyed Carthage and Numantia, two cities the most dangerous to this empire; let Lucius Paulus be in high esteem, whose triumphal chariot was adorned with Perseus, once a most powerful and noble prince; let Marius be in eternal honour, who twice delivered Italy from an invasion and the dread of servitude; let Pompey's name excel all these, whose actions and virtues are terminated by no other bounds but the course of the sun: yet, among all their praises, there will still some place be left for my glory; unless indeed it be a greater thing to open for us new provinces to which we may resort, than to secure a place for our victorious generals to return in triumph." And Velleius Paterculus, as if he thought no encomium too high for this great orator, laments his unhappy fate in these lofty strains, addressed to M. Antony, by whose order he was put to death: "You have taken from Cicero old age, and a life more miserable than death under your government; but his fame, and the glory of his actions and words, you have been so far from destroying, that you have increased them. He lives, and will live in the memory of all ages; and while this system of nature, however constituted, shall remain, (which scarce any Roman but himself conceived in his mind, comprehended by his genius, and illustrated with his eloquence), the praise of Cicero shall accompany it; and all posterity, while it admires his writings against you, will curse your treatment of him; and sooner shall mankind be lost to the world, than his name." It was a noble reply of Porus the Indian king, when, after his defeat by Alexander, being brought before him, and asked, *How he expected to be treated?* he answered, *Like a king.* And Valerius Maximus, speaking of Pompey's treatment of Tigranes king of Armenia after he had vanquished him, expresses it in a manner suited to the dignity and beneficence of the action, when he says, "He restored him to his former fortune, esteeming it as glorious to make kings, as to conquer them."

But the true sublime is consistent with the greatest plainness and simplicity of expression. And, generally speaking, the more plain and natural the images

appear, the more they surprise us. How succinct, and yet how majestic, is that expression of Cæsar upon his victory over Pharnaces: *I came, I saw, I conquered.* But there cannot be a greater or more beautiful example of this, than what Longinus has taken notice of from Moses. "The legislator of the Jews (says he), no ordinary person, having a just notion of the power and majesty of the Deity, has expressed it in the beginning of his laws in the following words: *And God said—what? Let there be light; and there was light. Let the earth be made; and it was made.*" This instance from the divine writer, and the character here given of him by that excellent critic, is the more remarkable, as he was himself a Pagan. And certainly no laboured description could raise in the mind an higher conception of the infinite power of the Deity, than this plain and short narration. To command nature itself into being by a word, represents it at once altogether boundless and unlimited.

It sometimes very much contributes to heighten the image of a thing, when it is expressed in so undetermined a manner, as to leave the mind in suspense what bounds to fix to the thought. Of this kind is that of Cicero, when he first raises an objection against the necessity of an acquaintance with polite literature in order to form a great man, and then answers it. The objection is founded upon the examples of several great and excellent persons among the Romans, who had raised themselves to the highest pitch of honour and dignity, and been very serviceable to their country, by the help of a good genius, without the advantage of much learning. In reply to which, he allows, that, where these are not united, nature or genius is of itself much preferable, and will carry a person further in the pursuit of great and noble designs, than learning without a genius; but that both are necessary to complete and perfect a truly great man. But we shall give what he says himself on this head, by which that property of a sublime thought we are now endeavouring to explain, will appear from his manner of expression: "I acknowledge (says he) that many persons of an exalted mind and virtue have, from a divine temper, without instruction, become moderate and grave; and I add likewise, that nature, without the assistance of learning, has frequently more contributed to honour and virtue, than learning where a genius has been wanting: But yet I must say, that where the direction and improvement of learning is added to a great and excellent genius, it is wont to produce something admirable and singular, which I know not how to describe." He knew very well, that, by leaving the minds of his hearers thus in suspense, they would form to themselves higher conceptions of what he intended, than from any idea he could convey to them in words. We may add to this another example from the same great orator, where he says, "Truly, if the mind had no views to posterity, and all its thoughts were terminated by those bounds in which the space of life is confined, it would neither fatigue itself with so great labours, nor be disquieted with so many cares and watchings, nor so often expose itself to death. But there is a certain active principle in every good man, which constantly excites his mind by motives of glory; and reminds him, that the remembrance of his name is not to end

with

with his life, but extend itself to all posterity." Of the like nature is that of Milton, when he describes Satan as flying from hell in quest of our earth, then newly formed. For, having repented that his wings failed him in the vast vacuity, he thus describes his fall:

Down he drops  
Ten thousand fathom deep; and to this hour  
Down had been falling, had not by ill chance  
The strong rebuff of some tumultuous cloud,  
Instind with fire and nitre, hurried him  
As many miles aloft.

Those words, by which his fall is expressed,

And to this hour  
Down had been falling,

leave the mind in suspense, and unable to fix any bounds to the vacuity; and by that means raise a greater and more surprising idea of its space, than any direct expression could have done. This image is very beautiful where it stands; but so much out of the common way of thinking, as to suit better with an epic poem, than the discourse of an orator.

§ 2. *The Sublime, with regard to Language.*

112 WHAT we have to offer upon this subject, will come under the three heads of *Elegance, Composition, and Dignity*; which comprehend all the properties of style.

113 I. *Elegance.* Those words and expressions chiefly contribute to form the sublime, which are most sonorous, and have the greatest splendor, force, and dignity. And they are principally such as these. Long words, when equally expressive, are rather to be chosen, than short ones, and especially monosyllables. So to conquer or vanquish and enemy, carries in it a fuller and more grand sound, than to beat an enemy. For which reason, likewise, compound words are often preferable to simple ones. So if we say, *Cæsar's army, when he was present, was always invincible*; this manner of expression has more of sublimity in it, than should we say, *Cæsar's army, when he was present, could never be conquered*. But the ancient languages have much the advantage of ours in both these respects; for their words are generally longer, and they are abundantly more happy in their compositions. The use of proper epithets does also in a particular manner contribute to this character. For as they denote the qualities and modes of things, they are, as it were, short descriptions; so that being joined to their subjects, they often greatly enlarge and heighten their image. Thus when the character of *divine poet* is given to Homer or Virgil, or *prince of orators* to Demosthenes or Cicero; it conveys to the mind a more sublime idea of them, than the bare mention of their name.

114 II. *Composition:* The force of which, as Longinus observes, is so great, that sometimes it creates a kind of sublime where the thoughts themselves are but mean, and gives a certain appearance of grandeur to that which otherwise would seem but common. But composition consists of several parts; the first of which, in the order we have hitherto considered them, is *period*. And here the case is much the same as with animal bodies, which owe their chief excellency to the union and just proportion of their parts. The several members, when separate from each other, lose both that

beauty and force, which they have when joined together in a complete body. In like manner sublimity arises from the several parts of a period so connected, as to give force, as well as beauty, to the whole. The periods therefore in this character should be of a proper length. If they are too short, they lose their just weight and grandeur, and are gone almost before they reach the ear; as on the contrary, when they are too prolix, they become heavy and unwieldy, and by that means lose their force. But more especially, nothing superfluous ought to be admitted, which very much enervates the force of a sentence. We shall exemplify this in a passage from Herodotus, where he is giving an account of the famous battle at Thermopylæ, between the Persians and Lacedæmonians. "Dieneces," says he, "the Spartan, being told by a Trachinian, before the engagement with the Medes, that when the barbarians came to shoot their arrows, they would fly so thick as to obscure the light of the sun; he was so far from being terrified at this, that, despising their number, he replied, he "was pleased with what his friend told him, since if the sun was obscured, they should fight in the shade, and not in the sun." The sense here is great and noble, but the sublimity of expression is spoilt in a great measure by those last words, and *not in the sun*, which are wholly superfluous. Cicero was sensible of this, and therefore he omits that member in relating the same story, and says only: "A Spartan, hearing that one of the Persians should say in an insulting manner, that when they came to engage, they should not be able to see the sun, for the multitude of their darts and arrows, replies, Then we shall fight in the shade." By stopping here, he gives the sentence much more life and emphasis. The next thing to be considered in composition, is the order and disposition of the several words and members of a sentence. The different placing but of one or two words will sometimes wholly destroy the grandeur of a sentence, and make it extremely flat. "This public act (says Demosthenes) dispelled the danger, which at that time, like a cloud, hung over the city." Let us vary the order a little, and read it thus: "This public act dispelled the danger, which like a cloud hung over the city at that time." What a different turn does the expression receive for the worse! The spirit and majesty of it are entirely lost.—And in placing the several parts or members, they ought to be so disposed, that what is most weighty and important should stand last. So Tully says of Catiline: "We ought to return thanks to heaven, that we have so often escaped so odious, so frightful, so dangerous a plague of the state." A thing may be odious, and frightful, and yet not dangerous; therefore he puts this in the last place, to give it the greater force, and make the deepest impression. Another thing to be attended to in composition, is the connection of the words with regard to the sound; that the pronunciation, in passing from one to another, may be most agreeable to the ear, and best suited to the nature of the subject. And as this is generally something grand and magnificent, such a contexture of them as will give the greatest force and energy to the expression is most proper for the sublime. Soft and languid sounds are very unsuitable to this character. They soothe and please the ear; but rather

rather sink and depress the mind, than excite it to things great and noble. In this respect therefore, our tongue, by its multitude of consonants, is more suitable for sublime discourses, than some other modern languages, which abound with vowels.

115 III. The last head to be considered, is the proper use of tropes and figures; which is here so necessary, that the title of *dignity* seems to have been given to this part of elocution, from the assistance it more especially affords to this character. For if, as has been observed from Longinus, compositions will sometimes create a sort of sublimity; this much oftener happens from the force and efficacy of some lively tropes and strong figures.

And as to *tropes*, bright metaphors are peculiarly suited to raise and animate the style. This is manifest from the nature of them, as they consist of contracted similes, reduced to a single word; which, if taken from things lofty and grand, must of consequence give a sublimity to the style. What can suggest to us a greater idea of the valour of Ajax, than Homer's calling him *the bulwark of the Greeks*; or of the Scipios, than when they are styled by Virgil, *the two thunderbolts of war*. A number of those, well chosen, contribute no less to the grandeur than to the beauty of discourse. Hyperbole sometimes gives the same force to an expression, if cautiously used, and so as not to exceed all appearance of truth. But the chief use of it is, where proper words will not express the just idea of the thing designed to be conveyed; and it may seem rather the offspring of necessity than choice. Of this nature is that of Herodotus, when speaking of the Lacedæmonians at Thermopylæ, he says: "They defended themselves with the swords they had left, and even with their hands and teeth, till the barbarians buried them under their arrows." It cannot be supposed strictly true, that so many arrows were thrown at them as to bury them; but having in the former part of the sentence represented their resolute defence in the strongest terms, by saying, that, naked and without arms, they engaged armed men with their hands and teeth, the following hyperbole seems not unnatural, and to intimate nothing more than what was necessary to quell such obstinate resolution and courage.

As to *figures*, whether verbal or those which consist in the sense, the nature of this character will easily direct to such as are most proper. But with respect to the latter, poets take greater liberties in the use of them than would be allowed in an orator. As their images are often formed for pleasure and delight, so they carry in them more of rapture and transport. But the orator's use of them being to set things in a stronger and clearer light, they are more sedate and moderate. Besides, an orator scarce ever has occasion for such fictitious images as we often meet with in poetry; though his ought to appear as natural, and its painting as strong and lively. We shall just mention some of the chief of those figures, which seem best suited for this purpose; though they are no less suited to the middle style, as has been shewn already, when taken from subjects of an inferior nature.

116 I. *Description*. Of this Justin gives us a fine instance, in a speech of king Philip the sixth of Macedon, wherein he represents the necessity of falling up-  
Vol. VIII.

on the Romans, who at that time were engaged in a war with Hannibal. "I behold," says he, "a cloud of a most dreadful and bloody war rising in Italy. I see a storm of thunder and lightning from the west, which will overspread all places with a vast shower of blood, into whatever country the tempest of victory shall drive it. Greece has undergone many violent shocks in the Persian, Gallic, and Macedonian wars; but these would all be found unworthy of regard, if the armies now engaged in Italy should march out of that country. I view the terrible and cruel wars which involve those nations through the courage of their forces, and skill of their generals. This rage and fury cannot cease by the destruction of one party, without the ruin of their neighbours. Indeed, Macedon has less reason to dread the savage conquerors, than Greece; because more prepared, and better able to defend itself: but I am sensible, those who attack each other so impetuously, will not confine their victories within those bounds; and that it will be our lot to engage the conquerors." So lively a picture of imminent and threatening danger, must needs alarm the most timorous, and excite them to a resolution to defend their country, and all that was dear to them. Such images give life and vigour to a discourse, and being artfully interwoven with proper arguments, influence the mind, and carry it away by an irresistible force; so that the hearer is not barely left to conclude the certainty of the thing, but moved by it, as it were, from ocular demonstration. The images therefore of the orator ought to be drawn from real things, or at least such as are probable; for if they are wholly fictitious and incredible, as many poetical images are, they may give pleasure, but will not convince the mind, nor sway the passions.

2. *Enumeration* has some affinity with the former figure; by which, if the several parts have each something grand in them, the whole, when brought together, and disposed in a just order, very much contributes to the sublimity. We shall produce an example of this from an English writer, containing a description of our globe, upon a survey of it after the general conflagration, which he represents in this strong light: "Such is the vanity and transient glory of this habitable world! By the force of one element breaking loose upon the rest, all the vanities of nature, all the works of art, all the labours of man, are reduced to nothing; all that we admired and loved before, as great and magnificent, is obliterated and vanished, and another form and face of things, plain, simple, and every where the same, overspreads the whole earth. Where are now the great empires of the world, and their great imperial cities; their pillars, trophies, and monuments of glory? Shew me where they stood, read the inscription, tell me the victor's name. What remains, what impressions, what difference or distinction, do you see in this mass of fire? Rome itself, eternal Rome, the great city, the empress of the world, whose domination or superstition, ancient or modern, make a great part of the history of the earth; what is become of her now? She laid her foundations deep, and her palaces were strong and sumptuous; *she glorified herself, and lived deliciously, and said in her heart, I sit a queen, and shall see no sorrow: but her hour is come, she is wiped away from the face*

117

Elocution.

of the earth, and buried in everlasting oblivion. But it is not cities only, and the works of mens hands; the everlasting hills, the mountains and rocks of the earth, are melted as wax before the sun, and *their place is no where found*. Here stood the Alps, the load of the earth, that covered many countries, and reached their arms from the ocean to the Black sea. This huge mass of stone is softened and dissolved, as a tender cloud into rain. Here stood the African mountains, and Atlas with his top above the clouds. There was frozen Caucasus, and Taurus, and Imaus, and the mountains of Asia; and yonder, towards the north, stood the Riphean hills, clothed in ice and snow; all these are vanished, dropped away, as the snow upon their heads†. These particulars considered separately, are all truly great and noble, and every way suited to the nature of the subject; but as they are here disposed, and rise in order, they both enlarge the idea, and heighten the image of that grand catastrophe.

† Burnet's Theory.

118

3. *Similitude* : Which serves very much for beauty and ornament; and when taken from great and sublime objects, adds a grandeur and magnificence to the things illustrated by it. We need go no farther for an example of this, than to the great critic so often mentioned already, who has treated upon the sublime in a style every way equal to the subject. He, then, comparing those two great works of Homer, his *Iliad* and *Odyssey*, thus describes them: "Homer composed his *Iliad*, when his mind was in its full strength and vigour; the whose body of the poem is dramatic, and full of action: whereas the best part of the *Odyssey* is taken up in narrations, which seem to be the genius of old age. So that one may compare him in this latter work to the setting sun, which still appears with the same magnificence, but has no longer the same heat and force." And soon after, speaking of the *Odyssey*, he says, "That piece may be called the reflux of his genius, which like the ocean ebbs, and deserts its shores." What nobler idea could possibly have been given of that great poet, than by those two similitudes of the sun and the ocean? And elsewhere, comparing those two great orators Demosthenes and Cicero, he shews the like sublimity of thought. Demosthenes, says he, "is sublime, in that he is close and concise; Cicero, in that he is diffused and extensive. The former, by reason of the violence, rapidity, strength, and fury, with which he rages and bears all before him, may be compared to a tempest and thunder; but the latter, like a great conflagration, devours and consumes all he meets, with a fire that is never extinguished, but wherever it advances continually gathers new strength."

119

4. *Antithesis*, or a sentence consisting of opposite parts, has often the same effect; as in the following instance of Cicero, where his view is to represent Pompey as a most consummate general. "Who," says he, "ever was, or need be more knowing, than this man? who from his childhood, and instruction at school, went into the army of his father, and learned the military art, in a very great war against the fiercest enemies: who while yet a boy, became a soldier under the greatest general; and when first a youth, was himself commander of a very great army: who has oftener engaged with the enemy in battle,

than any other person with his adversary in private contests; has waged more wars than others have read, and conquered more provinces than others have wished to govern: whose youth has been spent in acquiring the art of war, not by the precepts of others, but his own commands; not by defeats, but victories; not by campaigns, but triumphs."

120

5. *Apophrophe*. Among the articles charged against Demosthenes by his great adversary and rival Æschines, one was, that he had advised the Athenians to engage in a war against king Philip, wherein they had received a very great defeat. When he comes to answer that part of the charge, he does not say, as he might, "You have not been misled, my fellow-citizens, in exposing your lives for the liberties and safety of Greece; you are not without the most illustrious examples of such conduct: For who can say these great men were misled, who fought for the same cause in the plains of Marathon?" But instead of expressing himself thus, he gives the matter quite a different turn; and in a sort of rapture, appealing to those brave defenders of their country, says, "No, my fellow-citizens, you have not done wrong, you have not; I protest by the ghosts of those great men who fought for the same cause in the plains of Marathon." By this appeal to those ancient worthies whose memories were in the highest esteem at Athens, that it was the cause, and not the success, which rendered their actions so glorious, he artfully corroborates his assertion in a way which he knew must have the greatest weight with his audience.

As the proper subjects of this character are either divine things, or such as are in the highest esteem and regard among mankind, which often require laudatory discourses, or panegyric; these naturally admit of all the ornaments and assistance of eloquence. Which, however, must be used with discretion: for when the mind is wrapt up in thought, and stretched to the utmost of its powers in the pursuit of some noble and sublime idea, it cannot attend to all the lesser fineries and niceties of language; but, from its own vigour, and lively conception of things, will be led to express them in terms the most emphatical, and best suited to their nature. In such cases therefore, the sublimity must appear rather from the elevation of the thought, attended with a simplicity of expression, than from the ornaments and dress of the language. These things seem more natural when the mind is relaxed, and employed upon lower objects. Though, upon the whole, grandeur and majesty of expression is the proper mark of this character with relation to the language, as beauty and splendor is of the middle style.

#### CHAP. VIII. Of the Style of an Orator.

The style of an orator comprehends all the characters already explained, of *low*, *middle*, and *sublime*, as they are applied by him in the different parts of his province. For that the language must be suited to the nature of the subject, we have had occasion often to observe already; and the different view of the speaker or writer, necessarily occasions a variety in the manner of expression. Now an orator has three things in his view; to prove what he asserts, to represent it in an agreeable light, and to move the passions.

121

Elocution.

Elocution.

These are all necessary, we do not mean in the order wherein we have now mentioned them, but that the discourse may upon the whole have its desired effect upon the audience. For unless the mind be convinced of the truth of what is offered by solid and cogent arguments, neither will the most eloquent discourse afford a lasting pleasure, nor the most pathetic long influence the affections. Though, on the other hand, the hearers expect to be entertained at the same time they are informed; and therefore, unless the language be agreeable to their taste, they will soon call off their attention, and think but meanly of the speaker. And unless both these are warmed and animated by a becoming pathos, the speaker may very probably miss of his end, in bringing his audience over to his sentiments. For bare conviction is not sufficient with many persons to excite them to action. They will acquiesce in the truth of a thing which they cannot contradict, or will not give themselves the trouble to examine; and at the same time remain unconcerned to prosecute it. And the pleasure of a florid discourse will of itself soon vanish, like the harmony of music, or the charms of a fine poem. And therefore to captivate his audience, secure them in his interest, and push them upon action, it is necessary for the orator to engage their affections: these are, as it were, the springs of the soul, which, managed by a skilful hand, move and direct it at pleasure. Now each of these parts of an orator's province requires a different style. The *low style* is most proper for proof and information; because he has no other view here but to represent things to the mind in the plainest light, as they really are in themselves, without colouring or ornament. The *middle style* is most suited for pleasure and entertainment, because it consists of smooth and well-turned periods, harmonious numbers, with florid and bright figures. But the *sublime* is necessary in order to sway and influence the passions. Here the orator calls in all the assistance both of nature and art; the most raised and lofty thoughts, clothed with the brightest and strongest colouring, enter into this character.

But as an orator has frequently each of these views in the same discourse, we shall first give a summary description of the several characters of style, which we have formerly discoursed on more at large; that, by placing them together in one view, the difference between them may be more plain and obvious: and then we shall proceed to shew to what particular parts of a discourse each of them is more especially to be applied.

I. First, then, as shorter periods are proper in the *low style*, so less care is necessary in their turn and cadency. If a sentence now and then drop unexpectedly, and disappoint the ear, or has something rough and harsh in its composition, it is no blemish in this character. For as it is suited to the manner of common discourse, an appearance of regard to the subject, rather than the form of expression, is more becoming than any beauties of art. But the words should be well chosen and proper, suited to the ideas they are designed to convey; the expressions plain and clear, and the artificial ornaments few and modest. By *artificial ornaments* are here meant *tropes* and *figures*; and they are called *artificial*, because they vary from

the natural drefs of language, either in the words or manner of expression: though they are often used by those who are wholly unacquainted with the rules of art; and particularly metaphors, which persons who have the least command of language frequently run into through mere necessity, for want of a sufficient stock of proper words to convey their ideas. The low style therefore admits of these: but care should be taken to choose such as have been rendered familiar by use, or at least where the similitude is very plain and evident. Bold or lofty metaphors, or where the allusion is dark and remote, ought to be avoided. Nor is the moderate use of the other tropes wholly disagreeable to this style. And the same thing is to be said with respect to verbal figures, or such as consist in the particular disposition of the sentence, so that if the form of it be changed, the figure is lost. Of these, such as come nearest to the natural way of expression are most proper for this style; and therefore those which consist in a jingle of words, arising from the same or a like sound, are to be avoided, as carrying in them too much the appearance of art. Those likewise which consist in a repetition of the same word have often too great a force and vehemence for this mild and gentle character. And as to figures of sentences, which do not depend on the construction of words, but lie in the sense, many of them are too gay and sprightly, and others too rapid and impetuous, for the simplicity of the low style; so that only the more moderate and sedate ones are to be allowed a place here. It is therefore no wonder if persons are often mistaken in their notions of this character; the beauty of which consisting in a certain plainness and simplicity, without any thing in it but what seems natural and common, every one is apt to imagine he can readily be master of it, till by experience he finds the contrary. For the case is much the same here, as in persons of fashion and good breeding, whose behaviour and address is attended with that agreeable freedom and seeming negligence, which in appearance is very easy to express, but in reality is scarce imitable by others.

As the *middle style* is more adapted for pleasure and delight, it admits of all those beauties and ornaments which soothe and entertain the mind. It has more force and energy than the low style, but less than the sublime. Smooth and harmonious numbers, well-turned periods, of a just length, delightful cadency, and accurate disposition of the words, are suited to this style. The most beautiful and shining tropes, which strike the fancy, and all those verbal figures which, by a repetition, similitude, or proportion of sounds, please and gratify the ear, help to form this character. The like is to be said as to figures of sentences: The most florid and beautiful, such as enumeration, description, similitude, and the like, are here the most proper.

But it is the *sublime style* which perfects the orator. This requires the most forcible and emphatical words, the boldest metaphors, and strongest figures. In verbal figures, repetitions, synonyms, gradations, contraries, with others of a like force and energy, are chiefly employed here. But figures of sentences are the most considerable, and principally contribute to make up this character. Among these are similes taken from

lofty subjects, prosopopœia, apostrophe, exclamation, epiphonema, aposiopesis, and others of a like nature. But due care must likewise be taken of the form, construction, and harmony of the periods; which seem best disposed, when long and short ones are intermixed. For though round and swelling periods carry in them something grand and majestic, yet many times they move too slow to strike the passions; whereas short ones are more acute and pungent, and, by returning quick, awaken the mind, and raise the passions. But to render it complete, it must be supported with strong reason, grandeur of thought, and sentiments every way equal to the expression; without which it will be very liable to swell into bombast, and end barely in amusement.

II. Having given a short sketch of this part of the orator's furniture, we shall now go on to shew where, and in what manner, he is to make use of it. This will best appear by considering his principal view in each part of his discourse. Now the parts of a just oration (as we have formerly shewn) are six; *Introduction, Narration, Proposition, Confirmation, Confutation, and Conclusion*. Not that all these are necessary in every discourse; but it is proper they should all be mentioned, that we may consider what style is fittest for them, when they are necessary.

In the *introduction*, the orator has three things before him; to gain the esteem of his hearers, to secure their attention, and to give them some general notion of his subject. To set out modestly, is undoubtedly the most likely way to recommend himself. For to attempt to inflame an audience, before they are prepared for it, or see the reason of much warmth, is highly improper. A prudent speaker will, like Demosthenes, begin with temper, and rise gradually, till he has insensibly warmed his hearers, and in some degree engaged their affections in his favour. So that this part scarce rises above the middle style. And if it carry in it an air of pleasantry and good-humour, it is generally the more apt to engage the attention.

The *introduction* is usually followed by the *narration*, or a recital of such things as either preceded, accompanied, or followed upon the subject under consideration. Now as the qualities that recommend a narration are clearness, brevity, and probability; these sufficiently point out the style. Perspicuity arises from the choice of proper words, and such tropes as have been rendered most familiar by use; brevity requires moderate periods, whose parts are but little transposed; and a plain and simple dress, without ornament or colouring, is best suited to represent things probable: all which are the properties of the low style. And therefore Cicero says, *narrations come pretty near to our ordinary discourse*. Indeed, sometimes it is necessary not only to relate the facts themselves, but likewise to describe the manner in which they were performed. And then a further degree of art may be requisite to represent them with all their circumstances, and paint them to the mind in their proper colours.

The next part in order is the *proposition*, or subject of the discourse, in which there can be no room for ornament. But as it is the basis and foundation of the orator's whole design, it ought to be laid down in the

plainest and clearest terms, so as to leave no room for doubt or uncertainty what it is which he intends to discourse upon.

The next thing is *confirmation*, wherein the orator endeavours to maintain and defend his own cause, and to convince his hearers of the truth of it by reason and argument. Now the low style is certainly fittest for cool reasoning and debate. But the orator's method of reasoning often very much differs from that of the philosopher. The latter contents himself with the most plain and familiar manner of representing the truth, and thinks it sufficient if what he says be clearly understood. But the former, at the same time that he convinces the judgment, endeavours likewise to affect the passions, and that in a great variety of ways. So that in this part of the discourse the style is very different, according to the nature and circumstances of the cause. Sometimes, while he is dwelling upon the proof of a thing, he talks coolly, and reasons with the sedateness of a philosopher; and where any part of his argument appears doubtful or obscure, he endeavours with the same even temper to explain and clear it up. But frequently he intermixes with his proofs all the arts of persuasion, and embellishes his reasons with the greatest ornaments and beauties of eloquence.

Confirmation is usually followed by *confutation*, in which the orator endeavours to enervate and overthrow all that has been advanced in favour of the opposite side of the question. But as the style is much the same here as in the former part; what has been said upon this, may be sufficient for this likewise.

The last part above-mentioned is the *conclusion*. This consists of two branches, *recapitulation and address*. Recapitulation is a short recital of the several arguments, or at least the chief of them, which were before advanced in support of the cause; that, being brought together into a narrow compass, they may appear in a stronger light. Wherefore the language here ought rather to be forcible and strong than florid, because brevity and conciseness is a necessary quality. The other branch of the conclusion consists in an address to the passions, and is wholly persuasive; for which the speaker is now entirely at leisure. Indeed, this is often done occasionally in other parts of the discourse, particularly in the introduction and confirmation: But as in the former of these, his view is principally to secure the good opinion of the hearers, and excite their attention; and in the latter to defend his own side of the question by reason and argument; when these two points are gained, he has nothing left but to prevail with them to fall in with his design, and declare for him. And the best way to attain this is, by engaging their passions in his interest. Hence then, to use Quintilian's words, "All the springs of eloquence are to be opened. Now we are past the rocks and shallows, all the sails may be hoisted. And as the greatest part of the conclusion consists in illustration, the most pompous language and strongest figures have place here."

All the variety above-mentioned, however, is not always necessary. Regard must be had to the nature of the subject, the time, place, persons, and other circumstances; by all which the style is to be regulated.

*Pronunciation.* To discourse in a lofty and grand way upon a common topic, or in a low and flat manner upon a sublime argument, are both equally injudicious. Cicero refers us to some discourses of his own, as instances of each kind. His oration for Cæcina, he says, is written in the low style, that for the Manilian law in the middle style, and that for Rabirius in the sublime; and his Actions against Verres, with some others, are patterns of the variety here mentioned. And he gives us a very comprehensive description of a perfect orator in a very few words, when he says: "He is one who can speak upon a low subject acutely, upon a lofty subject with sublimity, and upon a moderate subject temperately." By which he means no more, than one who is master of the three characters here described, and knows when and how to use them. But although he

mentions several among the Greeks, and some few among the Romans, who excelled in one or other of these different kinds; yet one who excelled in them all, he supposes never to have existed, except in the imagination. The reason perhaps may be, because each of them seems to require a very different genius, so that it is scarce possible for the same person to succeed in them all. Since therefore it is so rare and difficult a matter to gain the command of each in any good degree, it is better perhaps for every one to pursue that which nature seems most inclined to, and to excel in it, than to strive against their genius. For every kind has its perfections; and it is more commendable to be master of one thing, than to do several but indifferently.

*Pronunciation.*

## PART IV. OF PRONUNCIATION.

### CHAP. I. Of Pronunciation in general.

128

**P**RONUNCIATION is also called *Actio* by some of the ancients. Though if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. But if we consider them as synonymous terms, in this large sense pronunciation or action may be said to be, *a suitable conformity of the voice, and the several motions of the body, in speaking, to the subject matter of the discourse.*

The best judges among the ancients have represented this as the principal part of an orator's province, from whence he is chiefly to expect success in the art of persuasion. When Cicero, in the person of Crassus, has largely and elegantly discoursed upon all the other parts of oratory, coming at last to speak of this, he says: "All the former have their effect as they are pronounced. It is the action alone that governs in speaking; without which the best orator is of no value, and is often defeated by one in other respects much his inferior." And he lets us know, that Demosthenes was of the same opinion, who, when he was asked what was the principal thing in oratory, replied, *Actio*; and being asked again a second and a third time, what was next considerable, he still made the same answer." By which he seemed to intimate, that he thought the whole art did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would scarce have taken so much pains in correcting those natural defects, under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly, by pronouncing long periods as he walked up-hill; both which methods contributed to the strengthening of his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he less careful in endeavouring to gain the habit of a becoming and decent gesture; for which purpose he used to pronounce his discourses

alone before a large glass. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a sword, which hung over him with the point downward. Such pains did this prince of the Grecian orators take to remove those difficulties, which would have been sufficient to discourage an inferior and less aspiring genius. And to how great a perfection he arrived in his action, under all these disadvantages, by his indefatigable diligence and application, is evident from the confession of his great adversary, and rival in oratory, Æschines. "Who, when he could not bear the disgrace of being worsted by Demosthenes in the cause of Ctesiphon, retired to Rhodes. And being desired by the inhabitants to recite to them his own oration upon that occasion, which accordingly he did; the next day they requested of him to let them hear that of Demosthenes; which having pronounced in a most graceful manner, to the admiration of all who were present, "How much more, (says he,) would you have wondered, if you had heard him speak it himself!" By which he plainly gave Demosthenes the preference in that respect. We might add to these authorities the judgment of Quintilian, who says, that "it is not of so much moment what our compositions are, as how they are pronounced; since it is the manner of the delivery, by which the audience is moved." And therefore he ventures to assert, that, "an indifferent discourse, assisted by a lively and graceful action, will have greater efficacy than the finest harangue, which wants that advantage."

The truth of this sentiment of the ancients, concerning the power and efficacy of pronunciation, might be proved from many instances; but one or two may here suffice. Hortensius, a cotemporary with Cicero, and while living next to him in reputation as an orator, was highly applauded for his action. But his orations after his death, as Quintilian tells us (for we have none of them now remaining), did not appear answerable to his character; from whence he justly concludes, there must have been something pleasing when he spoke, by which he gained his character, which was lost in reading them. But perhaps there is scarce a more considerable instance of this than in Cicero himself. After the death of Pompey, when

Cæsar

Pronunciation.

Cæsar had got the government into his own hands, many of his acquaintance interceded with him in behalf of their relations and friends, who had been of the contrary party in the late wars. Among others, Cicero solicited for his friend Ligarius; which Tubero understanding, who owed Ligarius a grudge, he opposed it, and undertook to reprove him to Cæsar as unworthy of his mercy. Cæsar himself was prejudiced against Ligarius; and therefore, when the cause was to come before him, he said, "We may venture to hear Cicero display his eloquence; for I know the person he pleads for to be an ill man, and my enemy." But, however, in the course of his oration, Cicero so worked upon his passions, that by the frequent alteration of his countenance, the emotions of his mind were very conspicuous. And when he came to touch upon the battle of Pharsalia, which had given Cæsar the empire of the world, he represented it in that moving and lively manner, that Cæsar could no longer contain himself, but was thrown into such a fit of shivering, that he dropped the papers which he held in his hand. This was the more remarkable, because Cæsar was himself one of the greatest orators of that age, knew all the arts of address, and avenues to the passions, and consequently was better prepared to guard against them. But neither his skill, nor resolution of mind, was of sufficient force against the power of oratory; but the conqueror of the world became a conquest to the charms of Cicero's eloquence; so that, contrary to his intention, he gave into his plea, and pardoned Ligarius. Now that oration is still extant, and appears exceedingly well calculated to touch the soft and tender passions, and springs of the soul; but we believe it can scarce be discernible to any in reading it, how it should have had so surprising an effect; which must therefore have been chiefly owing to the wonderful address and conduct of the speaker.

The more natural the pronunciation is, it will of consequence be the more moving, since the perfection of art consists in its nearest resemblance to nature. And therefore it is not without good reason, that the ancients make it one qualification of an orator, that he be a good man; because a person of this character will make the cause he espouses his own, and the more sensibly he is touched with it himself, his action will be the more natural, and by that means the more easily affect others in the same manner. Cicero, speaking upon this subject, says: "It is certain that truth (by which he means nature) in every thing excels imitation; but if that was sufficient of itself in action, we should have no occasion for art." In his opinion therefore (and who was ever a better judge?) art in this case, as well as in many others, if well managed, will assist and improve nature. But that is not all; for sometimes we find the force of it so great and powerful, that, where it is wholly counterfeit, it will for the time work the same effect as if it was founded in truth. This is well known to those who have been conversant with the representations of the theatre. In tragedies, though we are sensible that every thing we see and hear is feigned and counterfeit, yet such is the power of action, that we are oftentimes affected by it in the same manner as if they were all realities. Anger and resentment at the appearance of cruelty, concern and solicitude for distressed virtue, rise in our breasts; and

tears are extorted from us for oppressed innocence: Pronunciation. though at the same time, perhaps, we are ready to laugh at ourselves for being thus decoyed. If art then has so great an influence upon us, when supported only by fancy and imagination; how powerful must be the effect of a just and lively representation of what we know to be true and real?

How agreeable it is both to nature and reason, that a warmth of expression and vehemency of motion should rise in proportion to the importance of the subject and concern of the speaker, will further appear, by looking back a little into the more early and simple ages of the world. For the higher we go, the more we shall find of both. We shall give the observation of a very great man upon this head, in his own words. "The Romans (says he) had a very great talent this way, and the Greeks a greater. The eastern nations excelled in it, and particularly the Hebrews. Nothing can equal the strength and vivacity of the figures they employed in their discourse; and the very actions they used to express their sentiments; such as putting ashes on their heads, and tearing their garments, and covering themselves with sackcloth under any deep distress and sorrow of mind. I do not speak of what the prophets did to give a more lively representation of the things they foretold, because such figurative actions were the effect of divine inspiration. But even in other cases we find those people understood much better than we do how to express their grief, and fear, and other passions. And hence, no doubt, arose those surprising effects of eloquence, which we never experience now." Thus far this excellent writer. And what he says here with respect to the actions of the eastern nations, was in a good measure customary among the Greeks and Romans; if not entirely of the same kind, yet perhaps as vehement and expressive. They did not think language of itself sufficient to express the height of their passions, unless enforced by uncommon motions and gestures. Thus, when Achilles had driven the Trojans into their city with the greatest precipitation and terror, and only Hector ventured to tarry without the gates to engage him; Homer represents both king Priam and his queen under the highest consternation for the danger of their son. And therefore, in order to prevail with him to come into the city, and not fight with Achilles, they not only intreat him from the walls in the most tender and moving language imaginable; but he tears off his grey locks with his hands; and she in a flood of tears exposes her breasts, and adjures him by those paps which suckled him, to comply with their request. The poet knew very well, that no words of themselves could represent those agonies of mind he endeavoured to convey, unless heightened by the idea of such actions as were expressive of the deepest sorrow. And indeed this was anciently esteemed so requisite in an orator, that in matters of importance he was scarce thought to be in earnest, who wanted it. In one of Cicero's orations, he does not stick to argue in that manner with his adversary. "Would you talk thus (says he) if you was serious? Would you, who are wont to display your eloquence so warmly in the danger of others, act so coldly in your own? Where is that concern, that ardour, which used to extort pity even from children? Here is no emotion either of mind

Dial. of Eloquence, p. 92.

Pronunciation.

or body; neither the forehead struck, nor the thigh, nor so much as a stamp of the foot. Therefore, you have been so far from inflaming our minds, that you have scarce kept us awake."

As action therefore was judged so necessary a qualification in an orator among the ancients, so they made use of several methods and expedients for the better attaining it. The principal of which we shall briefly mention.

*Decency* of pronunciation is an habit. And as all habits are gained by time, so the sooner they are learned, they are generally acquired with greater ease. For while persons are young, they are not only more flexible, and capable of any particular bent, but they are likewise free from the trouble of encountering and subduing contrary habits, which doubles the labour, and increases the difficulty of attaining any laudable quality. Quintilian was very sensible of this in the case here before us; and therefore, in order to have persons trained up to it, he begins with them in their childhood, and defends so low as even to give directions how they should be taught to pronounce when they first learn to read. And he advises, that they should then be instructed where to suspend their voice, and make the proper pauses, both in distinguishing the several parts of the same sentence, and in separating one sentence from another: likewise when to raise, or sink their voice, or give it a proper inflection; to be slower or faster, more vehement or sedate, as the nature of the things may require; and that the tone of their voice be always manly and grave, but at the same time mixed with an agreeable sweetness. These things may perhaps appear in themselves small; but if duly attended to, they will be found of considerable service to bring us to a just and proper pronunciation. For in every thing that is to be attained by practice, it is a great advantage to set out right at first.

The ancients likewise had persons, whom they called *phonæstæ*, whose proper business it was to teach them how to regulate and manage their voice; and others, who instructed them in the whole art of pronunciation, both as to their voice and gestures. These latter were generally taken from the theatre, being some eminent experienced actors. So Quintilian, treating of the province of these persons, says: "The comedian ought to teach them how to relate facts, with what authority to advise, with what vehemence to express anger, and with what softness compassion." And speaking of gestures, he says, "He should admonish them to raise their countenance, not distort their lips, or stretch their mouths." With several other directions of the like kind. And we are told concerning the emperor M. Antoninus, usually called the philosopher, that, *His first masters were Euphorio the grammarian, and Genuinus the comedian.*

But though they made use of actors to instruct their youth in forming their speech and gestures, yet the action of an orator was much different from that of the theatre. Cicero very plainly represents this distinction, in the words of Crassus, when, speaking of orators, he says: "The motions of the body ought to be suited to the expressions, not in a theatrical way, mimicking the words by particular gesticulations; but in a manner expressive of the general sense; with a se-

Pronunciation.

date and manly inflection of the sides; not taken from the stage and actors, but from the exercise of arms and the palestra." And Quintilian says to the same purpose: "Every gesture and motion of the comedians is not to be imitated, nor to the same degree." They thought the action of the theatre too light and extravagant for the imitation of an orator; and therefore, though they employed actors to inform young persons in the first rudiments, yet they afterwards sent to the palestra, or schools designed on purpose to teach them a decent and graceful management of their bodies. And such schools, as Quintilian informs us, were in use both among the Greeks and Romans: Just as of later ages children learn to dance, in some measure with the same intention.

Being thus far prepared, they were afterwards sent to the schools of the rhetoricians. And here, as their business was to cultivate their style, and gain the whole art of eloquence; so particularly to acquire a just and accurate pronunciation by those exercises, in which for that end they were constantly employed. And as the Greeks were most celebrated for their skill in all the polite arts, and especially oratory; the Roman gentry and nobility generally sent their sons abroad, and placed them under the tuition of some Grecian master, to instruct them in the art of speaking, and by that means to fit them for the service of their country, either in the courts of judicature or the senate. Thus Cicero was sent to Rhodes, to study under the famous Molo, and Brutus under Pammenes; Cæsar was going to the same place when taken by pirates; and Augustus afterwards studied there under Apollodorus.

Nor, after all this pains and industry, did they yet think themselves sufficiently qualified to take upon them the character of orators. But it was their constant custom to get together some of their friends and acquaintance who were proper judges of such performances, and declaim before them in private. The business of these persons was to make observations both on their language and pronunciation. And they were allowed the greatest freedom to take notice of any thing they thought amiss, either as to inaccuracy of method, impropriety of style, or indecency of their voice or actions. This gave them an opportunity to correct any such defects at first, before they became habitual. What effects might not justly be expected from such an institution? Persons trained up in this manner, with all those advantages, joined to a good natural genius, could not fail of making very complete orators. Though even after they came to appear in public, they did not lay aside the custom of declaiming. For Quintilian tells us, that *C. Cæso used to practise it daily in his tent.* And Augustus is reported to have continued it during the war of Mutina against M. Anthony. Nor is it to be supposed, that so constant an attendance to this practice was only serviceable to them in their public performances; but it must necessarily affect their whole conduct, give them a freedom of speech, easiness of address and behaviour, and render them in all respects fine gentlemen, as well as excellent orators. And from hence perhaps we may see less reason to wonder at the surprising effects of some of their discourses, when we consider what pains they took to arrive at those abilities.

Having

Having thus far treated on pronunciation in general, we shall now proceed to consider the parts of it separately; which are, *voice* and *gesture*.

## CHAP. II. Of the Voice.

329

VOICE is one kind of sounds. Now the influence of sounds, either to raise or allay our passions, is evident from music. And certainly the harmony of a fine discourse, well and gracefully pronounced, is as capable to move us, if not in a way so violent and ecstatic, yet no less powerful, and more agreeable to our rational faculties. As the business of this chapter is to offer some considerations for the just and decent management of the voice, it may not be improper in the first place to observe in general, what nature does, when free and unconstrained. As persons are differently affected when they speak; so they naturally alter the tone of their voice, though they do not attend to it. It rises, sinks, and has various inflections given it, according to the present state and disposition of the mind. When the mind is calm and sedate, the voice is moderate and even; when the former is dejected with sorrow, the latter is languid; and when that is inflamed by passion, this is raised and elevated. It is the orator's business, therefore, to follow nature, and to endeavour that the tone of his voice appear natural and unaffected. And for this end, he must take care to suit it to the nature of the subject; but still so as to be always grave and decent. Some persons continue a discourse in such a low and drawing manner, that they can scarce be heard by their audience. Others again hurry on in so loud and boisterous a manner as if they imagined their hearers were deaf. But all the music and harmony of speech lies in the proper temperament of the voice between these extremes. In order to set this matter in a just light, it will be necessary to consider the principal affections or properties of the voice, and how they are to be regulated by an orator. Now these may all be referred either to *quantity* or *quality*.

The *quantity* of the voice consists in its *highness* or *lowness*, *swiftness* or *slowness*, and the intermediate degrees between them.

Every person who speaks in public, should endeavour, if he can, to fill the place where he speaks. But still he ought to be careful not to exceed the natural key of his voice. If he does, it will neither be soft nor agreeable; but either harsh and rough, or too shrill and squeaking. Besides, he will not be able to give every syllable its full and distinct sound; which will render what he says obscure, and difficult to be understood. He should therefore take care to keep his voice within reach, so as to have it under management, that he may raise or sink it, or give it any inflection he thinks proper: Which it will not be in his power to do, if he put a force upon it, and strain it beyond its natural tone.

The like caution is to be used against the contrary extreme, that the voice be not dropped, and suffered to sink too low. This will give the speaker pain in raising it again to its proper pitch, and be no less offensive to the hearers. For though the music of speech consists in the variations of the voice, yet they must be gradual to render them pleasant. Such sudden and great changes at once are rather to be esteemed

chafins in speaking, than variations. Besides, as they often prevent the hearers from taking in the sense of what is said, it gives them no small uneasiness that they are obliged to stretch their attention. Many persons are too apt to be guilty of this, especially at the end of a sentence, by dropping the last word; which ought in a particular manner to be expressed distinctly, because the meaning of the whole sentence often depends upon it.

The medium between these two is a moderate and even voice. But this is not the same in all; that which is moderate in one would be high in another. Every person therefore must regulate it by the natural key of his own voice. A calm and sedate voice is generally best; as a moderate sound is most pleasing to the ear, if it be clear and distinct. But this equality of the voice must also be accompanied with a variety, otherwise there can be no harmony; since all harmony consists in variety. Nothing is less pleasing, than a discourse pronounced throughout in one continued tone of the voice, without any change or alteration. Besides, a variation of the voice is an ease to the speaker; as the body is relieved by shifting its posture. The equality therefore we are here speaking of, admits a variety of inflections and changes within the same pitch. And when that is altered, the gradations, whether higher or lower, should be so gentle and regular, as to preserve a due proportion of the parts, and harmony of the whole; which cannot be done, when the voice is suddenly varied with too great a distinction. And therefore it should move from one key to another, so as rather to glide like a gentle stream, than pour down like a rapid torrent, as an ingenious writer has well expressed it. An even voice is best fitted to keep the mind to close attention. And therefore, in subjects designed only for instruction, without any address to the passions, there is little room for a variety of voice. For the voice ought to agree with the style; and as upon such subjects this should be equal, moderate, and smooth, so should the other. Every thing, as we say, is beautiful in its season; and there is a certain propriety in things, which ought always to be regarded. And therefore, an affected variety, ill placed, is as disagreeable to a judicious audience, as the want of it, where the subject requires it. We may find some persons, in pronouncing a grave and plain discourse, affect as many different tones, changes, and variations of their voice, as if they were acting a comedy; which is doubtless a very great impropriety. But the orator's province is not barely to apply to the mind, but likewise to the passions; which require a great variety of the voice, high or low, vehement or languid, according to the nature of the passions he designs to affect. So that for an orator always to use the same tone or degree of his voice, and expect to answer all his views by it; would be much the same thing as if a physician should propose to cure all distempers by one medicine. From hence it is evident, that although various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear; yet the degree of it should differ according to the nature of the subject and design of the speaker. And, as a perfect monotony is always unpleasant, so it can never be necessary in any discourse.

Pronunciation.

The next property of the voice above-mentioned was *fluency*. That some expressions ought to be pronounced faster and swifter than others, is very manifest. Gay and sprightly ideas should not only be expressed louder, but also faster, than such as are sad and melancholy. And when we press an adversary, the voice should be brisk and quick. But to hurry on in a precipitant manner without pausing, till stop for want of breath, is certainly a very great fault. This destroys not only the necessary distinction between sentence and sentence, but likewise between the several words of the same sentence; nay, and often occasions us to express our words by halves, while one is thrown so fast upon another, that we are not able to give each its full and just sound. By this means all the grace of speaking is lost, and in a great measure the advantage of hearing. For when the ears of the hearers cannot keep pace with the volubility of the speaker's tongue, they will be little the better for what he says. Besides, by not commanding his voice, and easing his breath at the proper pauses and points of distinction, he is often obliged to stop in the middle of a sentence; and so divides what should be continued, and joins what should be separated; which must necessarily destroy the sense, and confound his discourse. Young persons are very liable to this, especially at first setting out. And it often arises from diffidence. They are jealous of their performances, and the success they may have in speaking, which gives them a pain till it is over; and this puts them into a hurry of mind, which incapacitates them from governing their voice, and keeping it under that due regulation which perhaps they proposed to themselves before they began to speak. And the greater degree such persons have of a native and ingenuous modesty, accompanied with a laudable ambition to excel, they are commonly more exposed to this. For while on the one hand they are fired with an ardent desire to recommend themselves, and on the other are fearful of the event, this dubious state of mind is very apt to throw them off their guard, and run them into this excess. From which we may see the great advantage of having the voice well formed betimes; for when once it is become habitual to speak with justness and propriety, persons readily practise it without much attention or concern.

And as a precipitant and hasty pronunciation is culpable, so likewise on the other hand, it is a fault to speak too slow. This seems to argue a heaviness in the speaker. And as he appears cool himself, he can never expect to warm his hearers, and excite their affections. When not only every word, but every syllable is drawn out to too great a length, the ideas do not come fast enough to keep up the attention without much uneasiness. For till the sense is completed, the mind is in suspense; and, if it be held long in that situation, it will of course flag and grow tired. Indeed, in some cases, it is requisite the pronunciation should be slower than in others; as in representing things great and difficult; or in expressing some particular passions, as admiration or grief. But the extreme we are now speaking of, is a slowness equally continued through an whole discourse, which must necessarily render it flat and lifeless.

Now, to avoid either of the two extremes last men-

VOL. VIII.

2

tioned, the voice ought to be sedate and distinct. And in order to render it distinct, it is necessary, not only that each word and syllable should have its just and full sound, both as to time and accent; but likewise that every sentence, and part of a sentence, should be separated by its proper pause and interval. This is more easy to be done in reading, from the assistance of the points; but it is no less to be attended to in speaking, if we would pronounce in a distinct and graceful manner. For every one should speak in the same manner as he ought to read, if he could arrive at that exactness. Now the common rule given in pausing is, that we stop our voice at a comma till we can tell one, at a semicolon two, at a colon three, and at a full period four. And as these points are either accommodated to the several parts of the same sentence, as the first three; or different sentences, as the last; this occasions the different length of the pause, by which either the dependance of what precedes upon that which follows, or its distinction from it, is represented. And therefore, in the first three stops, the voice is rather to be suspended in different degrees or measures of time, than entirely dropt, to shew that the sense is not yet completed. But between sentence and sentence we respire, and begin anew. So that in long periods, the voice should be favoured by beginning low and sedately, that it may hold to the end without respiration; or if it will not, the breath ought to be recovered without sinking the voice. For if once the voice drop for want of breath before the period be finished, not only the beauty, but likewise the sense of it will be lost. Quintilian lays a great stress upon a due attention to these pauses; and says, "Though it may appear not so considerable in itself, yet all the other virtues of a good pronunciation are deficient without it."

Hitherto we have considered such properties of the voice as respect *quantity*, we come now to speak of its *qualities*. And the chief of these are *strength* or *weakness*, *clearness* or *obscureness*, *fullness* or *smallness*, *smoothness* or *roughness*. Now, one half of these is what every one would willingly choose, as he would wish to be free from the others. But it is not in our power to give ourselves what qualities of the voice we please; but only to make the best use we can of what nature has bestowed upon us. However, several defects of the voice are capable of being helped by care and proper means; as, on the other hand, the best voice may be greatly hurt by ill management and indiscretion. Temperance is a great preservative of the voice, and all excess is highly prejudicial to it. The voice must necessarily suffer, if the organs of speech have not their proper tone. And in order to their having this, they must be kept in a due temperature; that is, they must neither be too moist nor too dry. If they abound with fluids, these will obstruct the clearness of the voice, and render it obscure and confused; and if they are parched with drought, the voice will be harsh and rough. Now all excesses, as well as some bodily indispositions, are apt to affect the organs one or other of these ways.

A strong voice is very serviceable to an orator, because, if it want some other advantages, he is, however, capable to make himself heard. And if at any time he is forced to strain it, he is in less danger of its

32 K

fail-

failling him before he has finished his discourse. But he who has a weak voice, should be very careful not to strain it, especially at first. He ought to begin low, and rise gradually to such a pitch as the key of his voice will well carry him, without being obliged to sink again afterwards. Frequent inflections of the voice will likewise be some assistance to him. But especially he should take care to speak deliberately, and ease his voice, by allowing due time for respiration at all the proper pauses. It is an extreme much less inconvenient for such a person rather to speak too slow, than too fast. But this defect of a weak voice is sometimes capable of being helped, by the use of proper methods; as is evident from the instance of Demosthenes, before-mentioned.

A voice is said to be *clear*, when the organs of speech are suited to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is very pleasing and agreeable to the hearers; and no less an happiness to the speaker, as it saves him a great expence of spirits. For a moderate voice, if clear, will be as distinctly heard, as one much louder, if thick and obscure. Which is a great advantage to the speaker, because he can better keep his voice under command, and modulate it at pleasure, as the several parts and circumstances of his discourse may require. On the contrary, an obscure and confused voice is not always occasioned from a deficiency in the organ; but, many times, is the effect of custom and a bad habit. Some persons, either from want of due care in their education at first, or from inadvertency and negligence afterwards, run into a very irregular and confused manner of expressing their words; either by misplacing the accent, confounding the sound of the letters, or huddling the syllables one upon another, so as to render what they say often unintelligible. Indeed, sometimes this arises from a natural defect, as in the case of Demosthenes; who found a method to rectify that, as well as the weakness of his voice. But in faults of this kind, which proceed from habit, doubtless the most likely way to mend them is to speak deliberately.

A full voice is not the same, as a strong, nor a loud voice. It fills the ear, but it is often not pleasant. And therefore to render it so, as well as audible, it should be frequently varied. However, this seems better suited to the character of an orator, than a small and shrill voice: because it has something in it more grave and manly. And those, who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden compression of the organ, is apt to occasion a squeaking and very disagreeable sound.

A soft and smooth voice is of all the most musical, especially if it be flexible. And on the contrary, nothing is less harmonious than a voice that is harsh and rough. For the one grates as disagreeably upon the ear, as the other gives it pleasure and delight.

From the consideration of these several properties of the voice, we may conclude that to be the best, and fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and withal easily flexible to the several degrees and variations of sound which

every part of the discourse may require.

### CHAP. III. Of Gesture.

By this is meant, a suitable conformity of the motions of the countenance, and several parts of the body in speaking, to the subject-matter of the discourse. The word *gesture* is here used in a larger sense than is ordinarily done in common language. For we rarely make use of that word to denote the motions of the countenance, or any parts of it; but as these make a considerable part of our present subject, they must here be comprehended under this term.

It is not agreed among the learned, whether voice or gesture has the greater influence upon us. But as the latter affects us by the eye, as the former does by the ear, gesture in the nature of it seems to have this advantage, that it conveys the impression more speedily to the mind; for the sight is the quickest of all our senses. Nor is its influence less upon our passions; nay, in some instances it appears to act more powerfully. A cast of the eye shall express desire in as moving a manner, as the softest language; and a different motion of it, resentment. To wring the hands, tear the hair, or strike the breast, are all strong indications of sorrow. And he who claps his hand to his sword, throws us into a greater panic than one who only threatens to kill us. Nor is it in some respects less various and extensive than language. Cicero tells us, he often diverted himself by trying this with Roscius the comedian; who could express a sentence as many ways by his gestures, as he himself by words. And some dramas have been carried on wholly by mutes, who have performed every part by gestures only, without words, in a way very intelligent, as well as entertaining to the spectators. Well therefore might Cicero call *action* (or gesture) *the language of the body*, since it is capable in so lively a manner to convey both our ideas and passions. But with respect to oratory, gesture may very properly be called the *second part of pronunciation*; in which, as the voice should be suited to the impressions it receives from the mind, so the several motions of the body ought to be accommodated to the various tones and inflections of the voice. When the voice is even and moderate, little gesture is required; and nothing is more unnatural than violent motion, in discoursing upon ordinary and familiar subjects. The motions of the body should rise therefore in proportion to the vehemence and energy of the expression, as the natural and genuine effect of it.

But as gesture is very different and various as to the manner of it, which depends upon the decent conduct of several parts of the body; it will not be amiss to consider more particularly, the proper management of each of those parts. Now all gesture is either natural, or from imitation. By natural gesture we mean such actions and motions of the body, as naturally accompany our words, as these do the impressions of our minds. And these either respect the whole body, or some particular part of it. But before we enter upon this, give us leave just to observe, that it has been customary in all ages and countries, in making a set discourse before an assembly, to do it standing. Thus we read, that, *Abraham stood up, and spake unto the children of Heth.* And it seems as if

Pronunciation.

if he sat down, when he had ended his speech; because, immediately after the account of their answer, it is said again, that *Abraham stood up and bowed himself to the people of the land, the children of Heth*. In like manner Homer represents the Grecian princes, as standing up, when they made a speech, either to the army, or in their councils. So when Achilles has assembled the army, to inquire into the reason of the great plague which at that time raged among them, he rises up before he begins to speak, and sits down again when he has done. After him the prophet Calchas rises, and charges it upon Agamemnon; who rising up in a passion, does not refuse to comply with what Calchas proposed, but expresses his repentment at him for saying it. And upon another occasion, both Agamemnon and Nestor do the same in council. And Cicero acquaints us, that when Lentulus had been charged in the senate, as an associate with Catiline, he stood up to make his defence. Nor does the advantage of being better heard, seem to have been the only reason for so general an agreement in this posture; but it appears likewise to have been chosen, as the most decent and respectful. Sitting carries in it an air of authority, and is therefore a posture scarce used upon such occasions, unless perhaps where that is designed to be expressed by it. Wherefore it was a thing very much resented, that when Cæsar, after he had got the power into his hands, being once addressed to the senate, either refused to rise, as some say, or as others, one of his friends held him down by his gown.

But though standing appears to be the most proper posture for speaking in public, yet it is very unbecoming for the body to be entirely without any motion like a statue. It should not long continue in the same position, but be constantly changing, though the motion be very moderate. There ought to be no appearance of stiffness, but a certain ease and pliability, naturally suiting itself to every expression; by which means, when a greater degree of motion is necessary, it will appear less sudden and vehement. For as the raising, sinking, and various inflections of the voice must be gradual; so likewise should the motions of the body. It is only on some particular occasions, that an haughty vehemence and impetuosity is proper in either case.

As to the several parts of the body, the head is the most considerable. To lift it up too high has the air of arrogance and pride; to stretch it out too far, or throw it back, looks clownish and unmannerly; to hang it downwards on the breast, shews an unmanly bashfulness, and want of spirit; and to suffer it to lean on either shoulder, argues both sloth and indolence. Wherefore in calm and sedate discourse it ought to keep its natural state, an upright posture. However, it should not be long without motion, nor yet always moving; but gently turn sometimes on one side, and sometimes on the other, as occasions require, that the voice may be heard by all who are present; and then return again to its natural position. It should always accompany the other actions of the body, and turn on the same side with them; except when aversion to any thing is expressed, which is done by stretching out the right hand, and turning the head to the left. The ancients erected a statue of Venus in this posture, who

was called by the Greeks *Ανδροειδης*, and by the Latins *Verticordia*, and in English may be termed the *forbidding Venus*. But nothing is more indecent, than violent motions and agitations of the head. And therefore, when a witty writer, who is well known among us, would convey the most ridiculous idea of a pretender to knowledge, he expresses it thus:

For having three times shook his head  
To stir his wit up, thus he said. HUDIB.

But it is the countenance, that chiefly represents both the passions, and disposition of the mind. By this we express love, hatred; joy, sorrow; modesty, and confidence: by this we supplicate, threaten, soothe, invite, forbid, consent, or refuse; and all this without speaking. Nay, from hence we form a judgment not only of a person's present temper, but of his capacity and natural disposition. And therefore it is common to say, *such an one has a promising countenance, or that he promises little by his countenance*. It is true, this is no certain rule of judging; nor is it in the power of any one to alter the natural make of his countenance: however, it may put us upon endeavouring to gain the most pleasing aspect we can; since it is so natural for mankind to draw such conclusions from it; and some persons are so unhappy, as to render their countenance more disagreeable, than otherwise it would be, by ill habits.

But the several parts of the face bear their part, and contribute to the proper and decent motion of the whole. In a calm and sedate discourse, all the features retain their natural state and situation. In sorrow, the forehead and eyebrows lour, and the cheeks hang down. But in expressions of joy and cheerfulness, the forehead and eyebrows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips. And terror elevates both the brows and forehead. As these are the natural signs of such passions, the orator should endeavour to conform to them.

But as the eyes are most active and significant, it is the advice of Cicero that the greatest care should be taken in their management. And he gives this reason for it, "Because other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes, by so many different actions, which cannot possibly be represented by any gestures of the body, if the eyes are kept in a fixed posture." Common experience does in a great measure confirm the truth of this observation. We readily guess at a person's intention, or how he is affected to us, by his eyes. And any sudden change or emotion of the mind is presently followed by an alteration in the look. In speaking therefore upon pleasant and delightful subjects, the eyes are brisk and cheerful; as, on the contrary, they sink and are languid in delivering any thing melancholy and sorrowful. This is so agreeable to nature, that before a person speaks, we are prepared with the expectation of one or the other from his different aspect. So likewise in anger, a certain vehemence and intenseness appears in the eyes, which, for want of proper words to express it by, we endeavour to represent by metaphors taken from fire, the most violent and rapid element, and say in such cases, *the eyes sparkle, burn, or are inflamed*:

Pronunciation.

In expressions of hatred or detestation, it is natural to alter the look, either by turning the eyes aside, or downwards. Virgil has very justly observed this: for when he describes Æneas meeting with Dido in the Elysian shades and addressing her, he represents her disregard of him, by saying,

Diffidantly the look'd; then turning round,  
Still fix'd her eyes unmov'd upon the ground.

She shew'd her repentment for his former treatment of her, by not vouchsafing to look on him. Indeed, the eyes are sometimes turned downwards upon other occasions, as to express modesty. And if at any time a particular object be addressed to, whatever it be, the eyes should be turned that way. And therefore Philostratus very deservedly ridicules a certain rhetorician as guilty of a solecism in gesture, who, upon saying, *O Jupiter!* turned his eyes downward; and when he said, *O earth!* looked upward. A staring look has the appearance of giddiness and want of thought; and to contract the eyes, gives suspicion of craft and design. A fixed look may be occasioned from intensity of thought, but at the same time shews a disregard to the audience; and a too quick and wandering motion of the eyes denotes levity and wantonness. A gentle and moderate motion of the eyes is therefore in common most suitable, always directed to some of the audience, and gradually turning from side to side with an air of respect and modesty, and looking them decently in the face, as in common discourse: Such a behaviour will of course draw an attention. As in conversation, when a person addresses us in an handsome and becoming manner, we presently put ourselves in a posture to give what he says a proper reception. But as all the passions are in the most lively manner expressed in the eyes, their motions ought to vary according to the different nature of those passions they are suited both to discover in the speaker, and convey to his hearers; since, as the quickest access to the mind is by the sight, a proper well-timed look will sometimes sooner effect this than it can be done by words; as in discharging a cannon, we are struck with the light before we hear the sound.

As to the other parts of the body distinct from the head, the shoulders ought not to be elevated; for this is not only in itself indecent, but it likewise contracts the neck, and hinders the proper motion of the head. Nor, on the other hand, should they be drawn down, and depressed; because this occasions a stiffness both to the neck and the whole body. Their natural posture therefore is best, as being most easy and graceful. To shrug the shoulders has an abject and servile air; and frequently to heave them upwards and downwards is a very disagreeable sight.

A continued motion of the arms any way, is by all means to be avoided. Their action should generally be very moderate, and follow that of the hands, unless in very pathetic expressions, where it may be proper to give them a more lively spring.

The hands need never be idle. Quintilian seems to think them as necessary and powerful in action, as Cæsar does the eyes. "The hands (says he) without which all gesture is lame and weak, have a greater variety of motions than can well be expressed; for they are almost equal to our words. Do not we desire with them, promise, call, dismiss, threaten, beseech,

detest, fear, inquire, deny? Do not they express joy, sorrow, doubt, confession, penitence, measure, plenty, number, and time? Do not they excite, restrain, prove, admire, and shame? That in so great a variety of speech among all nations and countries, this seems to me the common language of all mankind." Thus far Quintilian. Now, all bodily motion is either upward or downward, to the right or left, forward or backward, or else circular. The hands are employed by the orator in all these, except the last. And as they ought to correspond with our expressions, so they ought to begin and end with them. In admiration, and addresses to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motion should generally begin from the left, and terminate gently on the right. In demonstrating, addressing, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back. But when the orator speaks of himself, his right-hand should be gently laid on his breast. When no other motion is necessary, the hands should be kept about as high as the breast, so as to make near a right angle with the arm. This is not only graceful, but likewise the most easy posture, and gives the least strain to the muscles. They should never be suffered to hang down, nor to loll upon the cushion or bar. The left hand should never move alone, but accommodate itself to the motions of the right. In motions to the left side, the right hand should not be carried beyond the left shoulder. In promises, and expressions of compliment, the motion of the hands should be gentle and slow; but in exhortations and applause more swift. The hands should generally be open; but in expressions of compunction and anger they may be closed. All finical and trifling actions of the fingers ought to be avoided; nor should they be stretched out and expanded in a stiff and rigid posture, but kept easy and pliable.

Neither the breast nor the belly should be thrust out: which in itself looks ungainly, and hinders the free motion of the trunk; which ought not to be kept too stiff and upright, but easy and flexible, always suiting itself to the motions of the head and hands. The feet should continue steady, and not give the body a wavering and giddy motion by frequently shifting; tho' some persons fall into that habit without moving their feet. Curio, a Roman orator, as Cicero tells us, was addicted to this; which occasioned a friend of his once to pass a joke upon him, by asking, *Who that was talking out of a boat?* The jest is too plain to need explication; for every one knows the waving of a boat will give the body such a motion.

The gestures we have hitherto discoursed of, are such as naturally accompany our expressions. And we believe those we have mentioned, if duly attended to, will be found sufficient to answer all the purposes of our modern pronunciation. The ancients, indeed, used several more vehement actions and gestures than we are accustomed to; as we have formerly shewn. Philip the Roman orator, as Cicero informs us, did not use to prepare his discourses; but spoke, as we say, *off-hand*. And he was wont to tell his friends, "he was never fit to talk till he had warmed his arm." He doubtless, therefore, used a more violent motion with his

pronunciation. his arms and hands than is common with us. And Cicero calls the arm projected the *orator's weapon*. Indeed, to extend or brandish the arm, carries in it an air of command and authority, which was not unbecoming the character of Philip, who was a person of the highest rank and quality. And therefore young orators, both among the Greeks and Romans, for a time used no motion of the arm, but kept it confined in their garment, as an argument of modesty, till age and experience allowed them to use greater freedom. Nor was it uncommon for the ancient orators to express the excess of their passions by tears. They thought nothing unbecoming that was natural; and judged it agreeable to the characters even of the bravest men, to be touched with a sense of humanity in great calamities: And therefore we find both Homer and Virgil make their greatest heroes shed tears on some occasions.

The other sort of gestures abovementioned are such as arise from imitation; as where the orator describes some action, or personates another speaking. But here great care is to be taken not to over-act his part, by running into any ludicrous or theatrical mimicry. It is sufficient for him so to represent things of this nature, as may best convey the image of them in a lively manner to the minds of the hearers; without any such change either of his actions or voice as are not suitable to his own character.

#### CHAP. IV. *Some particular rules for the Voice and Gesture.*

731 THE subject of pronunciation is of so great importance to an orator, that it can neither be too clearly laid down, nor too strongly inculcated. If we inquire into the causes of that surprising power it has over us, and by what means it so strongly affects us, this may in some measure appear by reflecting on the frame and constitution of human nature. For our infinitely great and wise Maker has so formed us, that not only the actions of the body are subject to the direction of the mind; but we are likewise endowed with various passions and affections, that excite us to pursue those things which make for our happiness, and avoid others which are hurtful to us. And as we are made for society, we are also furnished with speech, which enables us to converse one with another. And such is the contrivance of our make, and influence of our minds upon the mechanism of our bodies, that we can not only communicate our thoughts to each other, but likewise our passions. For, as Cicero well observes, "Every motion of the mind has naturally its peculiar countenance, voice, and gesture; and the whole body, every position of the face, and sound of the voice, like the strings of an instrument, act agreeably to the impression they receive from the mind." Nor is this all: but as every one is differently affected himself, he is capable to make the like impressions upon others, and excite them to the same motions which he feels in himself. As when two instruments are set to the same pitch, the strings of the one being touched, produce in the other the like sound. This common sympathy in the human frame shews how necessary it is that an orator should not only in general be well acquainted with the rules of pronunciation, but likewise know how to use them as occasion requires. For

a general knowledge of the rules of art is not of itself sufficient to perfect an art, without a further acquaintance with the particular application of them to their several cases and circumstances. Thus, for instance, it is not enough for an orator to understand all the beauties and ornaments of language, and which of them are suited to form the several kinds of style; unless he can likewise accommodate each of those characters to their proper subject. And so likewise in pronunciation, he ought not only to know the several qualities of the voice, and proper gestures of the body; but also when and where to make use of them. For not only different subjects, but also different parts of the same discourse, and even particular expressions, often require a difference in the manner of pronunciation, both as to the voice and gesture. Having therefore treated on both these parts of pronunciation in general, it may not be amiss now to consider, how they are to be applied in each of the two respects last mentioned.

We shall begin with the parts of a discourse, and treat of them in their natural order. And here the view and design of the speaker in each of them will easily help us to see the proper manner of pronunciation.

Let us suppose then a person presenting himself before an assembly, in order to make a discourse to them. It cannot be decent immediately to begin to speak so soon as ever he makes his appearance. He will first settle himself, compose his countenance, and take a respectful view of his audience. This prepares them for silence and attention. To begin presently, and hurry on, without first allowing either himself or his hearers time to compose themselves, looks as if he was rather performing a task, than had any design to please them; which will be very apt to make them as uneasy till he has done, as he seems to be himself. Persons commonly form some opinion of a speaker from their first view of him; which prejudices them either in his favour, or otherwise, as to what he says afterwards. A grave and sedate aspect inclines them to think him serious; that he has considered his subject, and may have something to offer worth their attention. A haughty and forbidding air occasions distaste, as it looks like disrespect. A wandering giddy countenance argues levity. A dejected drooping appearance is apt to raise contempt, unless where the subject is melancholy. And a cheerful aspect is a proper prelude to a pleasant and agreeable argument.

To speak low at first has the appearance of modesty, and is best for the voice; which, by rising gradually, will with more ease be carried to any pitch that may be afterwards necessary, without straining it. However, some variation of the voice is always proper to give it an harmony. Nay, and sometimes it is not improper for an orator to set out with a considerable degree of warmth, expressed by such an elevation of the voice, and gestures of the body, as are suited to represent the emotions of his mind. But this is not ordinarily the case. We have some few instances of this in Cicero; as in his oration for Roscius Amerinus, where the heinousness of the charge could not but excite his indignation against the accusers. And so likewise in that against Piso, and the two first against Catiline, which begin in the same manner, from the resentment

Pronunciation.

resentment he had conceived against their persons and conduct.

In the narration, the voice ought to be raised to somewhat an higher pitch. Matters of fact should be related in a very plain and distinct manner, with a proper stress and emphasis laid upon each circumstance, accompanied with a suitable address and motions of the body, to engage the attention of the hearers. For there is a certain grace in telling a story, by which those who are masters of it seldom fail to recommend themselves in conversation. The beauty of it consists in an easy and familiar manner of expression, attended with such actions and gestures as are suited to the nature of the things related, and help to enliven each particular circumstance and part of the discourse.

The proposition, or subject of the discourse, should be delivered with a very clear and audible voice. For if this be not plainly heard, all that follows in proof of it cannot well be understood. And for the same reason, if it be divided into several parts or branches, they should each be expressed very deliberately and distinctly. But as the design here is only information, there can be little room for gesture.

The confirmation admits of great variety, both of the voice and gestures. In reasoning, the voice is quick and pungent, and should be enforced with suitable actions. And as descriptions likewise have often a place here, in painting out the images of things, the orator should so endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands, as may best help the imagination of his hearers. Where he introduces another person speaking, or addresses to an absent person, it should be with some degree of imitation. And in dialogue the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction.

In confutation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, that the speaker may not seem to conceal, or avoid the force of them. Unless they appear trifling and unworthy of a serious answer; and then a facetious manner, both of expression and gesture, may be the properest way to confute them. For to attempt to answer in a grave and serious manner, what is in itself empty and ludicrous, is apt to create a suspicion of its having more in it than it really has. So when Tubero, in his accusation of Ligarius before Cæsar, had made it part of his charge, that Ligarius was in Africa during some part of the civil war between Cæsar and Pompey; Cicero in his answer, not thinking it deserved a serious reply, contents himself with barely mentioning it ironically. For thus he begins his defence of Ligarius: "Cæsar, my kinsman Tubero has laid before you a new crime, and till this day unheard of, that Q. Ligarius was in Africa." Every one must easily perceive, by the manner in which these words were pronounced, that the design of them was to make the charge appear ridiculous. But caution should be used not to represent any argument of weight in a ludicrous way, lest by so doing the speaker should more expose himself than his adversary.

Pronunciation.

In the conclusion, both the voice and gesture should be brisk and sprightly, which may seem to arise from a sense of the speaker's opinion of the goodness of his cause, and that he has offered nothing but what is agreeable to reason and truth; as likewise from his assurance that the audience agree with him in the same sentiments. In every undertaking that requires care and thought, persons are apt at first to be sedate and moderate; but when it is drawn to an end, and is near finished, it is very natural to appear more gay. If an enumeration of the principal arguments of the discourse be convenient, as it sometimes is, where they are pretty numerous, or the discourse is long; they ought to be expressed in the most clear and forcible manner. And if there be an address to the passions, both the voice and gesture must be suited to the nature of them, of which more will be said presently.

We proceed now to the consideration of particular expressions. And what we shall offer here, will be first in relation to single words, then sentences, and lastly the passions.

I. Even in those sentences, which are expressed in the most even and sedate manner, there is often one or more words which require an emphasis and distinction of the voice. Pronouns are often of this kind; as, *This is the man*. And such are many words, that denote the circumstances and qualities of things. Such as heighten or magnify the idea of the thing to which they are joined, elevate the voice; as *noble, admirable, majestic, greatly*, and the like. On the contrary, those which lessen the idea, or debase it, depress the voice, or at least protract the tone; of which sort are the words *little, mean, poorly, contemptible*, with many others. Some tropes likewise, as metaphors, and verbal figures, which consist in the repetition of a single word, should have a particular emphasis. As when Virgil says of the river Araxes, *It disdained a bridge*. And Nisus of himself in the same poem, *I, I am the man*; where the repeated word is loudest. This distinction of words, and giving them their proper emphasis, does not only render the expression more clear and intelligible; but very much contributes to the variation of the voice, and the preventing a monotony. And the different pronunciation of these words will also require a peculiar gesture.

II. In sentences, regard should be had to their length, and the number of their parts, in order to distinguish them by proper pauses. The frame and structure of the period ought likewise to be considered, that the voice may be so managed, as to give it the most musical accent. Unless there be some special reason for the contrary, it should end louder than it begins. And this difference of tone between the end of the former sentence, and the beginning of the next, not only helps to distinguish the sense, but adds to the harmony of the voice. And that the last syllables of a sentence might become more audible and distinct, was doubtless one reason why the ancient rhetoricians disliked short feet at the end of a period. In an antithesis, or a sentence consisting of opposite parts, one contrary must be louder than the other. As: "*He is gone, but by a gainful remove, from painful labour, to quiet rest; from unquiet desires to happy contentment, from sorrow, to joy; and from transitory time, to immortality.*" In a climax,

133

132

max,

Pronunciation.

Pronunciation.

max, or gradation, the voice should rise with it. So: "There is no enjoyment of property without government; no government without a magistrate; no magistrate without obedience; no obedience where every one acts as he pleases." And so in other gradations of a different form. As: "Since concord was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost." And again: "You would pardon him whom the senate hath condemned, whom the people of Rome have condemned, whom all mankind have condemned." We might mention several other figurative expressions, which require a particular conformation and management of the voice; but these, we presume, with some others we shall have occasion to name presently when we come to the passions, may be sufficient to guide us in the rest. But that it may appear more evidently how necessary a different inflection and variation of the voice is in most sentences, give us leave to shew how Quintilian illustrates it, by a passage which he takes from Cicero. The place is the beginning of Cicero's defence for Milo, and the words are these: "*Altho' I am apprehensive, it may seem base to discover fear when I enter upon the defence of a most courageous man; and it may appear very indecent, when Milo discovers more concern for the public safety, than for his own, not to shew a greatness of mind equal to his cause: yet this new form of the court terrifies my eyes, which cannot discern the ancient manner of the forum, and former custom of trials, whatever way they look: your bench is not surrounded with its usual attendants.*" This sentence consists of four members. And Quintilian supposes, that though these words are the beginning of a speech, and were accordingly expressed in a calm and submissive manner; yet that the orator used a great deal of variety in the pronunciation of their several parts. In the first member (as he imagines) his voice was more elevated in expressing the words, *a most courageous man*, than in those other parts of it, *I am apprehensive it may seem base, and, to discover fear*. In the second member he rose higher in saying, *when Milo discovers more concern for the public safety than for his own*; and then again as it were checked himself in what follows, *not to shew a greatness of mind equal to his cause*. The beginning of the third member, carrying a reflection in it, was spoke with a different tone of the voice, *this new form of the court terrifies my eyes*; and the other part of it more loud and distinctly, *which cannot discern the ancient manner of the forum, and former custom of trials*. And the last member was still more raised and audible, *your bench is not surrounded with its usual attendants*. And it must be supposed, that while he was saying this, he cast his eyes round the assembly, and viewed the soldiers whom Pompey had placed there; which renders the expression still more grave and solemn. If this was the manner of the ancient orators, and they were so exact and accurate in expressing their periods, and the several parts of them, as we have reason to believe they were; it must have given a very great force, as well as beauty, to their pronunciation.

III. That the passions have each of them both a different voice and action, is evident from hence; that we know in what manner a person is affected, by the tone of his voice, though we do not understand the sense of what he says, or many times so much as we

him; and we can often make the same judgment from his countenance and gestures. Love and esteem are expressed in a smooth and cheerful tone: but anger and resentment with a rough, harsh, and interrupted voice; for when the spirits are disturbed and ruffled, the organs are moved unequally. Joy raises and dilates the voice; as sorrow sinks and contracts it. Cicero takes notice of a passage in an oration of Gracchus, wherein he bewails the death of his brother, who was killed by Scipio; which in his time was thought very moving: "*Unhappy man (says he), whether shall I betake myself? where shall I go? Into the capitol: that flows with my brother's blood. Shall I go home? and behold my unhappy mother all in tears and despair?*" Though Gracchus had a very ill design in that speech, and his view was to excite the populace against their governors; yet (as Cicero tells us) when he came to this passage, he expressed himself in such moving accents and gestures, that he extorted tears even from his enemies. Fear occasions a tremor and hesitation of the voice; and assurance gives it strength and firmness. Admiration elevates the voice, and should be expressed with pomp and magnificence: *O surprising clemency, worthy of the highest praise and greatest encomiums, and fit to be perpetuated in lasting monuments!* This is Cicero's compliment to Cæsar, when he thought it for his purpose. And oftentimes this passion is accompanied with an elevation both of the eyes and hands. On the contrary, contempt sinks and protracts the voice. In the dispute between Cicero and Cælius, which of them should accuse Verres, Cicero puts this contemptuous question to him: "How are you qualified, Cælius, for such an undertaking? I will not ask, when you ever gave a proof of it; but when you so much as attempted it? Do you consider the difficulty of managing a public cause?" With much more to the same purpose. Tho' such kind of expressions require little gesture; yet sometimes a motion of the hand may not be improper, to signify disdain or averfion. We may suppose Cicero to have acted thus in his defence of Rabirius. For to shew his assurance of his client's cause, having used this expression in a very audible manner, "I wish I had it to say, that Rabirius had with his own hand killed Saturninus, who was an enemy to the Roman state:" some persons in the crowd began to raise a clamour, just as of later times hissing has been practised on the like occasions. Upon which Cicero immediately replies, "This noise does not disturb me, but please me; since it shows, though there are some weak persons, yet they are but few." Then presently after follows the expression we refer to: "Why do not you cease your clamour, since it only discovers your folly, and the smallness of your number?" All exclamations should be violent. When we address to inanimate things, the voice should be higher than when to animated beings; and appeals to heaven must be made in a loftier tone than those to men.

These few hints for expressing the principal passions, may, if duly attended to, suffice to direct our practice in others. Though after all, it is impossible to gain a just and decent pronunciation of voice and gesture merely from rules, without practice and an imitation of the best examples. Which shews the wis-

dom.

Pronunciation.

dom of the ancients, in training up their youth to it, by the assistance of masters, to form both their speech and actions.

But there is one thing, which ought always to be attended to; namely, that persons should well consider their own make and genius, especially with respect to the passions. We seldom find, that any actor can excel in all characters; but if he performs one well, he is deficient in another: And therefore they are commonly so prudent as to confine themselves to such as

best suit them. The case is the same in an orator; who should therefore keep within those bounds which nature seems to have prescribed for him. Some are better fitted for action than others, and most for some particular actions rather than others; and what fits well upon one would appear very awkward in another. Every one therefore should first endeavour to know himself, and manage accordingly. Though in most cases, nature may be much assisted and improved by art and exercise.

[From Professor Ward's *System of Oratory*.]

## O R C

Oratory  
Orchard.

ORATORY, among the Romanists, a closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotions.

ORB, in astronomy, denotes an hollow globe or sphere.

ORB, in tactics, is the disposing of a number of soldiers in circular form of defence. The orb has been thought of consequence enough to employ the attention of the famous marshal de Puysegur in his art of war, who prefers this position to throw a body of infantry in an open country, to resist cavalry, or even a superior force of infantry; because it is regular, and equally strong, and gives an enemy no reason to expect better success by attacking one place than another. Cæsar drew his whole army in this form, when he fought against Labienus. The whole army of the Gauls were formed into an orb, under the command of Sabinus and Cotta, when fighting against the Romans. The orb was generally formed fix deep.

ORBIT, in astronomy, the path of a planet or comet, or the curve that it describes in its revolution round its central body: thus, the earth's orbit is the curve which it describes in its annual course round the sun, and usually called the *ecliptic*. See ASTRONOMY, *passim*.

ORCADES, the Orkney Islands. See ORKNEY.

ORCHARD, a garden-department, consigned entirely to the growth of standard fruit-trees, for furnishing a large supply of the most useful kinds of fruit.

In the orchard you may have, as standards, all sorts of apple-trees, most sorts of pears and plums, and all sorts of cherries: which four species are the capital orchard fruits; each of them comprising numerous valuable varieties. But to have a complete orchard, you may also have quinces, medlars, mulberries, service-trees, filberts, Spanish nuts, berberries; likewise walnuts and chestnuts; which two latter are particularly applicable for the boundaries of orchards, to screen the other trees from the insults of impetuous winds and cold blasts. All the trees ought to be arranged in rows from 20 to 30 feet distance, as hereafter directed.

But sometimes orchards consist intirely of apple-trees, particularly in the cyder-making counties, where they are cultivated in very great quantities in large fields, and in hedge-rows, for the fruit to make cyder for public supply.

And sometimes whole orchards of very considerable extent are entirely of cherry-trees. But in this case, it is when the fruit is designed for sale in some great

## O R C

city, as London, &c. for the supply of which city, Orchard, great numbers of large cherry-orchards are in some of the adjacent counties, but more particularly in Kent, which is famous for very extensive cherry-orchards; many of which are entirely of that sort called *Kentish cherry*, as being generally a great bearer; others are stored with all the principal sorts of cultivated cherries, from the earliest to the latest kinds. See PRUNUS *Cerasus*.

A general orchard, however, composed of all the before-mentioned fruit-trees, should consist of a double portion of apple-trees or more, because they are considerably the most useful fruit, and may be continued for use the year round.

The utility of a general orchard, both for private use and profit, stored with the various sorts of fruit-trees, must be very great, as well as afford infinite pleasure from the delightful appearance it makes from early spring till late in autumn: In spring the various trees in blossom are highly ornamental; in summer, the pleasure is heightened by observing the various fruits advancing to perfection; and as the season advances, the mature growth of the different species arriving to perfection, in regular succession, from May or June, until the end of October, must afford exceeding delight, as well as great profit.

[Of the proper Extent, Situation, and Soil, for this Department.] As to the proper extent of ground for an orchard, this must be proportioned, in some measure, to the extent of land you have to work on, and the quantity of fruit required either for private use or for public supply: so that an orchard may be from half an acre to 20 or more in extent.

With respect to the situation and aspect for an orchard, we may observe very thriving orchards both in low and high situations, and on declivities and plains, in various aspects or exposures, provided the natural soil is good: we should, however, avoid very low damp situations as much as the nature of the place will admit; for in very wet soils no fruit trees will prosper, nor the fruit be fine: but a moderately low situation, free from copious wet, may be more eligible than an elevated ground, as being less exposed to tempestuous winds; though a situation having a small declivity is very desirable, especially if its aspect incline towards the east, south-east, or southerly, which are rather more eligible than a westerly aspect; but a north aspect is the worst of all for an orchard, unless particularly compensated by the peculiar temperament or good quality of the soil.

And as for soil, any common field or pasture that pro-

**Orchard.** produces good crops of corn, grafs, or kitchen-garden vegetables, is fuitable for an orchard, if it fhould prove of a loamy nature, it will be a particular advantage: any foil, however, of a good quality, not too light and dry, or too heavy, ftubborn, or wet, but of a medium nature, of a foft, pliant temperature, not lefs than one fpace deep of good ftaple, will be proper for this purpofe.

*Preparation of the Ground.* [The preparation of the ground for the reception of trees, is by trenching; or, if for very confiderable orchards, by deep ploughing; but trench-digging, one or two fpatdes, as the foil will admit, is the moft eligible, either wholly, or only for the prefent in the places where the lines of trees are to ftand, a fpace of fix or eight feet wide, all the way in each row, efpecially if it be grafs-ground, and intended to be kept in the fward; or if any under-crops are defigned to be raifed, the ground may be wholly trenched at firft: in either cafe trench the ground in the ufual way to the depth of the natural foil; and if in grafs, turn the fward clean to the bottom of each trench, which, when rotted, will prove an excellent manure.]

In planting orchards, however, on grafs-grounds, fome only dig pits for each tree, capacious enough for the reception of the roots, loofening the bottom well, without the labour of digging any other part of the ground.

The ground muft be fenced fecurely againft cattle, &c. either with a good ditch and hedge, or with a paling-fence, as may be moft convenient. See HEDGE.

*Method of planting the Trees.* [The beft feafon for planting all the forts of fruit-trees is autumn, foon after the fall of the leaf, from about the latter end of October until December; or indeed it might be performed any time in open weather from October until March.]

Chooſe principally full ftandards, with ftaight clean ftems, fix feet high; each with a branchy well-formed head, of from two or three to four or five years growth; and let ſeveral varieties of each particular ſpecies be choſen, that ripen their fruit at different times, from the earlieſt to the lateſt, according to the nature of the different forts, that there may be a proper ſupply of every fort regularly during their proper ſeaſon. Of apples and pears in particular, chooſe a much greater quantity of the autumnal and late-ripening kinds than of the early forts; but moſt of all of apples: for the ſummer-ripening fruit is moſt of ſhort duration, only proper for temporary ſervice; but the later-ripening kinds keep found ſome confiderable time for autumnal uſe; and the lateſt forts that ripen in October, continue in perfection for various uſes all winter, and ſeveral forts until the ſeaſon of apples come again.

Having made choice of the proper forts, and marked them, let them be taken up with the utmoſt care, ſo as to preferve all their roots as entire as poſſible; and when taken up, prune off any broken or bruifed parts of the roots, and juſt tip the ends of the principal roots, in general, with the knife, on the under ſide, with a kind of ſlope outward.

If the trees have been already headed, or ſo trained as to have branched out into regular ſhoots to form each a proper head, they muſt be planted with the ſaid heads entire, only retrenching or ſhortening any

irregular or ill-placed ſhoot that takes an awkward direction, or grows acroſs its neighbours, or ſuch as may run confiderably longer than all the reſt, &c.

The arrangement of the trees in the orchard muſt be in rows, each kind ſeparate, at diſtances according to the nature of growth of the different forts; but for the larger growing kinds, ſuch as apples, pears, plums, cherries, &c. they ſhould ſtand from 25 to 30 or 40 feet every way aſunder, though 25 or 30 feet at moſt is a reaſonable diſtance for all theſe kinds.

Each ſpecies and its varieties ſhould generally be in rows by themſelves, the better to ſuit their reſpective modes of growth: tho' for variety, there may be ſome rows of apples and pears arranged alternately, as alſo of plums and cherries; and towards the boundaries there may be ranges of leſſer growth, as quinces, medlars, filberts, &c. and the outer row of all may be walnut-trees, and ſome cheſnuts, ſet pretty cloſe to defend the other trees from violent winds.

According to the above diſtances, proceed to flake out the ground for making the holes for the reception of the trees; which if made to range every way, will have a very agreeable effect, and admit the currency of air, and the ſun's influence more effectually.

But in planting very extenſive orchards, ſome divide the ground into large ſquares or quarters, of different dimenſions, with intervals of fifty feet wide between; ſerving both as walks, and for admitting a greater currency of air; in different quarters planting different forts of fruit, as apples in one, pears in another, and plums and cherries in others, &c. and thus it may be repeated to as many quarters for each ſpecies and its varieties as may be convenient.

As to the mode of planting the trees: A wide hole muſt be dug for each tree, capacious enough to receive all the roots freely every way without touching the ſides. When the holes are all ready, proceed to planting, one tree in each hole, a perſon holding the ſtem erect, whiſt another trims in the earth, previously breaking it ſmall, and caſting it in equally all about the roots, frequently ſhaking the tree to cauſe the mould to ſettle in cloſe about all the ſmaller roots and fibres, and ſo as to raiſe the tree gradually up, that the crown of the roots may be but two or three inches below the general ſurface; and when the hole is filled up, tread it gently, firſt round the outſide, then near the ſtem of the tree, forming the ſurface a little hollow; and then if on the top of all is laid ſome inverted turf to the width of the holes, forming it with a fort of circular bank, three or four inches high, it will ſupport the tree, and guard the roots from drying winds and the ſummer's drought: obſerving that each tree ſtand perfectly upright, and that they range exactly in their proper rows.

**ORCHESTRA**, in the ancient theatres, a place in the form of a ſemicircle, where the dancing was performed. In the Greek theatres, the orcheltra made part of the ſtage; but, among the Romans, it answered nearly to our pit; only that in it were diſpoſed the ſeats for the ſenators, magiſtrates, veſtals, and other perſons of diſtinction.

**ORCHIS**, **FOOL-STONES**; a genus of the diandria order, belonging to the gynandria claſs of plants. There are a great many ſpecies; but the moſt remarkable are the following.

**Orchard**  
||  
**Orchis.**

Orchis,  
Ordeal.

1. The mascula, or male fool-stones, hath a root composed of two bulbs, crowned with oblong, broad, spotted leaves; upright stalks, a foot high; garnished with one or two narrow amplexicaule leaves; and terminated by a long spike of reddish-purple flowers, having the petals reflexed backward; a quadrilobed crenated lip to the nectarium, and an obtuse horn. The flowers of this species possess a very agreeable odour.

2. The morio, or female orchis, hath a double bulbous root, crowned with oblong, ribbed, spreading leaves; erect flower-stalks, eight or ten inches high; garnished with a few amplexicaule leaves; and terminated by a short loose spike of flowers, having connivent petals, a quadrifid crenated lip to the nectarium, and an obtuse horn.

3. The militaris, or man-orchis, hath a double bulbous root, crowned with oblong amplexicaule leaves; erect flower-stalks, eight or ten inches high; terminated by a loose spike of ash-coloured and reddish flowers, having confluent petals; a quinquefid, rough, spotted lip to the nectarium, and an obtuse horn. The structure of the flowers exhibit the figure of a naked man; and are often of different colours in the same flower, as ash-colour, red, brown, and dark-striped.

*Culture and Properties.* All the orchises are very hardy perennials, with bulbous fleshy roots. The flowers appear in May, June, and July, but principally in June: their mode of flowering is universally in spikes, many flowers in each spike; and each flower is composed of five petals in two series, and a nectarium. The season for removing them is in summer, after they have done flowering, when their leaves and stalks decay: plant them three inches deep, and let them remain undisturbed several years; for the less they are removed, the stronger they will flower.

The roots of all the species have a remarkable resemblance to the scrotum of animals, whence the name. This plant flourishes in various parts of Europe and Asia, and grows in our country spontaneously, and in great abundance. It is assiduously cultivated in the East; and the root of it forms a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. From it is made the alimentary powder called *salep*; which, prepared from foreign roots, is sold at five or six shillings per pound, though it might be furnished by ourselves at the sixth part of that price, if we chose to pay any attention to the culture of this plant. The orchis mascula is the most valued for this purpose. A dry and not very fertile soil is best adapted to its growth.

The properest time for gathering the roots, is when the seed is formed, and the stalk is ready to fall; because the new bulb, of which the salep is made, is then arrived to its full maturity, and may be distinguished from the old one, by a white bud rising from the top of it, which is the germ of the orchis of the succeeding year.

The culture of the orchis is an object highly deserving of encouragement from all the lovers of agriculture. And as the root, if introduced into common use, would furnish a cheap, wholesome, and most nutritious article of diet, the growth of it would be sufficiently profitable to the farmer. See *SALEP*.

**ORDEAL**, an ancient form of trial. See *TRIAL*. It was peculiarly distinguished by the appellation of

*judicium Dei*; and sometimes *vulgaris purgatio*, to distinguish it from the canonical purgation, which was by the oath of the party. This was of two sorts, either fire-ordeal, or water-ordeal; the former being confined to persons of higher rank, the latter to the common people. Both these might be performed by deputy: but the principal was to answer for the success of the trial; the deputy only venturing some corporal pain, for hire, or perhaps for friendship.

*Fire-ordeal* was performed either by taking up in the hand, unhurt, a piece of red-hot iron, of one, two, or three pounds weight; or else by walking, barefoot, and blindfold, over nine red-hot ploughshares, laid lengthwise at unequal distances: and if the party escaped being hurt, he was adjudged innocent; but if it happened otherwise, as without collusion it usually did, he was then condemned as guilty. However, by this latter method queen Emma, the mother of Edward the Confessor, is mentioned to have cleared her character, when suspected of familiarity with Alwyn bishop of Winchester.

*Water-ordeal* was performed, either by plunging the bare arm up to the elbow in boiling-water, and escaping unhurt thereby: or by casting the person suspected into a river or pond of cold water; and, if he floated therein without any action of swimming, it was deemed an evidence of his guilt; but, if he sunk, he was acquitted. It is easy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity still practised in many countries to discover witches, by casting them into a pool of water, and drowning them to prove their innocence. And in the Eastern empire the fire-ordeal was used to the same purpose by the emperor Theodore Lascaris; who, attributing his sickness to magic, caused all those whom he suspected to handle the hot iron: thus joining (as has been well remarked) to the most dubious crime in the world, the most dubious proof of innocence.

And indeed this purgation by ordeal seems to have been very ancient, and very universal in the times of superstitious barbarity. It was known to the ancient Greeks: for in the Antigone of Sophocles, a person, suspected by Creon of a misdemeanor, declares himself ready "to handle hot iron, and to walk over fire," in order to manifest his innocence; which, the scholiast tells us, was then a very usual purgation. And Grotius gives us many instances of water-ordeal in Bithynia, Sardinia, and other places. There is also a very peculiar species of water-ordeal, said to prevail among the Indians on the coast of Malabar; where a person accused of any enormous crime is obliged to swim over a large river abounding with crocodiles, and, if he escapes unhurt, he is reputed innocent. As in Siam, besides the usual methods of fire and water ordeal, both parties are sometimes exposed to the fury of a tiger let loose for that purpose: and, if the beast spares either, that person is accounted innocent; if neither, both are held to be guilty; but if he spares both, the trial is incomplete, and they proceed to a more certain criterion.

One cannot but be astonished at the folly and impiety of pronouncing a man guilty, unless he was cleared by a miracle; and of expecting that all the powers of nature should be suspended, by an immediate interposition of Providence to save the innocent, whenever

Ordeal.

Order  
Ordinary.

whenever it was presumptuously required. And yet in England, so late as king John's time, we find grants to the bishops and clergy to use the *judicium ferri, aquæ, et ignis*. And, both in England and Sweden, the clergy presided at this trial, and it was only performed in the churches or in other consecrated ground: for which Stiernhook gives the reason, *Non desuit illis opera et laboris pretium; semper enim ab ejusmodi judicio aliquid lucri sacerdotibus eveniebat*. But, to give it its due praise, we find the canon law very early declining against trial by ordeal, or *vulgaris purgatio*, as being the fabric of the devil, *cum sit contra preceptum Domini, Non tentabis Dominum Deum tuum*. Upon this authority, though the canons themselves were of no validity in England, it was thought proper (as had been done in Denmark above a century before) to diffuse and abolish this trial entirely in our courts of justice, by an act of parliament in 3 Hen. III. according to Sir Edward Coke, or rather by an order of the king in council.

ORDER, in architecture, is a system of the several members, ornaments, and proportions of columns and pilasters; or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole. See ARCHITECTURE, n° 41, &c.

ORDER is also used for a division, or class of any thing; thus the tribe of animals called *birds*, is subdivided into six orders. See ORNITHOLOGY, ZOOLOGY, &c.

Holy ORDERS, a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See ORDINATION.

Military ORDERS, are companies of knights, instituted by kings and princes, either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

Religious ORDERS, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.

ORDERS, in a military sense, all that is lawfully commanded by superior officers. Orders are given out every day, whether in camp, garrison, or on a march, by the commanding officer; which orders are afterwards given to every officer in writing by their respective sergeants.

ORDINAL, a book containing the order or manner of performing divine service.

ORDINAL Numbers, those which express order; as first, 2d, 3d, &c.

ORDINANCE, or ORDONNANCE, a law, statute, or command of a sovereign or superior: thus the acts of parliament are sometimes termed ordinances of parliament.

ORDINARY, in general, signifies common, usual; thus, an ambassador or envoy in ordinary, is one sent to reside steadily, and for a number of years, in the court of some foreign prince or state, in order to keep up a good understanding, and watch over the interest of his own nation.—This term is also applied to several officers in the king's household, who attend on common occasions. Thus we say, physician in ordinary, &c.

ORDINARY, or Honourable ORDINARY, in heraldry, a denomination given to certain charges properly be-

longing to that art. See HERALDRY, p. 3588.

ORDINATES, in geometry and conics, are lines drawn from any point of the circumference of an ellipse or other conic section, perpendicularly across the axis, to the other side. See CONIC SECTIONS.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

Ordination has always been esteemed the principal prerogative of bishops, and they still retain the function as a mark of spiritual sovereignty in their diocese. Without ordination, no person can receive any benefice, parsonage, vicarage, &c. A clerk must be 23 years of age before he can have any share in the ministry; and 24 before he can be ordained, and by that means be permitted to administer the sacrament. A bishop, on the ordination of clergymen, is to examine them in the presence of the ministers who assist him at the imposition of hands; and in case any crime, as drunkenness, perjury, forgery, &c. be alleged against any one that is to be ordained, either priest or deacon, the bishop ought to desist from ordaining him. The person to be ordained is to bring a testimonial of his life and doctrine to the bishop, and give account of his faith in Latin, and both priests and deacons are obliged to subscribe the 39 articles.

The ordination-days in the church of England, are the four Sundays immediately following the Ember-weeks, viz. the first Sunday in Lent, Trinity-Sunday, and the Sundays following the first Wednesday after September 14. and December 13.

In Scotland, where there are no bishops, the power of ordination is lodged in the presbytery. See PRESBYTERY.

ORDNANCE, a general name for all sorts of great guns used in war. See GUNNERY.

Boring of ORDNANCE. Till within these 10 years, iron ordnance were cast with a cylindrical cavity, nearly of the dimensions of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel-cutters fixed into the dog-head of a boring-bar iron. Three side-cutters equidistant were requisite to preserve the caliber straight and cylindrical; and a single cutter was used at the end of the bar to smooth the breech of the piece. In boring ordnance cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring bar, of a sufficient length to reach up to the breech of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water-wheel being set agoing, the bar and fullers are turned round, and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of casting guns hollow, and widening the calibers by these boring bars. For the body of iron of the hollow gun, being, at casting, in contact with the core that made the caliber within-side, and with the mould without-side, began to consolidate towards these sides in the first place, sooner than in the intermediate space, where of course the contraction of

Ordinates  
Ordinance.

Ordnance,  
Ordon-  
nance.

the iron takes place; by which means, all guns cast hollow became more or less spongy where they ought to have been most compact; and numberless cavities also were created round the cores, from stagnant air generated in them, which were too deep to be cut out by the boring.

To remedy these defects, iron ordnance is now universally cast solid, by which means the column of iron is greatly enlarged, and the grain more compressed; and the contraction of the iron becomes in the heart of the column, and consequently is cut out by the perforation for the caliber.

Plate  
CXXXII.

Guns are bored out of the solid reversely from the hollow method. The piece A is placed upon two standards BB, by means of two journeys, turned round by the water-wheel C, the breech D being introduced into the centre of the wheel, with the muzzle towards the sliding carriage E, which is pressed forwards by a rack F, and weights in the same way as the gun-carriage was in hollow boring. Upon this sliding carriage is fixed, truly horizontal and central to the gun, the drill-bar G, to the end of which is fixed a carp's-tongue drill or cutter H; which, being pressed forward upon the piece whilst it is turning round, perforates the bore, which is afterwards finished with bars and cutters as the hollow guns were. The principal difficulty of perforated solid guns truly central, arises from the contraction of the iron above-mentioned; which, resisting the drill unequally, tends to throw it out of the central line.

*Office of ORDNANCE*, an office kept within the tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land, in all the magazines, garrisons, and forts, in Great Britain.

The officers of the ordnance are, 1. The master-general, from whom are derived all orders and dispatches relating to the same. 2. The lieutenant-general, who receives orders from the master-general, and sees them duly executed; orders the firing of guns on days of rejoicing, and sees the train of artillery fitted out when ordered to the field. 3. The surveyor-general, who has the inspection of the ordnance, stores, and provisions of war in the custody of the store-keepers: he allows all bills of debt, keeps a check on labourers, &c. 4. The treasurer, through whose hands passes the money of the whole office, as well for payment of salaries as debentures; as also a clerk of the ordnance, and a clerk of deliveries.

*ORDONNANCE*, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole, and to one another; or, as Mr Evelyn expresses it, determining the measure of what is assigned to the several apartments. Thus ordonnance is the judicious contrivance of the plan or mould; as when the court, hall, lodgings, &c. are neither too large nor too small, but the court affords convenient light to the apartments about it: the hall is of fit capacity to receive company; and the bed-chamber, &c. of a proper size. When these divisions are either too great or too small, with respect to the whole, as where there is a large court to a little house, or a small hall to a magnificent palace, and the fault is in the ordonnance. See ARCHITECTURE.

*ORDONNANCE*, in painting, is used for the dispo-

sition of the parts of a picture, either with regard to the whole piece, or to the several parts, as the groups, masses, contrasts, &c. See PAINTING, n° 14.

*ORE*, in natural history, the compound mineral glebe, earth, stone, or other substance, which is sufficiently rich in metallic particles to be worth the while of purification, and by this means of separating the metal from it, whether gold, silver, copper, &c. See METALLURGY, Part i. sect. 2.

*ORENSE*, an ancient town of Spain, in the kingdom of Galicia, with a bishop's see. It is famous for its hot-baths; and is seated at the foot of a mountain, on the river Minho, over which there is a handsome bridge of one arch. W. Long. 7. 27. N. Lat. 42. 16.

*ORESTES*, in ancient history, king of Mycenæ, was the son of Agamemnon and Clytemnestra. At the instigation of his sister Electra, he revenged the death of his father, and did not even spare his own mother. He also killed Pyrrhus the son of Achilles, for taking away Hermione, who had been promised to him in marriage. It is said, that, after he had killed his mother, he went distracted; and that, to expiate his crime, he was obliged to go to the temple of Diana in the Chersonesus Taurica. His friend Pylades accompanied him thither: when king Thoas resolving to sacrifice him to Diana, to whom human victims were offered, Pylades resolving to be sacrificed to save his friend, assured that prince that he was Orestes; while Orestes, on the contrary, to prevent the death of Pylades, maintained that he alone was the true Orestes. During this generous contest, which rendered the friendship of Orestes and Pylades the admiration of the world, Iphigenia, who presided at Diana's sacrifices, knew again her brother Orestes, and delivered him from the danger to which he was exposed. Some days afterwards, Orestes, accompanied by Pylades, slew king Thoas, seized his treasures, and took his sister Iphigenia with him into Arcadia, 1144 B. C.

*ORFA*, a considerable town of Diarbeck in Asia, very pleasantly situated, pretty large, and well fortified. It formerly belonged to Persia; but is now in the Turkish dominions, and is a place of very good trade. It has a stately castle standing on a hill, which makes a great shew at a distance. They pretend to shew the well where Rachel watered her father's camels when Jacob met her, and they call it *Abraham's well*. E. Long. 37. 45. N. Lat. 36. 20.

*ORFORD*, a town of Suffolk in England, seated on the sea-coast between two channels. It was formerly a good fishing-town, but has now lost its trade; however, it has the title of an *earldom*, and sends two members to parliament. Here is a handsome church, whose steeple is a good sea-mark; and near it are the ruins of an old castle, and an holy house, where the seamen's wives used to pray for the safety of their husbands. E. Long. 1. 33. N. Lat. 52. 15.

*ORGAGNA* (Andrea), an excellent Italian painter, was born at Florence in 1329. In his youth he learned sculpture; he was also a poet and an architect. He had a fruitful genius, and his manner resembled that of the other painters of his time. Most of his works are at Pisa. The most admired of them is his picture of the Last Judgment, in which he painted his friends

Ore  
Orgagna

Organ,  
Organ.

friends among the blessed, and his foes in hell. He died in 1389.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation; in which sense the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called *organs*.

ORGAN, in music, the largest and most harmonious wind-instrument.

The invention of the organ is very ancient; though it is agreed that it was little used till the eighth century. It seems to have been borrowed from the Greeks. Vitruvius describes an hydraulic one in his tenth book of Architecture. The emperor Julian has an epigram in its praise. St Jerom mentions one with twelve pair of bellows, which might be heard a thousand paces, or a mile; and another at Jerusalem, which might be heard at the mount of Olives.

The church-organ consists of two parts; the main body, called the *great organ*; and the positive or *little organ*, which forms a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32 feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high, and 28 broad: its largest pipe is 13 inches diameter, and it has 16 pair of bellows.

The several parts of the church-organ are as follow. **IIII** is the sound-board: which is composed of two parts, the upper board or cover **HHH**, and the under board **HI**, which is much thicker than the other; each of these consists of several planks laid with their edges to each other, and joined very close together. In the under-side of the lower board there are made several channels, which run in the direction **LL**, **MM**, &c. and are continued as far as there are stops in the organ, and come almost to the edge **HK**. These channels are covered over very close with parchment or leather all the way, except a hole that is commonly at the fore-end next **HK**, upon which a valve or puff is placed. These channels are called *partitions*. When this valve or flap is shut it keeps out the air, and admits it when open. On the upper side of the lower board there are likewise cut several broad square channels, lying cross the former, but not so deep as to reach them; these lie in the direction **LN**, **PQ**, &c. To fit these channels, there are the same number of wooden sliders or registers **ff**, **ff**, &c. running the whole length; and these may be drawn out or thrust in at pleasure. The number of these is the same as that of the stops in the organ.

**IKKK** is the wind-chest, which is a square box fitted close to the under side of the lower board, and made air-tight, so that no air can get out but what goes through the valves along the partitions.

**VV** are the valves or puffs which open into the wind-chest; they are all inclosed in it, and may be placed in any part of it, as occasion shall require. One of these valves, with the spring that shuts it, and the wire that opens it, is represented by fig. 2.

**C**, **D**, **E**, **F**, &c. are the keys on which the fingers are placed when the organ is played: these keys lie over the horizontal bar of wood **W**, in which are stuck

an equal number of wire-pins **z**, **z**, on which keys are fixed; and the keys move up and down on the bar, as on a centre. There is another bar, against which the keys fall when put down, and which is here marked 3: on this also are several wires, which go through the keys, to guide them; and on this bar a lift is fastened to hinder the keys from knocking against the wood.

The keys are made to communicate with the valves several ways, as we shall now describe. First, **s**, **s**, **s**, are the key-rollers, moving on the pivots **t**, **t**: these rollers lie horizontally, one above another, and are of such a length as to reach from the valve to the key: **a**, **a**, **a**, are arms or levers fixed to the key-rollers: **w**, **w**, the valve-wires fixed to the arms **a**, **a**, and to valves **V**, and go through the holes **b**, **b**, in the bottom of the wind-chest: **b**, **b**, **b**, are likewise arms fixed to the key-rollers: **d**, **d**, **d**, the key-wires, fixed to the arms **b**, **b**, and to the keys **C**, **D**, **E**. Now, when the end of any one of the keys **C**, **D**, **E**, is put down, it pulls down the arm **b**, by the wire **d**, which turns about the roller **s** with the arm **a**, that pulls down the wire **w**, which opens the valve that is shut by the spring as soon as the pressure is taken off the key. In this construction there must be a worm-spring fastened to the key, and to the bar **W** on the further side, to keep down the end **s** of the key.

Another method of opening the valves is thus: **x**, **y**, **x**, **y**, are slender levers, moveable on the centres **1**, **1**: **s**, **x**, **s**, **x**, are wires going from the further ends of the keys to the ends **x** of the levers; **y**, **V**, **y**, **V**, are other wires, reaching from the ends **y** of the levers, through the holes **h**, to the valves **V**. So that putting down the key **C**, **D**, &c. raises the end **s**, which thrusts up the end **x** of the lever, by the wire **s**; this depresses the end **y** of the lever, which pulls down the wire **y**, **V**, and opens the valve **V**.

A third way of opening the valves is this: At the end of the key **h**, is a lever **8**, **9**, moving in the centre **7**. This makes, with the key, a compound lever. From the end **9**, a wire goes to the valve: Now the putting down the end **6** of the key, raises the end **8**, which depresses the end **9**, of the lever **8**, **9**, pulls down the wire, and opens the valve. There is only one of these drawn in the scheme, and but a few of the others, to avoid confusion.

**R**, **R**, are the rollers, to move the sliders, by help of the arms **cf**, **cf**, which are fixed horizontally in these rollers: **ke**, **ke**, are also levers fixed in the rollers; **le**, **le**, are the handles, which lie horizontally, and pass through the holes **l**, **l**; they are fastened to the lever **ke**, being moveable about a joint at **e**.

Now, any handle **lp**, being drawn out, pulls the end **e** toward **h**, which turns about **Rk**, along with the arm **cf**; and the end **f** pulls out the slider **fg**; and when **p** is thrust in, the arm **cf** likewise thrusts in the slider **fg**.

Upon the several rows of holes which appear on the top of the upper board, there are set up an equal number of rows of pipes. The pipes of an organ are of two kinds; the one has a mouth like a flute, the other with reeds. The first, called *pipes of mutation*, consist, (1.) of a foot **AABB** (fig. 3.) which is a hollow cone, that receives the wind that is to sound the pipe: (2.) To this foot is fastened the body of the

the

Organ.

Organ.

the pipe BBDD. Between the foot and the body of the pipe is a diaphragm or partition FEF, that has a long but narrow aperture by which the wind comes out; over this aperture is the mouth BBC, whose upper lip C, being level, cuts the wind as it comes out.

The pipes are of pewter, of lead mixed with a twelfth part of tin, and of wood. Those of pewter are always open at their extremities: their diameter is very small, and their found very clear and shrill. Those of lead mixed with tin are larger; and the shortest are open, the longest quite stopped; those of a mean size are partly stopped, and have beside a little ear on each side the mouth, to be drawn closer or set further asunder, in order to raise or lower the found. The wooden pipes are square, and their extremity is stopped with a valve or tampon of leather. The found of the wooden and leaden pipes is very soft; the large ones stopped are commonly of wood, the small ones of lead. The longest pipes give the gravest found, and the shortest the most acute: their lengths and widths are determined by a fixed proportion to their founds; and their divisions are regulated by a rule, which is called the *diapason*. The longest has commonly 16 feet; but in very large organs it has 32 feet. The pedal tubes are always upon, though made of wood and of lead. Whatever note any open pipe sounds, when its mouth is stopped it will found an octave lower; and a pipe of twice its capacity will likewise found an octave lower.

A reed-pipe consists of a foot AABB, (fig. 4.) that carries the wind into the shallot or reed CD, which is a hollow demi-cylinder, fitted at its extremity D, into a fort of mould, by a wooden tampon G. The shallot is covered with a plate of copper KKLL, fitted at its extremity II, into the mould, by the same wooden tampon. Its other extremity KK, is at liberty: so that the air entering the shallot makes it tremble or shake against the reed; and the longer that part of the tongue LL, which is at liberty, is made, the deeper is the found. The mould II, that serves to fix the shallot or reed, the tongue, tampon, &c. serves also to stop the foot of the pipe, and make the wind go out wholly at the reed. Lastly, in the mould is folded the tube HH, whose inward opening is a continuation of that of the reed: the form of this tube is different in different ranks of pipes. The degree of acuteness or gravity in the found of a reed pipe, depends on the length of the tongue, and that of the pipe CK, taken from the extremity of the shallot to the extremity of the tube. The quantity or intention of the found depends on the width of the reed, the tongue, and the tube; as also on the thickness of the tongue, the figure of the tube, and the quantity of wind. To diversify the founds of the pipes, a valve is added to the port-vent, which makes the wind go out in fits or shakes. In fig. 1. X represents a flute-pipe of wood, Z a flute-pipe of metal, Y a trumpet-pipe of metal. The pipes, to prevent them from falling, pass through holes made in boards, placed upon the upper board.

The pipes are made to communicate with the wind-chest in the following manner. There are holes bored that go through the upper and lower boards, and through the slider, (when it is drawn out), into the

Organ.

partition below; so that any pipes placed upon those holes will then communicate with the partition, which, by its valve, communicates with the wind-chest. But when the slider is thrust in, its holes do not answer to those in the upper and lower boards; therefore the communication is stopped, so that no wind can get to the pipe.

To every large organ there must be at least two pair of bellows, which are marked in fig. 1. by TU, TU. O, O, are the handles, moving upon the axis *nn*, *nn*. Each of these bellows consists of two boards, the lowest of which is immovable; and in this there is a valve *r*, opening inwards, and a tube leading to it, called the *conveying tube*. There is also a hole in this under board, from which a tube leads to the port-vent, which is a square tube marked 4, rising upward, and inserted into the under side of the wind-chest at 2. In the tube leading to the port-vent there is a valve that opens towards the port-vent, and suffers the air to go up the port-vent, but not to return. Now the handle O being pulled down, raises the upper board T, and the air enters through the valve *r*; and when the handle is let go, the weight of the upper board, which carries three or four pound to every square foot, continually descending, drives the air through the port-vent to the found-board: and as the bellows work alternately, one pair is constantly descending, which occasions a continual blast through the port-vent. In chamber-organs there is but one pair of bellows; but they are formed of three boards, in the manner of a smith's bellows, and so have a continual blast. All the internal structure of the organ is concealed from the sight by the front of the instrument, which stands upon the part between the numbers 3 and 6 (fig. 1.)

In every organ the number of partitions LL, MM, &c. there are in the found-board (fig. 1.) that of the valves V V, that of the rollers *s s*, or of the levers *x y* or 8 9 and their wires, and that of the keys ABC, &c. must be always equal. Large organs have commonly four or five sets of keys, beside those that belong to the pedals or large pipes, the stops to which are played by the feet. The keys of an organ are usually divided into four octaves; which are, the second sub-octave, first sub-octave, middle octave, and first octave. Each octave is divided into 12 stops or frets, of which seven are black and five white; the former mark the natural notes, and the latter the artificial notes, that is, flats and sharps. The number of keys, therefore, when there are four octaves, must be 48. Some organists add one or more stops to the first and second sub-octaves. The pedals have two or three octaves, at the option of the organist; so that the number of stops is indeterminate. The keys are placed between GG (fig. 1.), but the scheme could not contain them all. There are also as many handles *h h*, &c. rollers RR, &c. sliders *f f*, &c. as there are stops upon the organ; and it must be observed, that between the sliders *f f*, &c. there are as many sliders on the right hand, and the same number of handles and rollers, and other rows of pipes placed between LN, PQ, which could not be expressed in the figure.

The least pipes and partitions are placed toward the middle of the organ, and the greatest on the outside.

The

The stops of an organ have various denominations, according to the sounds they are to produce; some of which are diapason, principal, fifteenth, twelfth, tearce, cornet, trumpet, French horn, vox humana, flute, bassoon, cremona, &c. There is likewise a contrivance to swell the notes of some of the stops.

When this magnificent instrument is played, the handle *O* of the bellows is first put down, which raises the upper board *T*, and gives room for the air to enter by the valve *r*. Then the other handle *O* is put down; in the mean time the board *T*, belonging to the first handle, descending, and shutting the valve *r*, drives the air through the other valve, up the port-vent, and into the wind-chest. Then drawing out any handle, as that of the flute-stop *p* *h*, which draws out the slider *f* *g*, all the pipes in the set *LN* are ready to play, as soon as the keys *C, D, E*, &c. are put down: therefore, if the key *D* be put down, it opens the corresponding valve *m* *V*, through which the air enters into the pipe *X*, and makes it sound. In the same manner any other pipe in the set *LN*, will found when its key is put down; but no pipe, in any other set, will found till the slider be drawn out by its corresponding handle.

*Hydraulic ORGAN*, denotes a musical machine that plays by water instead of wind. Of these there are several in Italy, in the grottoes of vineyards. Ctesibius of Alexandria, who lived in the time of Ptolemy Evergetes, is said to have invented organs that played by compressing the air with water, as is still practised. Archimedes and Vitruvius have left us descriptions of the hydraulic organ.

*ORGASM*, an ecstacy, or impetuous desire of coition, occasioned by a turgescency of the feminal vessels.

*ORGIA*, in antiquity, feasts and sacrifices performed in honour of Bacchus, instituted by Orpheus, and chiefly celebrated on the mountains by wild distracted women called *Bacche*. See *BACCHANALIA*, and *DIONYSIA*.

*ORGUES*, in the military art, are thick long pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope or cord, over the gateway of a strong place, perpendicularly, to be let fall in case of the approach of an enemy.

*ORGUES*, is also used for a machine composed of several harquebuses or musket barrels bound together, by means whereof several explosions are made at the same time. It is used to defend breaches and other places attacked.

*ORGYA*, an ancient Grecian measure containing fix feet.

*ORIFICE*, the mouth or aperture of a tube, pipe, or other cavity.

*ORIGANUM*, *ORIGANY*, or *Marjoram*; a genus of the gymnospermia order, belonging to the didynamia class of plants. The principal species are, two hardy perennials and an annual for the open ground, and five perennials for the green-house: viz. 1. The vulgare, or wild pot-marjoram; 2. The heracleoticum, or winter sweet-marjoram. These are finely-scented aromatics, excellent for culinary purposes, particularly for broths, soups, &c. they have likewise merit for medical uses, and for giving fra-

grance to ointments; so that the plants are proper both for kitchen and physic gardens, and may also be employed in the pleasure-ground as plants of variety. 3. The marjorana, or annual sweet marjoram, is an aromatic of the highest fragrance, is admirable for kitchen use, and excellent for nosegays; so is proper both for the kitchen and pleasure garden, but more particularly the former. It is often called *knotted marjoram*, from the flowers growing in close knotted-like heads. The following mostly assume an undershrubby growth; frequently with abiding stalks, if they have shelter here in winter. 4. The dittamnus, or dittany of Crete; 5. The sipyleum, or origanum of mount Sipylus; 6. The creticum, or Cretan origany; 7. The smyrneum, or Smyrna origany; 8. The Ægyptiacum, or Egyptian origany. All these eight species of origanum flower in July and August; the flowers are small, monopetalous, ringent, universally hermaphrodite, and collected into verticilli round the stalks; succeeded by ripe seed in autumn; though in this country the annual marjoram and the three green-house sorts seldom perfect seed well, unless the autumn proves remarkably fine and warm: in default, however, of seed, the propagation of all the perennial sorts, both hardy and green-house kinds, is easily effected by slips of the roots, &c. And the seed of the annual sort is imported plentifully from France or Italy, by the seed-dealers.

*ORIENT*, a harbour of France, in the province of Bretagne, in the bottom of the bay of St Lewis. Since the year 1720, a handsome town has been built here, where the East India company have large magazines. The English attempted to become masters of it in 1746, but miscarried. W. Long. 3. 22. N. Lat. 47. 45.

*ORIGEN*, one of the most celebrated ecclesiastical writers, greatest geniuses, and most learned men of the primitive church, during the third century, was born at Alexandria, in the year 183; and was surnamed *Adamantus*, either from his indefatigable application to study, or the firmness he discovered amidst the torments he suffered for the faith. Leonides his father educated him with care, and made him apply to the study of the Holy Scriptures from his infancy, in which he made surprising progress. He had afterwards St. Clement of Alexandria for his master in divinity, and at 18 years of age succeeded that great man in the office of catechist, an important employment, which consisted in teaching divinity, and expounding the Scriptures. Leonides his father had suffered martyrdom the year before, during the persecution of Severus in 202; and Origen had shewn such eagerness to follow his father to martyrdom, that his mother was obliged to hide his cloaths, to prevent his going abroad. Origen had a great concourse of auditors who attended his school, some of whom were of the faithful, and the others pagans. He confirmed and strengthened the first in their faith, and converted most of the others; and there were such a number of martyrs amongst his disciples, that it might be said, that he kept rather a school of martyrdom than of divinity. He taught the doctrines of Christianity to the girls and women as well as to the men; and, taking in a too literal sense what Christ says of becoming voluntary eunuchs, castrated himself, to prevent his de-

serving

Origen.

Origenists

Orion.

serving or suffering scandal. He took a voyage to Rome in 214; and at his return published many works, by which he acquired an extraordinary reputation, that drew to him a great number of auditors. But Demetrius, bishop of Alexandria, conceiving a jealousy of him, endeavoured by various pretences to injure him. At length Origen went to Antioch, whither the empress Mammea had sent for him to hear him discourse on the Christian religion; he did not however stay long there, but returned to Alexandria, where he continued to teach till the year 288, when he left that city, and travelled into Achaia. In that journey he went into Palestine, and was ordained by the bishops of that province at 42 years of age. His being ordained by foreign bishops without the permission of Demetrius, renewed that prelate's resentment against him; on which Origen hastily returned to Alexandria, to endeavour to mollify him; but Demetrius drove him from thence in 231, and caused him to be excommunicated, and even deposed in a council held in Egypt. Origen then retired to Cæsaria in Palestine, where he raised a celebrated school, and had St Gregory Thaumaturgus, and a great number of other persons who were illustrious for their virtue and learning, for his disciples. He afterwards travelled to Athens; and then, at the desire of Firmilianus, staid sometime at Cæsariain Cappadocia; whence he was invited into Arabia, to convince and bring back to the truth Beryllus, bishop of Bostra, who maintained that the Word had no existence before his incarnation. Origen had the happiness to make him sensible of his mistake; and some years after was sent for into Arabia by an assembly of bishops, to dispute again the Arabians, who maintained that the souls of the dead remained in a state of insensibility till the general resurrection. At length the seventh persecution of the Christians began in the reign of Decius, and none were used with greater severity than Origen. He supported with incredible constancy the dreadful torments which the persecutors of the Christians invented against them; torments that were the more insupportable, as they were made to continue a long time, and as they took the greatest care to prevent his expiring in the midst of his tortures; but in the midst of the most excruciating torments, he discovered an heroic courage, and suffered nothing to escape him that was unworthy a disciple of Jesus Christ. He died at Tyre in 254, aged 69. He was the author of a great number of excellent works. The principal of those which have been handed down to us are, 1. A Treatise against Celsus, of which Spencer has given a good edition in Greek and Latin, with notes: this learned treatise has been translated into French by Elias Bouhereau, a protestant minister, born at Rochelle. 2. A great number of Homilies, with Commentaries on the Holy Scriptures. 3. *Philocalia*, and several other treatises. 4. Fragments of his Hexaples, collected by father Montfaucon, in two volumes folio. Of all Origen's books, the loss of the Hexaples is most to be regretted. This work was thus named from its containing six columns; in the first of which was the Hebrew text of the Bible; in the second, the same text in Greek characters; in the third, the Greek version of the Septuagint; in the fourth, that of Aquila; in the fifth, that of Symmachus; and in the

sixth, Theodotian's Greek version. This admirable work gave the first hint for our Polyglot Bibles. 5. The book of Principles; of which we have only an incorrect Latin version. In all his writings he discovers a surprising degree of modesty, candour, and humility; a noble and sublime genius, profound learning, and vast erudition. His manners were extremely pure, and he had a warm zeal for spreading the truths and morals of the gospel. The most complete edition of his works is that of father dela Rue, a Benedictine, in Greek and Latin.

He ought not to be confounded with another Origen, a Platonic philosopher, and the disciple and friend of Porphyry, who studied philosophy under Ammonius.

ORIGENISTS, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state; that they were holy intelligences, and had sinned in heaven before the body was created; that Christ is only the son of God by adoption; that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues one after another; that, in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

ORIGINAL, a first draught or design of any thing, which serves as a model to be imitated or copied.

ORIGINAL Sin, the crime of eating the forbidden fruit, of which, it is said, all mankind are guilty at their conception, by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human human race: and that, on his sinning, all that were to spring from him partook of his crimes.

ORIGUELA, a town of Spain in Valencia. It is seated between the mountains on the banks of the river Segura, in a place fortified by nature, and in a fertile plain, abounding in all things, especially corn. It is surrounded with pleasant gardens, and has a university and a bishop's see. It is defended by an old castle; and is the capital of a government independent of Valencia, whose jurisdiction extends thirty miles in length, and fifteen in breadth. W. Long. o. 56. N. Lat. 38. 22.

ORILLON, in fortification, is a small rounding of earth, faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See *Fortification*.

ORIOLOUS, in ornithology, a genus belonging to the order of piece. The bill is conical, convex, very sharp and straight; the superior mandible being much longer than the under one; and the tongue is forked and sharp. There are 20 species, principally distinguished by their colour.

ORION, in fabulous history, was the son of Jupiter, Neptune, and Mercury. For as these gods were visiting the earth, they entered the house of Hyrieus, a native of Tanagra, in Boeotia, under the character of benighted travellers, on account of his being famed for

Orion  
Orkney.

for hospitality to strangers. Hyrieus treated them in the best manner in his power; and even killed an ox, the only one he had, for their entertainment. At which the gods were so pleased, that they offered the old man whatever he would ask; who letting them know that he desired nothing so much as a son, they, to gratify his wish, caused the ox's hide to be brought before them, in which, having deposited their urine, they bad him keep it under ground for ten months. At the expiration of that term he dug it up, and found in it an infant, whom he at first called *Orion*, to express his origin; but afterwards changed it to *Orion*. He was a remarkable hunter: and Neptune gave him the power of walking on the surface of the waters, with the same speed that Iphiclus did over the ears of corn; on which he crossed from the continent of Greece to the island of Chios, where attempting to violate *Ærope*, the wife of king *Oenopion*, that monarch deprived him of his sight. He then travelled to *Lebos*, where he was kindly received by *Vulcan*, who gave him a guide to the palace of the sun, where he was restored to sight. He then made war on *Oenopion*; who escaping his vengeance by concealing himself under ground, he went to *Crete*, where he pursued his favourite exercise of hunting. But having offended *Diana*, that goddess put him to death, either by her arrows, or by sending a scorpion which gave him a mortal wound; but afterwards relenting, she prevailed on *Jupiter* to raise him to the skies, where he forms a constellation, remarkable for predicting rain and tempestuous weather.

**ORION**, in astronomy, one of the constellations of the southern hemisphere.—The word is formed from the Greek *ὄρεω*, “to make water;” the ancients supposing that it rained tempests at its rising and setting.—The stars in the constellation *Orion*, in Ptolemy's catalogue are 37, in Tycho's 62, in the *Britannic catalogue* 80.

**ORISTAGNI**, an ancient town of the island of *Sardinia*, with an archbishop's see. It is pretty large and well fortified; but thinly inhabited, on account of the unhealthy air: it is seated on the western coast, in a bay of the same name, in *E. Long.* 8. 58. *N. Lat.* 39. 55.

**ORIXA**, a kingdom of *Indostan*, lying on the gulf of *Bengal*. It is divided from the ancient kingdom of *Golconda*, by a ridge of mountains, the end of which runs a little way into the sea. It is fertile in corn and cattle, and they have several good towns and harbours on the coast; there are also manufactures of different kinds carried on throughout the kingdom. The prince is a *Gentoo*, who pays to the *Great Mogul* a tribute to the amount of about 12,000*l.* yearly.

**ORKNEY ISLANDS**, certain islands on the north of *Scotland*, from which they are separated by a frith 20 miles in length and 10 in breadth. They are 40 in number; but many are uninhabited, the greater part being small, and producing only pasture for cattle. The principal islands are denominated by the names of *Mainland*, *South Ronaldsha*, *Swinna*, *Flotta*, *Copinsha*, *Strupensha*, *Stronsa*, *Sanda*, &c. the terminations in *a*, or *ha*, being generally given in the *Teutonic* to such places as are surrounded by water. The currents and tides flowing between the islands are extremely rapid and dangerous. Near an island call-

ed *Swinna* are two great whirlpools, called the *swells of Swinna*, which are counted dangerous by mariners, especially in a calm. When sailors find themselves sucked into the vortex, it is said they throw out a barrel, or some bulky substance, which smooths the water till it is sucked down and thrown up at a considerable distance, during which time the ship passes over in safety. But when there is a breeze of wind, these whirlpools may be crossed without any danger.

The air of these islands is moist, on account of the neighbourhood of the sea; and frost and snow do not continue long. In some places the soil is bare and mountainous, and in others sandy and barren; however, many of the islands produce large crops of barley and oats, but no wheat or other grain excepting what is inclosed in gardens. These, when duly cultivated, produce all kinds of kitchen herbs and roots, bringing even fruit-trees to maturity; but out of them, in the open country, there is scarce a tree or shrub to be seen, except juniper, wild myrtle, heath, and the *cyur-hodon*: yet this deficiency cannot be imputed to the poverty of the soil, or the nature of the climate; for the trunks of large oaks are frequently dug up in the marshes. This is likewise the case in the most barren parts of the *Highlands of Scotland*, where not a shrub is to be seen above the surface of the earth: nay, the inhabitants frequently find, deep in the earth, the roots of large trees, evidently exhibiting marks of the ax by which they were felled; so that these northern parts must have undergone some strange revolutions. The *Orkneys* produce great variety of herbs and berries, grass and corn, which last is exported as far as *Edinburgh*. In some of the islands, the natives have discovered mines of tin, lead, and silver, though none of them are wrought to any advantage; in others, we find abundance of marl, grey and red slate, quarries of freestone, and even of marble and alabaster: when the wind rages to any violence, the sea throws in plenty of timber, torn from other countries; and, not unfrequently, the people find large pieces of ambergrease. The fresh water in these islands is very pure and limpid; and, though there are no large rivers in the *Orkneys*, the ground is well watered with lakes and pleasant rivulets, that not only serve to turn their mills, but also abound with trout of the most delicate flavour.

Besides the abundance of little horses, black cattle, sheep, swine, and rabbits, the inhabitants of the *Orkneys* rear all sorts of domestic animals and tame poultry. Their heaths and commons yield plenty of red deer, and all sorts of game; partridges, grouse, heath-cocks, plover, duck, teal, and widgeon: the sea-coast teems with seals and otters; and are visited by whales, cod, ling, tusk, herrings, and all manner of fish: on the shore they find *sperma ceti*, or *sepia*, and a great variety of shells and corallines, with a multitude of oysters, remarkably large muscles, crabs, and cockles. The rocks are covered with sea-fowl, wild geese, solan geese, barnacles, eagles, hawks, and kites. With respect to the barnacles, or, as the natives call them, the *clock geese*, they are said to be found in shells sticking by the bills to trees, in several islands. *Martin* affirms he has seen them in this situation, but could not perceive them alive; and indeed

Orkney.

the whole account of their generation and production, exhibited by the northern naturalists, is absurd and unphilosophical. The Orkney eagles are so strong, that, according to the reports of the country, they have been known to carry away young children in their talons. Certain it is, they make such havoc among the lambs, that he who kills an eagle is entitled by law to a hen from every house in the parish where it was killed. The king's falconer visits these islands every year, in order to fetch away the young hawks and falcons from their nests among the precipices: he enjoys a yearly salary of twenty pounds, and may claim a hen or a dog, from every house in the country, except those that are expressly exempted from this imposition.

The Orkneys, as well as the hills of Shetland, were originally peopled from Norway, in the ninth, tenth, or eleventh century; and the commonality still retain the language of that kingdom, distinguished by the name of *Norns*: they likewise preserve some customs of these Norwegian ancestors. The islands of Orkney have been at different times subdued by the Scots, and recovered by the Norwegians: at length they were sold by Magnus, king of Norway, to Alexander of Scotland, for the sum of 4000 merks Sterling, and a yearly acknowledgement of 100 merks. Since that period, the Orkneys have continued annexed to the crown of Scotland. The gentry of the Orkneys are civilized, polite, and hospitable; and live like those of Scotland, from whom they are chiefly descended. They live comfortably, are remarkably courteous to strangers, and drink a great quantity of wine, with which their cellars are generally well stored. Indeed the inhabitants of the Orkneys may be now justly deemed a Scotch colony. They speak the language, profess the religion, follow the fashions, and are subject to the laws, of that people. They are frugal, sagacious, circumspect, religious, and hospitable. Their mariners are remarkably bold, active, dexterous, and hardy. Many surprising instances of longevity occur here, as well as in Shetland, of persons living to the age of 140. The Orkney women are generally handsome and well-shaped, and bring forth children at a very advanced age. In the Orkneys, some particular lands are held by a tenure called *Udal Right*, from Ulcius, or Olaus, king of Norway, who farmed the lands, on condition of receiving one-third of the produce; and this right devolved in succession, without any charter granted by the sovereign. The inhabitants of Orkney, instead of measuring their corn, weigh it in pismores or pundlers. Their least denomination is a mark, consisting of 18 ounces, and 24 merks make a lispound, which is a Danish quantity. The poorer sort of people in the Orkneys appear very meanly habited, with a piece of seal-skin instead of shoes; and living chiefly on salt-fish, are subject to the scurvy. They are much addicted to superstitious rites; in particular, interpreting dreams and omens, and believing in the force of idle charms. The islands of Orkney, we have already observed, produce very bold, able, and hardy mariners. The common people, in general, are inured to fatigue, and remarkably adventurous, both in fishing during rough weather, and in climbing the rocks for the flesh, eggs, and down of sea-fowl. Former-

ly, while they were exposed to the invasions of the Norwegians, or western islanders, every village was obliged to equip a large boat well manned; and all the fencible men appeared in arms, when the alarm was given by the beacons lighted on the tops of the rocks and highest mountains. These beacons, known by the name of *ward-hills*, are still to be seen in every island. Their corn land they inclose with mud or stone walls, to preserve it from the ravages of their sheep, swine, and cattle, which wander about at random, without being attended by herdsmen: their ordinary manure, especially near the sea-coast, is sea-weed, which they carefully gather and divide into equal portions. Their sheep are marked on the ears and nose; but so wild, that when they have occasion to shear them in the month of May, they are obliged to hunt every individual, with dogs trained for that purpose. Their manner of catching sea-fowl is curious and particular. Under the rock where these fowls build, they row their boat, provided with a large net, to the upper corners of which are fastened two ropes, lowered down from the top of the mountain by men placed in that station. These hoisting up the net, until it be spread opposite to the cliffs in which the fowls are sitting, the boatmen below make a noise with a rattle, by which the fowls, being frightened, fly forwards into the bosom of the net, in which they are immediately enclosed and lowered down into the boat: they often practise the method used in Iceland and Norway, and are lowered down by a single rope from the summit of the mountain; this is the constant way of robbing the hawk's nest. In these islands some strange effects are produced by thunder and lightning. In the year 1680, the lightning entered a cow-house, in which 12 cows stood in a row, killed every second beast as the flood, and left the rest untouched. The distempers that prevail mostly in the Orkneys are agues, consumptions, scurvy, and itch. The agues, which abound in the spring, the natives cure with a diet-drink of biters and antiscorbutics infused in ale: for phthisical complaints they use the plant arby, and the caryophyllus marinus boiled with sweet milk.

The isles of Orkney and Shetland compose one stewartry, and send one member to the British parliament. The right of superiority to the Orkneys was dismembered from the crown by the union parliament, and granted for a certain yearly consideration to the earl of Moreton, by queen Anne, who appointed him hereditary steward and judiciary. This nobleman possesses the power of creating certain judges, called *bailiffs*. There is one of these established in every island and parish, with power to superintend the manners of the inhabitants, to hold courts and determine civil causes, according to the laws of Scotland, to the value of ten pounds Scotch money, amounting to 16s. 8d.: but all contests of higher import are referred to the decision of the steward or his deputy, who resides at Kirkwall, which is the seat of justice. Subservient to the bailiffs are six or seven of the most reputable and intelligent inhabitants, who oversee the conduct of their fellows, acting as constables, and make report of all enormities to the bailiff; who causes the delinquent to be apprehended and punished, if the crime be within the extent of his judicial power; otherwise he transmits him to Kirkwall, where he is tried  
by

Orkney  
Orleanois.Orleans  
Ormeau.

stone to fill up the entrance; above, the stone was sharpened into an edge; within were found some burned bones and red clay; and over it was placed a large flat stone for the preservation of the whole. These, in all probability were Roman catacombs. In Westra divers Danish graves have been discovered: in one of these appeared the skeleton of a man, with a sword on one side, and a Danish ax on the other. Some have been found buried with dogs, combs, knives, and other utensils. In many places of the country we find round hillocks or barrows, here known by the name of *brogh*, signifying, in the Teutonic language, burying-place, supposed to have been the cemeteries of the ancient Saxons. In different parts of these islands we see the remains of great buildings, believed to have been fortresses erected by the Danes or Norwegians when they possessed the country. One of these in the isle of Wyre, called the *castle of Coppi-row*, signifying a town of security, is surrounded by a fosse, and the first floor still remains above ground, a perfect square of stone wall, very thick, strongly built, and cemented with lime, the area within not exceeding ten feet in length. Of this Coppi-row the common people relate many idle fables. In the chapel of Clet, in the isle of Sanda, there is a grave 19 feet long, in which was found part of a man's back bone, larger than that of a horse. Human bones, of nearly the same size, have been dug up in Westra; and indeed this country is remarkable for producing men of a gigantic stature. Within the ancient fabric of Lady Kirk in South Ronaldshaw, there is a stone four feet long, and two feet broad, on which the print of two feet are engraven, supposed to be the place where, in times of Popery, penitents stood to do public penance.

ORLE, ORLET, or *Orlo*, in architecture, a fillet under the ovolo, or quarter round of a capital. When it is at the top or bottom of a shaft, it is called *cincture*. Palladio uses the word orlo for the plenith of the basis of the columns.

ORLE, in heraldry, an ordinary, in form of a fillet, drawn round the shield, near the edge or extremity thereof, leaving the field vacant in the middle. Its breadth is but half that of the tressure or bordure, which contains a sixth part of the shield; and the orle only a twelfth: besides, that the orle is its own breadth distant from the edge of the shield, whereas the bordure comes the edge itself. The form of the orle is the same with that of the shield, whence it resembles an escutcheon. See Plate CXLIV. fig. 1. (A.)

ORLEANOIS, a province of France, including the several districts of Orleanois-Propre, Beauce-Propre or Chartrain, Dunois, Vendomois, Blaisois, the greatest part of Gatinois, and Perche-Gouet. The principal rivers of it are the Loire, the Loiret, the Cher, the Laconie, the Aigle, the Hyere, the Yonne, and the Evre. There are also some remarkable canals, particularly those of Briare and Orleans. The river Loire, and the canals drawn from thence, greatly facilitate and promote the inland trade of the kingdom; and particularly of this government, which lies entirely within the jurisdiction of the parliament of Paris; and, besides the chief governor, has several subordinate ones.

Orleanois, in Latin *Aurelianensis Ager*, is bounded

on the south by Sologne, on the north by Upper-Beauce, on the east by Gatinois, and on the west by Dunois and Vendomois. The Loire divides it into Upper and Lower; the former lying to the north, and the latter to the south of that river. It yields plenty of grain, wine, wood, and fruit, and abounds in cattle, game, and fish. The principal places in it are,

Orleans, from which it derives its name, and is the capital, not only of it, but of the whole government. It was anciently called *Genabum* or *Genabum*, and afterwards *Aurelia*, *Aurelia*, and *Aurelianum*; and stands 20 leagues from Paris to the south, on the northern bank of the Loire, over which there is here a fine stone bridge of 16 arches, leading into a suburb on the south side of the river. In Julius Cæsar's time it was the capital of the Carnutes. Aurelian, the emperor, enlarged it, and gave it his name. It is one of the largest cities in the king; but meanly built, and most of the inhabitants are poor; though there are here several inferior courts of justice, with an university, at present in no great repute; a public library; a stately Gothic cathedral, and a great number of other churches, some of which are collegiate; a public walk, planted with several rows of trees; some sugar-bakers; a manufacture of stockings and sheep-skins; a seminary, in which divinity is taught; and a great trade in brandy, wine, spices, and several manufactures, which, with many other commodities, are conveyed from hence to Paris, and other places, by means of the Loire, and the canal which takes its name from the city. Some of the trading people are very rich. The canal begins about two miles above the city; is near 18 leagues in length; and terminates on the Loing, which falls into the Seine. To the north of the city is a forest, the largest in the whole kingdom, belonging to the duke of Orleans; to whom the timber felled in it brings in, one year with another, about 100,000 livres. Ever since the year 1344, this city has been a dukedom and peerage, and usually an appennage of some prince of the blood. Lewis XIV. gave it to his brother Philip; who begun and finished the canal, in whose family it still continues. The duties paid by vessels going up and down the canal, amount, in some years, to 150,000 livres. The bishop of this city is suffragan to the archbishop of Paris, and has a revenue of 24,000 livres, out of which his tax to Rome is 2000 florins. It is said, a new bishop, on the first day of his entering the city, has the privilege to release all the prisoners in it, except those committed for treason. On the eighth of May, 1429, Orleans, then closely besieged by the English, was relieved by Joan of Arc, commonly called the *Maid of Orleans*; and the anniversary of that deliverance is still kept here. To perpetuate the memory of it, a monument of brass was erected on the bridge, which is still in being.

ORLOPE, in the sea-language, the uppermost space or deck in a great ship, reaching from the main to the mizen-mast. In three-deck ships, the second and lowest decks are sometimes called *orlopes*.

ORMOND, the northern division of the county of Tipperary, in the province of Munster in Ireland. For a long time it gave the title of *earl*, and afterwards of *marquis* and *duke*, to the noble family of Butler, descended from a sister of Thomas à Becket archbishop of Canterbury; till, at the accession of George I. the

last

ORNITHOLOGY.

Plate CCXXXI.

last duke was attainted of high treason, and died abroad.

In that part of the country the family had great prerogatives and privileges granted by Edward III.

ORMUS, an island of Asia, about two leagues from the main land, almost at the mouth of the Persian gulph. It is about six leagues in circuit; but is quite barren, and has not a drop of fresh water. They catch excellent oysters about the island; and it yields plenty of fine white salt; also a kind of shining black sand, which is used for dusting writings, and is transported in considerable quantity to Europe. This island was for some time in possession of the Portuguese, when there was a very rich and populous town upon it, where all the trade of the Indies was managed; but that has long been in ruins, and there is now nothing

inhabited but the fort.

ORNITHOGALLUM, STAR OF BETHLEHEM; a genus of the monogynia order, belonging to the hexandria class of plants. There are seven species; all of them herbaceous perennials, rising from six inches to three feet high, having stalks terminated with long spikes of hexapetalous, star-shaped, white and yellow flowers. Six of the species are very hardy, and will prosper in any situation; but one, named the *capensis*, a native of the Cape of Good Hope, requires the assistance of artificial warmth to preserve it in this country. They are all easily propagated by off-sets from the roots. The bulbous roots of all the species are nutritious and wholesome.

## O R N I T H O L O G Y.

ORNITHOLOGY is a science which treats of birds; describes their form, external and internal; and teaches their economy and their uses. See BIRD.

A bird is an animal covered with feathers; furnished with a bill; having two wings, and only two legs; with the faculty, except in a very few instances, of removing itself from place to place through the air.—But before proceeding to analyse the characteristic parts of birds, it will be proper to premise an explanation of the terms used by naturalists in describing them.

EXPLANATION of some Technical Terms in Ornithology used by PENNANT and LINNÆUS.

Fig.

1. *Cere. Cera* THE naked skin that covers the base of the bill in the hawk kind.
2. *Capistrum* A word used by Linnæus to express the short feathers on the forehead just above the bill. In crows these fall forwards over the nostrils.
3. *Lorum* The space between the bill and the eye, generally covered with feathers; but in some birds naked, as in the black and white grebe.<sup>b</sup>
4. *Orbits. Orbita* The skin that furrounds the eye, which is generally bare; particularly in the heron and parrot.
5. *Emarginatum* A bill is called *rostrum emarginatum* when there is a small notch near the end: this is conspicuous in that of butcher-birds and thrushes.
6. *Vibrissæ* *Vibrissæ pectinatae*, stiff hairs that grow on each side the mouth, formed like a double comb, to be seen in the goatfucker, fly-catcher, &c.
7. *Basilar wing*  
*Alula spuria* A small joint rising at the end of the middle part of the wing, or the *cubitus*; on which

8. *Lesser coverts of the wings*  
*Tectrices primæ* are three or five feathers. The small feathers that lie in several rows on the bones of the wings. The under coverts are those that line the inside of the wings.
9. *Greater coverts*  
*Tectrices secundæ* The feathers that lie immediately over the quill-feathers and secondary feathers.
10. *Quill-feathers*  
*Primores* The largest feathers of the wings, or those that rise from the first bone.
11. *Secondary feathers*  
*Secundariæ* Those that rise from the second.
12. *Coverts of the tail*  
*Uropygium* Those that cover the base of the tail.
13. *Vent-feathers* Those that lie from the vent to the tail. *Criſsum Linnæi*.
14. *The tail. Rectrices*
15. *Scapular feathers* That rise from the shoulders, and cover the sides of the back.
16. *Nucha* The hind part of the head.
17. *Rostrum subulatum* A term Linnæus uses for a straight and slender bill.
18. To shew the structure of the feet of the kingfisher.
19. *Pes scanforius* The foot of the woodpecker formed for climbing. Climbing feet.
20. *Finned foot. Pes lobatus, pinnatus* Such as those of the grebes, &c. Such as are indented, as fig. 21. are called *scalloped*, such are those of coots and scalloped sandpipers.
22. *Pes tridactylus* Such as want the back toe.
23. *Semi-palmated. Pes semi-palmatus* When the webs only reach half way of the toes.
24. *Ungue pectico sessili* When the hind-claw adheres to the leg without any toe, as in the petrels.
25. *Digitis 4 omnibus palmatis* All the four toes connected by webs, as in the corvorants.
- Rostrum cultratum* When the edges of the bill are very sharp, such as in that of the crow.

External Parts. *Unguiculatum*

*Lingua ciliata*

*Integra*

*Lunibriciformis*

*Pedes compedes*

*Nares Lineares*

*Marginatae*

A bill with a nail at the end, as in those of the goofanders and ducks.

When the tongue is edged with fine bristles, as in ducks.

When plain or even.

When the tongue is long, round, and slender like a worm, as that of the woodpecker.

When the legs are placed so far behind as to make the bird walk with difficulty, or as if in fetters; as is the case with the auks, grebes, and divers.

When the nostrils are very narrow; as in sea gulls.

With a rim round the nostrils, as in the flares.

### SECT. I. External parts of Birds.

A BIRD may be divided into *head, body, and limbs.*

#### I. HEAD.

1. *BILL (rostrum)*, is a hard horny substance, consisting of an upper and under part, extending from the head, and answering to the mandibles in quadrupeds. Its edges generally plain and sharp, like the edge of a knife, *cultrated*, as are the bills of crows; but sometimes *serrated*, as in the toucan; or *jagged*, as in the gannet and some herons; or *pellinated*, as in the duck; or *denticulated*, as in the mergansers; but always destitute of real teeth immersed in sockets.

The base in falcons is covered with a naked skin or cere (*cera*); in some birds with a caraneous appendage, as the turkey; or a callous, as the curassow.

In birds of prey, the bill is hooked at the end, and fit for tearing: in crows, straight and strong for picking; in water-fowl, either long and pointed, for striking; or slender and blunt, for searching in the mire; or flat and broad, for gobbling. Its other uses are for building nests; feeding the young; climbing, as in parrots; or, lastly, as an instrument of defence, or offence.

2. *NOSTRILS (nares)*, the nice instruments of discerning their food, are placed either in the middle of the upper mandible, or near the base, or at the base, as in parrots; or behind the base, as in toucans and hornbills: but some birds, as the gannet, are destitute of nostrils. The nostrils are generally naked; but sometimes covered with bristles reflected over them, as in crows, or hid in the feathers, as in parrots, &c.

The fore-part of the head is called the *front (capistrum)*; the summit (*vertex*), or the *crown*: the hind part, with the next joint of the neck (*nucha*), the *nape*: the space between the bill and the eyes, which in herons, grebes, &c. is naked, (*lora*), the *straps*: the space beneath the eyes (*gene*), the *cheeks*.

3. *ORBITS (orbites)*, the eye-lids; in some birds naked, in others covered with short soft feathers.

Birds have no eye-brows; but the grouse kind have in lieu, a scarlet naked skin above, which are called *supercilia*; the same word is also applied to any line of a different colour that passes from the bill over the eyes.

4. *EARS.* Birds are destitute of auricles or exter-

nal ears, having an orifice for admission of sound; open in all but owls, whose ears are furnished with valves.

5. The *CHIN*, the space between the parts of the lower mandible and the neck, is generally covered with feathers; but, in the cock and some others, have caraneous appendages called *wattles (palearia)*; in others, is naked, and furnished with a pouch, capable of great dilatation (*jaculatur*), as in the pelican and corvorants.

6. *NECK (collum)*, the part that connects the head to the body, is longer in birds than any other animals; and longer in such as have long legs than those that have short, either for gathering up their meat from the ground, or striking their prey in the water, except in web-footed fowl, which are, by reverting their bodies, destined to search for food at the bottom of waters, as swans, and the like. Birds, especially those that have a long neck, have the power of retracting, bending, or stretching it out, in order to change their centre of gravity from their legs to their wings.

#### II. BODY.

1. Consists of the *BACK (dorsum)*; which is flat, freight, and inclines; terminated by the

2. *RUMP (uropygium)*, furnished with two glands, secreting a fattish liquor from an orifice each has, which the birds express with their bills to oil or anoint the discomposed parts of their feathers. These glands are particularly large in moist web-footed water-fowl; but in the grebes, which want tails, they are smaller.

2. *BREAST (pectus)*, is rigid and very muscular, defended by a forked bone, (*clavicula*), the merrythought.

The short-winged birds, such as grouse, &c. have their breasts most fleshy or muscular; as they require greater powers in flying than the long-winged birds, such as gulls, herons, which are specifically lighter, and have greater extent of sail.

4. *BELLY (abdomen)*, is covered with a strong skin, and contains the entrails.

5. The *VENT*, or vent-feathers, (*crissum*), which lies between the thighs and the tail. The anus lies hid in those feathers.

#### III. LIMBS.

1. *WINGS (ale)*, adapted for flight in all birds except the dodo, ostriches, great auk, and the penguins, whose wings are too short for the use of flying; but in the dodo and ostrich, when extended, serve to accelerate their motion in running; and in the penguins perform the office of fins, in swimming or diving.

The wings have near their end an appendage covered with four or five feathers called the *bastard wing*, (*ala notba*), and *alula spuria*.

The lesser coverts (*tertices*), are the feathers which lie on the bones of the wings.

The greater coverts are those which lie beneath the former, and cover the quill-feathers and the secondaries.

The quill-feathers (*primores*), spring from the first bones (*digiti metacarpi*) of the wings, and are 10 in number.

Quill-feathers are broader on their inner than exterior sides.

The secondaries (*secundarie*), are those that rise from the second part (*cubitus*), and are about 18 in number,

External Parts.

number, are equally broad on both sides. The primary and secondary wing-feathers are called *remiges*.

A tuft of feathers placed beyond the secondaries near the junction of the wings with the body. This, in water-fowl, is generally longer than the secondaries, and cuneiform.

The scapulars are a tuft of long feathers arising near the junction of the wings (*brachia*) with the body, and lie along the sides of the back, but may be easily distinguished, and raised with one's finger.

The inner coverts are those that clothe the under side of the wing.

The subaxillary are peculiar to the greater Paradise.

The wings of some birds are instruments of offence. The anhimas of Marégrave has two strong spines in the front of each wing. A species of plover, Edw. tab. 47. and 280. has a single one on each; the whole tribe of jacana, and the gambo, or four-winged goose of Mr Willoughby, the same.

2. The *TAIL* is the director, or rudder, of birds in their flight; they rise, sink, or turn by its means; for, when the head points one way, the tail inclines to the other side: it is, besides, an equilibrium or counterpoise to the other parts; the use is very evident in the kite and swallows.

The tail consists of strong feathers (*rectrices*), 10 in number, as in the woodpeckers, &c.; 12 in the hawk tribe, and many others; in the gallinaceous, the mergansers, and the duck kind, of more.

It is either even at the end, as in most birds; or forked, as in swallows; or cuneated, as in magpies, &c.; or rounded, as in the purple jacksaw of Catsby. The grebe is destitute of a tail, the rump being covered with down; and that of the cassowary with the feathers of the back.

Immediately over the tail, are certain feathers that spring from the lower part of the back, and are called the *coverts of the tail*, (*uropygium*).

3. *THIGHS*, (*femora*), are covered entirely with feathers in all land-birds, except the buffards and the ostriches; the lower part of those of all waders, or cloven-footed water-fowl, are naked; that of all web-footed fowl the same, but in a less degree; in rapacious birds, are very muscular.

4. *LEGS*, (*crura*); those of rapacious fowls very strong, furnished with large tendons, and fitted for tearing and a firm gripe. The legs of some of this genus are covered with feathers down to the toes, such as the golden eagle; others to the very nails; but those of most other birds are covered with scales, or with a skin divided into segments, or continuous. In some of the pies, and in all the passerine tribe, the skin is thin and membranous; in those of web-footed water-fowl, strong.

The legs of most birds are placed near the centre of gravity: in land-birds, or in waders that want the back toe, exactly so; for they want that appendage to keep them erect. Auks, grebes, divers, and penguins, have their legs placed quite behind, so are necessitated to sit erect: their pace is awkward and difficult, walking like men in fetters; hence Linnaeus styles their feet *pedes compedes*.

The legs of all cloven-footed water-fowl are long, as they must wade in search of food: of the palmated, short, except those of the flamingo, the avocet, and the

courier.

5. *FEET*, (*pedes*), in all land-birds that perch, have a large back toe: most of them have three toes forward, and one backward. Woodpeckers, parrots, and other birds that climb much, have two forward, two backward; but parrots have the power of bringing one of their hind toes forward while they are feeding themselves. Owls have also the power of turning one of their fore toes backward. All the toes of the *fruiſt* turn forwards, which is peculiar among land-birds: the tridactylous woodpecker is also anomalous, having only two toes forward, one backward: the ostrich is another, having but two toes.

6. *TOES*, (*digiti*). The toes of all waders are divided; but, between the exterior and middle toe, is generally a small web, reaching as far as the first joint.

The toes of birds that swim are either plain, as in the single instance of the common water-hen or gallinule; or pinnated, as in the coots and grebes; or entirely webbed or palmated, as in all other swimmers.

All the plover tribe, or charadrii, want the back-toe. In the swimmers, the same want prevails among the albatrosses and auks. No water-fowl perch, except certain herons, the corvora, and the flag.

7. *CLAWS*, (*ungues*). Rapacious birds have very strong, hooked, and sharp claws, vultures excepted. Those of all land-birds that roost on trees have also hooked claws, to enable them to perch in safety while asleep.

The gallinaceous tribe have broad concave claws for scraping up the ground.

Grebes have flat nails like the human.

Among water-fowl, only the skua, Br. Zool. II. p. 417. 3d edit. n° 234, and the black-toed gull, Br. Zool. II. p. 419. 3d edit. n° 435, have strong hooked or aquiline claws. All land-birds perch on trees, except the frutheous and some of the gallinaceous tribes. Parrots climb; woodpeckers creep up the bodies and boughs of trees; swallows cling.

All water-fowl rest on the ground, except certain herons, and one species of ibis, the spoonbill, one or two species of ducks and of corvora.

#### IV. FEATHERS.

FEATHERS are designed for two uses; as coverings from the inclemency of the weather, and instruments of motion through the air. They are placed in such a manner as to fall over one another, (*tegulatum*), so as to permit the wet to run off, and to exclude the cold; and those on the body are placed in a quincunx form; most apparent in the thick-skinned water-fowl, particularly in the divers.

1. The parts of a feather are, the shafts; corneous, strong, light, rounded, and hollow at the lower part; at the upper, convex above, concave beneath, and chiefly composed of a pith.

2. On each side the shafts are the vanes, broad on one side, narrow on the other; each vane consists of a multitude of thin laminae, stiff, and of the nature of a split quill. These laminae are closely braced together by the elegant contrivance of a multitude of small bristles; those on one side hooked, the other straight, which lock into each other, and keep the vanes smooth, compact, and strong.

The vanes near the bottom of the shafts are soft, unconnected,

connected, and downy.

3. Feathers are of three kinds. (1.) Such as compose instruments of flight : as the pen-feathers, or those which form the wings and tail, and have a large shaft. The vanes of the exterior side bending downward, of the interior upwards, lying close on each other, so that, when spread, not a feather misses its impulse on the air. The component parts of these feathers are described before.

(2.) The feathers that cover the body, which may be properly called the *plumage*, have little shaft, and much vane; and never are exerted or relaxed, unless in anger, fright, or illness.

(3.) The Down, (*plumæ*), which is dispersed over the whole body amidst the plumage, is short, soft, unconnected, consists of lanuginous vanes, and is intended for excluding that air or water which may penetrate or escape through the former. This is particularly apparent in aquatic birds, and remarkably so in the anserine tribe. There are exceptions to the forms of feathers. The vane of the subaxillary feathers of the Paradise are unconnected, and the laminae distant, looking like herring-bone. Those of the tail of the ostrich, and head of a species of curassow, curled. Those of the callosary consist of two shafts, arising from a common stem at the bottom : as do, at the approach of winter, (after moulting), those of the ptarmigans of arctic countries. The feathers of the penguins, particularly those of the wings, consist chiefly of thin flat shafts, and more resemble scales than feathers; those of the tail, like split whale-bone.

## SECT. II. Flight of Birds.

THE flight of birds is various; for, had all the same, none could elude that of rapacious birds. Those which are much on wing, or sit from place to place, often owe their preservation to that cause: those in the water, to diving.

Kites, and many of the falcon tribe, glide smoothly through the air, with scarce any apparent motion of the wings.

Most of the order of pies fly quick, with a frequent repetition of the motion of the wings. The Paradise floats on the air. Woodpeckers fly awkwardly, and by jerks, and have a propensity to sink in their progress.

The gallinaceous tribe, in general, fly very strong and swiftly; but their course is seldom long, by reason of the weight of their bodies.

The columbine race is of singular swiftness; witness the flight of the CARRIER-Pigeon.

The passerine fly with a quick repetition of strokes; their flight, except in migration, is seldom distant.

Among them, the swallow tribe is remarkably agile, their evolutions sudden, and their continuance on wing long.

Nature hath denied flight to the struthious; but still, in running, their short wings are of use, when erect, to collect the wind, and like sails to accelerate their motion.

Many of the greater cloven-footed water-fowl, or waders, have a slow and flagging flight; but most of the lesser fly swiftly, and most of them with extended legs, to compensate the shortness of their tails. Rails and gallinules, fly with their legs hanging down.

Coots and grebes, with difficulty are forced from the water; but when they rise, fly swiftly. Grebes, and also divers, fly with their hind parts downwards, by reason of the forwardness of their wings.

Web-footed fowl are various in their flight. Several have a failing or flagging wing, such as gulls. Penguins, and a single auk, are denied the power of flight. Wild geese, in their migrations, do not fly pell-mell, but in a regular figure, in order to cut the air with greater ease; for example, in long lines, in the figure of a >, or some pointed form or letter, as the ancients report that the cranes assumed in their annual migrations, till their order was broken by storms.

*Strymona sic gelidum, bruma peltate, relinquunt,  
Polaris te, Nile, GRUES, primoque volatus  
Effugunt varios, casu monstrante, figuras.  
Mex ubi percussit tentis NOTUS altior alas,  
Consulsu temere immixte glomerantur in orbes,  
Et turbata perit dispersis litera \* penais.*

\* TAA.

Lucan. lib. v. l. 711.

## SECT. III. Of the Nuptials, Nidification, and Eggs of Birds.

1. MOST birds are monogamous, or pair; in spring fixing on a mate, and keeping constant till the cares of incubation and educating the young brood is past. This is the case, as far as we know, with all the birds of the first, second, fourth, and fifth orders.

Birds that lose their mates early, associate with others; and birds that lose their first eggs will pair and lay again. The male, as well as the female, of several, join alternately in the trouble of incubation, and always in that of nutrition; when the young are hatched, both are busied in looking out for and bringing food to the nestlings; and, at that period the mates of the melodious tribes, who, before, were perched on some sprig, and by their warbling alleviated the care of the females confined to the nest, now join in the common duty.

Of the gallinaceous tribe, the greatest part are polygamous, at least in a tame state; the pheasant, many of the grouse, the partridges, and bustards, are monogamous; of the grouse, the cock of the wood, and the black game, assemble the females during the season of love, by their cries,

*Et venerem incertam rapiunt.*

The males of polygamous birds neglect their young; and, in some cases, would destroy them, if they met with them. The œconomy of the struthious order, in this respect, is obscure. It is probable that the three species in the genus ostrich are polygamous, like the common poultry, for they lay many eggs; the dodo is said to lay but one.

All waders or cloven-footed fowl are monogamous; and all with pinnated feet, are also monogamous, except the ruffs.

The swimmers or web-footed fowl observe the same order, as far as can be remarked with any certainty; but many of the auks assemble in the rocks in such numbers, and each individual so contiguous, that it is not possible to determine their method in this article.

It may be remarked, that the affection of birds to their young is very violent during the whole time of nutrition, or as long as they continue in a helpless state; but, so soon as the brood can fly and shift for itself, the parents neglect, and even drive it from their haunts, the

Nidification the affection ceasing with the necessity of it: but, during that period,

The mothers nurse it, and the fires defend.  
The young dismiss'd, to wander earth, or air,  
There stops the instinct, and there ends the care:  
The link dissolves; each seeks a fresh embrace;  
Another love succeeds, another race.

2. The Nest of a bird is one of those daily miracles that from its familiarity is passed over without regard. We stare with wonder at things that rarely happen, and neglect the daily operations of nature that ought first to excite our admiration and claim our attention.

Each bird, after nuptials, prepares a place suited to its species, for the depositing its eggs and sheltering its little brood: different genera, and different species, set about the task in a manner suitable to their several natures; yet, every individual of the same species collects the very same materials, puts them together in the same form, and chooses the same sort of situation for placing this temporary habitation. The young bird of the last year, which never saw the building of a nest, directed by a heaven-taught sagacity, pursues the same plan in the structure of it, and selects the same materials as its parent did before. Birds of the same species, of different and remote countries, do the same. The swallows of Britain, and of the remoter parts of Germany, observe the same order of architecture.

The nests of the larger rapacious birds are rude, made of sticks and bents, but often lined with something soft; they generally build in high rocks, ruined towers, and in desolate places: enemies to the whole feathered creation, they seem conscious of attacks, and seek solitude. A few build upon the ground.

Shrikes, the least of rapacious birds, build their nests in bushes, with moss, wool, &c.

The order of pies is very irregular in the structure of their nests. Parrots, and in fact all birds with two toes forward and two backward, lay their eggs in the hollows of trees. And most of this order creep along the bodies of trees, and lodge their eggs also within them.

Crows build in trees: among them, the nest of the magpie, composed of rude materials, is made with much art, quite covered with thorns, and only a hole left for admittance.

The nests of the orioles are contrived with wonderful sagacity, and are hung at the end of some bough, or between the forks of extreme branches. In Europe, only three birds have pensile nests; the common oriole, the parus pendulinus, or hang-nest titmouse, and one more. But in the torrid zones, where the birds fear the search of the gliding serpent and inquisitive monkey, the instances are very frequent; a marvellous instinct implanted in them for the preservation of their young.

All of the gallinaceous and struthious orders lay their eggs on the ground. The ostrich is the only exception, among birds, of the want of natural affection: "Which leaveth her eggs in the earth, and warmeth them in the dust, and forgetteth that the foot may crush them, or the wild beast may break them."

The columbine race makes a most artless nest, a few sticks laid across may suffice.

Most of the passerine order build their nests in shrubs or bushes, and some in holes of walls or banks.

Several in the Torrid Zone are pensile from the boughs of high trees; that of the taylor-bird, a wondrous instance†. Some of this order, such as larks, and the goatfucker, on the ground. Some swallows make a curious plaster-nest beneath the roofs of houses; and an Indian species, one of a certain glutinous matter, which are collected as delicate ingredients for soups of Chinese epicures. See the article *Birds-Nests*.

Most of the cloven-footed water-fowl, or waders, lay upon the ground. Spoonbills and the common heron build in trees, and make up large nests with sticks, &c. Storks build on churches, or the tops of houses.

Coots make a great nest near the water-side.

Grebes, in the water, a floating nest, perhaps adhering to some neighbouring reeds.

Web-footed fowl breed on the ground, as the avoet, terns, some of the gulls, mergansers, and ducks: the last pull the down from their breasts, to make a softer and warmer bed for their young. Auks and guillemots lay their eggs on the naked shelves of high rocks; penguins, in holes under ground: among the pelicans, that which gives name to the genus, makes its nest in the desert, on the ground. Shags, sometimes on trees; corvorants and gannets, on high rocks, with sticks, dried algæ, and other coarse materials.

3. Rapacious birds, in general, lay few Eggs; eagles, and the larger kinds, fewer than the lesser. The eggs of falcons and owls are rounder than those of most other birds; they lay more than six.

The order of pies vary greatly in the number of their eggs.

Parrots lay only two or three white eggs.

Crows lay six eggs, greenish, mottled with dusky.

Cuckoos, as far as we can learn, two.

Woodpeckers, wryneck, and kingsfisher, lay eggs of a clear white and semi-transparent colour. The woodpeckers lay six, the others more.

The nuthatch lays often in the year, eight at a time, white, spotted with brown.

The hoopoe lays but two cinerous eggs.

The creeper lays a great number of eggs.

The honeyfucker, the least and most defenceless of birds, lays but two: but Providence wisely prevents the extinction of the genus, by a swiftness of flight that eludes every pursuit.

The gallinaceous order, the most useful of any to mankind, lay the most eggs, from 8 to 20. *Benigna circa hoc natura, innocua et esculenta animalia fecunda generavit*, is a fine observation of Pliny. With exception to the bustard, a bird that hangs between the gallinaceous and the waders, which lays only two.

The columbine order lays but two white eggs; but the domestic kind, breeding almost every month, supports the remark of the Roman naturalist.

All of the passerine order lay from four to six eggs; except the titmice and the wren, which lay 15 or 18, and the goatfucker, which lays only two.

The struthious order, which consists but of two genera, disagree much in the number of eggs: the ostrich laying many, as far as 50; the dodo, but one.

System.

System.

The cloven-footed water-fowl, or waders, lay, in general, four eggs: The crane and the Norfolk plover, seldom more than two. All those of the snipe and plover genus are of a dirty white, or olive spotted with black, and scarce to be distinguished in the holes they lay in. The bird called the Land Rail, (an ambiguous species,) lays from 15 to 20. Of birds with pinnated feet, the coot lays seven or eight eggs, and sometimes more. Grebes, from four to eight, and those white.

The web-footed, or swimmers, differ in the number of their eggs. Those which border on the order of waders, lay few eggs; the avoet, two; the flamingo, three; the albatross, the auks, and guillemots, lay only one egg a-piece: the eggs of the two last are of a size strangely large in proportion to the bulk of the birds. They are commonly of a pale green colour, spotted, and striped variously, that not two are alike; which gives every individual the means of distinguishing its own on the naked rock, where such multitudes assemble.

Divers, only two.

Terns and gulls lay about three eggs, of a dirty olive, spotted with black.

Ducks lay from eight to twenty eggs; the eggs of all the genus are of a pale green, or white, and unspotted.

Penguins probably lay but one egg.

Of the pelican genus, the gannet lays but one egg; the shags or corvorants, six or seven, all white; the last, the most oblong of eggs.

A minute account of the eggs of birds might occupy a treatise of itself. This is only meant to shew the great conformity nature observes in the shape and colours of the eggs of congenerous birds; and also, that she keeps the same uniformity of colour in the eggs, as in the plumage of the birds they belong to.

Zinanni published, at Venice, in 1737, a treatise on eggs, illustrated with accurate figures of 106 eggs. Mr Reyger of Dantzick published in 1766, a posthumous work by Klein, with 21 plates, elegantly coloured: but much remains for future writers.

#### SECT. IV. System.

CONSIDERING the many systems that have been offered to the public of late years, Mr Pennant gives the preference to that composed by Mr Ray in 1667, and afterwards published in 1678; but observes, at the same time, that it would be unfair to conceal the writer, from whom our great countryman took the original hint of forming that system which has proved the foundation of all that has been composed since that period.

It was a Frenchman, Belon of Mans, who first attempted to range birds according to their natures; and performed great matters, considering the unenlightened age he lived in; for his book was published in 1555. His arrangement of rapacious birds is as judicious as that of the latest writers. For his second chapter treats of vultures, falcons, shrikes, and owls: in the two next, he passes over to the web-footed water-fowl, and to the cloven-footed: in the fifth, he includes the gallinaceous and struthious; but mixes with them the

plovers, buntings, and larks: in the sixth are the pies, pigeons, and thrushes; and the seventh, takes in the rest of the passerine order.

Notwithstanding the great defects that every naturalist will at once see in the arrangement of the lesser birds of this writer, yet he will observe a rectitude of intention in general, and a fine notion of system, which was left to the following age to mature and bring to perfection. Accordingly, Mr Ray, and his illustrious pupil the Hon. Francis Willughby, assumed the plan; but, with great judgment, sung into their proper Rations and proper genera those which Belon had confusedly mixed together. They formed the great division of terrestrial and aquatic birds; they made every species occupy their proper place, consulting at once exterior form and natural habit. They could not bear the affected intervention of aquatic birds in the midst of terrestrial birds. They placed the last by themselves; clear and distinct from those whose haunts and economy were so different.

The subjoined scheme of arrangement by Mr Pennant, is introduced with the following observations.

"Mr Ray's general plan is so judicious, that to me it seems scarce possible to make any change in it for the better: yet, notwithstanding he was in a manner the founder of systematic Zoology, later discoveries have made a few improvements on his labours. My candid friend Linnaeus will not take it amiss, that I, in part, neglect his example: for I premit the land-fowl to follow one another, undivided by the water-fowl, the grallæ and anseres of his system; but, in my generic arrangement, I most punctually attend to the order he has given in his several divisions, except in those of his anseres, and a few of his grallæ. For, after the manner of Mr Brisson, I make a distinct order of water-fowl with pinnated feet, placing them between the waders or cloven-footed water-fowl and the web-footed. The ostrich, and land-birds with wings useless for flight, I place as a distinct order. The trumpeter (*psophia* Linnaei), and the buffards, I place at the end of the gallinaceous tribe. All are land-birds. The first multiparous, like the generality of the gallinaceous tribe; the last granivorous, swift runners, avoiders of wet places; and both have bills somewhat arched. It must be confessed, that both have legs naked above the knees; and the last, like the waders, lay but few eggs. They seem ambiguous birds that have affinity with each order; and it is hoped, that each naturalist may be indulged the toleration of placing them as suits his own opinion."

"See Zoology."

Ornithomancy, Orobus.

Oroonoko  
Orpheus.

ORNITHOMANCY, a species of divination performed by means of birds; by the same with augury. See DIVINATION and AUGURY.

OROBUS, BITTER VETCH; a genus of the diandria order, belonging to the diadelphia class of plants. There are nine species. All of them have fibrous roots, which are perennial, but are annual in stalk, rising early in spring and decaying in autumn. They are very hardy plants, and prosper in any common soil of a garden. Molt of the forts are very floriferous, and the flowers conspicuous and ornamental for adorning the flower compartments. The flowers are universally of the papilionaceous or butterfly kind, consisting each of four irregular petals, *i. e.* a standard, two wings, and a keel; and are all succeeded by long taper seed-pods, furnishing plenty of ripe seed in autumn; by which the plants may be propagated abundantly, as also by parting the roots.

The Scots Highlanders have a great esteem for the tubercles of the roots of the tuberofus, or species sometimes called *wood-pea*. They dry and chew them in general to give a better relish to their liquor; they also affirm that they are good against molt disorders of the breast, and that by the use of them they are enabled to resist hunger and thirst for a long time. In Breadalbane and Ross-shire, they sometimes bruise and steep them in water, and make an agree-

able fermented liquor with them. They have a sweet taste, something like the roots of liquorice; and when boiled, we are told, they are nutritious and well flavoured; and in times of scarcity, they have served as a substitute for bread.

OROONOKO, a great river of terra firma, in South America, which rises in Popayan, and falls into the sea with 16 mouths.

ORPHAN, a fatherless child, or minor; or one that is deprived both of father and mother.

ORPHEUS, a celebrated poet and musician of antiquity. His reputation was established as early as the time of the Argonautic expedition, in which he was himself an adventurer; and is said by Apollonius Rhodius not only to have incited the Argonauts to row by the sound of his lyre, but to have vanquished and put to silence the fires by the superiority of his strains. Yet, notwithstanding the great celebrity he had so long enjoyed, there is a passage in Cicero, which says, that Aristotle, in the third book of his *Poetics*, which is now lost, doubted if such a person as Orpheus ever existed. But as the work of Cicero, in which this passage occurs, is in dialogue, it is not easy to discover what was his own opinion upon the subject, the words cited being put into the mouth of Caius Cotta. And Cicero, in other parts of his writings, mentions Orpheus as a person of whose exist-

Orpheus. once he had no doubts. There are several ancient authors, among whom is Suidas, who enumerates five persons of the name of *Orpheus*, and relates some particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to *one* the actions of *many*. But, however that may have been, we shall not attempt to collect all the fables that poets and mythologists have invented concerning him; they are too well known to need insertion here. We shall, therefore, in speaking of him, make use only of such materials as the best ancient historians, and the most respectable writers among the moderns, have furnished towards his history.

Dr Cudworth, in his *Intellectual System*, after examining and confuting the objections that have been made to the being of an Orpheus, and with his usual learning and abilities clearly establishing his existence, proceeds, in a very ample manner, to speak of the opinions and writings of our bard, whom he regards not only as the first musician and poet of antiquity, but as a great mythologist, from whom the Greeks derived the Thracian religious rites and mysteries.

"It is the opinion (says he) of some eminent philologists of later times, that there never was any such person as Orpheus, except in Fairy-land; and that his whole history was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there is nothing alleged for this opinion from antiquity, except the one passage of Cicero concerning Aristotle: who seems to have meant no more than this, that there was no such poet as Orpheus, anterior to Homer; or that the verses vulgarly called *Orphical*, were not written by Orpheus. However, if it should be granted that Aristotle had denied the existence of such a man, there seems to be no reason why his single testimony should preponderate against the universal consent of all antiquity: which agrees, that Orpheus was the son of Oeager, by birth a Thracian, the father or chief founder of the mythological and allegorical theology amongst the Greeks, and of all their most sacred religious rites and mysteries; who is commonly supposed to have lived before the Trojan war, that is, in the time of the Israelitish judges, or at least to have been senior both to Hesiod and Homer; and to have died a violent death, most affirming that he was torn in pieces by women. For which reason, in the vision of Herus Pamphilus, in Plato, Orpheus's soul passing into another body, is said to have chosen that of a swan, a reputed musical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the historic truth of Orpheus was not only acknowledged by Plato, but also by Iocrates, who lived before Aristotle, in his oration in praise of Buhria; and confirmed by the grave historian Diodorus Siculus, who says, that Orpheus diligently applied himself to literature, and when he had learned τα μυθολογούμενα, or the mythological part of theology, he travelled into Egypt, where he soon became the greatest proficient among the Greeks in the mysteries of religion, theology, and poetry. Neither was his history of Orpheus contradicted by Origen, when so justly provoked by Celsus, who had preferred him to our Saviour; and,

according to Suidas, Orpheus the Thracian was the first inventor of the religious mysteries of the Greeks, and that religion was thence called *Threskeia*, as it was a Thracian invention. On account of the great antiquity of Orpheus, there have been numberless fables intermingled with his history, yet there appears no reason that we should disbelieve the existence of such a man."

The bishop of Gloucester speaks no more doubtfully of the existence of Orpheus, than of Homer and Hesiod, with whom he ranks him, not only as a poet, but also as a theologian, and founder of religion.

The family of Orpheus is traced by Sir Isaac Newton for several generations: "Sefac passing over the Hellespont, conquers Thrace; kills Lycurgus, king of that country; and gives his kingdom and one of his singing-women to Oeagrus, the son of Tharops, and father of Orpheus; hence Orpheus is said to have had the muse Calliope for his mother."

He is allowed by most ancient authors to have excelled in poetry and music, particularly the latter; and to have early cultivated the lyre, in preference to every other instrument: so that all those who came after him were contented to be his imitators; whereas he adopted no model, says Plutarch; for before his time no other music was known, except a few airs for the flute. Music was so closely connected in ancient times with the most sublime sciences, that Orpheus united it not only with philosophy, but with theology. He abstained from eating animal food; and held eggs in abhorrence as aliment, being persuaded that the egg subsisted before the chicken, and was the principle of all existence: both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as those of Pythagoras many ages after.

With respect to his abstaining from the flesh of oxen, Gelfer supposes it may have proceeded from the veneration shewn to that animal so useful in tillage, in the Eleusinian mysteries, instituted in honour of Ceres, the goddess of agriculture. He might have added that, as these mysteries were instituted in imitation of those established in Egypt in honour of Osiris and Isis, this abstinence from animal food was of the the origin, and a particular compliment to Apis. But likeabbé Fraguier, in an ingenious dissertation upon the *Orphic Life*, gives still more importance to the prohibition; for as Orpheus was the legislator and humanizer of the wild and savage Thracians, who were cannibals, a total abolition of eating human flesh could only be established by obliging his countrymen to abstain from every thing that had life.

With respect to theology, Diodorus Siculus tells us, that his father Oeagrus gave him his first instructions in religion, imparting to him the mysteries of Bacchus, as they were then practised in Thrace. He became afterwards a disciple of the Idæi Daactyli in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed so much to his skill in theological matters, as his journey into Egypt; where being initiated into the mysteries of Isis and Osiris, or of Ceres and Bacchus, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worship, far superior to any one of his age and country. And being much

Orpheus.

Burney's  
Hist. of  
Music,  
p. 320 &c.

Orpheus. much connected with the descendants of Cadmus, the founder of Thebes in Boeotia, he resolved, in order to honour their origin, to transport into Greece the whole fable of Orpheus, and apply it to the family of Cadmus. The credulous people easily received this tale, and were much flattered by the institution of the ceremonies in honour of Orpheus. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he was become a citizen, admirably adapted this fable, and render it respectable, not only by his beautiful verses, and manner of singing them, but by the reputation he had acquired of being profoundly skilled in all religious concerns.

At his return into Greece, according to Pausanias, he was held in the highest veneration by the people, as they imagined he had discovered the secret of expiating crimes, purifying criminals, curing diseases, and appeasing the angry gods. He formed and promulgated an idea of a hell, from the funeral ceremonies of the Egyptians, which was received throughout all Greece. He instituted the mysteries and worship of Hecate among the Eginetes, and that of Ceres at Sparta.

Justin Martyr says, that he introduced among the Greeks near 360 gods; Hesiod and Homer pursued his labours, and followed the same clue, agreeing in the like doctrines, having all drank at the same Elysian fountain.

Profane authors look upon Orpheus as the inventor of that species of magic called *evocation of the manes*, or raising ghosts; and indeed the hymns which are attributed to him are mostly pieces of incantation, and real conjuration. Upon the death of his wife Eurydice, he retired to a place in Thesprotia, called *Aornas*, where an ancient oracle gave answers to such as evoked the dead. He there fancied he saw his dear Eurydice, and at his departure flattered himself that he followed him; but upon looking behind him, and not seeing her, he was so afflicted, that he soon died of grief.

There were persons among the ancients who made public profession of conjuring up ghosts, and there were temples where the ceremony of conjuration was to be performed. Pausanias speaks of that which was in Thesprotia, where Orpheus went to call up the ghost of his wife Eurydice. It is this very journey, and the motive which put him upon it, that made it believed he went down into hell.

But it is not only the poets who speak of conjuring up spirits; examples of it are to be found both in sacred and profane history. Perianther, the tyrant of Corinth, visited the Thesprotians, to consult his wife about something left with her in trust; and we are told by the historians, that the Lacedæmonians having starved Pausanias their general to death, in the temple of Pallas, and not being able to appease his manes, which tormented them without intermission, sent for the magicians from Thessaly, who, when they had called up the ghosts of his enemies, so effectually put to flight the ghost of Pausanias, that it never more chose to shew its face.

The poets have embellished this story, and given to the lyre of Orpheus, not only the power of silencing Cerberus, and of suspending the torments of Tartarus, but also of charming even the infernal dei-

ties themselves, whom he rendered so far propitious to his intreaties as to restore to him Eurydice, upon condition that he would not look at her till he had quitted their dominions; a blessing which he soon forfeited by a too eager and fatal curiosity.

All dangers past, at length the lovely bride  
In safety goes, with her melodious guide;  
Longing the common light again to share,  
And draw the vital breath of upper air:  
He first, and close behind him follow'd she;  
For such was Proserpine's severe decree.  
When strong desires th' impatient youth invade,  
By little caution, and much love betray'd:  
A fault which easy pardon might receive,  
Were lovers judges, or could hell forgive.  
For near the confines of ethereal light,  
And longing for the glimm'ring of a sight,  
Th' unwary lover cast a look behind,  
Forgetful of the law, nor matter of his mind.  
Straight all his hopes exhal'd in empty smoke;  
And his long toils were forfeit for a look.

DRYDEN'S Virgil.

Tzetzes explains the fable of his drawing his wife Eurydice from hell, by his great skill in medicine, with which he prolonged her life, or, in other words, snatched her from the grave. Æsculapius, and other physicians, have been said to have raised from the dead, those whom they had recovered from dangerous diseases.

The bishop of Gloucester, in his learned, ample, and admirable account of the Eleusinian mysteries, says, "While these mysteries were confined to Egypt their native country, and while the Grecian lawgivers went thither to be initiated, as a kind of designation to their office, the ceremony would be naturally described in terms highly allegorical. This way of speaking was used by Orpheus, Bacchus, and others; and continued even after the mysteries were introduced into Greece, as appears by the fables of Hercules, Castor, Pollux, and Theseus's descent into hell; but the allegory was so circumflamed, as to discover the truth concealed under it. So Orpheus is said to get to hell by the power of his harp:

*Thracia fretus citior, fidibusque canoris.*

Virg. Æn. VI. ver. 119.

That is, in quality of lawgiver; the harp being the known symbol of his laws, by which he humanized a rude and barbarous people.—Had an old poem, under the name of *Orpheus*, entitled, *A descent into Hell*, been now extant, it would perhaps have shewn us, that no more was meant than Orpheus's initiation."

Many ancient writers, in speaking of his death, relate, that the Thracian women, enraged at being abandoned by their husbands, who were disciples of Orpheus, concealed themselves in the woods, in order to satiate their vengeance; and, notwithstanding they postponed the perpetration of their design some time thro' fear, at length, by drinking to a degree of intoxication, they so far fortified their courage as to put him to death. And Plutarch assures us, that the Thracians stigmatized their women, even in his time, for the barbarity of this action.

Our venerable bard is defended by the author of the *Divine Legation*, from some insinuations to his disadvantage in Diogenes Laertius. "It is true (says he) if uncertain report was to be believed, the mysteries were

**Orpheus.** were corrupted very early; for Orpheus himself is said to have abused them. But this was an art the debauched myſtæ of later times employed to varnish their enormities; as the deteſted pederalts of after-ages, ſcandalized the blameleſs Socrates. Beſides, the ſtory is fo ill laid, that it is detected by the ſureſt records of antiquity; for in conſequence of what they fabled of Orpheus in the myſteries, they pretended he was torn in pieces by the women; whereas it appeared from the inſcription on his monument at Dium in Macedonia, that he was ſtruck dead with lightning, the envied death of the reputed favourites of the gods."

This monument at Dium, conſiſting of a marble urn on a pillar, was ſtill to be ſeen in the time of Pauſanias. It is ſaid, however, that his ſepulchre was removed from Libethra, upon mount Olympus, where Orpheus was born, and from whence it was transferred to Dium by the Macedonians, after the ruin of Libethra by a ſudden inundation which a dreadful ſtorm had occaſioned. This event is very minutely related by Pauſanias.

Vigil beſtows the firſt place in his Elyſium upon the legiſlators, and *theſe who brought mankind from a ſtate of nature into ſociety:*

*Magnanimi heros, nati melioribus annis.*

At the head of theſe is Orpheus, the moſt renowned of the European law-givers, but better known under the character of poet: for the firſt laws being written in meſure, to allure men to learn them, and, when learnt, to retain them, the ſable would have it, that by the force of harmony Orpheus ſoftened the ſavage inhabitants of Thrace:

—*Threicius longa cum veſte ſacerdos*  
*Obloquitur numeris ſcriptum diſcrimina vocum:*  
*Tamque eadem digiti, jam peſſime poſuiſſe eburn.*

*ÆN. lib. vi. ver. 645.*

The ſeven ſtrings given by the poet in this paſſage to the lyre of Orpheus, is a circumſtance ſomewhat hiſtorical. The firſt Mercurian lyre had, at moſt, but four ſtrings. Others were afterwards added to it by the ſecond Mercury, or Amphon: but according to ſeveral traditions preſerved by Greek hiſtorians, it was Orpheus who completed the ſecond tetrachord, which extended the ſcale to a heptachord, or *ſeven ſounds*, implied by the *ſeptem diſcrimina vocum*. For the aſſertion of many writers, that Orpheus added two new ſtrings to the lyre, which before had ſeven, claſhes with the claims of Pythagoras to the invention of the octachord, or addition of the ſound *proſambano-menos* to the heptachord, of which almoſt all antiquity allows him to have been the inventor. And it is not eaſy to ſuppoſe, that the lyre ſhould have been repreſented in ancient ſculpture with four or five ſtrings only, if it had had nine ſo early as the time of Orpheus, who flouriſhed long before ſculpture was known in Greece. See the article **LYRE**.

With reſpect to the writings of Orpheus, he is mentioned by Pindar as author of the Argonautics, and Herodotus ſpeaks of his Orphics. His hymns, ſays Pauſanias, were very ſhort, and but few in number: the Lycomides, an Athenian family, knew them by heart, and had an excluſive privilege of ſinging them, and thoſe of their old poets, Muſæus, Onomacritus,

Pamphus, and Olen, at the celebration of the Eleuſinian myſteries; that is, the prieſthood was hereditary in this family.

Jamblicus tells us, that the poems under the name of *Orpheus* were written in the Doric dialect, but have ſince been tranſdialected, or moderniſed. It was the common opinion in antiquity that they were genuine; but even thoſe who doubted of it, gave them to the earlieſt Pythagoreans, and ſome of them to Pythagoras himſelf, who has frequently been called the *ſollower of Orpheus*, and been ſuppoſed to have adopted many of his opinions.

Of the poems that are ſtill ſubſiſting under the name of *Orpheus*, which were collected and publiſhed at Nuremberg 1702, by Andr. Chriſt. Eſchenbach, and which have been ſince reprinted at Leiſpſie 1764, under the title of *OPHES APANTA*, ſeveral have been attributed to Onimacritus, an Athenian, who flouriſhed under the Pyſiſtratiæ, about 500 years before Chriſt. Their titles are, 1. The Argonautics, an epic poem. 2. Eighty-fix hymns; which are ſo full of incantations and magical evocation, that Daniel Heinfius has called them *veram Satane liturgiam*, "the true liturgy of the devil." Pauſanias, who made no doubt that the hymns ſubſiſting in his time were compoſed by Orpheus, tells us, that tho' leſs elegant, they had been preferred for religious purpoſes to thoſe of Homer. 3. *De lapidibus*, a poem on precious ſtones. 4. Fragments, collected by Henry Stevens. Orpheus has been called the *inventor*, or at leaſt the *propagator*, of many arts and doctrines among the Greeks. 1. The *combination of letters*, or the art of writing. 2. *Music*, the lyre, or cithara, of ſeven ſtrings, adding three to that of Mercury. 3. *Hexameter verſe*. 4. *Myſteries and theology*. 5. *Medicine*. 6. *Magic and divination*. 7. *Aſtrology*. Servius upon the ſixth *Æneid*, p. 450, ſays Orpheus firſt inflicted the *harmony of the ſpheres*. 8. He is ſaid likewiſe to have been the firſt who imagined a *plurality of worlds*, or that the moon and planets were inhabited.

**ORPIMENT**, in natural hiſtory, a ſoſſile ſubſtance uſually found in copper-mines, compoſed of thin flakes like the tales; theſe eaſily ſplit, are flexible, not elaſtic, ſoluble in oil, ſuſible in a moderate fire, and yield in burning an off-eſſive ſmell like garlic.

**ORPINE**, in botany. See **SEDUM**.

**ORRERY**, a curious machine for repreſenting the motions or phaſes of the heavenly bodies. See **ASTRONOMY**, n<sup>o</sup> 317.

It would be too great an undertaking here to give an account of the mechanism of the larger ſort of orreries, which repreſent the movements of all the heavenly bodies; nor indeed can it be done either by diagram or deſcription, to render it intelligible to the moſt diſcerning reader: but, inſtead of that, we ſhall exhibit an idea of the theory and ſtructure of an uſeful, conciſe, and portable planetarium, which any gentleman may have made for a ſmall expence, and will exhibit, very juſtly, the motions of all the primary planets about the ſun, by wheel-work; and thoſe that have ſecondaries, or moons, may have them placed about their primaries moveable by the hand, ſo that the whole ſhall be a juſt repreſentation of the ſolar ſyſtem, or true ſtate of the heavens, for any given time of the year.

Orpheus  
Orrery.

Orrey

Orfatio.

Orfi

Orthogra-  
phy.

In order to this we must compare, and find out the proportion, which the periodical times, or revolutions of the primary planets, bear to that of the earth: And they are such as are expressed in the table below, where the first column is the time of the earth's period in days and decimal parts; the second, that of the planets; the third and fourth are numbers in the same proportion to each other: as,

365,25 : 88      ♄ :: 83 : 20, for Mercury.

365,25 : 224,7      ♀ :: 52 : 32, for Venus.

365,25 : 686,9      ♂ :: 40 : 75, for Mars.

365,25 : 4332,5      ♃ :: 7 : 83, for Jupiter.

365,25 : 10759,3      ♄ :: 5 : 148, for Saturn.

If we now suppose a spindle or arbour with fix wheels fixed upon it in an horizontal position, having the number of teeth in each, corresponding to the numbers in the third column, viz. the wheel AM of 83 teeth, BL of 52, CK of 50 (for the earth), DI of 40, EH of 7, and FG of 5; and another set of wheels moving freely about an arbor, having the number of teeth in the fourth column, viz. AN of 20, BO of 32, CP of 50 (for the earth), DQ of 75, ER of 83, and FS of 148; then, if those two arbors of fixed and moveable wheels are made of the size, and fixed at the distance from each other, as here represented in the scheme, the teeth of the former will take those of the latter, and turn them very freely when the machine is in motion.

These arbors, with their wheel, are to be placed in a box, of an adequate size, in a perpendicular position: the arbor of fixed wheels to move in pivots at the top and bottom of the box; and the arbor of moveable wheels to go thro' the top of the box, to a proper height, on the top of which is to be placed a round ball, gilt with gold to represent the sun. On each of the moveable wheels is to be fixed a socket, or tube, ascending above the top of the box, and having on the top a wire fixed, and bent at a proper distance into a right angle upwards, bearing on the top a small round ball, representing its proper planets.

If then on the lower part of the arbor of fixed wheels be placed a pinion of screw-teeth, a winch turning a spindle with an endless screw, playing in the teeth of the arbour, will turn it with all its wheels; and these wheels will move the others about, with their planets, in their proper and respective periods of time, very exactly. For while the fixed wheel CK moves its equal CP once round, the wheel AM will move AN a little more than four times round, and so will nicely exhibit the motion of Mercury; and the wheel FG will turn the wheel FS about  $\frac{1}{29,5}$  round, and so

will truly represent the motion of Saturn: and the same is to be observed of all the rest.

ORREY (Earls of). See BOYLE.

ORRICE. See IRIS.

ORSATO (Sertorio), a celebrated antiquarian, historian, and poet, was born at Padua, in 1617, and early discovered a taste for literature and the sciences. He applied himself to searching out antiquities and ancient inscriptions; for which purpose he travelled thro' all the different parts of Italy, and in the mean time poetry was his amusement. When advanced in age, he taught natural philosophy in the university of Padua. He was also a member of the academy of the

Ricovrati. Having presented to the doge and senate of Venice, the history of Padua, which he had dedicated to them, he made a long speech, during which he struggled with a natural want, and died of suppression of urine, on the 3d of July 1678. He wrote a great number of books which are esteemed, some in Latin, and others in Italian.

He ought not to be confounded with *John Baptist OSSATO*, an able physician and antiquary, who was born at Padua, in 1673, and wrote, 1. *Dissertatio epistolaris de Lucernis antiquis*. 2. A dissertation *De patra antiquorum*. 3. A small treatise *De sternis veterum*; and some other works.

ORSI (John Joseph), an ingenious philologer and poet, was born at Bologna in the year 1652; and studied polite literature, philosophy, the civil law, and mathematics. His house was a kind of academy, where many persons of literature regularly assembled. He wrote many ingenious sonnets, pastorals, and other works in Italian, and died in 1733.

ORTEGAL CAPE, the most northern promontory of Spain, where there is also a castle of the same name. W. Long. 8. 20. N. Lat. 44. o.

ORTELIUS (Abraham), a celebrated geographer, born at Antwerp, in 1527, was well skilled in the languages and the mathematics; and acquired such reputation by his skill in geography, that he was sur-named the *Ptolemy of his time*. Justus Lipsius, and most of the great men of the 16th century, were Ortelius's friends. He resided at Oxford, in the reign of Edward VI. and came a second time into England, in 1577. His *Theatrum Orbis* was the completest work of the kind that had ever been published, and gained him a reputation equal to his immense labour in compiling it. He also wrote several other excellent geographical works; the principal of which are his *Theasaurus*, and his *Synonyma Geographica*. The world is likewise obliged to him for the *Britannia*, which he persuaded Camden to undertake. He died at Antwerp, in 1598.

ORTHODOX, in church-history, an appellation given to those who are found in all the articles of the Christian faith.

ORTHOGRAPHIC PROJECTION of the SPHERE, that wherein the eye is supposed to be at an infinite distance; so called, because the perpendiculars from any point of the sphere will all fall in the common intersection of the sphere with the plane of the projection. See GEOGRAPHY, n° 13. 41. and PROJECTION.

ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words, with all the proper and necessary letters; making one of the four greatest divisions or branches of grammar. See GRAMMAR.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore-right plan of any object, and of expressing the heights or elevations of each part. It is called *Orthography*, for its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

ORTHOGRAPHY, in perspective, is the fore-right side of any plane, i. e. the side or plane that lies parallel to a straight line, that may be imagined to pass through

Plate  
CCXXX.  
fig. 5.

O. thopnoea  
Oryza.

Oryza,  
Osborn.

through the outward convex points of the eyes, continued to a convenient length.

**ORTHOPNOEA**, a species or degree of asthma, where there is such a difficulty of respiration, that the patient is obliged to sit or stand upright, in order to be able to breathe. See *MEDICINE*, n° 396.

**ORTNAU**, a county of Germany, in the circle of Suabia, lying along the Rhine, and separating it from Alsace. It is bounded on the south by Breisau, on the north by the margravate of Baden, and on the east by the duchy of Wirtemberg. It contains three imperial towns; namely, Oßsenburg, Gegenbach, and Zell. It belongs partly to the house of Austria, partly to the bishopric of Spire, and partly to the county of Hannau.

**ORTIVE**, in astronomy, the same with *eastern*. The ortive or eastern amplitude, is an arch of the horizon intercepted between where a star rises, and the east point of the horizon, or point where the horizon and equator intersect.

**ORVIETO**, a town of Italy in the patrimony of St Peter, with a bishop's see and a magnificent palace. In this place there is a deep well, into which mules descend by one pair of stairs to fetch up water, and ascend by another. It is seated on a craggy rock, near the confluence of the rivers Pagli and Chiana. E. Long. 12. 10. N. Lat. 42. 42.

**ORYZA**, rice; a genus of the digynia order, belonging to the hexandria class of plants. There is but one species, namely the sativa or common rice. This plant is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is much esteemed for puddings, &c. it being too tender to be produced in these northern countries without the assistance of artificial heat; but from some seeds which were formerly sent to Carolina, there have been great quantities produced, and it is found to succeed as well there as in the eastern countries.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up. So that whoever would cultivate it in this country should sow the seeds upon a hot-bed; and when the plants are come up, they should be removed into pots filled with light rich earth, and placed in pans of water, which should be plunged into a hot-bed; and, as the water wastes, it must from time to time be renewed again. In July these plants may be set abroad in a warm situation, still preserving the water in the pans, otherwise they will not thrive; and, toward the latter end of August, they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable.—The leaves of rice are long, like the reed, and fleshy; the flowers blow on the top, like barley; but the seed which follows is disposed in clusters, each of which is inclosed in a yellow husk, ending in a spiral thread. The seed is oblong, or rather oval and white.

Rice is the chief commodity and riches of Damietta in Egypt. Dr Hasselquist gives the following description of the manner in which they dress and separate it from the husks. "It is pounded by hollow iron pestles of a cylindrical form, lifted up by a wheel worked by oxen. A person sitting between the two

pestles, pushes forward the rice when the pestles are rising; another sits, winnows, and lays it under the pestles. In this manner they continue working it until it is entirely free from chaff and husks. When clean, they add a 30th part of salt, and pound them together; by which the rice, formerly grey, becomes white. After this purification, it is passed through a fine sieve to part the salt from the rice; and then it is ready for sale." Damietta sells every year 60,800 sacks of rice, the greatest part of which goes to Turkey, some to Leghorn, Marseilles, and Venice.

Rice, according to Dr Cullen, is preferable to all other kinds of grain, both for largeness of produce, quantity of nourishment, and goodness. This, he says, is plain from macerating the different grains in water; for, as the rice swells to the largest size, so its parts are more intimately divided. Rice is said to affect the eyes; but this is purely prejudice. Thus it is alleged a particular people of Asia, who live on this grain, are blind-eyed: but if the soil be sandy, and not much covered with herbage, and as these people are much employed in the field, this affection of their eyes may be owing to the strong reflection of the rays of light from this sandy soil; and our author is the more inclined to this opinion, because no such effect is observed in Carolina, where rice is very commonly used.

Dr Percival informs us, that as a wholesome nourishment, rice is much inferior to saleg. He digested several alimentary mixtures prepared of mutton and water, beat up with bread, sea-biscuit, saleg, rice flour, sago powder, potato, old cheese, &c. in a heat equal to that of the human body. In 48 hours they had all acquired a vinous smell, and were in brisk fermentation, except the mixture with rice, which did not emit many air-bubbles, and was but little changed. The third day several of the mixtures were sweet, and continued to ferment; others had lost their intestine motion, and were sour; but the one which contained the rice was become putrid. From this experiment it appears that rice, as an aliment, is slow of fermentation, and a very weak corrector of putrefaction. It is therefore an improper diet for hospital patients; but more particularly for sailors, in long voyages, because it is incapable of preventing, and will not contribute much to check the progress of, that fatal disease, the sea-scurvy. Under certain circumstances, rice seems disposed of itself, without mixture, to become putrid. For by long keeping, it sometimes acquires an offensive savor. Nor, according to our author, can it be considered as a very nutritive kind of food, on account of its difficult solubility in the stomach. Experience confirms the truth of this conclusion; for it is observed by the planters in the West-Indies, that the negroes grow thin, and are less able to work, whilst they subsist upon rice.

**OSBORN** (Francis), an eminent English writer in the 17th century. He was educated in a private manner; and at ripe years frequented the court, and was master of the horse to William earl of Pembroke. Upon the breaking out of the civil wars, he adhered to the parliament party, and had several public employments conferred upon him. In the latter part of his life he lived at Oxford, in order to print several books, and to look after his son, for whom, by the favour of the parliament, he procured a fellowship in All-souls

Oſiris  
Oſnaburg.

Oſnaburg  
Oſſian.

fouls college. His Advice to a Son, fo ſoon as it was publiſhed, being complained of to Dr. John Tenant, vice-chancellor of Oxford, as of irreligious tendency, there was a propoſal made to have it publicly burnt; but that taking no effect, it was ordered that no bookſeller or others ſhould ſell it, which only made it ſell the faſter. He wrote alſo Hiſtorical Memoirs of the reigns of queen Elizabeth and king James I.; A Diſcourſe on the greatneſs and corruption of the church of Rome; A Diſcourſe upon Machiavel, &c. He died in 1659.

OSIRIS, the ſon of Jupiter and Niobe, reigned over the Argives; but afterwards delivered his kingdom to his brother Egialcus, and took a voyage into Egypt, of which he made himſelf maſter, and married Io or Iſis. He eſtabliſhed good laws there, and they were both after their death worſhipped as gods.

OSNABURG, a biſhopric of Germany, ſituated in the centre of the circle of Weltphalia between the Weſer and the Ems, having Minden on the eaſt, Munſter on the weſt, Diepholt on the north-eaſt, and Ravenſburg on the ſouth-weſt. It is about 45 miles long and 25 broad, producing ſome rye, ſeveral forts of turf, coals, marble, and good paſtorage. The inhabitants, who are a mixture of Proteſtants and Roman-catholics, breed a conſiderable number of cattle, eſpecially hogs, of which they make excellent bacon and hams; but a great part of the country conſiſts of heaths. By the treaty concluded here in 1648, the biſhopric was to be an alternative between the Roman-catholics and Lutherans; and the Lutheran biſhop was to be a younger prince of the houſe of Brunſwic Lunenburg, or, on failure thereof, of Brunſwic Wolfenbuttle. In conſequence of this ſettlement, his Britannic majeſty's ſecond ſon is now biſhop of Oſnaburg. The biſhop is able to raiſe 2500 men, his revenue being between 20,000 and 30,000 l. The chief manufactures of the country are a coarſe kind of linen cloth and yarn, which are ſaid to bring into it annually above 1,000,000 of rix dollars. There are alſo ſome woollen manufactures in Oſnaburg and Bramſche. The land-eſtates of the biſhopric, are the chapter, the knights, and the four towns. The diets are held at Oſnaburg, when called together by the biſhop. The count of Bar is hereditary ſeneſchal or ſteward, and preſident of the college of knights. The biſhop is a prince of the empire; and, in the matricula, is rated at 6 horſe and 36 foot, or 216 florins monthly in lieu of them. To the chamber of the empire he contributes, each term, 81 rix-dollars, 14 kruitzers and a half. The capital of this biſhopric is

OSNABURG, or *Oſnabruck*. It was formerly an imperial city, and one of the Hanſe-towns; but is now ſubject to the biſhop, though it ſtill enjoys many privileges, and a revenue of about 8000 or 9000 rix-dollars. It has its name from a bridge over the river Haſe, or Oſe, which divides it into the Old and New Town, and ſtands 67 miles weſt of Hanover, and 30 north-eaſt of Munſter, being ſurrounded with walls and ditches, but commanded by a mountain within cannon-ſhot. The magiſtracy of this city, which is rechoſen yearly on the ſecond of January, is Lutheran; and the churches belong, ſome to the Lutherans, and ſome to the Papifts. Both parties

Vol. VIII.

have the full and free exerciſe of their religion, whether the biſhop is Proteſtant or Papift. The biſhop's palace was built by biſhop Ernſt-Auguſtus, brother to king George I. It is well fortified, and ſeparated from the town by a bridge. In one of the apartments it died king George I. in the arms of his brother, on the 11th of June 1722. This was the firſt town in Weltphalia which received the Lutheran doctrine.

OSNABURG *Iſland*, one of the iſlands in the South Sea diſcovered by captain Wallis in 1767. It is a high, round iſland, not above a league in circuit; in ſome parts covered with trees, in others a naked rock. S. Lat. 22. 48. W. Long. 141. 34.

OSSA, a mountain of Theſſaly, near the Peneus, which runs between this mountain and Olympus; famous in the fabulous ſtory of the giants, (Homer, Virgil, Horace, Seneca, Ovid.) The bending and unbending of its pines, on the blowing of a ſtrong north wind, formed a claiſhing ſound like thunder, (Lucan.)

OSSAT (Arnauld de); born in the dioceſe of Auch in 1536, of mean parentage, was taken notice of by a gentleman in the dioceſe, who made him ſtudy with his ward the Lord of Caſtlenau de Magnoac. He ſtudied the law at Dijon under Cujace, and applied himſelf to the bar at Paris. He was ſecretary at Rome to M. de Foix, archbiſhop of Toulouſe; to cardinal Elze; and afterwards to cardinal de Joyeuſe, by the French king's expreſs command. After riſing to the hiſheſt dignities both in church and ſtate, in 1599 he was created a cardinal by pope Clement VIII. He died in 1604. An eminent French writer gives him the following character. "He was a man of prodigious penetration; applied himſelf to cloſely to affairs, and eſpecially was ſo judicious in forming his reſolutions, that it is almoſt impoſſible to find out one falſe ſtep in the many negotiations in which he was concerned." His works, and eſpecially his letters, have been much eſteemed in the learned world.

OSSIAN, the ſon of Fingal \*, a celebrated Celtic \* See the article Fingal, in the APPENDIX. poet, who flouriſhed about the end of the third and beginning of the fourth century. Several incidents in his poems point out this as his era: particularly the engagement of Fingal with Caracul, or Caracalla, the ſon of the emperor Severus, ſtyled by Oſſian, *The Son of the King of the world*; and another expedition under the conduct of Oſcar, againſt the uſurper Carauſius, the Caros of Oſſian, who aſſumed the purple in the year 287. This correſponds pretty nearly with the account given by the Iriſh hiſtories, which place the death of Fingal in the year 283, and the death of Oſcar (who died many years before his father Oſſian) in the year 296.

At ſuch a diſtance of time, it cannot be expected we ſhould be able to give a particular account of the life of Oſſian. The firſt expedition on which his father ſent him was, to raiſe a ſtone on the banks of Crona, to perpetuate the memory of a victory which the king of Morven had obtained at that place. The Highlanders talk of this as being emblematical of that immortality which heroes were to receive from his future compositions. In this expedition he was accompanied by Toſcar, father to the beautiful Malvina, the amiable companion of his grief, after the death of her beloved Oſcar, his ſon. It appears from his poems, that, in one of his early expeditions to Ireland, he had

fallen in love with and married Evirallin, daughter to Branno, petty king of Lego. "I went in suit of the maid of Lego's sable surge; twelve of my people were there, the sons of freamy Morven. We came to Branno, friend of strangers; Branno of the founding mail.—'From whence,' he said, 'are the arms of thee? Not easy to win is the maid that has denied the blue-eyed sons of Erin. But blest be thou, O son of Fingal! happy is the maid that waits thee. Though twelve daughters were mine, thine were the choice, thou son of fame.'—Then he opened the hall of the maid; the dark-haired Evirallin †." This Evirallin was the mother of his son Oscar, whose exploits he celebrates in many of his poems, and whose death he laments in the first book of Temora. Evirallin died some time before Oscar, (FING. B. iv.), who seems to have been her only child; and Ossian did not marry afterwards: so that his posterity ended in the death of Oscar; who seems to have died as he was about to be married to Malvina, the daughter of Tofcar. Several of her lamentations for her lover are recorded by Ossian, which paint her grief in the strongest and most beautiful colours.—"It is the voice of my love! few are his visits to my dreams.—But thou dwellest in the soul of Malvina, son of mighty Ossian. My sighs arise with the beams of the east; my tears descend with the drops of night. I was a lovely tree in thy presence, Oscar, with all my branches round me: but thy death came like a blast from the desert, and laid my green head low; the spring returned with its showers, but no green leaf of mine arose." *Poem of CROMA.*

The principal residence of Ossian was in the vale of Cona, now Glenco, in Argyleshire. See FINGAL, in APPENDIX.

His poems relate many of his expeditions to Ireland, Scandinavia, Clyde, and Tweed or Teutha. His exploits on these occasions, after making a large allowance for poetical exaggeration, shew him to have been no less a warrior than a poet. See OSSIAN'S WORKS, in the poems *Caliban and Colmal, Lathmon, Berrathon*, &c. By these expeditions, which were always undertaken for the relief of the distressed, the mind of Ossian seems to have been cultivated and enlarged beyond what is usually to be met with in so rude a period of society as that in which he lived. His poems breathe throughout, such a spirit of generosity and tenderness, especially towards the fair sex, as is seldom or never to be met with in the compositions of other poets who lived in a more advanced state of civilisation. He lived to an extreme old age; having survived all his family and friends, many of whom perished by a fatal accident, recorded in one of his poems called the *Fall of Tura* \*. Malvina, alone, the love of his son Oscar, remained with him till within a few years of his death, and paid him every attention that could be expected from the tender relation in which she stood to him. To her he addresses many of his poems, which seem to have been composed for the most part in his old age. Her death is pathetically lamented by him in the poem of *Berrathon*: towards the close of which, he gives the prefaces of his own departure; an event which he often wishes for, under the blindness and other calamities of his declining years. "Roll on, ye dark-brown years, for ye bring no joy on

"your course. Let the tomb open to Ossian, for his strength has failed. The sons of the song are gone to rest: my voice remains, like a blast, that roars, lonely, on the sea-surrounded rock, after the winds are laid. The dark mofs whitens there, and the distant mariner sees the waving trees †."—"But Ossian is a tree that is withered. Its branches are blasted and bare; no green leaf covers its boughs. From its trunk no young shoot is seen to spring. The breeze whistles in its grey mofs: the blast shakes its head of age.—The storm will soon overturn it, and strew all its dry branches with thee, O Dermid! and with all the rest of the mighty dead, in the green winding vale of Cona\*."

It is not certain at what age Ossian died; but from his having been long blind with years, and from the many contrasts, between his present and past situations, in poems composed, as it would appear, at a considerable distance of time from each other, it is most likely he lived to an extreme old age. The current tradition is, that he died in the house of a Culdee, called the *Son of Alpin*, with whom he is said to have held several conferences about the doctrines of Christianity. One of these dialogues is still preserved, and bears the genuine marks of a very remote antiquity; (*Dissertation prefixed to Ossian's Works.*) Several of Ossian's poems are addressed to this son of Alpin, who was probably one of those Christians whom the persecution under Dioclesian had driven beyond the pale of the Roman empire.

The poems of Ossian, tho' always held in the highest esteem by those who knew them, were allowed to remain in the obscurity of their original Gaelic, till Mr Macpherson, about 20 years ago, translated a collection of them into English, which immediately attracted the attention of every person who had a true taste for poetry. Dr Blair, in particular, introduced these poems into the world with those critical remarks, which do no less honour to himself than to the poet. According to that eminent critic, the two great characteristics of Ossian's poetry are tenderness and sublimity. Ossian is, perhaps, the only poet who never relaxes, or lets himself down into the light and amusing strain. He moves perpetually in the high region of the grand and pathetic. The events which he records are all serious and grave; the scenery wild and romantic. We find not in him an imagination that sports itself and dresses out gay trifles to please the fancy. His poetry, more perhaps than that of any other, deserves to be styled the *poetry of the heart*. It is a heart penetrated with noble sentiments, with sublime and tender passions; a heart that glows and kindles the fancy; a heart that is full, and pours itself forth. Of all the great poets, Homer is the one whose manner and whose times come the nearest to Ossian's. Homer's ideas were more enlarged, and his characters more diversified. Ossian's ideas fewer, but of the kind fittest for poetry; the bravery and generosity of heroes, the tenderness of lovers, and the attachment of friends. Homer is diffuse; Ossian abrupt and concise. His images are a blaze of lightning, which flash and vanish. Homer has more of impetuosity and fire; Ossian of a solemn and awful grandeur. In the pathetic, Homer has great power; but Ossian exerts that power much oftener, and has the character of tenderness more deeply im-

Ossian.

\* See *Galic Antiquities*.

printed

Osian. printed on his works. No poet knew better how to seize and melt the heart. With regard to dignity of sentiment, we must be surpris'd to find that the pre-eminence must clearly be given to the Celtic bard. This appears nowhere more remarkable than in the sentiments which he expresses towards his enemies. "U—thai fell beneath my sword, and the fons of Berra—thou fled.—It was then I saw him in his beauty, and the tear hung in my eye. Thou art fallen, young tree, I said, with all thy beauty round thee. Thou art fallen on thy plains, and the field is bare. The winds come from the desert, and there is no sound in thy leaves! Lovely art thou in death, son of car-borne Lathmore \*!" His supposition, that all the little feuds and differences of this life should be forgot in a future state, and that those who had once been foes would "stretch their arms to the same shell in "Loda," gives us the highest idea of the man as well as of the poet. "Daughter of beauty, thou art low! A strange shore receives thy corse. But the ghosts of Morven will open their halls, when they see thee coming. Heroes around the feast of dim shells, in the midst of clouds, shall admire thee; and virgins shall touch the harp of mist†."—"The feuds of other years by the mighty dead are forgotten. The warriors now meet in peace, and ride together on the tempest's wing. No clang of the shield, no noise of the spear, is heard in their peaceful dwellings. Side by side they sit, who once mixed in battle their steel. There, Lochlin and Morven meet at the mutual feast, and listen together to the song of their bards‡."

\* *Osian's Works*, poem of Berrathol.

† *Galic Antiquities*, poem of Trathal.

‡ *N. poem of Dargo*.

But the sublimity of moral sentiments, if they wanted the softening of the tender, would be in hazard of giving a stiff air to poetry. It is not enough that we admire. Admiration is a cold feeling in comparison of that deep interest the heart takes in tender and pathetic scenes. With scenes of this kind Osian abounds; and his high merit in these is incontestable. He may be blamed for drawing tears too often from our eyes; but that he has the power of commanding them, no man who has the least sensibility can question. His poems awake the tenderest sympathies, and inspire the most generous emotions. No reader can rise from him without being warmed with the sentiments of humanity, virtue, and honour.

But the excellency of these poems occasioned in many persons a doubt of their authenticity. Their genuineness, however, has been very ably defended by Dr Blair and Lord Kames, and warmly supported by the author of the *Galic Antiquities*, who has given the public some more remains of Osian's poetry.

As the nature of our work will not allow us to treat this matter at full length, we shall only give a brief view of the arguments offered in support of the authenticity of these poems, referring our readers to the authors just now mentioned for fuller satisfaction.

These compositions, say they, have all the internal marks of antiquity so strongly impressed upon them, that no reader of taste and judgment can deny their claim to it. They exhibit so lively a picture of customs which have disappeared for ages, as could be drawn only from nature and real life. The features are so distinct, that few portraits of the life continually passing before us are found to be drawn with so

much likeness. The manners uniformly relate to a very early stage of society; and no hint, no allusion to the arts, customs, or manners, of a more advanced period, appears throughout the poems. To that distinction of ranks, which is always found in adult societies, the poet appears to have been a perfect stranger. The first heroes prepare their own repasts, and indiscriminately condescend to the most menial services. Their quarrels arise from causes generally slight, but in such a period extremely natural. A rivalry in love, an omission at a feast, or an affront at a tournament, are often the foundation of a quarrel among single heroes. And the wars in which whole tribes are engaged, are carried on with a view, not to enlarge their territory, but to revenge perhaps the killing of a few deer on their mountains, or the taking forcibly away one of their women. Their occupation was war and hunting, and their chief ambition was to have their fame in the songs of the bards.

The notions of a future state, exhibited in these poems, are likewise strongly marked with the characters of antiquity. A creed so uncommon that the imagination of a modern could not be supposed to grasp so strong an idea of it from mere fancy, is uniformly supported throughout. This creed is extremely simple, but admirably suited to the times.

The language too, and the structure, of these poems, bear the most striking characters of antiquity. The language is bold, animated, and metaphorical, such as it is found to be in all infant-states; where the words, as well as the ideas and objects, must be few; and where the language, like the imagination, is strong and undisciplined. No abstract, and few general terms appear in the poems of Osian. If objects are but introduced in a simile, they are always particularized. It is "the young pine of Inishuna;" it is "the bow of the showery Lena." This character, so conspicuous in the poems of Osian, is a striking feature in the language of all early states; whose objects and ideas are few and particular, and whose ordinary conversation is of course highly figurative and poetical. A picture, therefore, marked with such striking features, could not be drawn without an original.

The whole texture of the composition is also, like the language, bold, nervous, and concise; yet always plain and artless; without any thing of that modern refinement, or elaborate decoration, which attend the advancement of literature. No foreign ornaments are hunted after. The wild and grand nature which lay within the poet's view, is the only source from which he draws his ornaments. Beyond this circle, his imagination, though quick and rapid, seldom made any excursion. We perceive his language always to be that of a person who saw and felt what he describes; who bore a part in the expeditions which he celebrates, and who fought in the battles which he sings.

In giving the external and more positive proofs of the authenticity of Osian's poems, it is observed,—That there have been in the Highlands of Scotland, for some ages back, a vast many poems ascribed to Osian: That these poems have been held in the highest veneration, repeated by almost all persons, and on all occasions. These are facts so well known, that nobody as yet has been hardy enough to deny them: There is not an old man in the Highlands, who will

Osian.

not declare, that he heard such poems repeated by his father and grandfather, as pieces of the most remote antiquity. There is not a district in the Highlands where there are not many places, waters, isles, caves, and mountains, which, from time immemorial, are called after the names of Ossian's heroes.—There is not a lover of ancient tale or poetry, however illiterate, who is not well acquainted with almost every single name, character, and incident; mentioned in those translations of Ossian's poems, which he may have never heard of.—Bards, who are themselves several centuries old, quote those poems, imitate them, and refer to them.—The ordinary conversation and comparisons of the Highlanders frequently allude to the customs and characters mentioned in them;—and many of their most common proverbs, established by the most ancient use, are lines borrowed from the poems of Ossian\*.—

The most ancient of the clans boast of deriving their pedigree, from some one of Ossian's heroes;—and many of the signs armorial assumed by them, are drawn from the feats ascribed to their predecessors in those poems†.—Manuscripts are mentioned, in which some of these have been preserved for several centuries‡; and a list of living names, in different parts of the Highlands, is appealed to, as persons who still repeat a part of these poems§.—Whilst Mr Macpherson was engaged in the translation, many respectable persons, gentlemen and clergymen, avowed to the public, that these were Ossian's poems, with which they had long been acquainted, and that the translation was literal¶. This appears also from the large specimens of the originals published and compared by proper judges. The originals lay a considerable time in the hands of the bookseller, for the inspection of the curious; they have been afterwards shown frequently to many of the best judges, and offered for publication if the editor had been favoured with subscriptions. In like manner, proposals are now circulating for printing the originals of the ancient poems lately translated by Mr Smith; a copy of which, in the event of subscriptions not coming in, is deposited with the Secretary to the *Highland Society* in London. It is likewise argued in support of the authenticity of these poems, that candid sceptics, on hearing some of them repeated by illiterate persons, who had never seen the translation, caused them to give the meaning of what they repeated, by an extempore translation into English, and by this means had all their doubts of the authenticity of Ossian removed\*. They urge further, that such passages of Ossian's works as are still repeated by some old men, are among the most beautiful parts of Ossian's poems; such as the battle of Lora, the most affecting parts of Carthon, Berrathon, the death of Oscar, and Dathula, or the children of Ufnoth, &c.: which gives a credibility to his being equal to the other parts of the collection, none of it being superior to these in merit.

To these, and the like arguments advanced in support of the authenticity of the poems ascribed to Ossian, we find little objected by such as are sceptics on this head, except general assertions, That such poems could not have been composed in so early a period;—that tradition could not preserve them so long;—and the remains to be met with from oral recitation are now so inconsiderable.

To this it has been answered, That poetry has been

cultivated with most success in the earliest stages of society; that in Greece, Orpheus, Linus, Hesiod, and Homer, wrote their admirable poems some ages before any thing had been written in prose in the Greek language; that the book of Job, written in a very early period of society, is highly poetical; that among the tribes of Lapland and America, there have been found, in the earliest state, some excellent pieces of poetry. That the Caledonians in particular, had some peculiar institutions, which tended to improve their poetry: their druids were among the most learned philosophers which perhaps any age or country produced; their bards or poets were the disciples of those druids, and were always a standing order, to which none but the most promising geniuses were admitted. This standing college of poets was furnished, not only with the fruits of their own long study and observation, but also with as much as merited to be preserved of the compositions of their predecessors in office, since the "light of the song" first dawned. They had the advantage of one another's conversation; which would excite their emulation, and make them aspire to eminence: They were always present, and generally engaged, in every grand operation that was transacted; which could not fail to inspire their muse with the truest poetic fire.

The case of Ossian was particularly favourable. He lived in an age when manners came to a considerable degree of refinement under the care of the Bards and Druids. Poetry in his day was considerably advanced; and the language, though strong and figurative, had undergone some degree of cultivation, and learned to flow in regular numbers, adapted to the harp, the favourite instrument of the times. As a prince and a warrior, his mind must have been expanded and much enlarged by his excursions to other countries. At home he had Ullin, Alpin, Carril, and Ryno, to converse with; all of them poets of eminence, who would have advantaged him greatly by their example and conversation. All these advantages, meeting with a native fire and enthusiasm of genius, as in the case of Ossian, may well be supposed to have produced poems that might challenge the veneration of ages.

But it is not to their merit alone that we owe the preservation of these poems so long by oral tradition. Other circumstances concurred; of which, the institution of the Bards deserves particular notice. In a country, the only one perhaps in the world in which there was always, from the earliest period almost to the present age, a standing order of poets, we cannot reasonably be surprised, either at finding excellent poems composed, or, after being composed, carefully preserved from oblivion. A great part of the business of this order was to watch over the poems of Ossian. In every family of distinction there was always one principal bard, and a number of disciples, who vied with each other in having these poems in the greatest perfection. Should the institution of the bards last for ever, the poems of Ossian could never perish.

Nor were they only the bards of great families who took an interel in these poems: the vassal, equally fond of the song with his superior, entertained himself in the same manner. This, with a life free from care, a spirit unbroken by labour, and a space of time unoccupied by any other employment or diversion, contributed to render the Highlanders a nation of singers

\* See examples under each of these heads in the *Galic Antiquities*, p. 93, 94, 95. † Ibid. p. 194. in note.

‡ Kames's *Sketches*, B. i. § *Galic Antiquities*, p. 95. 128. ¶ See list of names, Appendix to Dr Blair's Dissertation, *Ossian's Works*, 2d edit.

\* Pref. to Dr Percy's *Reliques of Old English Poetry*, 2d edit.

singers and poets. From such a people, the superior merit of Osian's poems would naturally procure every encouragement, which they always retained as long as the manners of the people remained unchanged.

Many other reasons conspired to preserve the poems of Osian. The martial and intrepid spirit which they breathed, made it the interest of the chieftains to preserve them: the strain of justice, generosity, and humanity, which runs through them, recommended them to the superintendants of religion, who well knew how much the morals of a people must be inured with those songs which they are continually repeating, and which have all the advantages of poetry and of music. In superstitious ages, the people revered these poems from their being addressed generally to some "son of the rock," supposed to be the tutelar saint of the place, or the great Irish apostle St Patrick. Besides, every hill and dale which the natives of the Highlands walked over, was classic ground. Every mountain, rock, and river, was immortalized in the song. This song would naturally be suggested by the sight of these objects, and every body would hum it as he walked along. All the proverbs and customs to which these poems gave rise, would operate in the same manner. The son would ask what they meant, and the father would repeat the song from which they were taken. The distinct and unaltered state in which the Highlanders remained for so long a course of ages, every clan, one generation after another, inhabiting the same valley, till towards the present century, contributed much to preserve their traditions and their poems; and the constant and general custom of repeating these in the winter-nights, kept them always alive in their remembrance.

To these causes and customs the preservation of Osian's poems, for so many ages, has been ascribed. But these causes and customs have ceased to exist; and the poems of Osian, of course, have ceased to be repeated.—Within a century back, the Highlands of Scotland have undergone a greater revolution than it had done for ten before that period. With a quicker pace the feudal system vanished; property fluctuated; new laws and new customs stepped in, and supplanted the old: and all this, with such sudden and such violent convulsions, as may well account for the shaking of a fabric which had stood so many ages, that it seemed to have bidden defiance to all the injuries of time. Even since Mr Macpherfon gathered the poems in his collection, the amusements, employments, and taste of the Highlanders are much altered. A greater attention to commerce, agriculture, and pasturage, has quite engrossed that partial attention which was paid, even then, to the song of the bard. In twenty years hence, if manners continue to change so fast as they do at present, the faintest traces will scarce be found of these tales and poems. "Osian himself is the last of his race; and he too shall soon be no more, for "his grey branches are already strewed on all the "winds."

Among the causes which make these poems vanish so rapidly, poverty and the iron rod should come in for a large share. From the baneful shade of those *murderers of the muse*, the light of the song must retire. No other reason needs be given why the present Highlanders neglect so much the songs of their

fathers.—Once, the humble, but happy vassal, sat at his ease, at the foot of his grey rock or green tree. Few were his wants, and fewer still his cares; for he beheld his herds sporting around him, on his then unmeasured mountain. He hummed the careless song, and tuned his harp with joy, while his soul in silence blessed his children.—Now, we were going to draw the comparison:

—*sed Cynthia aurem  
Vellit et almonit.*

It is more agreeable to remark, as another cause for the neglect of ancient poems and traditions, the growth of industry, which fills up all the blanks of time to more advantage, and especially the increase of more useful knowledge.—But above all, the extinction of the order of the bards hastened the catastrophe of Osian's poems. By a happy coincidence Macpherfon overtook the very last that remained of this order, (Macvurich, bard to Clanronald), and got his treasure. This fact (with the *red book* furnished by Mr Macdonald of Croisdart, and some other MSS.) accounts for Mr Macpherfon's having found these poems in greater number and perfection than they could ever since be met with. The fragments, however, which have since been gathered, give a credibility to every thing that has been said of the original grandeur of the building.

After giving this abstract of the *arguments* urged for the authenticity of Osian's poems, and of the answers to objections started against them, we shall conclude with referring those who wish to see the subject discussed on a different footing, namely, by an appeal to *facts*, to two pamphlets recently published, *Shaw's Inquiry*, and *Clark's Answer*: From the former of which, the authenticity of Osian's poems seemed to sustain a very formidable attack; till the latter appeared, exposed the impotence of the attempt, and shewed the unshaken basis on which the object of it rested. So that now we seem authorized to conclude, without the imputation of partiality, that the controversy is at last come to an end; and that the genuineness of the poems will be as universally established in other nations, as the originals have been admired for ages in the Highlands.

OSSIFICATION, the formation of bones; but more particularly the conversion of parts naturally soft to the hardness and consistence of bones.

OSSORY, the west division of Queen's-county in Ireland.

OSSORY (Bale bishop of). See *Bale*.

OSTADE (Adrian Van), an eminent Dutch painter born at Lubec in 1610. He was a disciple of Francis Hals, in whose school Brouwer was contemporary with him, where they contracted an intimate friendship. The subjects of his pencil were always of a low kind, he having nearly the same ideas as Teniers; diverting himself with clowns and drunkards in stables, ale-houses, and kitchens. His pictures are so transparent and highly finished, that they have the polish and lustre of enamel: they have frequently a force superior to Teniers; yet it were to be wished that he had not designed his figures so short. He is perhaps one of the Dutch masters who best understood the *chiaro oscuro*; and he was often employed to paint figures for the best landscape painters of his countrymen. He died in

Offuna 1685. His works, especially those of his best time and manner, are very scarce; so that when they are to be purchased, no price is thought too much for them. His prints etched by himself, large and small, consist of 54 pieces. Ostia # Ostracism.

OSSUNA, an ancient and considerable town of Andalusia in Spain; with an university, an hospital, and the title of a duchy. N. Lat. 37. 8. W. Long. 4. 18.

OSTALRIC, a town of Spain, in Catalonia. It had a strong castle, but was taken by the French and demolished in 1695. It is seated on the river Tordera, in E. Long. 2. 45. N. Lat. 24. 44.

OSTEND, a very strong sea-port town of the Netherlands, in Austrian Flanders, with a good harbour, and a magnificent town-house. It is not very large, but is very well fortified. This place was taken by the Dutch in 1706, but restored to the emperor in 1723; when an East India company was established here, but entirely suppressed by treaty in 1731. It was taken by the French in August 1745, after ten days siege; but rendered back by the treaty of Aix la Chapelle. E. Long. 2. 48. N. Lat. 51. 17.

OSTEOCOLLA, in natural history, though supposed by many to be an earth, is truly a crustated kind of spar defaced by earth, and therefore not transparent. It is usually found coating over vegetables, or other bodies, in form of incrustations; so that the true osteocolla is a tubular crustaceous spar of a very foul and coarse texture; and carries with it much more the appearance of a marl than of a species of spar. The masses of osteocolla, though regularly of the same figure, are very different in size; some of them not being thicker than a crow quill, while others are five and six inches in diameter; it is always, however, of a tubular figure, and a wrinkled rough surface. Osteocolla is frequent in Germany; where it is found buried near the surface of the earth, sometimes in strata of sand, but more frequently among marls; it should be chosen, for use, the purest that can be had, of a pale brown colour, and of a tolerably firm and close texture.—It has long been famous for bringing on a callus in fractured bones; its name, *osteocolla*, signifies “bone-glue,” or the “bone-binder.” It is also recommended as a diuretic, and as good in the fluor albus; but the present practice has rejected it.

OSTEOLOGY, that part of anatomy which treats of the bones. See ANATOMY, Part I.

OSTERVALD (John Frederick), a famous Protestant divine, was born at Neuchâtel in 1663; and made such rapid progress in his studies, that he became master of arts at Saumur before he was 16 years of age. He afterwards studied at Orleans and at Paris. At his return to Neuchâtel in 1699, he became pastor of the church there; and contracted a strict friendship with the celebrated John Alphonse Turretin of Geneva, and the illustrious Samuel Werenfels of Basil. The union of these three divines, which was called the *Triumvirate of the divines of Switzerland*, lasted till his death. Mr Osterwald acquired the highest reputation by his virtues, his zeal in instructing his disciples, and restoring ecclesiastical discipline. He wrote many books in French; the principal of which are, 1. A Treatise concerning the Sources of Corruption; which is a good moral piece. 2. A Catechism, or Instruction in the Christian Reli-

gion; which has been translated into German, Dutch, and English; and the Abridgment of the Sacred History, which he prefixed to it, was translated and printed in Arabic, in order to be sent to the East Indies, by the care of the Society for the propagation of the Gospel: and that Society, established in London, honoured him, by admitting him an honorary member. 3. A treatise against Impurity. 4. An edition of the French Bible of Geneva, with Arguments and Reflections, in folio. 5. *Ethica Christiana*. 6. *Theologia Compendium*, &c. He died in 1747, regretted by all who knew him.

OSTIA, a town formerly of note, on the left or south side and at the mouth of the Tiber, whence its name; the first Roman colony led by Ancus Martius, called *Colonia Ostiensis*. At this day it lies in ruins, only retaining its name. There were salt-works there, called *Saline Ostienses*, as early as the times of Ancus Martius, (Livy); from which the *Via Salaria*, which led to the Sabines, took its name, (Varro). It gave name to one of the gates of Rome, which was called *Ostiensis*, (Amman).

OSTIACKS, a people of Siberia in Asia, who inhabit the banks of the river Oby. See SIBERIA.

OSTRACION, in zoology, a genus of the amphibia nautes clais. It has ten long cylindrical obtuse teeth in each jaw; the aperture is linear; the body is covered with a bony tubulance, and it has no bely-fins. There are nine species; principally distinguished by the angles of their bodies, and number of fins near their tail.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt any thing against the public liberty. This punishment was called *ostracism*, from the Greek word *οστρακισμος*, which properly signifies a “shell;” but when applied to this object, it is used for the billet on which the Athenians wrote the names of the citizens whom they intended to banish. The learned are divided with regard to the substance of which this billet was formed: some insist that it was a small stone, or a piece of brick; some, that it was a piece of bark; and others assert, that it was a shell. The word admits most of these interpretations. But what determines its true sense, is the epithet given it by ancient authors, of *ceramicæ massæ*; which words signify, “The punishment of potter’s clay;” and this expression seems to us a proof, that the word *οστρακισμος*, when applied on this occasion, signifies a “piece of baked earth, in the form of a shell;” and undoubtedly the Latin authors had this idea of the word here, for they translated it by *testula*.

The ancients are likewise divided with regard to the time when ostracism was instituted. But they all agree, that the person who moved the law, was its first victim. But as to the name of its patron, and the time of its establishment, they differ extremely. Many are of opinion, that ostracism owes its origin to very remote times.

However that be, the punishment of ostracism was inflicted by the Athenians when their liberty was in danger. If, for instance, jealousy or ambition had sowed discord among the chiefs of the republic; and if different parties were formed, which threatened some

revolution

**Ostracism.** revolution in the state; the people assembled to propose measures proper to be taken in order to prevent the consequences of a division which in the end might be fatal to freedom. Ostracism was the remedy to which they usually had recourse on these occasions; and the consultations of the people generally terminated with a decree, in which a day was fixed for a particular assembly, when they were to proceed to the sentence of ostracism. Then they who were threatened with banishment, omitted no assiduity or art which might gain them the favour of the people. They made harangues to evince their innocence, and the great injustice that would be done them if they were banished. They solicited, in person, the interest of every citizen; all their party exerted themselves in their behalf; they procured informers to vilify the chiefs of the opposite faction. Some time before the meeting of the assembly, a wooden inclosure was raised in the forum, with ten doors, *i. e.* with as many as there were tribes in the republic; and when the appointed day was come, the citizens of each tribe entered at their respective door, and threw into the middle of the inclosure the small brick on which the citizen's name was written whose banishment they voted. The archons and the senate presided at this assembly, and counted the ballots. He who was condemned by 6000 of his fellow-citizens, was obliged to quit the city within ten days; for 6000 voices, at least, were requisite to banish an Athenian by ostracism.

The Athenians, without doubt, foresaw the inconveniences to which this law was subject; but they chose rather, as Cornelius Nepos hath remarked, sometimes to expose the innocent to an unjust censure, than to live in continual alarms. Yet as they were sensible that the injustice of confounding virtue and vice would have been too flagrant, they softened, as much as they could, the rigour of ostracism. It was not aggravated with the circumstances which were most dishonourable and shocking in the ordinary mode of exile. They did not confiscate the goods of those who were banished by ostracism. They enjoyed the produce of their effects in the places into which they were banished; and they were banished only for a certain time. But in the common banishment, the goods of the exiles were always confiscated, and no hopes were given them of ever returning to Athens.

The scholiast of Aristophanes informs us of a third difference betwixt ostracism and the common banishment. He says, that a particular place of retirement was assigned to those who were banished by ostracism, which was not appointed to the other exiles. We suspect, however, the truth of this observation; for Themistocles was certainly not limited in his banishment. That great man, as we are told by Thucydides, tho' his chief residence was at Argi, travelled over all the Peloponnesus.

This punishment, far from conveying the idea of infamy, became, at Athens, a proof of merit, by the objects on which it was inflicted; as Aristides the sophist justly observes, in his second declamation against the Gorgias of Plato, where he says, that ostracism was not an effect of the vindictive spirit of the people against those whom it condemned; that the law, whether good or bad (for he enters not into an examination of the question), was only meant to prune the

luxuriant growth of transcendent merit; that it condemned to an exile of ten years, only those illustrious men who were accused of being exalted far above other citizens by their conspicuous virtue; and that none of that public indignation was shewn to the exiles by ostracism, which commonly breaks out against criminals.

Such were the mitigations with which this law was introduced among the Athenians: and by them we see that they were sensible of all the inconveniences to which it was subject. They were indeed too enlightened a people, not to foresee the many instances of injustice which it might produce; that if in some respects it would be favourable to liberty, in others it would be its enemy, by condemning citizens without allowing them a previous defence, and by making a capricious and envious people arbiters of the fate of great men; that it might even become pernicious to the state, by depriving it of its best subjects, and by rendering the administration of public affairs an odious employment to men of capital talents and virtue.

However great the inconveniences of Ostracism were, it would not have been impossible to avoid them; and we may add, that this law would have been of service to the state, if the people by whom it was instituted had always had discernment enough only to give it force on such occasions as endangered liberty. But its fate was like that of almost all other laws which the wisest legislators have planned for the good of communities. Destined by their institution to maintain order, to repress injustice, and to protect innocence, men have found ways to pervert their application, and have made them instruments to gratify their private passions. Thus ostracism was established to prevent the dangerous enterprises of the great, and to preserve the vigour of the democracy; but the people of Athens, naturally jealous and envious, exerted that law, to remove men of eminent merit from the state, by whose presence they were repressed and intimidated. The fear of tyranny was commonly but a specious pretext with which they veiled their malignity. The repeated victories which they had gained over the Persians, had rendered them, says Plutarch, proud and insolent. Intoxicated with their prosperity, they arrogated all its glory to themselves; they were jealous of those citizens, whose political and military talents were the subjects of public eulogium. They thought the glory acquired by great men diminished their own reputation. An Athenian no sooner distinguished himself by a splendid action, than he was marked out as a victim by public envy. His reputation was a sufficient reason for his banishment.

**OSTRACITES**, in natural history, the name which authors have given the fossil oyster-shell. Ostracites has the same medical virtues with other absorbent and calcareous earths.

**OSTREA**, the **OYSTER**, in zoology, a genus belonging to the order of vermes testacea. The shell has two unequal valves; the cardo has no teeth, but a small hollowed it with transverse lateral streaks. There are 31 species, principally distinguished by peculiarities in their shells. The common oyster is reckoned an excellent food; and is eaten both raw, and variously prepared.

Ofſtea.

Britain has been noted for oyſters from the time of Juvenal, who, ſatyrizing an epicure, ſays,

*Circæis nata ſarent, æn  
Lucrinum ad Saxum, Rutuploneæ edita fundo,  
Ofſtea, callibat primo depredare merſæ.*

He, whether Circæ's rock his oyſters bore,  
Or Lucrine lake, or diſtant Richborough's ſhore  
Knew at firſt taſte.

The luxurious Romans were very fond of this fiſh, and had their layers or ſtews for oyſters as we have at preſent. Sergius Orata was the firſt inventor, as early as the time of L. Craſſus the orator. He did not make them for the ſake of indulging his appetite, but thro' avarice, and made great profits from them. Orata got great credit for his Lucrine oyſters; for, ſays Pliny, the Britiſh were not then known.

The ancients eat them raw, and ſometimes roaſted. They had alſo a cuſtom of ſtewing them with mallows and docks, or with fiſh, and eſteemed them very nourishing.

Britain ſtill keeps its ſuperiority in oyſters over other countries. Moſt of our coaſts produce them naturally; and in ſuch places they are taken by dredging, and are become an article of commerce, both raw and pickled. The very ſhells, calcined, become a uſeful medicine as an abſorbent. In common with other ſhells, they prove an excellent manure.

Stews or layers of oyſters are formed in places which nature never allotted as habitations for them. Thoſe near Colcheſter have been long famous; at preſent there are others that at leaſt rival the former, near the mouth of the Thames. The oyſters, or their ſpats, are brought to convenient places, where they improve in taſte and ſize. It is an error to ſuppoſe, that the fine green obſerved in oyſters taken from artificial beds, is owing to coppers; it being notorious how deſtructive the ſubſtance or the ſolution of it is to all fiſh. We cannot give a better account of the cauſe, or of the whole treatment of oyſters, than what is preſerved in the learned biſhop Sprat's hiſtory of the Royal Society, from p. 307, to 309.

"In the month of May, the oyſters caſt their ſpawn, (which the dredgers call their *ſpats*;) it is like to a drop of candle, and about the bignefs of a half-penny.

"The ſpat cleaves to ſtones, old oyſter-ſhells, pieces of wood, and ſuch like things, at the bottom of the ſea, which they call *cultch*.

"It is probably conjectured, that the ſpat in 24 hours begins to have a ſhell.

"In the month of May, the dredgers (by the law of the admiralty court) have liberty to catch all manner of oyſters, of what ſize ſoever.

"When they have taken them, with a knife they gently raiſe the ſmall brood from the *cultch*, and then they throw the *cultch* in again, to preſerve the ground for the future, unleſs they be ſo newly ſpat, that they cannot be ſafely levered from the *cultch*; in that caſe they are permitted to take the ſtone or ſhell, &c. that the ſpat is upon, one ſhell having many times 20 ſpats.

"After the month of May, it is felony to carry away the *cultch*, and puniſhable to take any other oyſters, unleſs it be thoſe of ſize, (that is to ſay) about

the bignefs of an half-crown piece, or when, the two ſhells being ſhut, a fair ſhilling will rattle between them.

"The places where theſe oyſters are chiefly caught, are called the *Pent-Burnham*, *Malden*, and *Celne-waters*; the latter taking its name from the river of Colne, which paſſeth by Colne-Cheſter, gives the name to that town, and runs into a creek of the ſea, at a place called the *Hythe*, being the ſuburbs of the town.

"This brood and other oyſters, they carry to the creeks of the ſea, at Brickel-Sea, Merſy, Langno, Fingrego, Wivenho, Toſebury, and Saltoſeaf, and there throw them into the channel, which they call their *beds* or *layers*, where they grow and fatten, and in two or three years the ſmalleſt brood will be oyſters of the ſize aforeſaid.

"Thoſe oyſters which they would have green, they put into pits about three feet deep in the ſalt-marſhes, which are overflowed only at ſpring-tides, to which they have ſluices, and let out the ſalt-water until it is about a foot and half deep.

"Theſe pits, from ſome quality in the ſoil co-operating with the heat of the ſun, will become green, and communicate their colour to the oyſters that are put into them in four or five days, tho' they commonly let them continue there ſix weeks or two months, in which time they will be of a dark green.

"To prove that the ſun operates in the greening, Toſebury pits will green only in ſummer; but that the earth hath the greater power, Brickel-Sea pits green both winter and ſummer: and for a further proof, a pit within a foot of a greening-pit will not green; and thoſe that did green very well, will in time loſe their quality.

"The oyſters, when the tide comes in, lie with their hollow ſhell downwards; and when it goes out, they turn on the other ſide: they remove not from their place, unleſs in cold weather, to cover themſelves in the ouſe.

"The reaſon of the ſcarcity of oyſters, and confequently of their dearneſs, is, becauſe they are of late years bought up by the Dutch.

"There are great penalties by the admiralty court, laid upon thoſe that fiſh out of thoſe grounds which the court appoints, or that deſtroy the *cultch*, or that take any oyſters that are not of ſize, or that do not tread under their feet, or throw upon the ſhore, a fiſh which they call a *five finger*, reſembling a ſpur-rowel, becauſe that fiſh gets into the oyſters when they gape, and fucks them out.

"The reaſon that ſuch a penalty is ſet upon any that ſhall deſtroy the *cultch*, is, becauſe they find that if that be taken away, the ouſe will increaſe, and the muſcles and cockles will breed there, and deſtroy the oyſters, they having not whereon to ſtick their ſpat.

"The oyſters are ſick after they have ſpat; but in June and July they begin to mend, and in Auguſt they are perfectly well: the male oyſter is black-lick, having a black ſubſtance in the ſin; the female white-lick (as they term it), having a milky ſubſtance in the ſin. They are ſalt in the pits, ſalter in the layers, but ſaltſt at ſea."

OSTRICH, in zoology. See STRUTHIO.

"The

Ofſtea.  
Ofſtrich.

Ostuni  
||  
Otaheitee.

OSTUNI, a town of Italy, in the kingdom of Naples, and in the Terra di Otranto, with a bishop's see. Its territory is well cultivated, and abounds with olives and almonds. It is seated on a mountain near the gulph of Venice, in E. Long. 17. 49. N. Lat. 49. 59.

OSWEGO, a fort of North America, seated on the fourth side of the lake Ontario, in W. Long. 70. 35. N. Lat. 45. 15.

OSWEIZEN, a town of Poland, in the Palatinate of Cracovia, with the title of a duchy. It carries on a great trade in salt, and is seated on the river Vistula. E. Long. 19. 47. N. Lat. 50. 1.

OTACOUS<sup>TIC</sup> INSTRUMENT, or *Auricular Tube*, an instrument to facilitate the hearing. See *Acoustics*, n° 26.

OTAHEITEE, a celebrated island of the South Sea, situated in W. Long. 149. 13. S. Lat. 17. 46. It was discovered by Captain Wallis in 1767; afterwards Mr Bougainville touched here, and it was visited by Captain Cook in 1773 and 1774.

The island consists of two distinct kingdoms, which are united by a narrow neck of land; the larger being called by the natives *Tiarabou*, or *O-Tahitee-Nue*; the smaller one, *Opoouenou*, or *O-Tahitee-Ete*. The circumference of both islands is about 40 leagues; the larger kingdom being divided into 43 districts. The country has a delightful romantic appearance. The coast viewed from the sea, presents a most beautiful prospect, being elevated like an amphitheatre. The island is skirted with a reef of rocks, and towards the sea is level, being covered with fruit-trees of various kinds, particularly the cocoa-nut. At the distance of about three miles from the shore, the country rises into lofty hills that are covered with wood, and terminate in peaks, from which large rivers are precipitated into the sea. The stones every where appear to have been burnt, not one being found which did not give manifest signs of fire; so that there is great reason for supposing, that this and the neighbouring islands are either the shattered remains of a continent, or were torn from rocks, which from the creation of the world have been the bed of the sea, and thrown up in heaps to a height which the waters never reach. What is further extraordinary, the water does not gradually grow shallow as we approach the shore, but is of immense depth close by the land; and the islands in this neighbourhood are almost every where surrounded by reefs, which appear to be rude and broken in the manner that some violent concussion would naturally leave the solid substance of the earth; and Mr Forster saw a rock with projecting longitudinal angles of black compact basalt. The exterior ranges of hills are sometimes entirely barren, and contain a great quantity of yellowish clay, mixed with iron ochre; but others are covered with mould and wood like the mountains in the internal parts of the country. Pieces of quartz are sometimes met with here; but no indications of precious minerals or metals of any kind have been observed, iron only excepted.

The air is extremely healthy and pleasant; the heat is not troublesome; and fresh meat will keep very well for two days, and fish one day. The winds do not blow constantly from the east, but generally a little breeze from east to south-east. The tide rises

Vol. VIII.

very little; and, being governed by the winds, is very uncertain. "The climate," says Mr Bougainville, "is so healthy, that notwithstanding the hard labour of the ships companies while on shore, though the men were continually in the water, and exposed to the meridian sun, though they slept upon the bare soil, and in the open air, none of them fell sick; those who were afflicted with the scurvy, and were sent on shore, regained their strength: although they were obliged to assist in the erecting of a fort, and had scarce one uninterrupted night, yet they were so far recovered in the short space of time they continued there, that they were afterwards perfectly cured on board."

Notwithstanding the great height of the inland mountains of Otaheitee, none of their rocks have the appearance of barrenness, every one of them being covered with woods. "We hardly believed our eyes," says M. de Bougainville, "when we saw a peak covered with woods up to its highest summit, which rises above the level of the mountains in the anterior parts of the southern quarter of this island. Its apparent size seemed to be more than 30 toises in diameter, and grew less in breadth as it rose higher. At a distance it might have been taken for a pyramid of immense height, which the hand of an able sculptor had adorned with garlands and foliage." One of the mates of the dolphin, with a party of marines and seamen, penetrated into the interior parts of the island; and having ascended, with great difficulty, a mountain which they supposed to be a mile high, they discovered mountains before them so much higher, that with respect to them they seemed to be in a valley: towards the sea the view was enchanting, the sides of the hills were beautifully clothed with wood, villages were every where interspersed, and the valleys between them afforded a still richer prospect; the houses stood thicker, and the verdure was more luxuriant; and Mr Forster, with other gentlemen, ascended to the summit of one of the highest mountains in the island, from whence they had a prospect of the island of Huahine, and some others lying at the distance of 40 leagues; from which we may form some judgment of the prodigious height of that mountain. The view of the fertile plain below them, and of a river making innumerable meanders, was delightful in the highest degree. The vegetation on the upper part of the mountains was luxuriant, and the woods consisted of many unknown sorts of trees and plants.

The soil of this island is a rich fat earth, of a blackish colour. It produces spontaneously, or with the slightest culture imaginable, a great variety of the most excellent fruits; such as bread-fruit, cocoa nuts, bananas of 13 sorts, plantains, potatoes, yams, a fruit known here by the name of *janbu*, and reckoned most delicious; sugar-canes, which the inhabitants eat raw; ginger; turmeric; a root of the fable kind, called by the inhabitants *pea*; a plant called *elbee*, of which the root only is eaten; a fruit that grows in a pod like that of a large kidney-bean, by the natives called *abee*; a tree called *aharra*, which produces fruit something like the pine-apple, and which is known in the East Indies by the name of *pandanus*; a shrub called *nono*; the *morinda*, which also produces fruit; a species of fern; a plant called *theve*; and the Chinese paper-mulberry, of the bark of which they make their cloth;

Soil and produce.

Climat.

**Otaheitee.** an herb which the inhabitants eat raw, its flavour somewhat resembling that of the West India spinach called *calletoon*, but its leaf very different; a plant which the natives call *ava* or *earva*, from the root of which they express a liquor, which, if drank to excess, intoxicates like wine or distilled spirits. Here are a sort of shady trees covered with a dark-green foliage, bearing golden-coloured apples, which, in juiciness and flavour, resemble the ananas or pine-apple. One of the most beautiful trees in the world received here the name of *Barringtonia*; it had a great abundance of flowers larger than lilies, and perfectly white, excepting the tips of their numerous chives, which were of a deep crimson. Such a quantity of these flowers were seen dropped off, that the ground underneath the tree was entirely covered with them. The natives called the tree *buddov*; and said, that the fruit, which is a large nut, when bruised and mixed up with some shell-fish, and thrown into the sea, intoxicates the fish for some time, so that they come to the surface of the water, and suffer themselves to be taken with people's hands. Several other maritime plants in tropical climates are found to have the same quality. Mr Dalrymple describes the method of catching fish with these plants as follows: The plant is thrust under the coral rocks or hollows where the fish haunt; the effect is most sensible in still water, though it is effectual in the open sea; for the same gentleman says, he has seen fish soon after float on the surface of the water half dead, and some totally without life; and where the effect is less violent, the fish will be seen under the water to have lost their poise, without coming up to the surface. Fish caught in this manner are not in the least noxious or ill tasted.

**Animals.**

In this island they have domestic poultry exactly resembling those of Europe: besides which there are wild ducks; also beautiful green turtle-doves; large pigeons of a deep blue plumage and excellent taste; a small sort of parquets, very singular on account of the various mixture of red and blue in their feathers; also another sort of a greenish colour, with a few red spots; the latter are frequently tamed, and are valued on account of their red feathers. Here is a kingfisher of a dark green, with a collar of the same hue round his white throat; a large cuckoo, and a blue heron. Small birds of various kinds dwell in the shady trees; and, contrary to the generally received opinion that birds in warm climates are not remarkable for their song, have a very agreeable note. There were no quadrupeds but dogs, hogs, and rats; and for these last the natives were said to have a scrupulous regard, inasmuch that they would by no means kill them; however, Capt. Cook, in 1773, turned about 14 cats on the island, which have probably reduced the number of these vermin. No frogs, toads, scorpions, centipedes, or any kind of serpent, have been found here: the ants, however, are troublesome, but not very numerous. When the Endeavour first arrived here in 1679, the flies were found excessively troublesome; but musketto nets and fly-flaps in some measure removed the inconvenience. Sydney Parkinson, in his journal, says, that notwithstanding these flies are so great a nuisance, the natives, from a religious principle, will not kill them. But there is a strange disagreement in the accounts of different voyagers con-

cerning this matter. For Mr Bougainville says, "this island is not infested by those myriads of troublesome insects that are the plague of other tropical countries." And Mr Forster says, "not a gnat or musketto hummed unpleasantly about us, or made us apprehensive of its bite." This inconvenience must therefore be felt at certain seasons of the year, and in certain districts of the country, more sensibly than at other times and places. There is great variety of excellent fish; and, according to Aitourou, a native who embarked with M. de Bougainville, there are sea-snakes on the shore of Otaheitee, whose bite is mortal.

The inhabitants of Otaheitee are a stout, well-made, active, and comely people. The stature of the men, in general, is from five feet seven to five feet ten inches; the tallest man seen by Captain Wallis measured six feet three inches and an half; and Captain Cook, in his second voyage, describes O-Too, the king of Otaheitee, to be of that height. "In order to paint "an Hercules or a Mars," says M. de Bougainville, "one could nowhere find such beautiful models." They are of a pale brown complexion; in general their hair is black, and finely frizzled; they have black eyes, flat noses, large mouths, and fine white teeth; the men wear their beards in many fashions, all of them plucking out a great part, and have prominent bellies. Most of them smell strong of the cocoa-nut oil. The women, in general, are much smaller, especially those of the lower rank or tawtows, which is attributed to their early and promiscuous intercourse with the men; whilst the better sort, who do not gratify their passions in the same unbridled manner, are above the middle stature of Europeans. Their skin is most delicately smooth and soft; they have no colour in their cheeks; their nose is generally somewhat flat, but their eyes are full of expression, and their teeth beautifully even and white. "The women," says M. de Bougainville, "have features not less agreeable than the generality of Europeans, and a symmetry of body and beautiful proportion of limbs which might vie with any of them." The complexion of the men is tawny; but those who go upon the water are much more red than those who live on shore. Some have their hair brown, red, or flaxen, in which they are exceptions to all the natives of Asia, Africa, and America, who have their hair black universally; here, in the children of both sexes, it is generally flaxen. The strongest expression is painted in the countenances of these people; their walk is graceful, and all their motions are performed with great vigour and ease. "I never beheld stouter men," says Sydney Parkinson. "The men of consequence on the island wear the nails of their fingers long, which they consider as a very honourable badge of distinction, since only such people as have no occasion to work can suffer them to grow to that length. This custom they have in common with the Chinese; but the nail of the middle finger on the right hand is always kept short, the meaning for which peculiarity could not be learned. Only one single cripple was met with among them, and he appeared to have been maimed by a fall. The women always cut their hair short round their heads. Both sexes have a custom of staining their bodies, which they call *tattooing*; both men and women have the hinder part of their thighs and loins marked very thick with black lines

**Otaheitee.**

bitants, &c.

Otaheite.

Otaheite.

lines in various forms; these marks are made by striking the teeth of an instrument somewhat like a comb just through the skin, and rubbing into the punctures a kind of paste made of foot and oil, which leaves an indelible stain. The boys and girls under twelve years of age are not marked; a few of the men, whose legs were marked in chequers by the same method, appeared to be persons of superior rank and authority. Mr Banks saw the operation of tattooing performed upon the backside of a girl about thirteen years old. The instrument used upon this occasion had thirty teeth; and every stroke, of which at least a hundred were made in a minute, drew an ichor or serum a little tinged with blood. The girl bore it with most stoical resolution for about a quarter of an hour; but the pain of so many hundred punctures as she had received in that time, then became intolerable. She first complained in murmurs, then wept, and at last burst into loud lamentations, earnestly imploring the operator to desist. He was, however, inexorable; and when she began to struggle, she was held down by two women, who sometimes soothed and sometimes chid her; and now and then when she was most unruly, gave her a smart blow. Mr Banks staid in a neighbouring house an hour, and the operation was not over when he went away; yet it was performed but upon one side, the other having been done some time before; and the arches upon the loins, in which they most pride themselves, and which give more pain than all the rest, were still to be done. Both men and women are not only decently but gracefully clothed, in a kind of white cloth that is made of the bark of a shrub, and very much resembles coarse China paper. Their dresses consist of two pieces of this cloth; one of them, having a hole made in the middle to put the head through, hangs down from the shoulders to the mid-leg before and behind; another piece, which is between four and five yards long, and about one yard broad, they wrap round the body in a very easy manner: This cloth is not woven; but is made like paper, of the macerated fibres of the inner bark spread out and beaten together. Their ornaments are feathers, flowers, pieces of shell, and pearls; the pearls are worn chiefly by the women. In wet weather they wear matting of different kinds, as their cloth will not bear wetting. The dresses of the better sort of women consist of three or four pieces: one piece, about two yards wide and eleven long, they wrap several times round their waist, so as to hang down like a petticoat as low as the middle of the leg; and thus they call *parau*. This simple drapery affords the sex an opportunity of displaying an elegant figure to the greatest advantage, according to the talents and taste of the wearer: no general fashions force them to disfigure instead of adorning themselves, but an innate carefulness is the companion of simplicity. To this cloth they give a very strong perfume.

7  
Of their  
houses.

The chief use which they make of their houses is to sleep in them; for unless it rains, they eat in the open air under the shade of a tree. These houses are no other than sheds, all built in the wood between the sea and the mountains: they are erected on an oblong square; their width is nearly half of their length; they are nothing more than a roof, not quite four feet from the ground, raised on three rows of pillars, one row on each side, and one in the middle. The roof resembles

our thatched houses in England, and consists of two flat sides inclining to each other. Their thatch consists of palm-leaves. The floor of their dwelling is covered with hay, over which they spread mats. Some of these erections are furnished with a stool, which is appropriated solely to the use of the master of the family: they consist of no other furniture except a few blocks of wood, which being square, one side is hollowed into a curve; and these they use as pillows, and with their apparel they cover themselves. In these open dwellings the whole family repose themselves at night. The size of the house is proportioned to the number that constitutes the family. The established order in these dormitories is, for the master and his wife to sleep in the middle; round them the married people; in the next circle the unmarried women; and in the next, at the same distance, the unmarried men; and the servants at the extremity of the shed; but in fair weather, the latter sleep in the open air. Some few dwellings, however, constructed for greater privacy, are entirely inclosed with walls of reeds, connected together with transverse pieces of wood, so as to appear somewhat like large bird-cages closely lined; in these houses there is commonly a hole left for the entrance, which can be closed up with a board.

Their candles are made of the kernels of a kind of oily nut, which they flick one above another on a skewer that is thrust through the middle of them; the upper one being lighted burns to the second, at the same time consuming that part of the skewer that goes through it; the second taking fire burns in the same manner down to the third, and so to the last; they burn a considerable time, and afford a pretty good light. The natives generally retire to rest about an hour after it is dark.

The food of the common people entirely consists of Food, <sup>8</sup>me-  
vegetables. These are, the bread-fruit, with bananas, <sup>9</sup>thod of  
plantains, yams, apples, and a sour fruit, which, though <sup>10</sup>cookers,  
not pleasant by itself, gives an agreeable relish to roasted <sup>11</sup>cc.  
bread-fruit, with which it is frequently beaten up. See the article *BREAD-FRUIT*. The flesh, which is reserved for the tables of the great, is either poultry, hogs, or dogs; the flesh of their fowls is not well tasted, but that of dogs is esteemed by the natives beyond pork. The smaller fish are generally eaten raw, as we eat oysters: every thing that can be procured from the sea is made an article of their food; for they will eat not only sea-insects, but what the seamen call *blubbers*, though some of them are so tough that they are obliged to suffer them to become putrid before they can be chewed. A very large shark being caught by the Dolphin's people was given to the natives; who soon cut it to pieces, and carried it away with great satisfaction.

They kill the animals they intend for food by suffocating them, which is done by stopping the mouth and nose with their hands; they then squeeze off the hair, by holding the animal over a fire, and scraping him with a shell: with this instrument they cut him up, and take out the entrails; which are washed, and put into cocoa-nut shells, together with the blood. Dogs are eaten that are fed wholly upon bread-fruit, cocoanuts, yams, and other vegetables, and are never suffered to taste any animal food; and those who have tasted the flesh of a dog thus fed, have declared it to be little inferior to English lamb. In order to dress

their

their food, they kindle a fire, by rubbing the end of one piece of dry wood upon the side of another, in the manner as a carpenter with us whets a chisel. They then dig a pit about half a foot deep, and two or three yards in circumference; they pave the bottom with large pebble stones, which they lay down very smooth and even, and then kindle a fire in it with dry wood, leaves, and the husks of cocoa-nuts. When the stones are sufficiently heated, they take out the embers, and rake up the ashes on every side; they then cover the stones with a layer of green cocoa-nut leaves, and wrap up the animal that is to be dressed in the leaves of the plantain. If it is a small hog, they wrap it up whole; if a large one, they split it. When it is placed in the pit, they cover it with the hot embers, and lay upon them bread-fruit and yams, which are also wrapped up in the leaves of plantain. Over these they spread the remainder of the embers, mixing among them some of the hot stones, with more cocoa-nut-tree leaves upon them, and then close up all with earth, so that the heat is kept in; the oven is kept thus closed a longer or shorter time, according to the size of the meat that is dressed. The meat, when taken out, is said to be better dressed than any other way. They use shells for knives; and carve very dexterously with them, always cutting from themselves. One of the principal attendants on Obeera, attempting the use of the knife and fork, could not feed himself therewith; but, by the mere force of habit, his hand came to his mouth, and the victuals at the end of his fork went way to his ear.

They are quite unacquainted with the method of boiling water, as they have no vessels among them that will bear the fire. Whilst the noble Obeera was one morning at breakfast with captain Wallis on board the Dolphin, the surgeon filled the tea-pot by turning the cock of a vase that stood upon the table. One of the lady's attendants observed this practice very attentively, and soon after turning the cock himself, received the water upon his hand; he no sooner felt himself scalded, than he roared and danced about in an extravagant manner. The other Indians, unapprised of the cause of these emotions, stood gazing at him in amazement, and not without some mixture of terror: but the gentlemen in company, who soon perceived the cause of the outcry, dispelled the apprehensions of their visitors; and some ointment being applied to the scald, good-humour and confidence were again restored. The gunner of the ship, who was appointed comptroller of the market which was established on shore with the natives, used to dine on the spot; the astonishment of these people was very great to see him dress his pork and poultry in a pot; at length an old man, who was extremely servicable in bringing down provisions to be exchanged, was put into possession of an iron pot, and from that time he and his friends ate boiled meat every day. Several iron pots were likewise given to Obeera and some of the chiefs; which were in constant use, and drew every body to see them; but although the particulars of two successive voyages of captain Cook to this island are circumstantially related, we hear no more of this improvement in the culinary art, or of the further assistance which has been rendered those people in supplying them with pots for boiling; but however de-

fruous the natives might be to eat boiled meat, it was not advisable to have such an article of barter as iron kettles, when a few spike nails, or a common hatchet, would procure one of their largest hogs.

Salt water is the usual sauce to their food; those who live near the sea have it furnished as it is wanted, others at a distance keep it in large bamboos. The kernels of the cocoa-nuts furnish them with another sauce: these, made into a paste something of the consistence of butter, are beat up with salt water, which has a very strong flavour; but though at first it seemed very nauseous, yet when the taste became familiar, it was much relished.

Their general drink is water, or the milk of the cocoa-nut. They shewed in general an aversion to strong liquors; and whenever any one of them happened to drink so freely with any of the ship's company as to be intoxicated, he resolutely refused to taste any thing that was likely to produce the same effect again; but they have a plant which they call *ava ava*, from the root of which they procure a liquor which has an inebriating quality. Their manner of preparing this strong drink is as simple as it is disgusting to an European. Several of the people take some of the root, and chew it till it is soft and pulpy; they then spit it out into a platter or other vessel, every one into the same: into this general receptacle water is poured according to the quantity prepared. The juice thus diluted, is strained through some fibrous stuff like fine shavings, after which it is fit for drinking, and it is always prepared for present use: it has a pepperish taste; drinks flat, and rather insipid; and though it intoxicates, yet captain Cook saw but one instance where it had that effect, as the natives generally drink it with great moderation, and but little at a time. Sometimes they chew this root as Europeans do tobacco, and sometimes they will eat it wholly.

They eat alone, or at least only in company with a guest that happens to call in; and the men and women never sit down together to a meal: the shade of a spreading tree serves them for a parlour; broad leaves spread in great abundance serve for a table-cloth; and if a person of rank, he is attended by a number of servants who seat themselves round him; before he begins his meal, he washes his mouth and hands very clean, and repeats this several times whilst he is eating. The quantity of food which these people eat at a meal is prodigious. Captain Cook says, he has seen one man devour two or three fishes as big as a perch; three bread-fruits, each bigger than two fists; 14 or 15 plantains, or bananas, each six or seven inches long and four or five round, and near a quart of the pounded bread-fruit. Men of rank are constantly fed by their women; and one of the chiefs who dined on board the ships in 1769, shewed such reluctance to feed himself, that one of the servants was obliged to feed him to prevent his returning without his meal. In one of the excursions which the gentlemen of the ships made into the country in 1773, they arrived at a neat house, where a very fat man, who seemed to be a chief of the district, was loling on his wooden pillow; before him two servants were preparing his desert, by beating up with water some bread-fruit and bananas in a large wooden bowl, and mixing with it a quantity of ferment-

taheitee. ted four paste called *mahie*. While this was doing, a woman who sat down near him, crammed down his throat by handfuls the remains of a large baked fish, and several bread-fruits, which he swallowed with a voracious appetite; his countenance was the picture of phlegmatic insensibility, and seemed to testify that all his thoughts centered in the gratification of his appetite. He scarce deigned to look at the strangers; and a few monosyllables which he uttered, were extorted from him to remind his feeders of their duty, when by gazing at them they grew less attentive to him.

That these people, who are remarkably fond of society, and particularly that of their women, should exclude its pleasures from the table, where, among all other nations, whether civil or savage, they have been principally enjoyed, is truly inexplicable. How a meal, which every where else brings families and friends together, comes to separate them here, was a singularity much inquired about, but never accounted for. "They ate alone," they said, "because it was right;" but why it was right to eat alone, they never attempted to explain. Such, however, was the force of habit in this instance, as it is in every other, that they expressed the strongest dislike, and even disgust, at their visitants eating in society, especially with women, and of the same victuals. "At first (says captain Cook) we thought this strange singularity arose from some superstitious opinion; but they constantly affirmed the contrary. We observed also some caprices in the custom, for which we could as little account as the custom itself. We could never prevail with any of the women to partake of the victuals at our table, when we were dining in company; yet they would go five or six together into the servants apartments, and there eat very heartily of whatever they could find: nor were they in the least disconcerted if we came in while they were doing it. When any of us have been alone with a woman, she has sometimes eaten in our company; but then she has expressed the great unwillingness that it should be known, and always extorted the strongest promises of secrecy. Among themselves, even two brothers and two sisters have each their separate baskets of provisions, and the apparatus of their meal. When they first visited us at our tents, each brought his basket with him; and when we sat down to table, they would go out, sit down upon the ground, at two or three yards distance from each other, and turning their faces different ways take their repast without exchanging a single word. The women not only abstain from eating with the men, and of the same victuals, but even have their victuals separately prepared by boys kept for that purpose, who deposit it in a separate shed, and attend them with it at their meals. But though they would not eat with us, or with each other, they have often asked us to eat with them, when we have visited those with whom we were particularly acquainted at their houses; and we have often upon such occasions eaten out of the same basket, and drank out of the same cup. The elder women, however, always appeared offended at this liberty; and if we happened to touch their victuals, or even the basket that contained it, they would throw it away."

After meals, and in the heat of the day, the middle-aged people of the better sort generally sleep. They

are indeed extremely indolent; and sleeping and eating are almost all that they do. Those that are older are less drowsy, and the boys and girls are kept awake by the natural activity and sprightliness of their age.

These islanders, who inhabit huts exposed to all the winds, and hardly cover the earth, which serves them for a bed, with a layer of leaves, are remarkably healthy and vigorous, and live to an old age without enduring any of its infirmities; their fevers are acute, and they retain their beautiful teeth to the last. M. de Bougainville describes an old man, whom they saw on their landing, who had no other character of old age, than that respectable one which is imprinted on a fine figure. His head was adorned with white hair, and a long white beard; all his body was nervous and fleshy; he had neither wrinkles, nor shewed any others tokens of decrepitude. This venerable man seemed displeased at the arrival of these strangers; he even retired without making any returns to the courtesies they paid to him; but he gave no signs either of fear, astonishment, or curiosity: very far from taking any part in the raptures which the multitude expressed, his thoughtful and suspicious air seemed to indicate, that he feared the arrival of a new race of men would interrupt the happiness he had so long enjoyed. From whence it may be inferred, that his mind was not a whit more impaired than his body. There are, however, several sorts of leprosy complaints on this island, which appear in cutaneous eruptions of the scaly kind; some were seen that had ulcers upon different parts of their bodies: yet they seemed little regarded by those who were afflicted with them, and no application whatever was used to them, not so much as to keep off the flies. But instances of them are rare, as the excellency of their climate, and the simplicity of their vegetable food, prevent almost all dangerous and deadly disorders. They are sometimes afflicted with the cholera, and coughs are not unknown among them; and the chiefs, who fare more sumptuously, as a punishment for their voluptuousness are sometimes attacked with a disorder similar to the gout, in which the legs are swelled and excessively painful. M. de Bougainville's surgeon assured him, that he had seen many with marks of the small-pox.

The usual method employed here to restore the sick to health, is by pronouncing a set form of words; after which the exorcist applies the leaves of the cocoa-tree plaited, to the fingers and toes of the sick; so that nature is left to conflict with the disease, without being assisted with any salutary application of art. But tho' they seem utterly destitute of medical knowledge, they appear to be no inconsiderable proficient in surgery, which they had an opportunity of proving while the Dolphin lay here. One of the seamen, when on shore, ran a large splinter into his foot; and the surgeon not being at hand, one of his comrades endeavoured to take it out with a pen-knife; but after putting the poor fellow to a great deal of pain, he was obliged to give it over: an old native, who had been very active and successful in establishing a good understanding between the ship's company and his countrymen, happening to be present, called a man from the other side of the river, who having examined the lacerated foot, fetched a shell from the beach, which he broke to a point with his teeth; with which instrument he laid

Otaheitee.

Otaheitee.

open the wound, and extracted the splinter. Whilst this operation was performing, the old man went a little way into the wood, and returned with some gum, which he applied to the wound upon a piece of the cloth that was wrapped round him, and in two days time it was perfectly healed. This gum was produced by the apple-tree; the furgeon of the ship procured some of it, and used it as a vulnerary balsam with great success. Captain Cook, in 1769, saw many of the natives with dreadful scars; one man, in particular, whose face was almost entirely destroyed: his nose, including bone, was perfectly flat; and one cheek and one eye were so beaten in, that the hollow would almost receive a man's fist; yet no one ulcer remained.

The venereal disease is said to have been entailed upon these people by the crew of M. de Bougainville's ships, who visited this island a short time after Captain Wallis had left it. In 1769, more than one-half of the crew in Captain Cook's ship had contracted it, during a month's stay here. The natives distinguished it by a name of the same import with rottenness, but of a more extensive signification. They described, in the most pathetic terms, the sufferings which the first victims to its rage endured; and told him that it caused the hair and the nails to fall off, and the flesh to rot from the bones; that it spread an universal terror and consternation among the inhabitants, so that the sick were abandoned by their nearest relations, left the calamity should spread by contagion, and were left to perish alone in such misery as till then had never been known among them. But there seems to be some reason to hope that they had found out a specific cure for it, as none were seen on whom it had made a great progress; and one who went from the ship infected, returned, after a short time, in perfect health. Both Captain Cook and Mr Forster, in their relations of their voyage in the Resolution, endeavour to establish the opinion, that this scourge of licentiousness was felt in the South-Sea islands, previous to any of the modern voyages that have been made thither, and that it was an indigenous disease there. But if that conclusion is well founded, how comes it, that at all the places where the Resolution touched in 1773, which had been before visited by the Endeavour in 1769, such as New Zealand for instance, the crew, more or less, became infected by their commerce with the women, and not at all so at places which they visited, for the first time, in the Resolution?

Manufac-  
tures.

The principal manufacture among the Otaheiteans is their cloth. This is made of the bark of trees, which are of three kinds, *viz.* the Chinese mulberry-tree, or *outa*; the bread-fruit tree, or *ooroo*; and one that is described by Dr Hawkesworth as resembling the wild fig-tree of the West Indies. Of all these the paper mulberry affords the best cloth; what is made from that being both finer, softer, whiter, and better suited to take a colour; the *ooroo* produces cloth much inferior in contexture; and the last is very coarse, in colour resembling the darkest brown paper; but this last is the only kind that withstands water. See the article BARK.—They likewise prepare a red dye; which is made by mixing the yellow juice of a small species of fig, which the natives call *mattee*, with the greenish juice of a sort of fern or bindweed, or of several other plants, which produce a

bright crimson: and this the women rub with their hands, if the piece is to be uniformly of a colour; or they make use of a bamboo reed if the piece is to be marked, or sprinkled into different patterns. The colour fades very soon, and becomes of a dirty red; but notwithstanding this defect, and its being liable to be spoiled by rain, the cloth thus stained is highly valued, and is worn only by the principal inhabitants of the country. The inhabitants perfume their clothes with certain plants; concerning which, Mr Forster made all possible inquiry. Tahea, a friendly native, shewed him several plants which are sometimes used as substitutes; but the most precious sort he either could not, or would not point out: and from the account of Omai it appears, that there are no less than 14 different sorts of plants employed for this purpose.

Matting is another Otaheitean manufacture; and in this they are so dextrous, that they produce finer mats than any made in Europe. Rushes, grass, the bark of trees, and the leaves of a plant called *wharrou*, are the materials which they work up for this purpose. Their matting is applied to various uses: the coarser kind is employed for sleeping on in the night, or sitting on through the day; the finer sort is converted into garments in rainy weather, their cloth being soon penetrated by wet. They are very dextrous in making basket and wicker-work: their baskets are of a vast number of different patterns, many of them exceedingly neat; and the making them is an art practised by every one, both men and women.

Instead of hemp, they make ropes and lines of the bark of a tree; and thus they are provided with fishing-nets; the fibres of the cocoa-nut furnish them with thread, with which they fasten the different parts of their canoes, &c. The bark of a nettle which grows in the mountains, and is called *orawa*, supplies them with excellent fishing-lines, capable of holding any kind of fish; and their hooks are made of mother-of-pearl, to which they fix a tuft of hair, made to resemble the tail of a fish. Instead of making them bearded, the point is turned inwards. They make also a kind of seine of a coarse broad grass, the bladder of which are like flags. These they twist and tie together in a loose manner, till the net, which is about as wide as a large sack, is from 60 to 80 fathoms long. This they haul in smooth shoal water; and its own weight keeps it so close to the ground, that scarcely a single fish can escape. They make harpoons of cane, and point them with hard wood; with which they can strike fish more effectually than an European can with one headed with iron.

The tools used by the Otaheiteans for all their purposes are, an adze, made of stone; a chisel or gouge, made of bone, generally the bone of a man's arm between the wrist and elbow; a rasp of coral, and the skin of a sting-ray; also coral and sand, as a file or polisher; and with these they fell timber, cleave and polish it, and hew stone. The stone which makes the blade of their adzes is a kind of basalt, of a grey or blackish colour; not very hard, but of considerable toughness: they are formed of different sizes; some that are intended for felling, weigh from six to eight pounds; others that are used for carving, not more than as many ounces: but it is necessary to sharpen these rude tools almost every minute; for which purpose a

to  
Working-  
tools.

Otaheitee.

cocoa-nut shell full of water and a stone are always at hand. With such tools they generally take up several days in felling a tree; but after it is down, and split into planks, they smooth them very dexterously and expeditiously with their adzes, and can take off a thin coat from a whole plank without missing a stroke.

12  
Weapons.

Their weapons are slings, which they use with great dexterity; pikes headed with the flings of fling-rays; and clubs of about six or seven feet long, made of a very hard wood. Thus armed, they are said to fight with great obduracy; and to give no quarter to man, woman, or child, who happens to fall into their hands during the battle, nor for some time afterwards, till their passion subsides. They have likewise bows and arrows; but the arrows are good for nothing except to bring down a bird, being headed only with stone, and none of them pointed. They have targets of a semi-circular form, made of wicker-work, and plaited strings of the cocoa-nut fibres, covered with glossy, bluish-green feathers belonging to a kind of pigeon, and ornamented with many shark's-teeth, arranged in three concentric circles.

13  
Canoes.

Their boats or canoes are of three different sorts. Some are made out of a single tree, and hold from two to six men. These are principally employed in fishing; the others are constructed of planks very dexterously sewed together; they are of different sizes, and will hold from 10 to 40 men: they generally lash two of these together, and set up two masts between them; or if they are single, they have an on-trigger on one side, and only one mast in the middle; and in these vessels they will sail far beyond the sight of land. The third sort seems to be principally designed for pleasure or shew. These are very large, but have no sail; and in shape resemble the gondolas of Venice. The middle is covered with a large awning; and some of the people sit upon it, and some under it. The plank of which these vessels are constructed, is made by splitting a tree, with the grain, into as many thin pieces as possible. The boards are brought to the thickness of about an inch, and are afterwards fitted to the boat with the same exactness that might be expected from an expert joiner. To fasten these planks together, holes are bored with a piece of bone fixed into a stick for that purpose. Through these holes a kind of plaited cordage is passed, so as to hold the planks strongly together. The seams are caulked with dry rushes; and the whole outside of the vessel is painted over with a kind of gummy juice, which supplies the place of pitch.

14  
Character,  
manners,  
&c.

The Otaheiteans are a very industrious people, and friendly in their dispositions; but, like all other nations not fully civilized, their passions are extremely violent, and they are very fickle. The manner of singling out a man here for a chosen friend is by taking off a part of your clothing and putting it upon him. Their usual manner of expressing their respect to strangers, or to their superiors, at a first meeting, is by uncovering themselves to the middle. They have a custom of saluting those who sneeze, by saying *euaroaiat-eatoua*, "May the good eatoua awaken you," or "May not the evil eatoua lull you asleep!"

Their propensity to theft is great, inasmuch, that Mr Bougainville says, "even in Europe itself one cannot see more expert filchers than the people of this

country;" and indeed, in all the voyages made by Captain Cook and others, they had abundant experience of this disposition of the natives, which often produced quarrels, and sometimes even fatal effects. In their behaviour they are extremely lascivious, almost beyond credibility. A woman of distinction who visited Mr Banks used the following ceremony on her first approach to the stranger. After laying down several young plantain-leaves, a man brought a large bundle of cloth; which having opened, he spread it piece by piece on the ground, in the space between Mr Banks and his visitants. There were in all nine pieces: having spread three pieces one upon another, the lady came forward, and, stepping upon them, took up her garments all around her to her waist; she then turned three times round, after which she dropped the veil: when other three pieces were spread, she practised the same ceremony; and so the third time, when the last three pieces were laid out: after which the cloth was again rolled up, and delivered to Mr Banks as a present from the lady, who with her attending friend came up and saluted him. From the unbridled licentiousness of these people, the French gave this island the name of the *New Cythera*. Nay, to such a degree do they carry their libidinous excesses, that a number of the principal people, it is related, have formed themselves into a society, in which every woman is common to every man. This society is distinguished by the name of *Arreey*, the members of which have meetings from which all others are excluded. At these meetings the passions are excited by a studied course of sensuality, and the coarsest and most brutal pleasures are enjoyed by the whole company. If, however, notwithstanding these excesses, any of the female members of this community should prove with child, unless she can procure some man to adopt the child as his own, not all the strong affections of a mother, if such are not entirely eradicated by a course of life subversive of the feelings as well as the modesty of nature, can save the life of the precondemned innocent; but the child as soon as born is smothered, and the mother is left at liberty to renew her former course of execrable prostitution. Should any man be found to co-operate with a woman in saving the life of a child, they are both excluded for ever from the *arreey*, and are considered as man and wife. The woman from that time is distinguished by the term *whannow-nenu*, "the bearer of children;" which in this part of the world only is considered as a term of reproach; and so depraved are these people, that being a member of such a society is boasted of as being a privilege, instead of being stigmatised as the foulest crime. The *arreeys* enjoy several privileges, and are greatly respected throughout the Society Islands, as well as at Otaheitee; nay, they claim a great share of honour from the circumstance of being childless. Tupia, one of the most intelligent natives, when he heard that the king of England had a numerous offspring, declared, that he thought himself much greater, because he belonged to the *arreeys*. That this society indulge themselves in promiscuous embraces, and that every woman is common to every man, is contradicted by Mr Forster. He says, that these *arreeys* choose their wives and mistresses from among the prostitutes; and from this circumstance, as well as their extreme voluptuousness, they

Otaheitee.

they have seldom any reason to dread the intrusion of children. He had the following circumstances related to him by Omai or Omiah, one of the natives, who was brought to England. He said, that the pre-eminence and advantages which a man enjoyed as arroyo were so valuable, as to urge him against his own feelings to destroy his child; that the mother was never willing to consent to the murder; but that her husband and other arroyos persuaded her to yield up the child; and that where intrigues were not sufficient, force was sometimes made use of. But above all, he added, that this action was always perpetrated in secret; inasmuch, that not even the *towns*, or attendants of the house were present; because, if it were seen, the murderers would be put to death.

Both men and women constantly wash their whole bodies three times a-day in running water, and are remarkably cleanly in their clothes. They are most expert swimmers, being accustomed to the water from their infancy. Captain Cook relates the following remarkable instance of their expertness. On a part of the shore where a tremendously high surf broke, inasmuch that no European boat could live in it, and the best European swimmer, he was persuaded, would have been drowned, as the shore was covered with pebbles and large stones, yet here were 10 or 12 Indians swimming for their amusement. Whenever a surf broke near them, they dived under it, and rose again on the other side. The stern of an old canoe added much to their support. This they took out before them, and swam with it as far as the outermost breach; when two or three getting into it, and turning the square end to the breaking wave, were driven in towards the shore with incredible rapidity, sometimes almost to the beach; but generally the wave broke over them before they got half way; in which case they dived, and rose to the other side with the canoe in their hands, and swimming out with it again, were again driven back. This amazing expertness drew the Captain's attention for more than half an hour; during which time none of the swimmers attempted to come ashore, but seemed to enjoy the sport in the highest degree. At another time, one of the officers of the quarter-deck intending to drop a bead into a canoe for a little boy of six years of age, it accidentally missed the boat, and fell into the sea; but the child immediately leaped overboard, dived after it, and recovered it. To reward him for this feat, some more beads were dropped to him; which excited a number of men and women to amuse the officers with their amazing feats of agility in the water, and not only fetched up several beads scattered at once, but likewise large nails, which, from their weight, descended quickly to a considerable depth. Some of these people continued a considerable time under water; and the velocity with which they were seen to go down, the water being extremely clear, was very surprising. Here a green branch of a tree is used as an emblem of peace, in exact conformity to the custom of the ancient nations.

The language of these islanders is soft and melodious; it abounds with vowels, and the pronunciation of it is easily acquired; but it was found excessively difficult to teach the natives to pronounce a single English word; probably not only from its abounding with consonants, but from some peculiarity in its

structure; for Spanish and Italian words, if ending in a vowel, they pronounced with the greatest ease. A sufficient acquaintance has not been formed with it to determine whether it is copious or not; but it is certainly very imperfect, being totally without inflexion either of nouns or verbs. Few of the nouns have more than one case, and few of the verbs more than one tense. It was impossible to teach the islanders to pronounce the names of their guests. They called Captain Cook *Tote*; Mr Hicks, the first lieutenant *Hei*, &c. and in this manner they formed names for almost every man in the ship. In some, however, it was not easy to find any traces of the original; and they were perhaps not mere arbitrary sounds formed upon the occasion, but signified words in their own language; and it seems that they could perfectly remember these appellations at the distance of four years, by their inquiries after such gentlemen as were absent on the second voyage by name. Mr Monkhouse, a midshipman, they called *Matte*, which in their language signifies *dead*; because he commanded a party that killed a man for stealing a musket. The nearest imitation they could reach of king George, was by calling him *Kihiago*.

A map of Otaheite, engraved for Captain Cook's first voyage, was taken out, and laid before Tuahoe the high admiral, without informing him of what it was; however, he immediately found it out, and was overjoyed to see a representation of his own country. He pointed out all the districts of it, naming every one of them in their order.

These people have a remarkable sagacity in foretelling the weather, particularly the quarter from whence the wind will blow. In their long voyages they steer by the sun in the day, and in the night by the stars; all of which they distinguish by separate names, and know in what part of the heavens they will appear in any of the months during which they are visible in their horizon. They also know the times of their annual appearing and disappearing, with more precision than would easily be believed by an European astronomer. Their time they seem to reckon by moons, 13 of which make a year. The day they divide into six parts, and the night into an equal number. They judge of the time of the day by the height of the sun, but they cannot ascertain the time of the night by the stars. In numeration, the greatest length they can go is 200; that is, when they have counted each of their fingers and toes ten times over. When they take the distance from one place to another, they express it by the distance which is required to pass it.

The government of the Otaheiteans seems greatly to resemble the early state of the European nations under the feudal system. Their orders of dignity are *earce-rahie*, which answers to king; *earce*, baron; *manabouni*, vassal; and *townou*, vassal. There are two kings in the island, one being the sovereign of each of the peninsulas of which it consists. Each of them is treated with great respect by all ranks, but does not appear to be invested with so much power as is exercised by the earces in their own districts. When the king, whom they called *O-Too*, made a visit to Captain Cook, the chiefs, who happened to be there before him, immediately stripped themselves in great haste. Captain Cook took notice of it, upon which they said *earce*, *earce*, signifying, that it was an account

count of O-Too being present: but this was the only outward token of respect they paid him; for they never rose from their seats, or made any other obeisance.

The *carrees* are lords of one or more of the districts into which each of the peninsulas is divided, and of which there are 43 in the larger one. These parcel out their territories to the *manahounis*, who superintend the cultivation of the ground. The lowest class, called *tou-tous*, seem to be nearly under the same circumstances with the vassals in feudal governments. They do all the laborious work, cultivate the land, catch fish, fetch wood and water, &c. Each of the *carrees* keeps a kind of court, and has a great number of attendants, chiefly the younger brothers of their own tribe; and among these some hold particular offices, but of which little more is known than some of their names.

In this country a child succeeds to his father's titles and authority as soon as he is born; and thus the king no sooner has a son born, than his sovereignty ceases. A regent is then chosen; and the father generally retains his power under that title, until his child becomes of age. The child of the baron succeeds to the titles and honours of his father as soon as it is born, as well as the son of the king; so that a baron who was yesterday called *carree*, and was approached with the ceremony of lowering the garments, so as to uncover the upper part of the body, is to-day, if his wife happens to be delivered of a child, reduced to the rank of a private man; all marks of respect being transferred to the child, if it is suffered to live, though the father still continues possessor and administrator of his estate. But the acquiescence which the lower class of people, or *toutous*, yield to the command of their chiefs, is very remarkable. They are not suffered to taste any animal-food, although they are employed in feeding it for their lords. They endure patiently very severe blows, if, when collected into a large body, they in any manner press upon or annoy the king or a chief in his progress: and all this passive spirit is preferred without any power being lodged in the hands of the king to exact it; for he uses no military force, nor is even attended with body-guards.

There are but few actions which are reckoned crimes among the Otaheiteans. Adultery, however, is sometimes punished with death; but in general, the woman escapes with a severe beating, and the gallant passes unnoticed. The regulation of public justice is not confined to the magistrate; for the injured party redresses his own wrong by inflicting whatever punishment he can upon the offender: but in matters of notorious wrong, the chiefs sometimes interpose. The nobility have livery for their servants; and in proportion as the master's rank is more or less elevated, these falshes are worn higher or lower, being fastened close under the arms of the servants belonging to the chiefs, and going round the loins of those belonging to the lowest class of nobility. Several parts of the island seem to be private property, which descend to the heir of the possessor on his death, and the descent seems to fall indifferently on man or woman. Captain Cook was of opinion, that the number of inhabitants on the whole island amounted to 204,000, including women and children.

The religious language of the Otaheiteans, like that of the Gentoo Bramins, is different from what is used in common discourse; but, according to the accounts we have of their notions concerning the origin of the world, nothing can be more ridiculous. They imagine that the Supreme Deity, besides a great many female defendants, has one son named *Tane*; and to him they direct their worship, though they do not believe that the good or bad conduct of mankind here on earth makes them more or less acceptable to this divinity. They believe the existence of the soul after death, and of a greater or lesser degree of happiness to be then enjoyed; but they seem to have no conception of a state of punishment or of suffering hereafter. The share of happiness which they imagine every individual will enjoy in this future state, will be assigned to him according to the rank he holds on earth. We are not, however, told wherein they suppose the happiness of this future state to consist; but it is most probably a pretty exact imitation of a Mahomedan paradise, for these voluptuaries can hardly be supposed capable of imagining any pleasure independent of the intercourse of the sexes.

The priesthood seems to be hereditary in one family or tribe; and as it is said to be numerous, probably those of that order are restrained from becoming members of the Arroy: but whether or not any peculiar decorum is necessary to be observed, hath not yet appeared. These priests are professedly the men of science; but their knowledge is altogether frivolous and useless; for it consists in being conversant with the names of their different divinities, and such absurd traditions as have been handed down among them from one generation to another. Their religious notions being deposited in an unknown tongue, they are respected because they are not understood; and as the cure of the soul is no object of regard, the most important concern to these people, the cure of their bodies, is committed to the priests, and much parade is used in their attempts to recover the sick, though their remedies consist of ridiculous ceremonies and enchantments rather than any thing else.

The marriages of these people are merely secular contracts: but no one has a right to perform the operation of tattooing, except the priests; and this being a custom universally adopted by the natives, it may be supposed, that the performing it is a very lucrative employment. The males in general undergo a kind of circumcision, which it is disgraceful not to comply with, and which is likewise the exclusive privilege of the priests to perform. But what most establishes the credit of this order of men is their skill in astronomy and navigation.

Captain Cook, who had some reason to believe that, among the religious customs of this people, human sacrifices were sometimes offered up to their deities, went to a morai, or place of worship, accompanied by Captain Furneaux, having with them a sailor who spoke the language tolerably well, and several of the natives. In the marai was a tupapow, a kind of bier, with a shed erected over it, on which lay a corpse and sums provisions. Captain Cook then asked if the plaitain were for the Eatua? If they sacrificed to the Eatua hogs, dogs, fowls, &c.? To all of which an intelligent native answered in the affirmative. He then asked

Otaheitee. e] if they sacrificed men to the Eatua? He was answered, *taato eno*, "bad men they did; first *tiparraby*, beating them till they were dead." He then asked if good men were put to death in this manner? His answer was no, only *taato eno*. The Captain then asked if any Earees were? The native replied, they had hogs to give the Eatua, and again repeated *taato eno*. He was then asked if towtoes, who had no hogs, dogs, or fowls, but yet were good men, were ever sacrificed to the Eatua? The answer still was no, only bad men. Many other questions were put to him; all his answers to which seemed to confirm the ideas that men for certain crimes were condemned to be sacrificed to the gods, provided they did not possess any property which they might give for their redemption. However, in pursuing such inquiries as these, no certain information could be obtained, on account of the slight knowledge which had been acquired of the language of the country; but according to further accounts which Captain Cook received from Omai, it seems to rest with the high-priest to single out the victims for sacrifice; who, when the people are assembled on any solemn occasion, retires alone into the house of God, and stays there for some time; when he comes out, he informs the assembly that he has seen and conversed with the great god, (the high-priest alone having that privilege), and that he has asked for a human sacrifice; and tells them he has desired such a person, naming a man present, who has most probably, on some account or other, rendered himself obnoxious to this ghastly father. The words are no sooner gone out of his mouth, than the devoted wretch is put to death; for his guilt cannot be doubted, after the oracle has pronounced his doom.

On this island was seen the figure of a man constructed of basket-work, rudely made, but not ill designed: it was something more than seven feet high, and rather too bulky in proportion to its height. This wicker skeleton was completely covered with feathers, which were white where the skin was to appear, and black in the parts which it is their custom to paint or stain, as well as upon the head, which was designed to represent hair. Upon the head also were four protuberances; three in front, and one behind, which the Indians called *tate etc*, little men. The image was called *Manice*; it was a representation of *Mauve*, one of their Eatuas, or gods of the second class, and was said to be the only one of the kind on Otaheitee.

These people pray at sun-rise and sun-set. They have also a number of superstitious practices, in order to conciliate the influence of evil genii. E-Tee, a chief, who seemed to be the king's prime minister in 1774, very seriously asked Mr Forster whether they had a god (*Eatau*) in their country, and whether they prayed to him (*epooe?*) When he told them that they acknowledged a Divinity who had made every thing, and was invisible, and that they were accustomed to address their petitions to him, he seemed to be highly pleased, and repeated their words with comments of his own, to several persons who sat round him; seeming thereby to intimate, that the ideas of his countrymen corresponded with theirs in this respect.

Their marais are used both as burying-grounds and places of worship; they are approached with the most

wonderful expressions of reverence and humility; and this, it should seem, not because any there is esteemed sacred, but because they there worship an invisible being, for whom they entertain the most reverential respect, although not excited by the hope of reward, or the dread of punishment. Though they do not appear to have any visible object of worship, yet, says Captain Cook, this island, and indeed the rest that lie near it, have a particular bird, some a heron, and others a king-fisher, to which they pay a particular regard, and concerning which they have some superstitious notions, respecting good or bad fortune, as we have of the swallow and robin-redbreast, and will on no account molest or kill them. One of these cemeteries, or places of worship, was known to Captain Cook, on his first voyage, by the name of Tootahah's marai, then the regent; but when, on his second voyage, after the death of that chief, he called it by that name, Maratata, a chief that accompanied the party, interrupted him, intimating, that it was no longer Tootahah's after his death, but was then known as O-Too's marai, the then reigning prince. A fine moral for princes! daily reminding them of mortality whilst they live, and teaching them, that after death they cannot call even that ground their own which their dead corpse occupies! The chief and his wife, on passing by it, took their upper garments from their shoulders. From hence it should seem, that the royal family have a particular marai, and that it always bears the name of the reigning prince.

An Indian, who had snatched away a musket from a sentry whilst on duty, was, by the inhumanity of a midshipman who commanded the guard, pursued and shot. The unhappy fate of this poor fellow gave an opportunity for seeing the manner in which these people treat their dead. They placed the corpse in the open air till the bones became quite dry: a shed was erected close by the house where the deceased had resided; it was about 15 feet long, and eleven broad; one end was left quite open; the other end, and the two sides, were partly inclosed with a sort of wicker-work. The bier was a frame of wood, like that on which the sea-beds, called *cots*, are placed, with a matted bottom, and supported by four posts, at the height of about four feet from the ground. The body was covered first with a mat, and then with white cloth; by the side of it lay a wooden mace, one of their weapons of war; and near the head of it, which lay next to the close end of the shed, lay two cocoa-nut shells; at the other end a bunch of green leaves, with some dried twigs, all tied together, were stuck in the ground, by which lay a stone about as big as a cocoa-nut. Near these lay one of the young plantain-leaves that are used for emblems of peace, and close by it a stone ax. At the open end of the shed also hung, in several strings, a great number of a palm-nuts; and without the shed was stuck up in the ground a stem of a plantain tree, about six feet high, upon the top of which was placed a cocoa-nut shell full of fresh water; against the side of one of the posts hung a small bag, containing a few pieces of bread-fruit ready roasted, which had not been put in all at one time, some being fresh, and others stale. This minute examination of their manner of treating their dead, seemed to be very unwelcome to the natives. The food so placed by the

Otaheitee.

Otaheitee.

corps is designed as an offering to their gods. They cast in, near the body, small pieces of cloth, on which the tears and blood of the mourners have been shed; for in their paroxysms of grief it is an universal custom to wound themselves with a shark's tooth. The mourner is always a man; and he is dressed in a very singular habit. When the bones are stripped of their flesh, and become dry, they are buried. This regard to their dead is very remarkable: one of the ship's company happening to pull a flower from a tree which grew on one of their sepulchral inclosures, an Indian came suddenly behind him and struck him; and a party of sailors, who were sent to get some stones for ballast for the ship, had like to have been embroiled with the natives, by pulling down some part of an inclosure of this kind. The shade under which their dead are laid is called *tupapou*; the inclosure in which their bones are deposited is called *morai*; these latter, as has been already related, are also places of worship. As soon as a native of Otaheitee is known to be dead, the house is filled with relations, who deplore their loss; some by loud lamentations, and some by less clamorous, but more genuine expressions of grief. Those who are in the nearest degree of kindred, and are really affected by the event, are silent; the rest, are one moment uttering passionate exclamations in a chorus, and the next laughing and talking without the least appearance of concern. In this manner the remainder of the day on which they assemble is spent, and all the succeeding night. On the next morning the body is shrouded in their cloth, and conveyed to the sea-side on a bier, which the bearers support upon their shoulders, attended by the priest, who having prayed over the body repeats his sentences during the procession. When it arrives at the water's edge, it is set down upon the beach; the priest renews his prayers, and taking up some of the water in his hands, sprinkles it towards the body, but not upon it. It is then carried back 40 or 50 yards; and soon after brought again to the beach, where the prayers and sprinkling are repeated. It is thus removed backwards and forwards several times; and while these ceremonies have been performing, a house has been built, and a small space of ground railed in. In the centre of this house, or *tupapou*, as they term it, posts are set up to support the bier, which is at length conveyed thither, and placed upon it; and here the body remains to putrify, till the flesh is wholly wasted from the bones. These houses of corruption are of a size proportioned to the rank of the person whose body they are to contain. Those allotted to the lower class are just sufficient to cover the bier, and have no railing round them. The largest that was seen was 11 yards long; and such are ornamented according to the abilities and inclination of the surviving kindred, who never fail to lay a profusion of good cloth about the body, and sometimes almost cover the outside of the house. Garlands of the fruit of the palm-nut, or pandanus, and cocoa-leaves, twisted by the priests in mysterious knots, with a plant called by them *ethee no morai*, which is particularly consecrated to funeral solemnities, are deposited about the place; provision and water are also left at a little distance. As soon as the body is deposited in the *tupapou*, the mourning is renewed. The women assemble, and are led to the door by the nearest relation, who strikes a

shark's tooth several times into the crown of her head; the blood copiously follows, and is carefully received upon pieces of linen, which are thrown under the bier. The rest of the women follow this example; and the ceremony is repeated at the interval of two or three days, as long as the zeal and sorrow of the parties hold out. The tears also which are shed upon these occasions, are received upon pieces of cloth, and offered as oblations to the dead. Some of the younger people cut off their hair, and that is thrown under the bier with the other offerings. This custom is founded on a notion, that the soul of the deceased, which they believe to exist in a separate state, is hovering about the place where the body is deposited; that it observes the actions of the survivors, and is gratified by such testimonies of their affectionate grief. Whilst these ceremonies are carrying on by the women, the men seem to be wholly insensible of their loss; but two or three days after, they also begin to perform a part. The nearest relations take it in turn to assume the dress, and perform the offices.

The chief mourner carries in his hand a long flat stick, the edge of which is set with shark's teeth; and in a phrenzy, which his grief is supposed to have inspired, he runs at all he fees, and if any of them happen to be overtaken, he strikes them most unmercifully with his indented cudgel, which cannot fail to wound them in a dangerous manner. The processions continue at certain intervals for five moons; but are less and less frequent, by a gradual diminution, as the end of that time approaches. When it is expired, what remains of the body is taken down from the bier; and the bones, having been scraped and washed very clean, are buried according to the rank of the person, either within or without a morai. If the deceased was an earce, or chief, his skull is not buried with the rest of his bones, but is wrapped up in fine cloth, and put in a kind of box made for that purpose, which is also placed in the morai. This coffin is called *ewharre no te orometua*, "the house of a teacher, or master." After this the mourning ceases, except some of the women continue to be really afflicted at the loss, and in that case they will suddenly wound themselves with the shark's tooth wherever they happen to be. The ceremonies, however, do not cease with the mourning; for prayers are still paid by the priest, and offerings made at the morai. Some of the things, which from time to time are deposited there, are emblematical: a young plantain is said to represent the deceased, and a bunch of feathers the Deity who is invoked. The priest places himself over against the symbol of the god, accompanied by some of the relations, who are furnished with a small offering: he repeats his orison in a set form, consisting of separate sentences; at the same time weaving the leaves of the cocoonut into different forms, which he afterwards deposits upon the ground where the bones have been interred: the Deity is then addressed by a shrill scream, which is used only upon that occasion. When the priest retires, the tuft of feathers is removed, and the provisions are left to putrify, or be devoured by the rats.

This ceremony of mourning, as described above, was performed by Tiropo, one of the wives of Tubourai Tamaide; who, when the bleeding from the wounds which she had thus given herself ceased, looked up

Otaheite.

with a smile on the company round her, and who had before inquired of her, very earnestly, the cause of her behaviour, without receiving any answer, or having been at all noticed by her. She then began to pick up some small pieces of cloth which she had spread to catch the blood; and having got them all together, she went to the shore, and threw them into the sea. She then plunged into the river; and having washed her whole body, returned to the company as cheerful as ever. To add to the singularity of this conduct, the Indians who stood round her all the time that this frantic distress was performing, conversed with great indifference and jocularly.

There is not a more ancient custom handed down to us than that of cutting the body to express grief and distress of mind. In the code of laws delivered by Moses to the Israelites, 1400 years before the Christian æra, this practice is expressly forbidden to that people: "Ye shall not cut yourselves, or make any baldness between the eyes for the dead," Deut. xiv. 1. Hence it may be supposed that this rite prevailed in Egypt, from whence the Jews derived most of those propensities which were inhibited by their great legislator. We are told likewise in the book of Kings, of the priests of Baal wounding themselves, after they had long waited in vain for the supernatural intervention of their idol. D'Arvieux informs us, that the modern Arabs retain the same custom, and that the part they chiefly wound is their arms. The difference in the practice as now prevailing in O-Tahitee and Arabia seems to be, that in the first none but the women make use of it, and in the latter it is confined to the men, and generally used to express their desperate passion for some favourite mistress.

The mourning which is worn here is an head-dress of feathers, the colour of which is consecrated to death, and a veil over the face. This dress is called *ceeva*. The whole nation is said to appear thus on the death of their king. The mourning for fathers is very long. The women mourn for their husbands, but not the husbands for their wives.

We shall conclude this account of Otaheite with the history of *Omai*, or as he is improperly called *O-miah*, who was brought over to England. He was a native of Ulitea, or Raiatea; and embarked at Huahine with Captain Furneaux, on board the adventure, in September 1773; and the two ships separating in a storm on the coast of New-Zealand a few months afterwards, the voyage of the Adventure was brought to a much earlier conclusion than that of the Resolution, for she arrived at Spithead the 14th of July following. This youth is said to have had some property in his native soil, of which he was dispossessed by the people of Bolabola; but he was not one of the caroes, or gentry of that country, but of the middling class of people. He was eminent neither for figure, shape, nor complexion; his colour being of a deep hue, resembling a towtow, or one of the common people; and both Captain Cook and Mr Forster agree in thinking him no proper sample of the inhabitants of those islands, in respect to personal beauty. However, they are both of opinion, that the qualities of his heart and head resembled those of his countrymen in general, and that no one of the natives would have given more general satisfaction by his behaviour whilst

he remained in England. He is described as possessing a good understanding, quick parts, and honest principles: not an extraordinary genius like Tupia; yet not at all deficient in intelligence, which appears from his knowledge of the game of chess, in which he made an amazing proficiency. His principal patrons, whilst in England, were, the earl of Sandwich, Mr Banks, and Doctor Solander. His noble patron introduced him to his Majesty at Kew; and, during his stay in England, he was caressed by many of the principal nobility. He naturally imitated that easy and elegant politeness which is prevalent among the great, and which is one of the ornaments of civilized society. Indeed he adopted the manners, the occupations, and amusements of his companions in general, and gave many proofs of a quick perception, and a lively fancy. He appears, however, to have been treated, whilst he resided here, rather as a fashionable exhibition, than as a rational being. No attention seems to have been paid to the enriching his mind with useful knowledge, such as might have rendered him a valuable acquisition to his country on his return thither; no means were used to instruct him in agriculture, or any mechanical art or useful manufacture; and, above all, to possess him with a moral sense; to teach him the exalted ideas of virtue, and the sublime principles of revealed religion. After a stay of two years in England, and having been inoculated for the small-pox, he embarked with Captain Cook, on board the Resolution, on his return home, loaded with a profusion of presents. At parting with his friends here, his tears flowed plentifully, and his whole behaviour bespoke him to be sincerely affected at the separation: but though he lived in the midst of amusements during his residence in England, his return to his native country was always in his thoughts; and tho' he was not impatient to go, he expressed a satisfaction as the time of his return approached.

OTALGIA, the EAR-ACH, in medicine. See there n° 314. and p. 4869.

OTIS, in ornithology, a genus of birds belonging to the order of grallæ. There are four species, principally distinguished by their colour. One of the species, the tarda, or bustard, is the largest of the British land-fowl; the male at a medium weighing 25 pounds; there are instances of some very old ones weighing 27. The breadth nine feet; the length near four. Besides the size and difference of colour, the male is distinguished from the female by a tuft of feathers about five inches long on each side of the lower mandible. Its head and neck are ash-coloured: the back is barred transversely with black and bright rust-colour: the greater quill-feathers are black: the belly white: the tail is marked with broad red and black bars, and consists of twenty feathers: the legs dusky.

The female is about half the size of the male: the crown of the head is of a deep orange, traversed with black lines; the rest of the head is brown. The lower part of the fore-side of the neck is ash-coloured: in other respects it resembles the male, only the colours of the back and wings are far more dull.

These birds inhabit most of the open countries of the south and east parts of this island, from Dorsetshire, as far as the Wolds in Yorkshire. They are exceeding

Otaheite

Ots,

Otranto  
Otway.Ov-1  
Overbury.Plate  
CCXXXII

exceeding shy, and difficult to be shot; run very fast, and when on the wing can fly, though slowly, many miles without resting. It is said that they take flight with difficulty, and are sometimes run down with grehounds. They keep near their old haunts, seldom wandering above 20 or 30 miles. Their food is corn and other vegetables, and those large earth-worms that appear in great quantities on the Downs before sun-riſing in the ſummer. Theſe are replete with moiſture, anſwer the purpoſe of liquids, and enable them to live long without drinking on thoſe extenſive and dry tracts. Beſides this, nature hath given the males an admirable magazine for their ſecurity againſt draught, being a pouch, whoſe entrance lies immediately under the tongue, and which is capable of holding near ſeven quarts; and this they probably fill with water, to ſupply the hen when ſitting, or the young before they can fly. Buſtards lay only two eggs, of the ſize of thoſe of a gooſe, of a pale olive-brown, marked with ſpots of a dark colour; they make no neſt, only ſcrape a hole in the ground. In autumn they are (in Wiſhire) generally found in large turnep-fields near the Downs, and in flocks of 50 or more.

OTRANTO, or TERRA D'OTRANTO, a province of Italy in the kingdom of Naples; bounded on the north by the Terra di Bari and by the gulph of Venice, on the eaſt by the ſame gulph, and on the ſouth and weſt by a great bay which is between that and the Baſilicata. It is a mountainous country, abounding in figs, olives, and wine. It is often viſited by locuſts, and by Algerine pirates, who carry off all the people they can catch into ſlavery. But to keep them off, there are a great many forts on the coaſts.

OTRANTO, a city of Italy, in the kingdom of Naples, and capital of the province of the ſame name, with a commodious harbour, an archbiſhop's ſee, and a ſtrong citadel where the archbiſhop reſides. It was taken by the Turks in 1480, who did a great deal of miſchief: and it has frequently ſuffered much from the Algerines. It is a large handſome place, ſeated on the gulph of Venice, in E. Long. 18. 35. N. Lat. 40. 21.

OTWAY (Thomas) an eminent tragic poet, was the ſon of Mr Humphry Otway, rector of Wolbeding in Suffex; and was born at Trotton in that county, on the 3d of March 1651. He was educated at Oxford; when, leaving the univerſity without a degree, he retired to London, where he commenced player, but with indifferent ſucceſs. However, the ſprightlineſs of his converſation gained him the favour of Charles Fitz-Charles earl of Plymouth, who procured him a cornet's commiſſion in one of the new-raiſed regiments ſent into Flanders; but he returned from thence in very neceſſitous circumſtances, and applied himſelf again to writing for the ſtage. In comedy he has been deemed too licentious; which, however, was no great objection to his pieces in the profligate days of Charles II. But, in tragedy, few Engliſh poets have ever equalled him; and perhaps none ever excelled him in touching the paſſions, particularly the tender paſſion. There is generally ſomething familiar and domeſtic in the fable of his tragedies, and there is amazing energy in his expreſſion.—The heart that doth not melt at

the diſtreſſes of his Orphan muſt be hard indeed! But though Otway poſſeſſed in ſo eminent a degree the rare talent of writing to the heart, yet he was not very favourably regarded by ſome of his contemporary poets, nor was he always ſucceſſful in his dramatic compoſitions. After experiencing many reverſes of fortune in regard to his circumſtances, but generally changing for the worſe, he at laſt died wretchedly in a public houſe on Tower-hill; whither, it is ſuppoſed, he had retired in order to avoid the preſſure of his creditors. Some have ſaid, that down-right hunger compelling him to fall too eagerly on a piece of bread, of which he had been for ſome time in want, the firſt mouthful choaked him, and inſtantly put a period to his days.—His dramatic writings are nine in number; the moſt admired of which are, *The Orphan*, and *Venice Preserved*. He had alſo made ſome tranſlations, and wrote ſeveral miſcellaneous poems. His whole works are printed in two pocket-volumes.

OVAL, an oblong curvilinear figure, otherwiſe called *ellipſis*. See *ELLIPſIS*. However, the proper oval, or egg-ſhape, differs conſiderably from that of the ellipſis, being an irregular figure, narrower at one end than at another; whereas the ellipſis, or mathematical oval, is equally broad at each end: though, it muſt be owned, theſe two are commonly confounded together; even geometers calling the oval a *false ellipſis*.

OVARY, in anatomy, that part of a female animal wherein the ova or eggs are formed or lodged. See *ANATOMY*, n<sup>o</sup> 372, m.

OVARIUM, in botany, a name by which botaniſts, who are fond of aſſimilating the animal and vegetable kingdoms, have diſtinguiſhed the germen or feed-bud, as containing the rudiments of the future feed.

OVATION, in the Roman antiquity, a leſſer triumph, allowed to commanders for victories won without the effuſion of blood; or for defeating a mean and inconfiderable enemy. The ſhow generally began at the Albanian mountain, whence the general with his retinue made his entry into the city on foot, with many flutes or pipes ſounding in concert as he paſſed along, and wearing a garland of myrtle as a token of peace. The term ovation, according to Servius, is derived from *ovis*, a ſheep; becauſe on this occaſion the conqueror ſacrificed a ſheep, as in triumph he ſacrificed a bull.

OUDENARDE, a rich and ſtrong town of Auſtrian Flanders, in the middle of which there is a conſiderable fort. The river Scheld runs acroſs this place with its environs, whoſe ſoil is very fertile, and forms a conſiderable chatellany. They have here a manufacture of very fine linen and curious tapeſtry. This town was beſieged by the French in 1708; but they were obliged to raiſe the ſiege by the duke of Marlborough and prince Eugene, who entirely defeated their army, killing 3000 on the ſpot, and taking 7000 priſoners. E. Long. 3. 42. N. Lat. 50. 49.

OVERBURY (Sir Thomas), a learned and worthy Engliſh gentleman, was born in 1581; and ſtudied at Queen's college, Oxford, after which he removed to the Middle-temple London. He afterwards travelled for ſome time, and returned a moſt accomplished perſon;

Overbury.

Over.

son; when he contracted an intimate acquaintance with Sir Robert Carr, knight of the bath, who being soon after taken into his majesty's favour, had Mr Overbury knighted at Greenwich. Sir Thomas perceiving the familiarity which subsisted between his patron Carr, now made viscount Rochester, and the lady Frances, the wife of Robert earl of Essex, was so much displeased at it, that he endeavoured to dissuade him from keeping her company, and from proceeding in the base design he had formed of having her first divorced from her husband, and then marrying her. The viscount, rejecting this honest advice, told what he had said to the lady, who was as remarkable for her wickedness as for her beauty; on which they immediately resolved on his destruction. About this time, the king wanting to send an ambassador abroad, the viscount recommended Sir Thomas Overbury. His majesty approving the choice, the viscount imparted the king's intentions to Sir Thomas; but, under a treacherous shew of friendship, dissuaded him from accepting of that employment, as it might hinder him from a better way of advancement; promising that he would prevent his majesty from being displeased at his refusal. The viscount then went to the king, and artfully incensing his majesty against Sir Thomas for refusing to obey his commands, that gentleman was committed to the tower for his contempt, on the 21st of April 1613, where he continued till he was dispatched by poison on the 15th of September following, and his body was interred in the tower-chapel the same day. About two years after, the whole contrivance of his death was discovered. On this several persons were condemned and executed; but tho' Carr, earl of Somerset, and the lady Frances his countess, were condemned to death for contriving the murder, and hiring the persons who were concerned in it, the king only banished them from court, and afterwards pardoned them. Sir Thomas Overbury wrote several poems, &c. and an account his travels.

OVEN, a kind of domestic furnace, used for baking bread, pies, tarts, &c. of a circular structure, with a very low roof, well lined, both on the top, bottom, and sides, with stone; it has a small entrance in the front, which is exactly fitted by a kind of door, which being clapped to the mouth of the oven confines the heat, while bread, pies, or puddings, are baking. Over this, pastry-cooks, &c. have another oven built much in the same manner, which is used for such things as require a less degree of heat. Ovens are heated by burning dry wood, faggots, &c. in them, till all the parts are equally hot.

OVER-HAULING, the act of opening and extending the several parts of a tackle, or other assemblage of ropes, communicating with blocks or dead-eyes. It is used to remove those blocks to a sufficient distance from each other, that they may be again placed in a state of action, so as to produce the effect required.

OVER-Hauling, is also vulgarly expressed of an examination or inspection into the condition of a person or thing.

OVER-Rake, among seamen: When a ship riding at anchor so overbeats herself into an high sea, that she is washed by the waves breaking in upon her, they say the waves over-rake her.

OVER-Reach, in farriery. See there, § xl. 2.

OVERSMAN, in Scots law, a person appointed by arbiters, or by the parties submitters, to determine the matter submitted, in case the parties disagree in their opinion.

OVERT, the same with "open;" thus an overt act signifies an act which, in law, must be clearly proved; and such is to be alleged in every indictment for high treason.

OVERTURE, or OUVERTURE, opening or prelude; a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, comedy, concert of music, &c.—The overture of the theatre or scene, is a piece of music usually ending with a figure; the overture of a jubilee is a general procession, &c.

OVERYSSEL, one of the Seven United Provinces; bounded on the east by the bishopric of Munster, on the north by Friesland and the territory of Groningen, on the west by the river Yssel, and on the south by the county of Zutphen and the bishopric of Munster. It is divided into three distinct parts; which are, the territories of Drenfe, Twente, and Salland. There are many morasses in this province, and but few inhabitants, in comparison of the rest. Its greatest riches consist in turfs; which are dug up here, and sent to the neighbouring provinces, particularly Holland.

OVIEDO, a town of Spain, and capital of Asturias d'Oviedo, with a bishop's see, and an university; situated at the confluence of the rivers Ove and Deva, which form the Asta, 50 miles north-west of Leon, and 208 north-west of Madrid. W. Long. 5. 47. N. Lat. 43. 23.

OUGHTRED (William), an eminent mathematician, was born at Eaton in 1573, and educated in the school there, whence he was elected to king's college in Cambridge, of which he afterwards became fellow. Having received holy orders, he left the university about the year 1603, and was presented to the rectory of Aldbury, near Guildford in Surry; and about the year 1628, was appointed by the earl of Arundel to instruct his son in the mathematics. He kept a correspondence by letters with some of the most eminent scholars of his time, upon mathematical subjects; and the most celebrated mathematicians of that age owed most of their skill to him, whose house was full of young gentlemen that came from all parts to receive his instruction. It is said, that, upon hearing the news of the vote at Westminster for the restoration of king Charles II. he expired in a sudden transport of joy, aged 88. He wrote, 1. *Clavis Mathematica*; which was afterwards published in English. 2. A description of the double horizontal dial. 3. *Opuscula Mathematica*; and several other works. He left also behind him a great number of papers upon mathematical subjects, which are now in the museum of William Jones, Esq; F. R. S.

OVID, or Publius Ovidius Naso, a celebrated Latin poet of the Augustan age, was a Roman knight, born at Sulmo, in the 43<sup>d</sup> year before the Christian æra. He studied rhetoric under Arelius Fuscus, and for some time frequented the bar; but was afterwards disgusted with that study, and applied himself entirely to poetry. Ovid, after having obtained the esteem of Augustus, incurred his displeasure; and was banished

Over

Ovid.

to

to Tomos, a city on the Pontus Euxinus, near the mouth of the Danube, when he was 50 years of age. Several writers have said that he was banished for being one of the lovers of Julia the daughter of Augustus, whom, according to them, he mentions under the name of *Corinna*; but Aldus Minutius has plainly refuted this notion. Ovid himself says, that his being sent into exile was occasioned by the licentiousness of his verses, and his having seen by accident and involuntarily something which he ought not to have seen. He in vain made use of all the turns of his wit to appease the emperor; but not all his addresses could procure his being again received into favour. He died in the country of the Getæ, aged 57, after having spent seven years in his banishment. His works and their character are well known.

OVILIA, or SEPTA, in ancient Rome, a place in the Campus Martius, at first railed in like a sheep-pen, whence its name. Afterwards it was mounted with marble, and beautified with walks and galleries, as also with a tribunal, or seat of justice. Within this precinct or inclosure, the people were called to give their suffrages for the election of magistrates. The ascent into the ovilia was not by stairs, but by pontes, or narrow boards, laid there for the occasion; on which account *de ponte defici*, signified "to be deprived of the privilege of voting;" and persons thus dealt with were called *de pontani*.

OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, the SHEEP, in zoology, a genus of the mammalia class, and of the order of pecora; the characters of which are these: The horns are concave, turned backwards, and full of wrinkles; there are eight fore-teeth in the under-jaw, and no dog-teeth. The species are,

1. Aries, or ram and ewe, the horns of which are shaped like a half-moon, and compressed.

The sheep, unquestionably a mild and gentle creature, is also represented by Buffon as the most stupid, defenceless, and timid of all quadrupeds; inasmuch that, without the assistance of man, it could never, he thinks, have subsisted or continued its species in a wild state.

"The female is absolutely devoid of every art and of every mean of defence. The arms of the ram are feeble and awkward. His courage is only a kind of petulance, which is useless to himself, incommensurable to his neighbours, and is totally destroyed by castration. The wedder is still more timid than the sheep. It is fear alone that makes sheep so frequently assemble in troops: upon the smallest unusual noise, they run close together; and these alarms are always accompanied with the greatest stupidity. They know not how to fly from danger, and seem not even to be conscious of the hazard and inconvenience of their situation. Wherever they are, there they remain obstinately fixed; and neither rain nor snow can make them quit their station. To force them to move or to change their route, they must be provided with a chief, who is learned to begin the march: the motions of this chief are followed, step by step, by the rest of the flock. But the chief himself would also continue immovable, if he were not pushed off by the shepherd,

or by his dog, an animal which perpetually watches over their safety, which defends, directs, separates, assembles, and, in a word, communicates to them every movement necessary to their preservation.

"Of all quadrupeds, therefore, sheep are the most stupid, and derive the smallest resources from instinct. The goat, who so greatly resembles the sheep in other respects, is endowed with much more sagacity. He knows how to conduct himself on every emergency: he avoids danger with dexterity, and is easily reconciled to new objects. But the sheep knows neither how to fly nor to attack; however imminent her danger, she comes not to man for assistance, but willingly as the goat; and, to complete the picture of timidity and want of sentiment, she allows her lamb to be carried off, without attempting to defend it, or showing any marks of resentment. Her grief is not even expressed by any cry different from that of ordinary bleating."

But the annotator upon this article in the Edinburgh translation of Buffon, denies the above to be the natural character of the animal. "All tame animals," he observes, "lose a portion of that sagacity, dexterity, and courage, which they are obliged to employ against their enemies in a wild state; because they have been long accustomed to rely upon the protection of man. Sheep, when enslaved by men, tremble at the voice of the shepherd or his dog. But, on those extensive mountains where they are allowed to range without controul, and where they seldom depend on the aid of the shepherd, they assume a very different mode of behaviour. In this situation, a ram or a wedder boldly attacks a single dog, and often comes off victorious. But when the danger is of a more alarming nature, like man, they trust not to the prowess of individuals, but have recourse to the collected strength of the whole flock. On such occasions, they draw up into one compact body; they place the young and the females in the centre; and the strongest males take the foremost ranks, keeping close by each others sides. Thus an armed front is presented on all quarters, and cannot be attacked without the greatest hazard of destruction. In this manner they wait, with firmness and intrepidity, the approach of the enemy. Nor does their courage fail them in the moment of attack. For, if the aggressor advances within a few yards of the line, the ram darts upon him with such impetuosity, as lays him dead at their feet, unless he saves himself by flight. Against the attacks of single dogs, or foxes, they are, when in this situation, perfectly secure. Besides, a ram, regardless of danger, often engages a bull, and never fails to conquer him; for the bull, by lowering his head, without being sensible of his defenceless condition, receives between his horns the stroke of the ram, which usually brings him to the ground.

"In the selection of food, few animals discover greater sagacity than the sheep; nor does any domestic animal show more dexterity and cunning in its attempts to elude the vigilance of the shepherd, and to steal such delicacies as are agreeable to its palate. When perfectly tamed, and rendered domestic, the sportive gambols and troublesome tricks of the animal, are too well known to require any description."

As to the accusations contained in the latter part of the

Ovis.

the character above quoted; every person, it is observed, who has attended to those animals, at least in this country, must know that they are not altogether just.

Thid. p. 466.  
notes.

“Individuals in a state of subjection, seem to have no idea of resisting the attacks of an enemy. But they soon learn that their protection lies in the shepherd or his dog: for, when it becomes necessary, in Britain, to watch the folds, in order to prevent assaults from foxes or dogs, upon the first alarm the whole flock run with violence to the place where the watchmen are stationed; so that, when they chance to sleep, they are often hurt by the sheep trampling upon them. On other occasions, they never choose to make a very close approach either to men or dogs; but the sense of immediate danger makes them forget their usual timidity, and their sagacity teaches them where their safety lies. When the female is robbed of her lamb, she bleats in a manner that strongly marks the anguish she feels. In the eagerness of her search, her eye-balls seem to start from their sockets; and her irregular and distracted motions, joined to the violence and constancy of her bleatings, are evident indications of the most puxigent grief.”

But whatever may be its manners or its mental qualities, this animal is of the most extensive utility to man. We are clothed by its fleece. The flesh is a delicate and wholesome food. The skin, dressed, forms different parts of our apparel; and is used for covers of books. The entrails, properly prepared and twined, serve for strings for various musical instruments. The bones calcined (like other bones in general), form materials for tests for the refiner. The milk is thicker than that of cows, and consequently yields a greater quantity of butter and cheese; and in some places is so rich, that it will not produce the cheese without a mixture of water to make it part from the whey. The dung is a remarkably rich manure; inasmuch that the folding of sheep is become too useful a branch of husbandry for the farmer to neglect. Nature, in short, has given this animal nothing that does not redound to our benefit.

The ram is capable of generation at the age of 18 months; and the ewe can be impregnated when a year old. One ram is sufficient for 40 or 50 ewes. He ought to be large and well proportioned; his head should be thick and strong, his front wide, his eyes black, his nose flat, his neck thick, his body long and tall, his testicles massy, and his tail long. White is the best colour for a ram. The ewes whose wool is most plentiful, bushy, long, soft, and white, are most proper for breeders, especially when at the same time they are of a large size, have a thick neck, and move nimbly.

In this climate ewes fed in good pastures admit the ram in July or August; but September or October are the months when the greatest part of our ewes, if left to nature, take the ram. They go with young about five months, and generally bring forth but one at a time, though frequently two: in warm climates, they may bring forth twice in a year; but in Britain, France, and most parts of Europe, only once. They give milk plentifully for seven or eight months. They live from 10 to 12 years: they are capable of bringing forth as long as they live, when properly managed; but are generally old and useless at the age of se-

ven or eight years. The ram, who lives 12 or 14 years, becomes unfit for propagating when eight years old.

When the male lambs are not intended to be kept for propagation, but fattened for food, they ought to be castrated at the age of five or six months. This operation is performed two ways: in the one, an incision is made, and the testicles taken out; in the other, a ligature is tied tight round the scrotum, above the testicles, which soon destroys the vessels which nourish them. After castration they are called *wedders*.

The ram, ewe, and wedder, when one year old, lose the two foreteeth of the under jaw; six months afterwards, they lose the two foreteeth next to these; and at the age of three years, the teeth are all replaced. The age of a ram may likewise be discovered by their horns, which always appear the first year, and frequently as soon as they are brought forth. These horns uniformly acquire an additional ring every year, as long as the creature lives. The ewes commonly have no horns, but a kind of long protuberances in place of them: however, some of them have two, and some four horns.

In Spain, and the southern parts of Europe, the flocks are kept in shades or stables during the night: but in Britain, where there is now no danger from wolves, they are allowed to remain without, both night and day; which makes the animals more healthy, and their flesh a more wholesome food. Dry and mountainous grounds, where thyme and sheep's fescue grass abound, are the best for the pasturing sheep.

The sheep is subject to many diseases: some arise from insects which deposit their eggs in different parts of the animal: others are caused by their being kept in wet pastures; for as the sheep requires but little drink, it is naturally fond of a dry foil. The dropsy, vertigo, (the *pendro* of the Welsh), the phtisis, jaundice, and worms in the liver, annually make great havoc among our flocks: for the first disease, the shepherd finds a remedy by turning the infected into fields of broom; which plant has been also found to be very efficacious in the same disorder among the human species.—The sheep is also infested by different sorts of insects: like the horse, it has its peculiar *œstrus* or gadfly, which deposits its eggs above the nose in the frontal sinuses; when those turn into maggots, they become excessive painful, and cause those violent agitations that we so often see the animal in. The French shepherds make a common practice of castrating the sheep, by trepanning and taking out the maggot; this practice is sometimes used by the English shepherds, but not always with the same success. Besides these insects, the sheep is troubled with a kind of tick and louse, which magpies and starlings contribute to ease it of, by lighting on its back, and picking the insects off.

2. The guineensis, or Guinea sheep, has pendulous ears, lax hairy dew lips, and a prominence on the hind part of the head. The wool is short, like that of a goat. It is a native of Guinea.

3. The streptæcoris, or Cretan sheep, has frait carinated horns, twined in a spiral manner. It is a native of mount Iola.

OUNCE, a little weight, the 16th part of a pound avoirdupois, and the 12th part of a pound Troy. The word

Ovis,  
Ounce.

Ounce  
Owen.

word is derived from the Latin, *uncia*, "the twelfth part of any whole," called *as*; particularly in geometrical measures, an inch, or the 12th part of a foot. See INCH and AS.

OUNCE, in zoology. See LEO.

OVOLO, or OVUM, in architecture, a round moulding, whose profile, or sweep, in the Ionic and Composite capitals, is usually a quadrant of a circle: whence it is also commonly called the *quarter round*. It is usually cut with representations of eggs and arrow-heads or anchors placed alternately.

OUSE, a river which rises in the north of Yorkshire, runs south-east by York, Cawood, and Selby, and falls into the Humber to the west of St Cay.

OUSE, a river which rises near Fitwell in Oxfordshire, and proceeds to Buckingham, Stony-Stratford, and Newport-Pagnel, in Buckinghamshire; from thence it proceeds to Bedford, and, turning north-east, it passes on to Huntingdon and Ely, till at length it arrives at Lynn-Regis in Norfolk, and falls into the sea.

OUSTIOUG, a town of the Russian empire, and capital of a province of the same name, with an archbishop's see and a castle; seated on the river Suchana, over-against the mouth of the Jug, in E. Long. 43. 25. N. Lat. 61. 48.

OUSTIOUG, a province of the Russian empire, bounded on the north by Dwina, on the east by the forest of Zirani, on the south by Wologda, and on the west by Cargapol and Waga. It is divided into two parts by the river Suchana; is full of forests; and the rivers yield plenty of fish, which the inhabitants dry in the sun, and which make their principal nourishment.

OUT-POSTS, in a military sense, a body of men posted beyond the grand guard; called *out posts*, as being the rounds or limits of the camp.

OUTLAW, signifies one that is deprived of the benefit of the law, and therefore held to be out of the king's protection. See the next article.

OUTLAWRY, is where a person is outlawed, and so that account loses the benefit of a subject.—The process of outlawry lies in indictments of treason or felony, and also of trespass *vi et armis*, conspiracy, &c. And by statute, persons may be outlawed in many civil actions; as debt, case, covenant, &c.

OVUM ANGUINUM. See ANGUINUM.

OUTWORKS, in fortification, all those works made without-side the ditch of a fortified place, to cover and defend it. See FORTIFICATION.

OUZEL, in ornithology; a species of MOTACILLA.

OWEN (Thomas), a judge of the common-pleas, was the son of Richard Owen, Esq; of Condovery in Shropshire, and educated at Oxford; whether in Christ-church college, or Broadgate hall, is not determined. Having taken a degree in arts, he left the university, and entered himself of Lincoln's inn in London, where in process of time he became an eminent counsellor. In 1583 he was elected Lent-reader to that society. In 1590 he was made serjeant at law, and queen's serjeant soon after. He arrived at length at the dignity of judge of the common-pleas; which office he is said to have executed, during five years, with great abilities and integrity. He died in 1598; and was buried on the south side of the choir in Westminster abbey, where a monument was erected to his memory. He had the reputation of a learned man, and a patron of literature.

VOL. VIII.

He was the author of "Reports in the common pleas, wherein are many choice cases, most of them thoroughly argued by the learned serjeants, and after argued and resolved by the grave judges of those times, with many cases wherein the difference of the year-books are reconciled and explained." Lond. 1656, fol.

OWEN (Dr John), an eminent and learned dissenting minister, was born in 1616, at Hadham, in Oxfordshire, of which place his father was vicar. He made such surprising proficiency in learning, that at twelve years of age he was admitted into Queen's College, Oxford, and in 1635 was made master of arts; but soon after, disapproving the new regulations made by archbishop Laud their chancellor, with which he refused to comply, he was obliged, in 1637, to leave the college; when taking orders, he became chaplain to Sir Robert Dormer of Afcot in Oxfordshire, and was at the same time tutor to his eldest son. He was afterwards chaplain to John Lord Lovelace of Hurley, in Berkshire; when the civil war breaking out, he openly avowed the cause of the parliament; which was so resented by an uncle, who had intended to leave him his estate, that he discarded him, and left it to another. Yet though Lord Lovelace sided with the king, he treated his chaplain with great civility: but on his going to join the royal army, Mr Owen went to London, and soon after joined the non-conformists. In 1642 he published his book, intitled, *A display of Arminianism*, which laid the foundation of his future advancement: for the committee for purging the church of scandalous ministers were so pleased with it, that Mr White their chairman sent him a presentation of the living of Fordham in Essex: but when he had been there about a year and a half, the patron hearing that the sequestered incumbent was dead, presented another to the living; upon which the Earl of Warwick gave Mr Owen the living of Coggeshall. He had not, however, been long at that town before he left the Presbyterians; and, joining the independents, formed a church there. He was now sent for several times to preach before the parliament; and among the rest on the 28th of February 1648-9, the day of humiliation for the intended expedition to Ireland. Cromwell, who was present at this last discourse, and had never heard him before, was extremely pleased with it, and desired his company into Ireland, and that he would reside in the college of Dublin. This he did; but returned in about half a year. Soon after Cromwell sent him into Scotland; but he also returned from thence after about half a year's stay at Edinburgh. He was then promoted to the deanery of Christ-church, Oxford; whither he went in 1651; and Cromwell, being now chancellor of the university, nominated him his vice-chancellor. The next year he was created doctor of divinity by diploma. Dr Owen enjoyed the post of vice-chancellor five years; during which he behaved with the greatest moderation: for, though often solicited, he never molested the meeting of the royalists at the house of Dr Willis the physician, where divine service was performed according to the liturgy of the church of England; and though he was a commissioner for ejecting scandalous ministers, he frequently overruled his brethren in favour of those royalists who were distinguished by their merit. At the death of Cromwell, he was removed from the vice-chancellorship;

Owen.

and at the Restoration was ejected from his deanery of Christ-church. But he had provided himself a comfortable retreat at an estate he had purchased at Hadham. He now employed himself in preaching as often as he had an opportunity, and in writing books; one of which, intitled *Fiat Lux*, falling in the hands of Lord Clarendon, he was so pleased with it, or (as is said) from policy pretended to be so, that he sent for Dr Owen, and, acknowledging the service he had done by it to the Protestant religion, offered to prefer him in the church, if he would conform; but he desired to be excused.—His moderation drew him respect from persons of opposite principles; and in the number of his friends were Dr Wilkins bishop of Chelster, and Dr Barlow bishop of London. He died at Ealing in 1683. His works are printed in seven volumes, folio.

OWL, in ornithology. See STRIX.

OWLING, so called from its being usually carried on in the night, is the offence of transporting wool or sheep out of this kingdom, to the detriment of its staple manufacture. This was forbidden at common law, and more particularly by statute 11 Edw. III. c. 1, when the importance of our woollen manufacture was first attended to; and there are now many later statutes relating to this offence, the most useful and principal of which are those enacted in the reign of Queen Elizabeth, and since. The statute 8 Eliz. c. 3. makes the transportation of live sheep, or embarking them on board any ship, for the first offence forfeiture of goods, and imprisonment for a year, and that at the end of the year the left hand shall be cut off in some public market, and shall be there nailed up in the openest place; and the second offence is felony. The statutes 12 Car. II. c. 32. and 7 & 8 Will. III. c. 28. make the exportation of wool, sheep, or fuller's earth, liable to pecuniary penalties, and the forfeiture of the interest of the ship and cargo by the owners, if privy; and confiscation of goods, and three years imprisonment to the master and all the mariners. And the statute 4 Geo. I. c. 11. (amended and farther enforced by 12 Geo. II. c. 21. and 19 Geo. II. c. 34.) makes it transportation for seven years, if the penalties be not paid.

OXALIS, WOODSORREL; a genus of the pentagynia order, belonging to the decandria class of plants. There are seven species; of which the only remarkable is the acetosella, or common wood-sorrel. This grows naturally in moist shady woods, and at the sides of hedges in many parts of Britain, so is but seldom admitted into gardens. The roots are composed of many scaly joints, which propagate in great plenty. The leaves arise immediately from the roots upon single long foot-stalks, and are composed of three heart-shaped lobes. They are gratefully acid, and of use in the scurvy and other putrid disorders.

OXFORD, the capital of a county of the same name in England, celebrated for its university, and pleasantly situated in a plain, with a fine fruitful country all around. The composition of the name is obvious. In the British times it seems to have been a place of study; but in the Saxon era, it was noted only for a religious house dedicated to St Frideswide, till Alfred built three colleges, one for grammarians, another for philosophers, and a third for divines. Learning continued

to flourish till the city was sacked and burnt by the Danes in the reign of Ethelred; and after that, Harold, surnamed *Harefoot*, treated it with great severity upon some provocation he had received. It seems to have been besieged and taken by William the Conqueror, and to have been deserted by the learned from that time till about the year 1129, when one Robert Pullen began to read lectures in divinity: and such was the resort of students to it, that in the reign of King John there were not fewer than three thousand. Robert d'Oily, a Norman, to whom William the Conqueror had given the greatest part of it, built a castle on the west side in 1071; and he is also supposed to have surrounded it with walls. In a palace built by Henry I. was born Richard I. commonly called *Cœur de Lion*. About the tenth of King John, there happened a quarrel between the citizens and students; in consequence of which many of the latter quitted it, but returned again a few years afterwards. Here Henry III. held a parliament to settle the differences betwixt him and his barons; when he confirmed the privileges granted to the university by his predecessors, and added others of his own. In this reign the students are said to have been 30,000; who were all excommunicated by the pope for some rudeness to his legate. In Edward III's time, they were split into two factions, called the *northern* and *southern men*; a division which was attended with many disorders and much violence, but in a short time concord and harmony again prevailed. As colleges began about this time to be founded and endowed, we shall here present our readers with a list of them, together with the time when, and the persons by whom, they were founded.

Colleges.	Founders.	Kings reigned.
University.	King Alfred.	Alfred.
Baliol.	{ Sir John Baliol, father to the king of Scots.	{ Henry III.
Merton.	{ Walter Merton, lord chancellor and bishop of Rochester.	{ Edward I.
Oriel.	Edward the Second.	Edw. II.
Exeter.	Walter Stapleton, bishop.	Edw. II.
Queen's.	Robert Eglesfield, B. D.	Edw. III.
New College.	{ William of Wickham, bishop of Winchester, lord chancellor.	{ Edw. III.
Lincoln.	{ Richard Fleming, bishop of Lincoln.	{ Henry VI.
All Souls.	{ Hugh Chicheley, archbishop of Canterbury.	{ Henry VI.
Magdalen.	{ William Wainfleet, bishop of Winchester, lord chancellor.	{ Henry VI.
Brazen-Nose.	{ William Smith, bishop of Lincoln, and Richd. de Sutton, Esq.	{ Hen. VIII.
Corpus-Christi.	{ Richard Fox, bishop of Winchester, and lord privy-seal.	{ Hen. VIII.
Christ Church.	Henry VIII.	Hen. VIII.
Trinity.	Sir Thomas Pone.	Mary.
St John Baptist.	{ Sir Thomas White, merchant of London.	{ Mary.
Jesus.	Queen Elizabeth.	Elizabeth.
Wadham.	Nicholas and Dorothy Wadham.	James I.
Pembroke.	{ Thomas Tisdale, Esq; and Dr Richard Whitwick.	{ James I.
Worcester	was called <i>Gloucester-hall</i> till lately, that it was endowed by Sir Thomas Coke, and made collegiate.	
Hartford	was <i>Hart-hall</i> till 1740, that it was erected into a college.	

All these are richly endowed, and have fine gardens, libraries, chapels, &c. The halls in which the students maintain themselves, except a few that have exhibitions, are these: St Edmund's, belonging to Queen's college; Magdalen, to Magdalen college; St Alban's

Oxford. ban's, to Merton; St Mary's, to Oriel; New-Inn, to New-College. Several persons have been great benefactors to particular colleges, as Dr Ratcliffe to University-college; colonel Codrington and Dr Clarke, to All-souls; queen Caroline, to Queen's; the before-mentioned Dr Clarke and Mrs Eaton, to Worcester; Dr Wake, archbishop of Canterbury, to Christ-church. The most considerable of these colleges are Magdalen's and Christ-Church, which are as noble foundations as any in the world. The church of the latter is the cathedral, and has a dean, eight canons, eight chaplains, eight singing men, eight choristers, a teacher of music, and an organist. Each of the colleges has its visitor appointed by its statutes, except Christ-Church, which is subject to the visitation of the Sovereign alone. The other remarkable buildings belonging to the university are, first, the public schools; secondly, the Bodleian or public library; thirdly, Ratcliffe's library, a most elegant structure, for building and furnishing which, Dr Ratcliffe left 40,000l.; fourthly, the theatre, built by Sheldon, archbishop of Canterbury; fifthly, the museum, in which is an laboratory and a repository for natural and artificial rarities and antiquities; sixthly, the Clarendon printing-house, so called, because it was built partly with the money arising to the university by the sale of Lord Clarendon's library. To the south of Magdalen college lies the physic garden, instituted by the Earl of Danby, and much improved by Dr Sherard. It contains five acres, in which is a complete series of such plants as grow naturally, disposed in their respective classes together with two neat and convenient green-houses, stocked with a valuable collection of exotics, and a hot-house, where various plants brought from the warmer climates are raised. The whole body of the university, including professors, fellows, and students of all sorts, exceeds 3000. Each college has its particular statutes and rules for its government. There are four terms in the year for public exercises, &c. and particular days and hours for public lectures by the several professors. The university is governed by a chancellor, high-steward, vice-chancellor, two proctors, a public orator, a keeper of the archives, a regenter, three squire-beadles, and three yeomen-beadles. As to the city, it has had the same privileges granted to it as London, particularly an exemption from toll all over England. It is governed by a mayor, high-steward, recorder, four aldermen, eight assistants, two bailiffs, a town clerk, two chamberlains, all that have borne the office of bailiff and chamberlain, and twenty-four common-council men: but these are subject to the chancellor or vice-chancellor of the university in all affairs of moment; and not only the mayor, but the principal citizens, and sheriff of the county, take an oath to maintain the privileges of the university. The city, including the colleges, is one of the largest in England, having thirteen parish-churches, besides the cathedral, well built, clean, and regular. At the entrance of the town from the Woodstock and Banbury roads, a neat hospital bath been lately erected by the trustees of Dr Ratcliffe's bequest, out of the surplus money remaining after defraying the expence of his library. The male line of the family of Vere, to whom the city had given the title of earl for 500 years, failing in Aubrey de Vere, who was twentieth earl, queen Anne conferred the title

upon Robert Harley, a descendant of the Veres, in whose family it still continues. The chief trade of the city is in malt, conveyed in barges to London.

OXFORDSHIRE, a county of England, bounded on the west by Gloucestershire; on the south, where it is broadest, the river Isis divides it from Berkshire; on the east, it is bounded by Buckinghamshire; and on the north, where it terminates in a narrow point, it has on the one side Northamptonshire, and on the other Warwickshire. It extends from Cleydon to Caverham 42 miles in length, and from Cleydon to Farrington 26 in breadth, making about 130 in circumference; within which are contained one city, 15 market-towns, 280 parishes, 14 hundreds, 534,000 acres, and about 120,000 souls. The air is fresh and pleasant, and the soil rich and fertile. The lower parts consist of meadows and corn-fields, and the higher were covered with woods till the civil wars; in which they were so entirely destroyed, that wood is now extremely scarce and dear, except in what is called the chiltern, and so is coal; of consequence fuel bears an exorbitant price. The county is extremely well watered; for besides the Isis, Tame, Cherwell, Evenlode, and Windrush, there is a great number of lesser rivers and brooks. One of the four great Roman ways passes quite through it, entering at the parish of Chinner, and going out at that of Goring. There is another lesser one, that extends between Colnbrook and Wallingford, called *Gremesdike*. The county sends nine members to parliament, viz. two for the shire, two for the city, two for the university, two for new Woodstock, and one for Banbury.

OXGANG, or OXGATE, is generally taken, in our old law-books, for 15 acres, or as much ground as a single ox can plough in a year.

OXUCLÆ, in natural history, the name of a genus of fossils of the class of selenite, but of the columnar, not the rhomboidal kind. Of this genus there are only two known species: 1. A fine kind with thin flakes and transverse filaments, found in the clayey banks of the river Nen, near Peterborough in Northamptonshire; and, 2. A dull kind with thick plates and longitudinal filaments. This is not uncommon in Yorkshire, and lies sometimes in a yellow, and sometimes in a blue clay.

OXUS, or JIHN, a large river of Asia, which rises in the mountains north of India; and running north-west, through Ubec Tartary, separates that country from Persia, and falls into the Caspian sea in 44° N. Lat.

OXYCRATE, in pharmacy, a mixture of vinegar and water, proper to alluage, cool, and refresh. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

OXYGLYCU, a species of drink prepared of the sweetest honey-combs macerated and boiled. The combs, from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept; and, when diluted with cold water, is to be drank in the summer-time, in order to remove thirst.

OXYMEL, in pharmacy, a composition of vinegar and honey. See PHARMACY.

OYER, in law-books, seems to have been anciently used for what is now called *affixer*. See ASSISE.

O yes  
Oyster.

OYES, a corruption of the French OYEZ, *Hear ye*; a term or formula frequently used by the criers in our courts on making proclamations, or to enjoin silence.

OYSTER, in zoology, see OSTREA.

The oyster affords the curious in microscopic observations a very pleasing entertainment. In the clear liquor many little round living animalcules have been found, whose bodies being conjoined, form spherical figures, with tails not changing their place otherwise than by sinking to the bottom, as being heavier than the fluid; these have been seen frequently separating, and then coming together again. In other oysters, animalcules of the same kind were found, not conjoined, but swimming by one another, whence they seemed in a more perfect state, and were judged by Mr Lieuwenhoek to be the animalcules in the roe or semen of the oyster.

A female oyster being opened, incredible multitudes of small embryo oysters were seen, covered with little shells, perfectly transparent, and swimming along slowly in the liquor; and in another female, the young ones were found of a browner colour, and without any appearance of life or motion.

Monsieur Joblot also kept the water running from oysters three days, and it appeared full of young oysters swimming about nimbly in it; these increased in size daily; but a mixture of wine, or the vapour of vinegar, killed them.

In the month of August oysters are supposed to breed, because young ones are then found in them. Mr Lieuwenhoek, on the 4th of August, opened an oyster, and took out of it a prodigious number of minute oysters, all alive, and swimming nimbly about in the liquor, by means of certain exceeding small organs, extending a little way beyond their shells; and these he calls their beards. In these little oysters, he could discover the joinings of the shells; and perceived that there were some dead ones, with their shells gaping. These, tho' so extremely minute, are seen to be as like the large oysters in form as one egg is to another.

As to the size of them, he computes, that 120 of them in a row would extend an inch; and consequently, that a globular body, whose diameter is an inch, would, if they were also round, be equal to 1,728,000 of them. He reckons 3000 or 4000 are in one oyster, and found many of the embryo oysters among the bairds; some fastened thereto by slender filaments, and others lying loose: he likewise found animalcules in the liquor 500 times less than the embryo oysters.

It is not very uncommon to see on oyster-shells, when in a dark place, a shining matter or bluish light, like a flame of brimstone, which sticks to the fingers when touched, and continues shining and giving light for a considerable time, though without any sensible heat. This shining matter being examined with a microscope, was found to consist of three sorts of animalcules; the first whitish, and having 24 or 25 legs on a side, forked, a black speck on one part of the head, the back like an eel with the skin stripped off. The

second fort, red, resembling the common glow-worm, with folds on its back, but legs like the former; a nose like a dog's, and one eye in the head. The third fort, speckled, with a head like a foal, with many tufts of whitish hairs on the sides of it. Some much larger and greyish might be seen, having great heads, two horns like a snail's, and six or eight whitish feet; but these did not seem to shine.

OYSTER-CATCHER. See HEMATOPUS.

OYSTER-SHELLS. See CHEMISTRY, n° 345.

OZENA, a foul and malignant ulcer of the nose, distinguished by its fetor, and often accompanied with a caries of the bones of the nose.

OZELL (John), a well known translator, was educated in Christ's Hospital, was possessed of a competent fortune, and always enjoyed good places; being auditor-general of the city and bridge accounts, of St Paul's cathedral, and of St Thomas's hospital. Notwithstanding his attention to business, he still retained a love for polite literature: and though he did not appear as an original author, yet having made himself master of most of the living languages, he favoured the world with many translations from these, as well as from the Latin and Greek; which, if they are not the most elegant, are generally faithful and true to the originals. He died in the year 1743.

OZANAM (James), an eminent French mathematician, born at Boligneux in Bresse, in 1640, of a wealthy family. His father gave him a good education, and designed him for the church: but some mathematical books falling into his hands, inspired him with a love for that science; and though he had no master to instruct him, he made such progress in it, that, at 15 years of age, he wrote a piece in mathematics, which he thought proper to insert in the works he afterwards published. He at length taught that science at Lyons; and his mathematical lessons brought him in a considerable revenue, till the year 1701: at which period, a war breaking out on the succession to the crown of Spain, he lost almost all his scholars, and was reduced to a very melancholy situation; and his wife dying the same year, he was so afflicted, that he never perfectly recovered it. In 1702, he was admitted into the Royal Academy of Sciences; and died of an apoplexy, in 1717.—He was of a mild and serene temper, of singular generosity, and of a cheerful disposition.—He would not allow himself to know more of religion than the common people. He used to say, that "it was the business of the doctors of Sorbonne to dispute, of the Pope to decide, and of a mathematician to go to heaven in a perpendicular line." His works are very numerous, and have met with the approbation of the learned. The principal are, 1. Practical geometry, 12mo. 2. A mathematical dictionary. 3. A course of mathematics, 5 vols, 8vo. 4. Mathematical and philosophical recreations, the most complete edition of which is that of 1724, in 4 vols 8vo. 5. An easy method of surveying. 6. New elements of algebra, a work much commended by Monsr. Leibnitz. 7. Theoretical and practical perspective, &c.

Oyster  
Ozanam.

## P.

**P**, or *p*, the 15th letter and 11th consonant of the alphabet; the sound of which is formed by expressing the breath somewhat more suddenly than in forming the sound of *b*; in other respects these two sounds are pretty much alike, and are often confounded one with another. When *p* stands before *t* or *f*, its sound is lost; as in the words *psalm*, *psychology*, *ptolemaic*, *ptisan*, &c. When placed before *h*, they both together have the sound of *f*; as in *philosophy*, *physic*, &c.

As an abbreviation, *P* stands for *Publius*, *Pondo*, &c. *P.A.DIG.* for *Patricia Dignitas*; *P. C.* for *Patres Conscripti*; *P. F.* for *Publii Filius*; *P. P.* for *Propositum*, or *Proposium publicæ*; *P. R.* for *Populus Romanus*; *P. R. S.* for *Prætoris sententia*, *P. R. S. P.* for *Præses provincia*.

In the Italian music, *P* stands for *piano*, or "softly;" and *P. P.* for *pianissimo*, or "very softly."

Among astronomers, *P. M.* is used to denote *post meridiem*, or afternoon.

Among physicians, *P* stands for *pugil*, or the eighth part of an handful, *P. Æ. parter æquales*, or equal parts of the ingredients; *P. P.* signifies *pulvis patrum*, or Jesuit's bark in powder; and *ppt. præparatus*, or prepared.

As a numeral, *P* signifies the same with *G*, viz. 400; and with a dash over it thus, *Ġ*, 400,000.

**PABULUM**, among natural philosophers, the same with **FUEL**.

**PACE**, a measure taken from the space between the two feet of a man in walking; usually reckoned two feet and a half, and in some men a yard or three feet. The geometrical pace is five feet; and 60,000 such paces make one degree on the equator.

**PACE**, in the manege, is of three kinds, viz. walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

Horses which go shuffling, or with mixed paces between the walk and amble, are for the most part of no value; which commonly proceeds from their fiery temper, but sometimes from a weakness in their reins or legs.

**PACE** (Richard), a learned Englishman, born about the year 1482. He was educated at the charge of Thomas Langton bishop of Winchester, whom he served as an amanuensis, and afterwards entered into the service of cardinal Bainbridge. His accomplishments rendered him so acceptable to Henry VIII. that he made him secretary of state; and, entering into orders, he was admitted prebendary in the church of York, archdeacon of Dorset, and dean of St Paul's, &c. which preferments were conferred on him during his absence on foreign embassies. In 1524, he was sent to Rome on the death of pope Leo X. to solicit the papal chair for cardinal Wolsey; but a new Pope was elected before his arrival, a circumstance that proved the epocha of his troubles. He fell under the displeasure of the disappointed cardinal; and being soon after employed as ambassador at Venice, he was so neglected and hardly used, that he was seized with a

phrenzy: upon which the king ordered him home; and being carefully attended by the physicians at the king's command, he was in a short time restored to the use of his reason, and then applied himself to the study of the Hebrew tongue. Being now introduced to his Majesty, he remonstrated against the Cardinal's cruelty: who being ordered to clear himself, summoned Pace before him, sitting in judgment with the duke of Norfolk and others; who condemned Pace, and sent him to the Tower; where he remained two years, till he was discharged by the king's command.—When he was enlarged, he resigned his deaneries, and died in retirement at Stepney in 1532; after having wrote several works, and enjoyed the esteem of the learned among his contemporaries; especially of Sir Thomas More, and Erasmus.

**PACHAMAC**, a valley of Peru, in South America, ten miles south of Lima; celebrated for its pleasantness and fertility, but more on account of a magnificent temple built by the Incas of Peru, to the honour of their god. When the Spaniards conquered Peru, they found immense riches therein.

**PACHODECARTHOMBIS**, in natural history, the name of a genus of fossils, of the class of *silemites*, expressing a thick rhomboidal body composed of ten planes.

**PACHSU**, a small island in the Mediterranean sea, near the coast of Epirus, and in European Turkey. It lies south of Corfu, and is subject to Venice.

**PACIFIC OCEAN**, that vast ocean which separates Asia from America. It is called *Pacific*, from the moderate weather the first mariners who sailed in it met with between the tropics: and it was called *South Sea*, because the Spaniards crossed the isthmus of Darien from north to south, when they first discovered it; tho' it is properly the Western ocean, with regard to America.

**PACK**, in commerce, denotes a quantity of goods, made up in loads, or bales, for carriage.

A pack of wool is 17 stone and 2 pounds, or a horse's load.

**PACKET**, or **PACKET-Boat**, a vessel appointed by the government to carry the mail of letters, packets, and expresses, from one kingdom to another by sea, in the most expeditious manner. Thus, the packet-boats, under the direction of the post-master-general of Great Britain, carry the mails from Dover to Calais, from Falmouth to Lisbon, from Harwich to Helvoetsluys, and from Parkgate to Dublin.

**PACTOLUS** (anc. geog.), a river of Lydia, called *Chrysorrhæa*, for its rolling down golden sand, according to Herodotus, Plutarch, Pliny, and Strabo; rising in mount Tmolus, (Strabo). From this river Cræsus is thought to have had all his riches. In Strabo's time it ceased to roll down any. It ran thro' Sardes; after which it fell into the Hermus, and both together into the Ægean Sea at Phocæa in Ionia. A river celebrated by Virgil, Ovid, Lucan, Lycophron, Horace, Apollonius.

**PACKAGE**, is a small duty of one penny in the pound,

pound, paid for all goods not particularly rated.

PACOS, in zoology. See CAMELUS.

PACUVIUS (Marcus), of Brundisium in Calabria, a tragic poet in high reputation about the year of Rome 600. He was nephew of Ennius; published several theatrical pieces, tho' we have only some fragments of his poetry remaining; and died at Tarentum at above 90 years of age.

PADANARAM (Bible), literally the *plains of Aram, or Syria*; translated by the Seventy, simply *Mesopotamia*, or *Mosopotamia*, of Syria; by the Vulgate, *Syrie*; the Syrians on this and on the other side of the Euphrates, not differing remarkably from each other in language and manners, as Josephus allows.

PADDOC, or PADDOC-COURSE, a piece of ground encompassed with pales or a wall, and taken out of a park for exhibiting races with greyhounds, for plates, wagers, or the like.

A paddoc is generally a mile long, and a quarter of a mile broad: at the one end is a little house where the dogs are to be entered, and whence they are slipped; near which are pens to inclose two or three deer for the sport. Along the course are several posts, viz. the low post, which is 160 yards from the dog-house and pens; the quarter of a mile post, half-mile post, and pinching post; besides the ditch, which is a place made to receive the deer, and preserve them from farther pursuit. And near this place are seats for the judges chosen to decide the wager.

The keepers, in order to slip the dogs fairly, put a falling collar upon each, slipped round a ring; and the deer being turned loose, and put forward by a teaser, as soon as he is arrived at the low-post, the dog-house door is thrown open, and the dogs slipped. If now the deer swerve so much, as that his head is judged nearer the dog-house than the ditch before he arrive at the pinching-post, it is no match, and must be run over again three days after: but if the deer runs straight beyond the pinching-post, then that dog which is nearest when he swerves, or is blanced by any accident, wins the match; but if no such swerve happens, then the match is won by the dog who first leaps the ditch.

PADERBORN, a duchy of Germany in the circle of Westphalia, has the county of Lippe on the north and west; Hesse-Cassel and Waldeck, on the south; and Munster, with the duchy of Westphalia, on the west. Its greatest length from east to west is about 40 miles, and its breadth where widest 30. Some parts of it yield good pasture, and breed abundance of cattle; but it is not very fruitful in corn. There is a heath called the *Senne* or *Sende*, of great extent, but very barren and desolate. There are, however, good iron mines in the country, with salt and medicinal springs, plenty of deer and other game; and it is watered with several rivers abounding with fish, as the Weser, the Dimer, the Bever, the Nette, the great Emmer, the Lippe, the Alme, and the Pader. It contains 54 parishes, in which are 25 market-towns, and 16 monasteries. The Roman Catholic is the predominant religion of the country, yet there are also many Protestants in it. The bishopric was erected by Charlemagne, towards the close of the eighth century; and the cathedral was consecrated by pope Leo in

perlon, anno 796. The bishop is sovereign of the Paderborn country, a prince of the empire, and suffragan of the archbishop of Mentz. His revenue is about 30,000 pounds a year, and he is able to raise 3000 men. In the matricula, his assessment is 18 horse and 34 foot, or 352 florins monthly in lieu of them. Towards the charges of the sovereign courts of the empire, he pays for each term, 162 rix-dollars and 29 kruitzers. The chapter consists of 24 caputular canons, who must prove their noble extraction by four descents. The arms of the bishopric are a cross or, in a field gules. For the government of it, and the administration of justice, there are several councils and colleges under the bishop. Here are also a hereditary marshal, fewer, cup-bearer, chamberlain, steward, and purveyor. It was in this bishopric that Quintilius Varus, with the Roman army under his command, was routed by the Germans under Arminius.

PADERBORN, the capital of the above bishopric. It stands 40 miles north-west of Cassel, 50 south-east of Munster, and 60 south-west of Hanover; being a large, populous, well built, and well fortified city. Its name is compounded of *pader*, a rivulet, which rises just under the high altar of the cathedral, and *born*, i. e. a spring. It was one of the Hanse-towns; and, till 1604, an imperial city. The cathedral is a grand fabric, inferior to few in the empire. There is a gold crucifix in it of 60 pounds weight, presented by Otho II. The university, of which the Jesuits have the direction, was founded in 1592, and the walls were built in the beginning of the 11th century. In 1530, an attempt was made to introduce Lutheranism; but 16 of the principal citizens who had embraced it were executed, and the rest obliged to abjure it. Duke Christian of Brunswick carried off from hence, in 1692, the silver images of the 12 apostles, and the silver coffin of St Lotharius; and had them coined into money, with this inscription, *God's Friend, the Priests' Enemy*. The trade of this town, though formerly great, is now inconsiderable; and the inhabitants subsist mostly by agriculture, and breeding of cattle. Though the bishop has a palace in the city, he resides (when he vouchsafes to visit this country, which is seldom, having other and more valuable benefices) at Neuhaus, seven miles off, where he has a magnificent castle. Charlemagne, and other emperors, sometimes resided here, and held diets of the empire.

PADUA, an ancient, large, and celebrated city of Italy, with an university and a bishop's see. It is also capital of the Paduano; but is much less considerable than it was formerly: for it now contains no more than 30,000 inhabitants, whereas it formerly had 100,000, and many of the houses are gone to ruin: however, the hall where justice is administered, is a superb structure. The cathedral church, and the college of the university, are in that part called the *Old Town*; and there are piazzas under all the houses, where persons may walk without being exposed to the weather. The garden of the university is curious, on account of the number of plants. Here a student may take his degrees, let him be of what sect of Christianity he will; nay, though he should be a Jew or a Turk. The patron of this city is St Anthony, who lies in the cathedral; they have such a veneration for him, that the

beggars

**PADUANO** beggars do not ask charity in the name of God, but for the love of St Anthony. The Jews live in a distinct part of the city; and the neighbouring mountains produce excellent wine and oil, with delicious fruit. It was taken by the Venetians in 1706. It is seated on the rivers Brentac and Bachiglione, in a fine plain; and is about seven miles in circumference. E. Long. 11. 55. N. Lat. 45. 24.

**PADUANO**, a small province of Italy, in the territory of Venice, bounded on the east by the Dogado, on the south by the Polesino di Rovigo, on the west by the Veronese, and on the north by the Vicentino. Its soil is well watered; and is one of the most fertile in Italy. The province is about 40 miles in length, and 35 in breadth. Padua is the capital town.

**PADUAN**, among the medalists, a modern medal struck in imitation of the antique, or a new medal struck with all the marks and characters of antiquity. This name is properly applicable to those medals only that were struck, in the seventh century, by an Italian painter, born at Padua; who succeeded so well in the imposture, that the best judges are at a loss to distinguish his medals from the genuine ones. Tho' it is frequently used in general for all medals of this kind.

**PADUS**, anciently called *Eridanus*, especially by the Greeks; a river famous for the fable of Phaeton, (Ovid). It rises in mount Vesulus, in the Alpes Cothiz, from three springs, dividing the Cisalpine Gaul into the Transpadana and Cispadana, (Strabo); and, swelled by other rivers falling into it on each side from the Alps and Appennines, it discharges itself with a course from west to east, at seven mouths, into the Adriatic, (Mela). The lake thro' which it discharges itself into the sea, is called by the natives the *Seven Seas*. Now the *Po*.

**PADUS**, in botany. See **PRUNUS**.

**PÆAN**, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph. See **APOLLO**.

**PÆAN**, in the ancient poetry, a foot consisting of four syllables; of which there are four kinds, the pæan primus, secundus, &c.

The pæan primus consists of one long syllable and three short ones, or a trochæus and pyrrhichius, as *temporibus*; the pæan secundus consists of a short syllable, a long, and two short, or an iambus and a pyrrhichius, as *potentia*; the pæan tertius consists of two short syllables, a long and a short one, or a pyrrhichius and a trochæus, as *animatus*; the pæan quartus consists of three short syllables and a long one, or a pyrrhichius and iambus, as *celeritas*.

**PÆDO-BAPTISM**; infant-baptism, or that conferred on children.

**PÆONIA**, **PIONY**; a genus of the digynia order, belonging to the polyandria class of plants. There are two species, both of them very hardy, and will flourish in any common soil. They are large herbaceous flowering perennials, with tuberous roots, sending up strong annual stalks from one to three feet in height; terminated by very large flowers of a beautiful red colour, and much larger than any rose. The common officinal, or male piony, also is remarkable for its capsules turning backward, opening and displaying their red inside, together with the numerous seeds, in a singular

ly agreeable order, appearing very ornamental after the flower is past. The plants may be propagated either by parting the roots, or by seed. This plant was formerly celebrated in nervous dilempters, but the present practice pays very little regard to it.

**PÆSTUM**, called *Pesidonia* by the Greeks, a town of Lucania, on the Sinus Pælinus: an ancient colony prior to the first Punic war, according to Livy; but later, according to Velleius. *Pæstane rose* were in great esteem, and produced twice a-year. (Virgil, Ovid).

**PAGAN**, a heathen, gentile, or idolater; one who adores false gods. See **MYTHOLOGY**.

**PAGANALLA**, certain festivals observed by the ancient Romans in the month of January. They were instituted by Servius Tullius, who appointed a certain number of villages (*pagi*), in each of which an altar was to be raised for annual sacrifices to their tutelar gods; at which all the inhabitants were to assist, and give presents in money, according to their sex and age, by which means the number of country-people was known. The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

**PAGANELLUS**, in ichthyology. See **GOMBUS**.

**PAGANISM**, the religious worship and discipline of pagans; or, the adoration of idols and false gods. See **IDOLATRY** and **MYTHOLOGY**.

**PAGEANT**, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shews, processions, &c.

**PAGI** (Antony), a very famous Cordelier, and one of the ablest critics of his time, was born at Rogné in Provence in 1624. He took the habit in the convent at Arles in 1641, and was at length four times provincial of his order; but his religious duties did not prevent his vigorous application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is, "A Critique upon the Annals of Baronius;" where, following the learned cardinal year by year, he has rectified an infinite number of mistakes, both in chronology and in the representation of facts. He published the first volume in 1689, dedicated to the clergy of France, who allowed him a pension: the whole was printed after his death, in 4 vols. folio, at Geneva, in 1705, by the care of his nephew Francis Pagi, of the same order. He wrote some other things before his death, which happened in 1699; and had the character of an able historian as well as of a learned and candid critic. His nephew, Francis, above mentioned, wrote "A Chronological Abridgment of the history of the Popes," in Latin, 3 vols. 4to. Francis had also a nephew, Anthony Pagi, who added three more volumes to the History of the Popes; of which two more were intended, if not executed.

**PAGNINUS** (Santes), a Dominican, illustrious for his skill in the Oriental languages, was born at Lucca in 1466. He applied himself to examine the vulgar translation of the Scriptures; and believing it to be either not of Jerom, or greatly corrupted, he undertook a new one from the present Hebrew text. It appears by a letter from Picus Mirandula to him, that he spent 25 years on this work, which is the first modern translation from the Hebrew; and the Jews who

Pæstum  
Pælinus.  
Pægninus.

Paged,  
Pain.

read it, affirmed it to be more exact than the ancient translations: this, however, was his fault; for his scrupulous servile adherence to the letter of the original text, has, according to father Simon, made his translation obscure, barbarous, and full of solecisms. He afterward translated the New Testament from the Greek, as he had done the Old from the Hebrew, laying the Vulgar all the while before him; and dedicated it to pope Clement VII. He was also the author of a Hebrew Grammar and Lexicon, which Buxtorf made great use of in compiling his; and died in 1536.

PAGOD, or PAGODA, a name whereby the East Indians call the temples where they worship their gods.

PAGOB, or Pagoda, is also the name of a gold and silver coin, current in several parts of the East Indies.

PAIN. See METAPHYSICS, n<sup>o</sup> 23, 71.

As the brain is the seat of sensation, so it is of pain. Boerhaave, and most other authors on this subject, assign a stretching of the nerves as the only immediate cause of pain: but as the nerves do not appear to consist of fibres, this cause of pain does not seem to be well-founded; nor indeed will it be easy to treat this subject clearly, but in proportion as the means of sensation are understood.

Many kinds of pain are met with in authors: such as, A gravitative pain; in which there is a sense of weight on the part affected, which is always some fleshy one, as the liver, &c. A pulsative pain; which, Galen says, always succeeds some remarkable inflammation in the containing parts, and is observed in abscesses while suppurating. A tensive pain, which is also called a *disfending* pain; it is excited by the distension of some nervous, muscular, or membranous part, either from some humour, or from flatulence. An acute pain is, when great pain is attended with quick and lively sensations: A dull pain is, when a kind of numbness is as much complained of as the pain is.

The mediate and more remote causes of pain are generally obvious; and when so, the cure will consist for the most part in removing them: for though in many instances the chief complaint is very distant from the seat of these causes, yet their removal is the proper method of relief. See MEDICINE, *passim*.

## P A I N T I N G.

PAINTING is the art of representing to the eyes, by means of figures and colours, every object in nature that is discernible by the sight; and of sometimes expressing, by figures, the various emotions of the mind.

1. It is to be imagined that men must naturally and very early have conceived an idea of the first principles of the art of painting: the shadow of each plant and animal, and of each edifice, must have afforded them the means of conceiving the method of imitating the figures of all bodies whatever. But as in the first ages of the world the art of writing was unknown, as mankind were ignorant of astronomy, and as their year certainly did not consist of the same number of days as does that of the moderns, how is it possible to determine the epoch, the precise date, of the rise of each art or science? The Egyptians pretend that painting was in

Pain.

Perhaps all pains may be included, with irritation, in those that have spasm or inflammation for their source. When pain is owing to inflammation, the pulse 'tis quicker than in a natural state; it is also generally full, hard, and tense; the pain is equal, throbbing, and unremitting. If a spasm is the cause, the pulse is rarely affected; at intervals the pain abates, and then returns with some degree of aggravation; gentle motion sometimes abates, or even cures, in some instances: but in inflammatory cases no such effects are ever experienced. See Dr Lobb's *Treatise on Painful Disorders*.

The pain so frequently attendant on child-bed women, called *after-pains* (from their happening only after being delivered of a child), are often occasioned by scooping to fetch away coagulated blood, which is a needless endeavour. When no improper treatment in delivering the secundines can be suspected, the irritability of the uterus alone is to be considered as the cause. Care should be taken not to confound these after-pains with, or mistake the pains attending puerperal fevers for, the colic. After-pains come by fits, and soon go off; but return at different intervals, which are longer each day, and after two or three days are usually at an end, though sometimes they continue seven or eight: notwithstanding these pains, the lochia flow properly, and generally more abundantly after the cessation of each fit; this does not happen in colicky complaints, nor is the belly so free from tumefaction when the puerperal fever is attendant.

As these pains are of the spasmodic kind, anodynes and gentle opiates, with frequent draughts of warm caudle, camomile tea, &c. are all that are required in order to their relief.

Among the various causes of pain, a singular one is related in the third vol. of the *Lond. Med. Obs. and Inq.* p. 241, &c. Some persons who had taken cold during their being salivated, were afflicted with pains which resisted all the usual methods of relief: at length the author of the narrative referred to, suggested the cause; and by exciting a fresh salivation, the pains abated; the spitting was kept up a little while, and permitted to abate with some caution; and thus the cures were completed.

use among them many ages before it was known among the Greeks: And the matter is highly probable; for the Egyptians being the most ancient people, the Greeks drew from them many other branches of learning; the hieroglyphics of the former were, moreover, a sort of painting. Diodorus Siculus, l. ii. c. 4. relates, that Semiramis, having re-established Babylon, built there a wall of two leagues and a half in circumference, the bricks of which were painted before they were burnt, and represented various kinds of animals. He adds, that she had another wall, on which were the figures of all sorts of animals painted in their natural colours: and that there were among them even pictures which represented hunting-matches and combats. This is, in fact, an anecdote of great antiquity.

2. The Greeks were acquainted with the art of writing: they were highly ostentatious, and had among them

mea

men of real genius. This was sufficient to make them attribute the invention of all the arts and sciences to themselves. Their authors, however, do not agree about the inventor of painting. Pliny, in his *Natural History*, l. xxxv. c. 12. assures us, that Dibutades, a potter of Sicyon, invented the art of making figures in clay; but that he owed the invention to his daughter, who, on taking leave of her lover that was going to a distant country, contrived to trace on a wall, by the means of a lamp, the outline of his shadow: the father, by applying his clay to those lines, formed a statue, which he hardened in his stove; and which was preserved in the temple of the Nymphs, till the time that Mummius signalized himself by the destruction of Corinth. Love, therefore, was the first master of painting; and that god seems, at this day, to have renewed in France that method of the Greeks, by those portraits drawn from shadows, which they call a *la Silhouette*. It should seem, however, that neither the Greek historians, nor Pliny, were acquainted with that book of Moses intitled *Genesis*; for they would have there seen, in the xxxi chapter, that Rachel, the wife of Jacob, stole from her father Laban his images, or little figures of household gods; which was in the time of the highest antiquity: that Aaron afterwards made in the desert a golden calf; that the ark of the covenant of the Hebrews was ornamented with figures of cherubims; that Moses forbade the people the use of images: all of which supposes a knowledge of design.

Be this as it may, the Greeks seem to have carried the art to great perfection; if we may believe the stories related of their Apelles and Zeuxis.

3. The Romans were not without considerable masters in this art, in the latter times of the republic, and under the first emperors; but the inundation of barbarians, who ruined Italy, proved fatal to painting, and

almost reduced it to its first elements. It was in Italy, however, that the art returned to its ancient honour, and in the beginning of the 15th century; when Cimabue, betaking himself to the pencil, translated the poor remains of the art, from a Greek painter or two, into his own country. He was seconded by some Florentines. The first who got any reputation was Ghirlandai, Michael Angelo's master; Pietro Perugino, Raphael Urbin's master; and Andrea Verocchio, Leonardo Da Vinci's master. But the scholars far surpassed the masters; they not only effaced all that had been done before them, but carried painting to the highest perfection of which it is capable. It was not by their own noble works alone that they advanced painting; but by the number of pupils they bred up, and the schools they formed. Angelo, in particular, founded the school of Florence; Raphael, the school of Rome; and Leonardo, the school of Milan; to which must be added the Lombard school, established about the same time, and which became very considerable under Giorgione and Titian.

Besides the Italian masters, there were others on this side the Alps, who had no communication with those of Italy: such were Albert Durer, in Germany; Holbens, in Switzerland; Lucas, in Holland; and others in France and Flanders. But Italy, and particularly Rome, was the place where the art was practised with the greatest success; and where, from time to time, the greatest masters were produced.

To Raphael's school, succeeded that of the Coraccios; which has lasted, in its scholars, almost to the present time.

It is of the different parts of this art thus re-established, extended, and improved, that we are here to treat.

## PART I. Principles of the ART, and the Order of the Artist's STUDIES.

### SECT. I. *Of the First Exercises of a Painter.*

4. IT is not a matter of so little importance, as some are, perhaps, apt to imagine, upon what drawings a pupil is first put to exercise his talents. Let the first profiles, the first hands, the first feet, given him to copy, be of the best masters, so as to bring his eye and his hand early acquainted with the most elegant forms, and the most beautiful proportions. A youth, employed in copying the work of a middling painter, in order to proceed afterwards to something of Raphael's, having said, in the hearing of a master, That he did it in order to bring his hand in; the master, as sensibly as wittily, replied, "Say rather, to put it out." A painter, who has early acquired a fine style, finds it an easy matter to give dignity to the meanest features, while even the works of a Praxiteles or a Glycon are sure to suffer in the hands of another. A vessel will ever retain the scent which it has first contracted.

It would be proper also to make the pupil copy some fine heads from the Greek and Roman medals: not so much for the reasons just now laid down, as to make him acquainted, if we may use the expression, with those personages which in time he may have occasion to introduce into his pieces; and, above all, to improve him

early in the art of copying from relief. Hence he will learn the rationale of light and shade, and the nature of that *chiar-oscuro*, by which it is, properly speaking, that the various forms of things are distinguished. To this it is owing, that a boy will profit more by drawing after things in relief, though but meanly executed, than by copying the most excellent drawings. But, whatever he does, care should be taken to make him do it with delight, and finish it in the most accurate manner. Nothing in the world is so necessary as diligence; especially at the first entrance upon any study. Nor must he ever expect to have the compasses in his eye, who has not first had them for a long time in his hand.

### SECT. II. *Of Anatomy.*

5. To ask if the study of anatomy is requisite to a painter, is the same thing as to ask if, in order to learn any science, a man must first make himself acquainted with the principles of it. It would be throwing away time to cite, in confirmation of this truth, the authorities of the ancient masters, and the most celebrated schools. A man, who is unacquainted with the form and construction of the several bones which support and govern the human frame, and does not know in what manner the muscles moving these bones are fixed to them,

Anatomy.

them, can make nothing of what appears of them thro' the integuments with which they are covered; and which appearance is, however, the noblest object of the pencil. It is impossible for a painter to copy faithfully what he sees, unless he thoroughly understands it. Let him employ ever so much time and study in the attempt, it cannot but be attended with many and great mistakes: just as it must happen to a man, who undertakes to copy something in a language which he does not understand; or to translate into his own, what has been written in another, upon a subject with which he is not acquainted.

It seldom happens, that nothing more is required of a painter than to copy exactly an object which he has before him. In still and very languid attitudes, in which every member is to appear motionless and dead, a living model may, no doubt, yield for a long time a faithful image, and prove an useful pattern to him, But in regard to gestures any way sudden, motions any way violent, or those momentary attitudes which it is more frequently the painter's business to express, the case is quite different. In these a living model can hold but an instant or two; it soon grows languid, and settles into a fixed attitude, which is produced by an instantaneous concurrence of the animal-spirits. If, therefore, a painter possesses not so thoroughly all the principles of anatomy, as to be at all times able to have immediate recourse to them; if he knows not the various manners in which the several parts of the human body play, according to their various positions; living models, far from proving an useful pattern to him, will rather tend to lead him astray, and make him lose sight of truth and nature, by exhibiting the very reverse of what is required, or at least exhibiting it in a very faint and imperfect manner. In living models, we often behold those parts slow, which should be very quick; those cold and torpid, which should have the greatest share of life and spirit in them.

Nor is it, as some may be apt to imagine, merely to represent athletic and vigorous bodies, in which the parts are most bold and determined, that anatomy is requisite: it should be understood, to represent persons of the most delicate frame and condition, even women and children, whose members are smoothest and roundest, though the parts made known by it are not to be strongly expressed in such objects; just as logic is equally requisite under the polished insinuations of the orator and the rough arguments of the philosopher.

But it is needless to spend much time in proving, that a painter should be acquainted with anatomy; or in showing, how far his acquaintance with it should extend. For instance, it is unnecessary for him to enter into the different systems of the nerves, blood-vessels, bowels, and the like; parts which are removed from the sight, and which therefore may be left to the surgeon and the physician, as being a guide in the operations of the former and in the prescriptions of the latter. It is enough for the painter, to be acquainted with the skeleton; in other words, with the figure and connection of the bones, which are, in a manner, the pillars and props of the human body; the origin, progress, and shape, of the muscles, which cover these bones; as also the different degrees in which nature has clothed the muscles with fat,

Anat. my.

for this substance lies thicker upon them in some places than in others. Above all, he should know, in what manner the muscles effect the various motions and gestures of the body. A muscle is composed of two tendinous and slender parts, one called the *head*, the other the *tail*, both terminating at the bones; and of an intermediate part, called the *belly*. The action of a muscle consists in an extraordinary swelling of this intermediate part, while the head remains at rest, so as to bring the tail nearer the head, and consequently the part, to which the tail of the muscle is fixed, nearer to that part into which the head is inserted.

There are many motions, to effect which several of the muscles (for this reason called *co-operating muscles*) must swell and operate together, while those calculated to effect a contrary motion (and therefore called *antagonist muscles*) appear soft and flaccid. Thus, for example, the biceps and the brachii internus labour when the arm is to be bent, and become more prominent than usual; while the gemellus, the brachii externus, and the anconæus, whose office is to extend the arm, continue, as it were, flat and idle. The same happens respectively in all the other motions of the body. When the antagonist muscles of any part operate at one and the same time, such part becomes rigid and motionless. This action of the muscle is called *tonic*.

Michael Angelo intended to have given the public a complete treatise upon this subject; and it is no small misfortune, that he never accomplished so useful a design. This great man, having observed, as we are told in his life by Condivi, that Albert Durer was deficient on the subject, as treating only of the various measures and forms of bodies, without saying a word of their attitudes and gestures, though things of much greater importance, resolved to compose a theory, founded upon his long practice, for the service of all future painters and statuary. And, certainly, no one could be better qualified to give anatomical precepts for that purpose, than he, who, in competition with Da Vinci, designed that famous cartoon of naked bodies, which was studied by Raphael himself, and afterwards obtained the approbation of the Vatican, the greatest school of the art we are now treating of.

The want of Michael Angelo's precepts may, in some measure, be supplied by other books written on the same subject by Moro, Cesio, and Tortebat; and lately by Bouchardon, one of the most famous statuary in France. But nothing can be of equal service to a young painter, with the lessons of some able dissector; under whom, in a few months, he may make himself master of every branch of anatomy which he need be acquainted with. A course of osteology is of no great length; and of the infinite number of muscles discovered by curious myologists, there are not above 80 or 90, with which nature sensibly operates all those motions which he can ever have occasion to imitate or express. These, indeed, he should closely study, these he should carefully store up in his memory, so as never to be at the least loss for their proper figure, situation, office, and motion.

But there is another thing besides the dissection of dead bodies, by which a young painter may profit greatly; and that is, anatomical casts. Of these we have

Anatomy.

Anatomy.

have numbers by several authors; nay some, which pass under the name of *Basarrotti* himself. But there is one, in which, above all the rest, the parts are most distinctly and lively expressed. This is the performance of *Hercules Lelli*, who has, perhaps, gone greater lengths in this kind of study than any other master. We have, besides, by the same able hand, some casts of particular parts of the human body, so curiously coloured for the use of young painters, as to represent these parts exactly as they appear on removing the integuments; and thus, by the difference in their colour as well as configuration, render the tendinous and the fleshy parts, the belly and the extremities, of every muscle suprisingly distinct; at the same time that, by the various direction of the fibres, the motion and play of these muscles become very obvious; a work of the greatest use, and never enough to be commended! Perhaps, indeed, it would be an improvement, to give the muscles various tints; those muscles especially, which the pupil might be apt to mistake for others. For example, though the mastoidei, the deltoides, the sartorii, the fascia lata, the gastrocnemii, are, of themselves, sufficiently distinguishable, it is not so with regard to the muscles of the arm and of the back, the right muscles of the belly, and some others, which, either on account of the many parts into which they branch, or of their being interwoven one with another, do not so clearly and fairly present themselves to the eye. But let the cause of confusion to young beginners be what it will, it may be effectually removed by giving, as already hinted, different colours to the different muscles, and illuminating anatomical figures; in the same manner that maps are, in order to enable us readily to distinguish the several provinces of every kingdom, and the several dominions of every prince.

The better to understand the general effect, and remember the number, situation, and play of the muscles, it will be proper to compare, now and then, the anatomical casts, and even the dead body itself, with the living body covered with its fat and skin; and above all things, with the Greek statues still in being. It was the peculiar happiness of the Greeks, to be able to characterize and express the several parts of the human body much better than we can pretend to do; and this, on account of their particular application to the study of naked figures, especially the fine living ones which they had continually before their eyes. It is well known, that the muscles most used are likewise the most protuberant and conspicuous; such as, in those who dance much, the muscles of the legs; and in boatmen, the muscles of the back and arms. But the bodies of the Grecian youth, by means of their constant exertion of them in all the gymnastic sports, were so thoroughly exercised, as to give the statuary with much more perfect models than ours can pretend to be. It is not to be doubted, but that, for the same reason, the Greek painters attained the highest degree of perfection in the figures of those pieces of theirs so much cried up by ancient authors; and it is a great pity, that we have not even those copies of nature to direct our studies. For the faults observable in the ancient paintings, which have been dug up in great numbers, especially within these few years, do not so much tend to prove that the

Greeks were any way deficient in this art, as the pieces themselves, taken all together, that they had carried it to the highest degree of perfection. For, if in pictures drawn upon walls, which it was therefore impossible to rescue from fire, and in little country towns, and at a time when the art was at its lowest ebb, there appears, in the opinion of the best judges, such excellence of design, colouring, and composition, that one would apt to attribute most of them to the school of Raphael; what must we think of the pictures, drawn at an earlier period, by their ablest masters and for their most flourishing cities and most powerful monarchs; of pictures admired in a country like Greece, where every art was brought to such a degree of perfection, that no passion could resist their music, no sentiment resist their mimic arts; of pictures cried up by Pliny\*, the soundness of whose judgment in matters of this kind displays itself in so many passages of his works; collected at such expence by Julius Cæsar†, of whose fine taste, the works composed by him, and still extant, are a most incontestable proof? But what evinces still better the excellence of the ancients in painting, is that to which they arrived in statuary, her sister art. Both daughters of design, they both enjoyed in common the same models, which, more perfect in the happy climate of Greece than in any other part of the globe, must have been of as great service to the Apelleles and the Zeuxifes, in the drawing of their figures, as they were to the Apolloniuses, the Glycons, and the Agathes, in carving those statues which the world has still the happiness of possessing. These masters, being besides assisted by a proper insight into anatomy, and thoroughly acquainted with the various play of the muscles according to the various attitudes of the body, and with the different degrees of strength with which each particular muscle was to be expressed in each particular attitude, were thereby enabled to give truth, motion, and life, to all their works.

There are a great many exercises, which a young painter should go through while engaged in the study of anatomy, in order to make himself more thoroughly master of that science. For example: The thighs of any figure, a Laocoon for instance, being given, he should add to them legs suitable to that state in which the muscles of the thighs are represented, that is, the muscles which serve to bend and extend the legs, and to effectuate in them such a precise position and no other. To the simple contour of an anatomy, or a statue, he should add the parts included by it, and give it a system of muscles conformable to the quality of that particular contour; for every contour denotes some one certain attitude, motion, exertion, and no other. Exercises of this kind would soon establish him in the most fundamental principles of painting, especially if he had an opportunity of comparing his drawings with the statue or cast from which the parts given him to work upon were taken, and thereby discovering and correcting his mistakes. This method is very like that used by those who teach the Latin tongue; when, having given their scholars a passage of Livy or Cæsar already translated into their mother-tongue, to translate back into Latin, they make them compare their work with the original next.

### SECT. III. Of Perspective.

6. THE Study of perspective should go hand

\* Nat. Hist.  
lib. xxxvi.  
c. 25.  
† Suetonius,  
in vit. Cæsar.  
cap. 27.

*Perspective.* with that of anatomy, as not less fundamental and necessary. In fact, the contour of an object drawn upon paper or canvas, represents nothing more than such an interfection of the visual rays sent from the extremities of it to the eye, as would arise on a glass put in the place of the paper or canvas. Now, the situation of an object at the other side of a glass being given, the delineation of it on the glass itself depends entirely on the situation of the eye on this side of the glass; that is to say, on the rules of perspective: a science which, contrary to the opinion of most people, extends much farther than the painting of scenes, floors, and what generally goes under the name of *quadratura*. Perspective, according to that great master da Vinci, is to be considered as the reins and rudder of painting. It teaches in what proportion the parts fly from, and lessen upon, the eye; how figures are to be marshalled upon a plain surface, and fore-shortened. It contains, in short, the whole rationale of design.

Such are the terms which the masters best grounded in their profession have employed to define and commend perspective: so far were they from calling it a *fallacious art*, and an *insidious guide*; as some amongst the moderns have not blushed to do, insinuating that it is to be followed no longer than it keeps the high road, or leads by easy and pleasant paths. But these writers plainly show, that they are equally ignorant of the nature of perspective, which, founded as it is on geometrical principles, can never lead its votaries astray; and of the nature of their art, which, without the assistance of perspective, cannot, in rigour, expect to make any progress, nay, not so much as delineate a simple contour.

Those, too, who would persuade us, that the ancient masters of Greece knew nothing of perspective, show, that they themselves know little or nothing of painting. They allege, as a proof of this their idle assertion, that the rules of perspective are violated in the most of the ancient pictures that have reached us; as though the mistakes and blunders of middling artists were a sufficient ground for calling in question the merit of others, who were allowed to excel in their profession. Now, not to insist on the absurdity of such a supposition, which we have already exposed, Pamphilus, the master of Apelles, and the founder of the noblest school of all Greece, has affirmed in the most express terms, that, without geometry, painting must fall to the ground †. It is well known, besides, that the ancients practised the art of painting in perspective upon walls, in the same way that it is now done \* *Vitravius*, by the moderns ‡; and that one of the walls of the Theatre of Claudius Pulcher, representing a roof covered with tiles, was finished in so masterly a manner, that the rooks, a bird of no small sagacity, taking it for a real roof, often attempted to alight upon it †. We are likewise told, that a dog was deceived to such a degree, by certain steps in a perspective of Dento's, that, expecting to find a free passage, he made up to them in full speed, and dashed out his brains; thus immortalizing by his death the pencil of the artist, which had been the occasion of it. But, what is still more, *Vitravius* ‡ tells us in express terms, by whom, and at what time, this art was invented. It was first practised by Agatharcus, a contemporary of Æschylus,

in the theatre of Athens; and afterwards reduced to Perspective, certain principles, and treated as a science, by Anaxagoras and Democritus; thus faring like all other arts, which exalted in practice before they appeared in theory. The thing, perhaps, may be thus accounted for. Some painter, who happened to be a very accurate observer of nature, first exactly represented those effects which he saw constantly attend the images offered to our eyes by exterior objects; and these effects came afterwards to be demonstrated by geometricians as so many necessary consequences, and reduced to certain theorems: just as from those chief d'œuvres of the human mind, the *Iliad* of Homer, and *Oedipus* of Sophocles, both built upon the most accurate observations of nature, Aristotle found means to extract the rules and precepts contained in his art of poetry. It is therefore clear, that, so early as the age of Pericles, perspective was reduced into a complete science; which no longer continued confined to the theatre, but made its way into the schools of painting, as an art not less necessary to painters in general, than it had been found to scene-painters in particular. Pamphilus, who founded in Scion the most flourishing school of design, taught it publicly; and from the time of Apelles, Protogenes, and the other bright luminaries of painting amongst the ancients, it was practised by the Greek painters, in the same manner that it was, so many ages after, by Bellini, Pietro Perugino, and others, down to the days of Titian, Raphael, and Corregio, who put the last hand to painting, and gave it all that perfection it was capable of receiving.

Now, a painter having formed a scene in his mind, and supposed, as it is customary, that the capital figures of this scene lie close, or almost close, to the back of his canvas, he is, in the next place, to fix upon some point on this side of the canvas, from which he would choose his piece should be seen. But in choosing this point, which is called the *point of sight*, regard should be had to its situation to the right or left of the middle of the canvas: but, above all things, to its distance and its height with respect to the lower edge of the canvas; which edge is called the *base line*, and is parallel with the horizontal line that passes through the eye. For by assuming the point of sight, and consequently the horizontal line, too low, the planes, upon which the figures stand, will appear a great deal too shallow; as, by assuming it too high, they will appear too steep, so as to render the piece far less light and airy than it ought to be. In like manner, if the point of sight is taken at too great a distance from the canvas, the figures will not admit of degradation enough to be seen with sufficient distinctness; and if taken too near it, the degradation will be too quick and precipitate to have an agreeable effect. Thus, then, it appears, that no small attention is requisite in the choice of this point.

When a picture is to be placed on high, the point of sight should be assumed low, and *vice versa*; in order that the horizontal line of the picture may be, as near as possible, in the same horizontal plane with that of the spectator; for this disposition has an amazing effect. When a picture is to be placed very high, as, amongst many others, that of the purification by Paolo Veronese, engraved by le Fèvre, it will be proper

† *Plin. Hist. Nat.* lib. xxxv. c. 10.

\* *Vitravius*, by the moderns ‡; and that one of the walls of the Theatre of Claudius Pulcher, representing a roof covered with tiles, was finished in so masterly a manner,

† *Plin. Hist. Nat.* lib. xxxv. c. 4.

‡ *In Pref. Lib. vii.*

*Perspective.* to assume the point of sight so low, that it may lie quite under the picture, no part of whose ground is, in that case, to be visible; for, were the point of sight to be taken above the picture, the horizontal ground of it would appear sloping to the eye, and both figures and buildings as ready to tumble head foremost. It is true, indeed, that there is seldom any necessity for such extraordinary exactness; and that, unless in some particular cases, the point of sight had better be rather high than low: the reason of which is, that, as we are more accustomed to behold people on the same plane with ourselves, than either higher or lower, the figures of a piece must strike us most when standing on a plane nearly level with that upon which we ourselves stand. To this it may be added, that by placing the eye low, and greatly shortening the plane, the heels of the back figures will seem to bear against the heads of the foremost, so as to render the distance between them far less perceptible than otherwise it would be.

The point of sight being fixed upon, according to the situation in which the picture is to be placed, the point of distance is next to be determined. In doing this, a painter should carefully attend to three things: first, that the spectator may be able to take in, at one glance, the whole and every part of the composition; secondly, that he may see it distinctly; and thirdly, that the degradation of the figures and other objects of the picture be sufficiently sensible. It would take up too much time to lay down certain and precise rules for doing all this, considering the great variety in the sizes and shapes of pictures; for which reason we must leave a great deal to the discretion of the painter.

But there is a point still remaining, which will not admit of the least latitude. This is, the delineation of the picture, when once the point of sight has been fixed upon. The figures of a picture are to be considered as so many columns erected on different spots of the same plane; and the painter must not think of designing any thing, till he has laid down, in perspective, all those columns which are to enter his composition, with the most scrupulous exactness. By proceeding in this manner, he may not only be sure of not committing any mistake in the diminution of his figures according to their different distances, but may flatter himself with the thoughts of treading in the steps of the greatest masters, especially Raphael, in whose sketches (such was his respect to the laws of perspective) we frequently meet with a scale of degradation. It is to the punctual observance of these laws, that we are to attribute the grand effect of some paintings by Carpaccio and Mantegna, so careless in other respects; whereas a single fault against them is often sufficient entirely to spoil the works of a Guido, in spite of the sublimity and beauty of his superior style.

Now, as the demonstration of the rules of perspective depends on the doctrine of proportions, on the properties of similar triangles, and on the intersection of planes, it will be proper to put an abridgement of Euclid into the hands of the young painter, that he may understand these rules fundamentally, and not stand confined to a blind practice of them: but, then, there is nothing in this author, relative to the art of paint-

ing, which may not be easily acquired in a few months. For, as it would be of no use to a painter to lanch out into the anatomical depths of a Monro or an Albinus, it would be equally superfluous to perplex himself with the intricacies of the higher geometry with a Taylor, who has handled perspective with that rich profoundness, which we cannot help thinking does a great deal more honour to a mathematician, than it can possibly bring advantage to a simple artist.

But though a much longer time were requisite to become a perfect master of perspective, a painter, surely, ought not to grudge it; as no time can be too long to acquire that knowledge, without which he cannot possibly expect to succeed. Nay, we may boldly affirm, that the shortest road in every art is that which leads through theory to practice. It is from theory that arises that great facility, by means of which a man advances the quicker, in proportion as he is surer of not taking a wrong step: whilst those, who are not grounded in the science, labour on in perpetual doubt; obliged, as a certain author expresses it, to feel out their way with a pencil, just as the blind, with their sticks, feel for the streets and turnings, with which they are not acquainted.

As practice, therefore, ought in every thing to be built upon principle, the study of Optics, as far as it is requisite to determine the degree in which objects are to be illuminated or shaded, should proceed hand in hand with that of perspective: And this, in order that the shades, cast by figures upon the planes on which they stand, may fall properly, and be neither too strong nor too light; in a word, that those most beautiful effects of the chiar-oscuro may run no risk of ever receiving the lie from truth, which sooner or later discovers itself to every eye.

#### SECT. IV. Of Symmetry.

7. THE study of symmetry, it is obvious, should immediately follow that of anatomy: for it would avail little to be acquainted with the different parts of the human body, and their several offices, were we at the same time ignorant of the order and proportion of these parts in regard to the whole in general, and each other in particular. The Greek statuary distinguished themselves above all others, as much by the just symmetry of their members, as by their skill in anatomy; but Polyceutes surpassed them all by a statue, called the *Rule*, from which, as from a most accurate pattern, other artists might take measures for every part *Plinii* of the human body. These measures, to say nothing *Nat. Hist. lib. xxxiv. c. 8.* of the books which treat professedly of them, may now be derived from the Apollo of Belvedere, the Laocoon, the Venus of Medicis, the Pannus, and particularly the Antinous, which last was the rule of the learned Poussin.

Nature, which in the formation of every species seems to have aimed at the last degree of perfection, does not appear to have been equally solicitous in the production of individuals. She considers, one would think, those things as nothing, which have a beginning and an end, and whose existence is of so short a duration, that they may be said, in a manner, to come into the world merely to leave it. She seems, in some sort, to abandon individuals to second causes; and if from

Symmetry.

from them there now and then breaks forth a primitive ray of perfection, it is too soon eclipsed by the clouds of imperfection that constantly attend it. Now, Art soars up to the archtypes of Nature; collects the flowers of every beauty, which it here and there meets with; combines all the perfect models that come in its way; and proposes them to men for their imitation. Thus, the painter, who had before him a company of naked Calabrian girls, traced, as la Casa† ingeniously expresses it, the respective beauties which they had as they were borrowed from one single body; that, by making each of them restore to this imaginary form what the had borrowed from it, he might be furnished with a complete pattern; rightly imagining, that from such an union, and of such beauties, must result the beauty of an Helen. This was likewise the practice of the ancient statuary, when about to form in brass or marble the statues of their gods or heroes. And, thanks to the hardness of these materials, some of their works, containing united all that possible perfection which could be found scattered here and there in individuals, subsist to this day as patterns not only of exact symmetry, but of supereminent grandeur in the parts, gracefulness and contrast in the attitudes; in short, as paragons in every kind, and the very mirrors of beauty. In them we behold precept joined with example: in them we see where the great masters of antiquity deviated with a happy boldness from the common rules; or rather made them bend to the different characters they were to represent. In their Niobe, for instance, which was to breathe majesty like Juno, they have altered some parts that appear more delicate and slender in their Venus, the pattern of female beauty. The legs and thighs of the Apollo of Belvedere, by being made somewhat longer than the common proportion of these limbs to the rest of the body seems to admit, contribute not a little to give him that ease and freedom which correspond so well with the activity attributed to that deity; as, on the other hand, the extraordinary thickness of the neck adds strength to the Farnesian Hercules, and gives him something of a bull-like look and robustness.

It is the general opinion of painters, that the ancients were not as happy in representing the bodies of children, as they are allowed to have been in representing those of women and men; especially those of their gods; in which they excelled to such a degree, that with these gods were often worshipped the artists who had carved them. Yet the Venus of Gnibus by Praxiteles was not more famous than her Cupid, on whose account alone people flocked to Thepizé‡. To children, say they, the ancients knew not how to impart that softness and effeminacy, which Piamingo has since contrived to give them, by representing their cheeks, hands, and feet, swelled, their heads large, and with scarce any belly. But such critics seem to forget, that these first sketches of nature very seldom come in the painter's way, and that this puny and delicate state has not in its form even the least glimmering of perfection. The ancients never undertook to represent children less than four or five years old; at which age the superfluous humours of the body being in some measure digested, their members began to assume such a contour and proportion, as may serve to point out what they are afterwards likely to

be. This observation is confirmed by the children Symmetry, which we meet with in ancient basso-relievos and paintings: for they are all doing one thing or another; like those most beautiful little Cupids in a picture at Venice, who are playing with the arms of Mars, and lifting up the ponderous sword of that deity; or that little urchin in the Danæe of Caracci, who empties a quiver of his arrows, in order to fill it with the golden shower. Now, what can be a greater blunder in point of costume, than to attribute actions, which require some degree of strength and judgment, to infancy, to that raw and tender age so totally unable to govern and support itself?

Let a young painter consider the Greek statues ever so often, of whatever character or age they may be represented, it is impossible he should ever consider them without discovering new beauties in them. It is therefore impossible he should copy them too often, according to that judicious motto placed by Moratti on his print called *The School*. This truth was acknowledged by Rubens himself: for though, like one bred, as he was, in the foggy climate of the Low Countries, he generally painted from the life; in some of his works he copied the ancients; nay, he wrote a treatise on the excellency of the ancient statues, and on the duty of a painter to study and imitate them. As to the satirical print, or rather pasquinade, of the great Titian, in which he has represented a parcel of young monkeys aping the groupe of Laocoon and his sons; he intended nothing more by it than to lash the dulness and poverty of those artists, who cannot so much as draw a figure without having a statue before them as a model.

In fact, reason requires, that an artist should be so much master of his art, as seldom to stand in need of a pattern. To what other purpose is he to sweat and toil from his infancy, and spend so many days and nights in studying and copying the best models; especially the finest faces of antiquity, which we are still possessed of; such as the two Niobes, mother and daughter; the Ariadne, the Alexander, the young Nero, the Silenus, the Nile; and likewise the finest figures; for instance, the Apollo, the Gladiator, the Venus, and others; all which (as was said of Pietro Felta), he should have, as it were, perfectly by heart? With a stock of excellencies like these, treasured up in his memory, he may one day hope to produce something of his own without a model; form a right judgement of those natural beauties which fall in his way; and, when occasion offers, avail himself properly of them.

It is very ill done to send boys to an academy to draw after naked figures, before they have imbibed a proper relish for beautiful proportions, and have been well-grounded in the true principles of symmetry. They should first learn, by studying the precious remains of antiquity, to improve upon life; and discern where a natural figure is faulty through stiffness in the members, or clumsiness in the trunk, or in any other respect; so as to be able to correct the faulty part, and reduce it to its proper bounds. Painting, in this branch, is, like medicine, the art of taking away and adding.

It must not, however, be dissembled, that the methods hitherto laid down are attended with some danger;

† In *Galatea*. See also the *Life of Zeuxis*, by Carlo Dati, note 22.

‡ Cic. in *Verror.*, de *signis*. *Sirach*, lib. ix. *Plin.* *Nat. Hist.* lib. xxxvi. 4. 5.

**Symmetry.** ger: for by too slavish an attention to statues, the young painter may contract a hard and dry manner; and by studying anatomies too servilely, a habit of representing living bodies as stripped of their skin: for, after all, there is nothing but what is natural, that, besides a certain peculiar grace and liveliness, possesses that simplicity, ease, and softness, which is not to be expected in the works of art, or even in those of nature when deprived of life. Poussin himself has now and then given into one of these extremes, and Michael Angelo very often into the other: but from this we can only infer, that even the greatest men are not infallible. It is, in short, to be considered as one instance, among a thousand, of the ill life those are wont to make of the best things, who do not know how to temper and qualify them properly with their contraries.

But no such danger can arise to a young painter from confining himself for a long time to mere design, so as not to attempt colouring till he has made himself master of that branch. If, according to a great master †, colours in painting are in regard to the eye what numbers in poetry are in regard to the ear, so many charms to allure and captivate that sense; may we not affirm, that design is in the same art what propriety of language is in writing, and a just utterance of sounds in music? Whatever some people may think, a picture designed according to the rules of perspective and the principles of anatomy, will ever be held in higher esteem by good judges, than a picture ill designed, let it be ever so well coloured. Annibal Caracci set so great a value upon the art of contour, that, according to some expressions of his which have reached us, he considered almost every thing else as nothing in comparison with it. And this his judgment may be justified, by considering, that nature, though she forms men of various colours and complexions, never operates in their motions contrary to the mechanical principles of anatomy, nor, in exhibiting these motions to the eye, against the geometrical laws of perspective: a plain proof, that, in point of design, no mistake is to be deemed trifling. Hence we are enabled to feel all the weight of those words in which Michael Angelo, after he considered a picture drawn by a prince of the Venetian school, addressed Vasari: "What a pity it is," said he, "that this man did not set out by studying design!" As the energy of nature shines most in the smallest subjects, so the energy of art shines most in imitating them.

#### SECT. V. Of Colouring.

8. It must likewise be of great service to a painter desirous to excel in colouring, to be well acquainted with that part of Optics which has the nature of light and colours for its object. Light, however simple and uncompounded it may appear, is nevertheless made up, as it were, of several distinct substances; and the number, and even dose, of these ingredients, has been happily discovered by the moderns. Every undivided ray, let it be ever so fine, is a little bundle of red, orange, yellow, green, azure, indigo, and violet rays, which, while combined, are not to be distinguished one from another, and from that kind of light called *white*; so that white is not a colour *per se*, as the learned da Vinci ‡ (so far, it seems, the precursor of Newton) expressly affirms, but an assemblage of colours. Now, these

colours, which compose light, although immutable in themselves, and endued with various qualities, are continually, however, separating from each other in their reflection from and passage through other substances, and thus become manifest to the eye. Grays, for example, reflects only green rays, or rather reflects green rays in greater number than it does those of any other colour; and one kind of wine transmits red rays, and another yellowish rays: and from this kind of separation arises that variety of colours with which nature has diversified her various productions. Man, too, has contrived to separate the rays of light by making a portion of the sun's beams pass through a glass prism; for after passing through it, they appear divided into several pure and primitive colours, placed in succession one by the other, like so many colours on a painter's pallet.

Now, though Titian, Correggio, and Vandyke, have been excellent colourists, without knowing any thing of these physical subtleties, that is no reason why others should neglect them. For it cannot but be of great service to a painter to be well acquainted with the nature of what he is to imitate, and of those colours with which he is to give life and perfection to his designs; not to speak of the pleasure there is in being able to account truly and solidly for the various effects and appearances of light. From a due tempering, for example, and degrading, of the tints in a picture; from making colours partake of each other, according to the reflection of light from one object to another; there arises, in some measure, that sublime harmony which may be considered as the true music of the eye. And this harmony has its foundation in the genuine principles of optics. Now this could not happen in the system of those philosophers, who held, that colours did not originally exist in light, but were, on the contrary, nothing else than so many modifications which it underwent in reflecting from or passing through other substances; thus subject to alterations without end, and every moment liable to perish. Were that the case, bodies could no more receive any hues one from another, nor this body partake of the colour of that, than scarlet, for example, because it has the power of changing into red all the rays of the sun or sky which immediately fall upon it, has the power of changing into red all the other rays reflected to it from a blue or any other colour in its neighbourhood. Whereas, allowing that colours are in their own nature immutable one into another, and that every body reflects more or less every sort of coloured rays, though those rays in the greatest number which are of the colour it exhibits, there must necessarily arise, in colours placed near one another, certain particular hues or temperaments of colour: nay, this influence of one colour upon another may be so far traced, that three or four bodies of different colours, and likewise the intenseness of the light falling upon each, being assigned, we may easily determine in what situations, and how much, they would tinge each other. We may thus, too, by the same principle of optics, account for several other things practised by painters; inasmuch that a person, who has carefully observed natural effects with an eye directed by solid learning, shall be able to form general rules, where another can only distinguish particular cases.

But after all, the pictures of the best colourists are, it

† Poussin; in his *Life*, by Bellori.

‡ Trattato della Pittura, c. 14.

Colouring—it is universally allowed, the books in which a young painter must chiefly look for the rules of colouring; that is, of that branch of painting which contributes so much to express the beauty of objects, and is so requisite to represent them as what they really are. Giorgione and Titian seem to have discovered circumstances in nature, which others have entirely overlooked; and the last in particular has been happy enough to express them with a pencil as delicate as his eye was quick and piercing. In his works we behold that sweetness of colouring which is produced by union; that beauty which is consistent with truth; and all the insensible transmutations, all the soft transitions, in a word, all the pleasing modulations, of tints and colours. When a young painter has, by close application, acquired from Titian, whom he can never sufficiently dwell upon, that art which, of all painters, he has best contrived to hide, he would do well to turn to Bassano and Paolo, on account of the beauty, boldness, and elegance of their touches. That richness, softness, and freshness of colouring, for which the Lombard school is so justly cried up, may likewise be of great service to him. Nor will he reap less benefit by studying the principles and practice of the Flemish school; which, chiefly by means of her varnishes, has contrived to give a most enchanting lustre and transparency to her colours.

But whatever pictures a young painter may choose to study the art of colouring upon, he must take great care that they are well preserved. There are very few pieces which have not suffered more or less by the length, not to say the injuries, of time; and perhaps that precious patina, which years alone can impart to paintings, is in some measure akin to that other kind which ages alone impart to medals; inasmuch as, by giving testimony to their antiquity, it renders them proportionately beautiful in the superstitious eyes of the learned. It must indeed be allowed, that if, on the one hand, this patina bestows, as it really does, an extraordinary degree of harmony upon the colours of a picture, and destroys, or at least greatly lessens, their original rawness, it, on the other hand, equally impairs the freshness and life of them. A piece seen many years after it has been painted, appears much as it would do, immediately after painting, behind a dull glass. It is no idle opinion, that Paolo Veronese, attentive above all things to the beauty of his colours, and what is called *scintillo*, left entirely to time the care of harmonizing them perfectly and (as we may say) mellowing them. But most of the old masters took that task upon themselves; and never exposed their works to the eyes of the public, until they had ripened and finished them with their own hands. And who can say whether the *Christ* of Moneta, or the *Nativity* of Bassano, have been more improved or injured (if we may so speak) by the touchings and retouchings of time, in the course of more than two centuries? It is indeed impossible to be determined. But the studious pupil may make himself ample amends for any injuries which his originals may have received from the hands of time, by turning to truth, and to Nature which never grows old, but constantly retains its primitive flower of youth, and was itself the model of the models before him. As soon, therefore, as a young painter has laid a proper foundation for good colouring, by studying the best

masters, he should turn all his thoughts to truth and nature. And it would perhaps be well worth while to have, in the academies of painting, models for colouring as well as designing; that as from the one the pupils learn to give their due proportion to the several members and muscles, they may learn from the other to make their carnations rich and warm, and faithfully copy the different local hues which appear quite distinct in the different parts of a fine body. To illustrate still farther the use of such a model, let us suppose it placed in different lights; now in that of the sun, now in that of the sky, and now again in that of a lamp or candle; one time placed in the shade, and another in a reflected light. Hence the pupil may learn all the different effects of the completion in different circumstances, whether the livid, the lucid, or transparent; and, above all, that variety of tints and half-tints, occasioned in the colour of the skin by the epidermis having the bones immediately under it in some places, and in others a greater or less number of blood-vessels or quantity of fat. An artist who had long studied such a model, would run no risk of degrading the beauties of nature by any particularity of style, or of giving into that preposterous fulness and floridness of colour which is at present so much the taste. He would not feed his figures with roses, as an ancient painter of Greece shrewdly expressed it, but with good beef; a difference, which the learned eye of a modern writer *Webb*, could perceive between the colouring of Barocci and dial. 1. that of Titian. To practise, in that manner, is, according to a great master, no better than inuring one's self to the commission of blunders. What statues are in design, nature is in colouring; the fountain-head of that perfection to which every artist, ambitious to excel, should constantly aspire: and accordingly the Flemish painters, in consequence of their aiming solely to copy nature, are in colouring as excellent as they are wont to be awkward in designing.

#### SECT. VI. Of the Camera Obscura.

9. We may well imagine, that could a young painter but view a picture by the hand of nature herself, and study it at his leisure, he would profit more by it than by the most excellent performances by the hand of man. Now, nature is continually forming such pictures in our eye. The rays of light coming from exterior objects, after entering the pupil pass through the crystalline humour; and, being there refracted in consequence of the lenticular form of that part, proceed to the retina, which lies at the bottom of the eye, and stamp up it, by their union, the image of the object towards which the pupil is directed. The consequence of which is, that the soul, by means as yet unknown to us, receives immediate intelligence of these rays, and comes to see the objects that sent them. But this grand operation of nature, the discovery of which was reserved for our times, might have remained an idle amusement of physical curiosity, without being of the least service to the painter, had not means been happily found of imitating it. The machine contrived for this purpose, consists of a lens and mirror so situated, that the second throws the picture of any thing properly exposed to the first, and that too of a competent largeness, on a clean sheet of paper, where it may be seen and contemplated at leisure.

As this artificial eye, usually called a *camera optica* or *obscura*, gives no admittance to any rays of light, but those coming from the thing whose representation is wanted, there results from them a picture of inexpressible force and brightness; and as nothing is more delightful to behold, so nothing can be more useful to study, than such a picture. For, not to speak of the justness of the contours, the exactness of the perspective and of the chiaroscuro, which exceeds conception; the colours are of a vivacity and richness that nothing can excel; the parts which stand out most, and are most exposed to the light, appear surprisingly loose and resplendent; and this looseness and resplendency declines gradually, as the parts themselves sink in, or retire from the light. The shades are strong without harshness, and the contours precise without being sharp. Wherever any reflected light falls, there appears, in consequence of it, an infinite variety of tints, which, without this contrivance, it would be impossible to discern. Yet there prevails such a harmony amongst all the colours of the piece, that scarce any one of them can be said to clash with another.

After all, it is no way surprising, that we should, by means of this contrivance, discover, what otherwise we might justly despair of ever being acquainted with. We cannot look directly at any object that is not surrounded by so many others, all darting their rays together into our eyes, that it is impossible we should distinguish all the different modulations of its light and colours. At least we can only see them in so dull and confused a manner, as not to be able to determine any thing precisely about them. Whereas, in the camera obscura, the visual faculty is brought wholly to bear upon the object before it; and the light of every other object is, as it were, perfectly extinguished.

Another most astonishing perfection in pictures of this kind is, the diminution of the size, and of the intenseness of light and colour, of the objects and all their parts, in proportion to their distance from the eye. At a greater distance, the colours appear more faint, and the contours more obscure. The shades, likewise, are a great deal weaker in a less or more remote light. On the other hand, those objects, which are largest in themselves, or lie nearest to the eye, have the most exact contours, the strongest shades, and the brightest colours: all which qualities are requisite to form that kind of perspective which is called *aerial*; as though the air between the eye and external objects, not only veiled them a little, but in some sort gnawed and preyed upon them. This kind of perspective constitutes a principal part of that branch of painting, which regards the foreshortening of figures, and likewise the bringing them forward, and throwing them back in such a manner as to make us lose sight of the ground upon which they are drawn. It is, in a word, this kind of perspective, from which, assisted by linear perspective, arise

*Dolce cose a vedere, e dolci inganni;*

“Things sweet to see, and sweet deceptions.”

Nothing proves this better than the camera obscura, in which nature paints the objects which lie near the eye, as it were, with a hard and sharp pencil, and those at a distance with a soft and blunt one.

The best modern painters among the Italians have availed themselves greatly of this contrivance; nor is it possible they should have otherwise represented things

so much to the life. It is probable, too, that several of the Tramontane masters, considering their success in expressing the minutest objects, have done the same. Every one knows of what service it has been to Spagnoletto of Bologna, some of whose pictures have a grand and most wonderful effect. We once happened to be present where a very able master was shewn this machine for the first time. It is impossible to express the pleasure he took in examining it. The more he considered it, the more he seemed to be charmed with it. In short, after trying it a thousand different ways, and with a thousand different models, he candidly confessed, that nothing could compare with the pictures of so excellent and imitable a master. Another, no less eminent, has given it as his opinion, that an academy, with no other furniture than the book of da Vinci, a critical account of the excellencies of the capital painters, the casts of the finest Greek statues, and the pictures of the camera obscura, would alone be sufficient to revive the art of painting. Let the young painter, therefore, begin as early as possible to study these divine pictures, and study them all the days of his life, for he never will be able sufficiently to contemplate them. In short, painters should make the same use of the camera obscura which naturalists and astronomers make of the microscope and telescope; for all these instruments equally contribute to make known and represent nature.

#### SECT. VII. Of Drapery.

10. DRAPERY is one of the most important branches of the whole art, and accordingly demands the greatest attention and study. It seldom happens that a painter has nothing but naked figures to represent; nay, his subjects generally consist of figures clothed from head to foot. Now the flowing of the folds in every garment depends chiefly upon the relief of the parts that lie under it. A certain author, we forget his name, observes, that as the inequalities of a surface are discoverable by the inequalities in the water that runs over it, so the posture and shape of the members must be discernible by the folds of the garment that covers them. Those idle windings and gatherings, with which some painters have affected to cover their figures, make the clothes made up of them look as if the body had fled from under them, and left nothing in its place but a heap of empty bubbles, fit emblems of the brain that conceived them. As from the trunk of a tree there issue here and there boughs of various forms, so from one mistress-fold there always flow many lesser ones: and as it is on the quality of the tree that the elegance, compactness, or openness of its branches chiefly depends; it is, in like manner, by the quality of the stuff of which a garment is made, that the number, order, and size of its folds must be determined. To sum up all in two words, the drapery ought to be natural and easy, so as to show what stuff it is, and what parts it covers. It ought, as a certain author expresses it, to cover the body, as it were merely to show it.

It was formerly the custom with some of our masters to draw all their figures naked, and then drape them; from the same principle that they first drew the skeletons of their figures, and afterwards covered them with muscles. And it was by proceeding in this manner that they attained to such a degree of truth in expressing

fining the folds of their drapery, and the joints and direction of the principal members that lay under it, so as to exhibit in a most striking manner, the attitude of the person to whom they belonged. That the ancient sculptors clothed their statues with equal truth and grace, appears from many of them that are still in being; particularly a Flora lately dug up in Rome, whose drapery is executed with so much judgment, and in so grand and rich a style, that it may vie with the finest of their naked statues, even with the Venus of Medicis. The statues of the ancients had so much beauty when naked, that they retained a great deal when clothed. But here it must be considered, that it was usual with them to suppose their originals clothed with wet garments, and of an extreme fineness and delicacy, that, by lying close to the parts, and in a manner clinging to them, they might the better show what these parts were. For this reason a painter is not to confine himself to the study of the ancient statues, lest he should contract a dry style, and even fall into the same faults with some great masters who, accustomed to drape with such light stuffs as sit close to the body, have afterwards made the coarsest lie in the same manner, so as plainly to exhibit the muscles underneath them. It is therefore proper to study nature herself, and those modern masters who have come nearest to her in this branch; such as Paolo Veronese, Andrea del Sarto, Rubens, and above all, Guido Reni. The flow of their drapery is soft and gentle; and the gatherings and plaits are so contrived, as not only not to hide the body, but to add grace and dignity to it. Their gold, silk, and woollen stuffs, are so distinguishable one from another, by the quality of their several lustres, and the peculiar light and shade belonging to each, but above all by the form and flow of their folds, that the age and sex of their figures are hardly more discoverable by their faces. Albert Durer is another great master in this branch, inasmuch that Guido himself was not ashamed to study him. There are still extant several drawings made with the pen by this great man, in which he has copied whole figures from Albert, and scrupulously retained the flow of his drapery as far as his own peculiar style, less harsh and sharp, but more easy and graceful, would allow. It may be said that he made the same use of Albert, that our modern writers ought to make of the best authors of the 13th century.

#### SECT. VIII. Of Landscape and Architecture.

11. WHEN our young painter has made a sufficient progress in those principal branches of his art, the designing, perspective, colouring, and drapery of human figures, he should turn his thoughts to landscape and architecture: for, by studying them, he will render himself universal, and qualified to undertake any subject; so as not to resemble certain literati, who, tho' great masters in some articles, are mere children in every thing else.

The most eminent landscape painters are Poussin, Lorraine, and Titian.

Poussin was remarkable for his great diligence. His pieces are quite exotic and uncommon; being set off with buildings in a beautiful but singular style; and with learned episodes, such as poets reciting their verses to the woods, and youths exercising themselves in the

several gymnastic games of antiquity; by which it plainly appears, that he was more indebted for his subjects to the descriptions of Pausanias, than to nature and truth.

Lorraine applied himself chiefly to express the various phenomena of light, especially those perceivable in the heavens. And, thanks to the happy climate of Rome, where he studied and exercised his talents, he has left us the brightest skies, and the richest and most gloriously cloud-tipt horizons that can be well conceived. Nay, the sun himself, which, like the Almighty, can be represented merely by his effects, has scarce escaped his daring and ambitious pencil.

Titian, the great confident of nature, is the Homer of landscape. His scenes have so much truth, so much variety, and such a bloom in them, that it is impossible to behold them, without wishing, as if they were real, to make an excursion into them. And perhaps the finest landscape that ever issued from mortal hands, is the back ground of his *Martyrdom of St Peter*; where by the difference between the bodies and the leaves of his trees, and the disposition of their branches, one immediately discovers the difference between the trees themselves; where the different soils are so well expressed, and so exquisitely clothed with their proper plants, that a botanist has much ado to keep his hands from them. See Part II. Sect. ii.

Paolo Veronese is in architecture, what Titian is in landscape. To excel in landscape, we must, above all things, study nature. To excel in architecture, we must chiefly regard the finest works of art; such as the fronts of ancient edifices, and the fabrics of those moderns who have best studied and best copied antiquity. Next to Brunelleschi and Alberti, who were the first revivers of architecture, came Bramante, Giulio Romano, Sansovino, Sanmicheli, and lastly Palladio, whose works the young painter should above all the rest diligently study and imprint deeply on his mind. Nor is Vignola to be forgot; for some think he was a more scrupulous copier of antiquity, and more exact, than Palladio himself, inasmuch that most people consider him as the first architect among the moderns. For our part, to speak of him, not as fame, but as truth seems to require, we cannot help thinking, that rather than break through the generality of the rules contrived by him to facilitate practice, he has in some instances deviated from the most beautiful proportions of the antique, and is rather barren in the distribution and disposition of certain members. Moreover, the extraordinary height of his pedestals and cornices hinders the column from showing in the orders designed and employed by him, as it does in those of Palladio. Amongst that great variety of proportions to be met with in ancient ruins, Palladio has been extremely happy in choosing the best. His profiles are well contrived, yet easy. All the parts of his buildings hang well together. Grandeur, elegance, and beauty, walk hand in hand in them. In short, the very blemishes of Palladio, who was no slave to conveniency, and sometimes perhaps was too profuse in his decorations, are picturesque. And we may reasonably believe, that it was by following so great a master, whose works he had continued before his eyes, that Paolo Veronese formed that fine and masterly taste which enabled him to embellish his compositions with such beautiful structures.

SECT. IX. *Of the Costume.*

12. THE study of architecture cannot fail, in another respect, of being very useful to the young painter, inasmuch as it will bring him acquainted with the form of the temples, theatres, basilics, and other buildings of the Greeks and Romans. Besides, from the basso-relievos with which it was customary to adorn these buildings, he may gather, with equal delight and profit, the nature of their sacrifices, arms, military engravings, and dresses. The study of landscape, too, will render familiar to him the form of the various plants peculiar to each soil and climate, and such other things as serve to characterise the different regions of the earth. Thus by degrees he will learn what we call *costume*, one of the chief requisites in a painter; since, by means of it, he may express with great precision the time and place in which his scenes are laid.

The Roman school has been exceedingly chaste in this branch. So was the French, as long as it continued under the influence and direction of Poussin, whom we may justly style the *Learned Painter*; whereas the Venetian school has been to the last degree careless, not to say licentious. Titian made no difficulty of introducing in an *Ecce Homo* of his, pages in a Spanish garb, and the Austrian Eagle on the shields of the Roman soldiers. It is true indeed, that once he placed in the back ground of a *Crowning-with-Thorns*, a bust carrying the name of the emperor Tiberius, under whom our Saviour suffered: but it is likewise true, that, as if he thought it unbecoming a painter to pay any regard to such minutæ of learning and the costume, he shewed himself perfectly indifferent about them in all his other works. Tintoret, in a *Fall of Manna*, has armed his figures with muskets. And Paolo Veronese, in a *Last Supper*, presents us with Swiss, Levantine, and other strange figures. In short, he has been so careless in this way, that his pieces have been often considered as so many beautiful masquerades.

It is impossible to express how much a picture suffers by such looseness and fancy, and sinks as a bastard of the art in the esteem of good judges. Some people, indeed, are of opinion that so scrupulous an observance of the costume is apt to hurt pictures, by depriving them of a certain air of truth arising, they think, from those features and habits to which we are accustomed; and which are therefore apt to make a greater impression, than can be expected from things drawn from the remote sources of antiquity: adding withal, that a certain degree of licence has ever been allowed those artists who in their works must make fancy their chief guide. See, say they, the Greeks; that is, the masters of Raphael and Poussin themselves. Do they ever trouble their heads about such niceties? The Rhodian statues, for example, have not scrupled to represent Laocœon naked; that is, the Priest of Apollo naked in the very act of sacrificing to the gods, and that too in presence of a whole people, of the virgins and matrons of Ilium. Now, continue they, if it was allowable in the ancient statues to neglect probability and decency to such a degree, to have a better opportunity of displaying their skill in the anatomy of the human body; why may it not be allowable in modern painters, the better to attain the end of their art, which is deception, to depart now and then a little

from the ancient manners and the too rigorous laws of the costume? But these reasons, we beg leave to observe, are more absurd than they are ingenious. What! are we to draw conclusions from an example, which, far from deciding the dispute, gives occasion to another? The learned are of opinion, that those Rhodian masters would have done much better, had they looked out for a subject in which, without offending so much against truth, and even probability, they might have had an equal opportunity of displaying their knowledge of the naked. And certainly no authority or example whatever, should tempt us to do any thing contrary to what both decency and the reason of things require, unless we intend, like Carpioti, to represent

*Sogni d'inferni, e sole di romanzi.*

"The dreams of sick men, and the tales of fools."

No: a painter, the better to attain the end of his art, which is deception, ought carefully to avoid mixing the antique with the modern, the domestic with the foreign; things, in short, repugnant to each other, and therefore incapable of gaining credit. A spectator will never be brought to consider himself as actually present at the scene, the representation of which he has before him, unless the circumstances which enter it perfectly agree among themselves, and the field of action, if we may use the expression, in no shape belies the action itself. For instance, the circumstances, or, if you please, the accessories, in a *Finding of Moses*, are not, surely, to represent the borders of a canal planted with rows of poppies, and covered with country-houses in the European taste; but the banks of a great river shaded with clusters of palm-trees, with a Sphinx or an Anubis in the adjacent fields, and here and there in the back-ground a towering pyramid. And indeed the painter, before he takes either canvas or paper in hand, should on the wings of fancy transport himself to Egypt, to Thebes, or to Rome; and summoning to his imagination the physiognomy, the dresses, the plants, the buildings, suitable to his subject, with the particular spot he has chosen to lay his scene, so manage his pencil, as, by the magic of it, to make the enraptured spectators fancy themselves there along with him.

SECT. X. *Of Invention.*

13. As the operations of a general should, all, ultimately tend to battle and conquest; so should all the thoughts of a painter to perfect invention. Now, the studies which we have been hitherto recommending, will prove so many wings by which he may raise himself, as it were, from the ground, and soar on high, when desirous of trying his strength this way, and producing something from his own fund. Invention is the finding out probable things, not only such as are adapted to the subject in hand, but such, besides, as by their sublimity and beauty are most capable of exciting suitable sentiments in the spectator, and of making him, when they happen to be well executed, fancy that it is the subject itself in its greatest perfection, and not a mere representation of it; that he has before him. We do not say true things, but probable things; because probability or verisimilitude is, in fact, the truth of those arts which have the fancy for their object. It is, indeed, the business and duty of both naturalists and historians, to draw objects as they find them, and

represent them with all those imperfections and blemishes, to which, as individuals, they are subject. But an ideal painter, and such alone is a true painter, resembles the poet: instead of copying, he imitates; that is, he works with his fancy, and represents objects endued with all that perfection which belongs to the species and may be conceived in the archetype.

"*'Tis nature all, but nature methodized;*"

says an eminent poet, speaking of poetry: And the same may be said of painting; but it is nature methodized, and made perfect. Inasmuch, that the circumstances of the action, exalted and sublimed to the highest degree of beauty and boldness they are susceptible of, may, though possible, have never happened exactly such as the painter fancies and thinks proper to represent them. Thus, the piety of *Æneas*, and the anger of *Achilles*, are things so perfect in their kind, as to be merely probable. And it is for this reason that poetry, which is only another word for invention, is more philosophical, more instructive, and more entertaining, than history.

Here it is proper to observe, what great advantages the ancient had over the modern painters. The history of the times they lived in, fraught with great and glorious events, was to them a rich mine of the most noble subjects, which, besides, often derived no small sublimity and pathos from the mythology upon which their religion was founded. So far were their gods from being immaterial, and placed at an infinite distance above their worshippers; so far was their religion from recommending humility, penance, and self-denial, that, on the contrary, it appeared calculated merely to flatter the senses, inflame the passions, and poison the fancy. By making the gods partake of our nature, and subjecting them to the same passions, it gave man hopes of being able to mix with those who, though greatly above him, resembled him, notwithstanding, in so many respects. Besides, those deities of theirs were in a manner visible, and to be met at every step. The sea was crowded with Tritons and Nereids, the rivers with Naiads, and the mountains with Dryads. The woods swarmed with Fauns and Nymphs, who, in these obscure retreats, sought an asylum for their stolen embraces. The most potent empires, the most noble families, the most celebrated heroes, all derived their pedigree from the greater divinities. Nay, gods interested themselves in all the concerns of mankind. Apollo, the god of long arrows, flood by the side of *Hector* in the fields of *Troy*, and inspired him with new strength and courage to batter down the walls and burn the ships of the Greeks. These, on the other hand, were led on to the fight and animated by *Minerva*, preceded by Terror, and followed by Death. Jove nods, his divine locks shake on his immortal head; Olympus trembles. With that countenance, which allays the tempest, and restores serenity to the heavens, he gathers kisses from the mouth of *Venus*, the delight of gods and of men. Among the ancients, every thing sported with the fancy; and in those works which depend entirely on the imagination, some of our greatest masters have thought they could not do better than borrow from the Pagans, if we may be allowed to say it, their pictures of *Tartarus*, in order to render their own drawings of hell more striking.

After all, there have not been wanting able inven-

tors in painting among the moderns. Michael Angelo, notwithstanding the depth and boldness of his own fancy, is not ashamed, in some of his compositions, to *Dantize*; as *Phidias* and *Apelles* may be said formerly to have *Homerized*. Raphael, too, tutored by the Greeks, has found means, like *Virgil*, to extract the quintessence of truth; has seasoned his works with grace and nobleness, and exalted nature, in a manner, above herself, by giving her an aspect more beautiful, more animating, and more sublime, than she is, in reality, accustomed to wear. In point of invention, *Domenichino* and *Annibal Carracci* come very near *Raphael*, especially in the pieces painted by them in Rome; nor does *Poussin* fall very short of him in some of his pictures, particularly in his *Ester before Ahasuerus*, and his *Death of Germanicus*, the richest jewel belonging to the *Barberine* family. Of all the painters who have acquired any extraordinary degree of reputation, no one studied less to set off his pieces by bold and beautiful circumstances, or was more a stranger to what is called *poetical perfection*, than *Jacopo Bassano*. Among the numberless instances we could produce of his carelessness this way, let it suffice to mention a *Preaching of St Paul* painted by him in a place, near that of his birth, called *Marostega*. Instead of representing the apostle full of a divine enthusiasm, as *Raphael* has done, and thundering against the superstitions of the heathen in an assembly of Athenians; instead of exhibiting one of his auditors struck to the quick, another persuaded, a third inflamed; he makes him hold forth, in a village of the Venetian state, to a parcel of poor peasants and their wives, who take not the least notice of him; the women especially, who seem to mind nothing but the country labours in which he had found them employed. After all, this is an admirable piece; and would be a perfect one, had the painter not disgraced it so much by the poverty of his ideas.

With regard to invention, painting and poetry resemble each other so much in many other respects, besides that of combining in every action all the beauty and elegance it will admit, that they well deserve the name of *sister arts*. They differ, however, in one point, and that too of no small importance. It is this. The poet, in the representation of his story, relates what has already happened, prepares that which is still to come, and so proceeds, step by step, through all the circumstances of the action; and, to operate the greater effect on his hearers, avails himself of the succession of time and place. The painter, on the contrary, deprived of such helps, must be content to depend upon one single moment. But what a moment! A moment, in which he may conjure up, at once, to the eyes of the spectator, a thousand objects; a moment, teeming with the most beautiful circumstances that can attend the action; a moment, equivalent to the successful labours of the poet. This the works of the greatest masters, which are every where to be seen, sufficiently evince; among others, the *St Paul at Lystra*, by *Raphael*, whom it is impossible not to praise as often as this picture is mentioned. In order to give the spectator a thorough insight into the subject of this piece, the painter has placed, in the front of it, the cripple already restored to his limbs by the Apostle, fired with gratitude towards his benefactor, and exciting his countrymen to yield him all kinds of honour.

Invention.

Invention.

Webb,  
diol. 7.

honour. Round the cripple are some figures lifting up the skirts of his coat, in order to look at the legs reduced to their proper shape, and acknowledging by gestures full of astonishment the reality of the miracle; an invention, says a certain author, a professed admirer of antiquity, which might have been proposed as an example in the happiest age of Greece.

We have another shining instance of the power of painting to introduce a great variety of objects on the scene at the same time, and of the advantage it has in this respect over poetry, in a drawing by the celebrated la Fage, which, like many other pieces of his, has not as yet been engraved, though worthier, perhaps, of that honour than any other performance of the kind. This drawing represents the descent of Æneas into hell. The field is the dark caverns of Pluto's kingdom, through the middle of which creeps slowly the muddy and melancholy Acheron. Nearly in the centre of the piece appears Æneas with the golden bough in his hand, and with an air of astonishment at what he sees. The Sybil, who accompanies him, is answering the questions which he asks her. The personage there is the ferryman of the pitchy lake, by which even the gods themselves are afraid to swear. Those, who, crowding in to the banks of the river, numberless as the leaves shaken off the trees by autumn blasts, express, with outstretched hands, an impatience to be ferried to the opposite shore, are the unhappy manes, who, for want of burial, are unqualified for that happiness. Charon, accordingly, is crying out to them, and with his lifted-up oar driving them from his boat, which has already taken in a number of those who had been honoured with the accustomed funeral rites. Behind Æneas and the Sybil we discover a confused groupe of wretched souls, lamenting bitterly their misfortune in being denied a passage; two of them wrapped up in their clothes; and, in a fit of despair, sunk upon a rock. Upon the first lines of the piece stands a third groupe of uninhumed shades, Leucæpes, Orontes, and, in the midst of them, the good old Palinurus, formerly master and pilot of the hero's own vessel, who with joined hands most earnestly desires to be taken along with him into the boat, that, after death, at least, he may find some repose, and his dead body no longer remain the sport of winds and waves. Thus, what we see scattered up and down in many verses by Virgil, is here, as it were, gathered into a focus, and concentrated by the ingenious pencil of the painter; so as to form a subject well worthy of being exposed, in more shapes than one, to the eyes of the public.

When a painter takes a subject in hand, be it historical, be it fabulous, he should carefully peruse the books which treat of it, imprint well on his mind all the circumstances that attend it, the persons concerned in it, and the passions with which they must have been severally animated; not omitting the particulars of time and place. His next business is to create it, as it were, anew, observing the rules already laid down for that purpose: From what is true, choosing that which is most striking; and clothing his subject with such accessory circumstances and actions, as may render it more conspicuous, pathetic, and noble, and best display the powers of the inventive faculty. But, in doing this, great discretion is requisite; for, let his ima-

gination grow ever so warm, his hand is never to execute any thing that is not fully approved by his judgment. Nothing low or vulgar should appear in a lofty and noble argument; a fault, of which some of the greatest masters, even Lampicri and Poussin, have been now and then guilty.

The action must be one, the place one, the time one. We need not say any thing of those painters, who, like the writers of the Chinese and Spanish theatre, cram a variety of actions together, and so give us, at once, the whole life of a man. Such blunders, it is presumed, are too gross to be feared at present. The politeness and learning of the age seem to demand considerations of a more refined nature; such as, that the episodes introduced in the drama of a picture, the better to fill and adorn it, should be not only beautiful in themselves, but indispensably requisite. The games celebrated at the tomb of Anchises in Sicily, have a greater variety in them, and more sources of delight, than those that had been before celebrated at the tomb of Patroclus under the walls of Troy. The arms forged by Vulcan for Æneas, if not better tempered, are at least better engraved than those which the same god had forged several ages before for Achilles. Nevertheless, in the eyes of judges, both the games and the arms of Homer are more pleasing than those of Virgil, because the former are more necessary in the *Iliad*, than the latter in the *Æneid*. Every part should agree with, and have a relation to, the whole. Unity should reign even in variety; for in this, beauty consists. This is a fundamental maxim in all the arts whose object it is to imitate the works of nature.

Pictures often borrow no small grace and beauty from the fictions of poetry. Albani has left us, in several of his works, sufficient proofs of the great share the belles letters had in refining his taste. But Raphael, above all others, may, in this branch too, be considered as a guide and master. To give but one instance out of many; what a beautiful thought was it to represent the river himself, in a *Passage of Jordan*, supporting his waters with his own hands, in order to open a way to the army of the Israelites! Nor has he displayed less judgment in reviving, in his designs engraved by Agostino of Venice, the little loves of Aëtius, playing with the arms of Alexander, conquered by the beauty of Roxana.

Among the ancients, Apelles and Parrhasius were those who distinguished themselves most in allegorical subjects, in which the inventive faculty shows itself to the greatest advantage; the first by his picture of Calumny †, the second by that of the Genius of the Athenians\*. The ancient painter called *Galaton*, gave likewise a fine proof of his genius in this branch, by in the *Life* representing a great number of poets greedily quenching their thirst in the waters gushing from the mouth of the sublime Homer. And to this allegory, according to Guigni, Pliny ‡ has an eye, when he calls that prince of poets, the *fountain of wits*. But it is, after all, no way surprising that we should often meet such fine flights of fancy in the ancient artists. They were not guided in their works by a blind practice: they were men of polite education; conversant with the letters of the age in which they lived; and the companions, rather than the servants, of the great

Webb,  
diol. 4.

Disposition

men who employed them. The finest allegorical painter among the moderns was Rubens; and he was, accordingly, much celebrated for it. The best critics, however, find fault with his uniting in Luxemburg gallery, the queen-mother, in council, with two cardinals and Mercury. Nor is there less impropriety in his making Tritons and Nereids, in another piece of the same gallery, swim to the queen's vessel through the galleys of the knights of St Stephen. Such freedoms are equally disgusting with the prophecies of Sannazaro's Proteus, concerning the mystery of the incarnation; or the Indian kings of Camens, reasoning with the Portuguese on the adventures of Ulysses.

The best modern performances in picturesque allegory are, certainly, those of Poussin; who availed himself, with great discretion and judgment, of the vast treasures with which, by a close study of the ancients, he had enriched his memory. On the other hand, le Brun, his countryman, has been very unhappy this way. Ambitious to have every thing his own, instead of allegories, he has filled the gallery of Versailles with enigmas and riddles, of which none but himself was qualified to be the Oedipus. Allegory must be ingenious, it is true; but then it must be equally perspicuous; for which reason, a painter should avoid all vague and indeterminate allusions, and likewise those to history and heathen mythology which are too abstruse to be understood by the generally of spectators. The best way, perhaps, to symbolize moral and abstract things, is to represent particular events: as Caracci did, by advice of Monsignore Agucchi, in the Farnesian palace. For example, what can better express a hero's love towards his country, than the virtuous Decius consecrating himself boldly to the infernal gods, in order to secure victory to his countrymen over their enemies? What finer emblems can we desire, of emulation, and an insatiable thirst for glory, than Julius Cæsar weeping before the statue of Alexander in the temple of Hercules at Gades? of the inconstancy of fortune, than Marius sitting on the ruins of Carthage, and receiving, instead of the acclamations of an army joyfully saluting him imperator, orders from a licitor of Sextilius to quit Africa? of indiscretion, than Candaules, who, by shewing the naked beauties of his wife to his friend Gyges, kindled a passion that soon made him repent his folly? Such representations as these require no comment; they carry their explanation along with them. Besides, supposing, and it is the worst we can suppose, that the painter's aim in them should happen not to be understood, his piece would still give delight. It is thus that the fables of Ariosto prove so entertaining, even to those who understand nothing of the moral couched under them; and likewise the *Æneis*, though all do not comprehend the allusions and double intent of the poet.

#### SECT. XI. Of Disposition.

14. So much for invention. *Disposition*, which may be considered as a branch of invention, consists in the proper stationing of what the inventive faculty has imagined, so as to express the subject in the most lively manner. The chief merit of disposition may be said to consist in that disorder, which, wearing the appearance of mere chance, is, in fact, the most studied

effect of art. A painter, therefore, is equally to avoid the dryness of those ancients who always planted their figures like so many couples in a procession, and the affectation of those moderns who jumble them together as if they were met merely to fight and squabble. In this branch Raphael was happy enough to choose the just medium, and attain perfection. The disposition of his figures is always exactly such as the subject requires. In the *Battle of Constantine*, they are confusedly clustered with as much art, as they are regularly marshalled in *Christ's commitment of the keys to St Peter* and constituting him prince of the apostles.

Let the inferior figures of a piece be placed as they will, the principal figure should strike the eye most, and stand out, as it were, from among the rest. This may be effected various ways, as by placing it on the foremost lines, or in some other conspicuous part of the piece; by exhibiting it, in a manner, by itself; by making the principal light fall upon it; by giving it the most resplendent drapery; or, indeed, by several of these methods, nay, by all of them together. For, being the hero of the picturesque fable, it is but just that it should draw the eye to itself, and lord it, as it were, over all the other objects.

According to Leon Battista Alberti, painters should follow the example of comic writers, who compose their fable of as few persons as possible. For, in fact, a crowded picture is apt to give as much pain to the spectator, as a crowded road to the traveller.

Some subjects, it must be granted, require a number, nay, a nation, as it were, of figures. On these occasions, it depends entirely on the skill of the painter to dispose of them in such a manner, that the principal ones may always make the principal appearance; and contrive matters so, that the piece be not overcrowded, or want convenient rests and pauses. He must, in a word, take care that his piece be full, but not charged. In this respect, the *Battle of Alexander* by Le Brun are master-pieces which can never be sufficiently studied; whereas nothing, on the other hand, can be more unhappy than the famous *Paradise* of Tintoret, which covers one entire side of the great council-chamber at Venice. It appears no better than a confused heap of figures, a swarm, a cloud, a chaos, which pains and fatigues the eye. What a pity it is that he did not dispose this subject after a model of his own, now in the gallery of Bevilacqua at Verona! In this last, the several choirs of martyrs, virgins, bishops, and other saints, are judiciously thrown into so many clusters, parted here and there by a fine fleecy of clouds; so as to exhibit the innumerable host of heaven drawn up in a way that makes a most agreeable and glorious appearance. There goes a story, to our purpose, of a celebrated master, who in a drawing of the Universal Deluge, the better to express the immensity of the waters that covered the earth, left a corner of his paper without figures. Being asked, if he did not intend to fill it up: No, said he; do not you see that my leaving it empty is what precisely constitutes the picture?

The reason for breaking a composition into several groups is, that the eye, passing freely from one object to another, may the better comprehend the whole. But the painter is not to stop here; for these groups

are,

Polym.  
dial. 18.See Bellori's  
Life of Caracci.

Disposition

Disposition.

are, besides, to be so artfully put together, as to form rich clusters, give the whole composition a singular air of grandeur, and afford the spectator an opportunity of discerning the piece at a distance, and taking the whole in, as it were, at a single glance. These effects are greatly promoted by a due regard to the nature of colours, so as not to place together those which are apt to pain by their opposition, or distract by their variety. They should be so judiciously disposed as to temper and qualify each other.

A proper use of the *chiaroscuro* is likewise of great service on this occasion. The groups are easily parted, and the whole picture acquires a grand effect, by introducing some strong falls of shade, and, above all, one principal beam of light. This method has been followed with great success by Rembrandt in a famous picture of his, representing the Virgin at the foot of the cross on mount Calvary; the principal light darting upon her through a break of the clouds, while the rest of the figures about her stand more or less in the shade. Tintoret, too, acquired great reputation, as well by that brilliancy with which he enlivened his figures, as by his masterly manner of shading them; and Polidoro de Caravaggio, though he scarce painted any thing but basso-reliefs, was particularly famous for introducing with great skill the effects of the *chiaroscuro*, a thing first attempted by Mantegna in his *Triumph of Julius Caesar*. It is by this means that his compositions appear so strikingly divided into different groups, and, among their other perfections, afford so much delight thro' the beautiful disposition that reigns in them.

In like manner, a painter, by the help of perspective, especially that called *aerial*, the opposition of local colours, and other contrivances which he may expect to hit upon by studying nature, and those who have best studied her before him, will be able not only to part his groups, but make them appear at different distances, so as to leave sufficient passages between them.

But the greatest caution is to be used in the pursuit of the methods here laid down; especially in the management of the *chiaroscuro*, that the effects attributed to light and shade, and to their various concomitants, may not run counter to truth and experience. This a capital point. For this purpose, a painter would do well to make, in little figures, as Tintoret and Poussin used to do, a model of the subject that he intends to represent, and then illuminate it by lamp or candle light. By this means he may come to know with certainty, if the *chiaroscuro*, which he has formed in his mind, does not clash with the reason of things. By varying the height and direction of his light, he may easily discover such accidental effects as are most likely to recommend his performance, and so establish a proper system for the illuminating it. Nor will he afterwards find it a difficult matter to modify the quality of his shades, by softening or strengthening them, according to the situation of his scene, and the quality of the light falling upon it. If it should happen to be a candle or lamp light scene, he would then have nothing to do but consider his model well, and faithfully copy it.

In the next place, to turn a groupe elegantly, the best pattern is that of a bunch of grapes adopted by Titian. As, of the many grains that compose a bunch

of grapes, some are struck directly by the light, and those opposite to them are in the shade, whilst the intermediate ones partake of both light and shade in a greater or less degree; so, according to Titian, the figures of a groupe should be so disposed, that, by the union of the *chiaroscuro*, several things may appear as it were but one thing. And in fact it is only from his having pursued this method, that we can account for the very grand effect of his pieces this way, in which it is impossible to study him too much.

The mannerists, who do not follow nature in the track of the masters just mentioned, are apt to commit many faults. The reason of their figures casting their shades in this or that manner seldom appears in the picture, or at least does not appear sufficiently probable. They are, besides, wont to trespass all bounds in splashing their pieces with light, that is, in enlivening those parts which we usually term the deads of a picture. This method, no doubt, has sometimes a very fine effect; but it is, however, to be used with no small discretion, as otherwise the whole loses that union, that pause, that majestic silence, as Caracci used to call it, which affords so much pleasure. The eye is not less hurt by many lights scattered here and there over a picture, than the ear is by the confused noise of different persons speaking all together in an assembly.

Guido Reni, who has imparted to his paintings that gaiety and splendour in which he lived, seems enamoured with a bright and open light; whereas Michael Angelo da Caravaggio, who was of a fullen and savage disposition, appears fondest of a gloomy and clouded sky; so that neither of them were qualified to handle indifferently all subjects. The *chiaroscuro* may likewise prove of great service to a painter in giving his composition a grand effect; but, nevertheless, the light he chooses must be adapted to the situation of the scene where the action is laid: nor would he be less faulty, who in a grotto or cavern, where the light entered by a chink, should make his shades soft and tender, than him who should represent them strong and bold in an open sky-light.

But this is not, by many, the only fault which mannerists are apt to be guilty of in historical pieces, and particularly in the disposition of their figures. To say nothing of their favourite groupe of a woman lying on the ground with one child at her breast, and another playing about her, and the like, which they generally place on the first lines of their pieces; nor of those half-figures in the back ground peeping out from the hollows contrived for them: they make a common practice of mixing naked with clothed figures; old men with young; placing one figure with its face towards you, and another with its back; they contrast violent motions with languid attitudes, and seem to aim at opposition in every thing; whereas oppositions never please, but when they arise naturally from the subject, like antitheses in a discourse.

As to foreshortened figures, too much affectation in using or avoiding them is equally blameable. The attitudes had better be composed than otherwise. It very seldom happens that there is any occasion for making them so impetuous as to be in danger of losing their equilibrium; a thing too much practised by some painters.

Hogarth's  
Anal. of  
Beauty.

In regard to drapery, equal care should be taken to avoid that poverty, which makes some matters look as if, through mere penury, they grudging clothes to their figures; and that profusion which Albani imputed to Guido, saying, that he was rather a tailor than a painter. The ornaments of dress should be used with great sobriety; and it will not be amiss to remember what was once said to an ancient painter: "I pity you greatly; unable to make Helen handsome, you have taken care to make her fine."

Let the whole, in a word, and all the different parts of the disposition, possess probability, grace, costume, and the particular character of what is to be represented. Let nothing look like uniformity of manner; which does not appear less in the composition than it does in colouring, drapery, and design; and is, as it were, that kind of accent, by which painters may be as readily distinguished as foreigners are, by pronouncing in the same manner all the different languages they happen to be acquainted with.

#### SECT. XII. *Of the Expression of the Passions.*

15. That language which above all others a painter should carefully endeavour to learn, and from nature herself, is the language of the passions. Without it the finest works must appear lifeless and inanimate. It is not enough for a painter to be able to delineate the most exquisite forms, give them the most graceful attitudes, and compose them well together; it is not enough to dress them out with propriety, and in the most beautiful colours; it is not enough, in fine, by the powerful magic of light and shade to make the canvass vanish. No; he must likewise know how to clothe his figures with grief, with joy, with fear, with anger; he must, in some sort, write on their faces what they think and what they feel; he must give them life and speech. It is indeed in this branch that painting truly soars, and in a manner rises superior to itself; it is in this branch she makes the spectator apprehend much more than what she expresses,

The means employed in her imitations by painting, are the circumscription of terms, the *chiaroscuro*, and colours; all which appear solely calculated to strike the visual faculty. Notwithstanding which, she contrives to represent hard and soft, rough and smooth surfaces, which are objects of the touch; and this by means of certain tints, and a certain *chiaroscuro*, which has a different look in marble, in the bark of trees, in downy and delicate substances. Nay, she contrives to express sound and motion, by means of light and shade, and certain particular configurations. In some landscapes of Diderich, we almost hear the water murmur, and see it tremble along the sides of the river, and of the boats upon it. In the *Battle of Burgogne* we are really apt to fancy that the trumpet sounds; and we see the horse, who has thrown his rider, scamper along the plain. But what is still more wonderful, painting, in virtue of her various colours and certain particular gestures, expresses even the sentiments and most hidden affections of the soul, and renders her visible, so as to make the eye not only touch and hear, but even kindle into passion, and reason.

Many have written, and amongst the rest the famous le Brun, on the various changes, that, according to the various passions, happen in the muscles of the

face, which is, as it were, the dumb tongue of the soul. They observe, for example, that in fits of anger, the face reddens, the muscles of the lips puff out, the eyes sparkle; and that, on the contrary, in fits of melancholy, the eyes grow motionless and dead, the face pale, and the lips sink in. It may be of service to a painter to read these and such other remarks; but it will be of infinitely more service to study them in nature itself, from which they have been borrowed, and which exhibits them in that lively manner which neither tongue nor pen can express.

But if a painter is to have immediate recourse to nature in any thing, it is particularly in treating those very minute and almost imperceptible differences, by which, however, things very different from each other are often expressed. This is particularly the case with regard to the passions of laughing and crying; as in these, however contrary, the muscles of the face operate nearly in the same manner. As the famous Pietro de Cortona was one day finishing the face of a crying child in a representation of the Iron Age, with which he was adorning the floor, called the *Hot bath*, in the royal palace of Pitti, Ferdinand II. who happened to be looking over him for his amusement, could not forbear expressing his approbation, by crying out, "Oh how well that child cries!" To whom the artist,—"Has your majesty a mind to see how easy it is to make children laugh? Behold, I'll prove it in an instant!" And taking up his pencil, by giving the contour of the mouth a concave turn downwards, instead of the convex upwards which it before had, and with little or no alteration in any other part of the face, he made the child, who a little before seemed ready to burst its heart with crying, appear in equal danger of bursting its sides with immoderate laughter; and then, by restoring the altered features to their former position, he soon set the child a-crying again. [*Lectures of Philip Baldinucci, in the academy of la Crusca. Lystrato, &c.*]

According to Leonardo da Vinci, the best masters that a painter can have recourse to in this branch, are those dumb men, who have found out the method of expressing their sentiments by the motion of their hands, eyes, eyebrows, and in short every other part of the body. This advice, no doubt, is very good; but then such gestures must be imitated with great sobriety and moderation; lest they should appear too strong and exaggerated, and the piece should show nothing but pantomimes, when speaking figures alone are to be exhibited; and so become theatrical and second-hand, or, at best, look like the copy of a theatrical and second-hand nature.

We are told strange things of the ancient painters of Greece in regard to expression: especially of Aristides; who, in a picture of his, representing a woman wounded to death at a siege, with a child crawling to her breast, makes her appear afraid, lest the child, when she was dead, should, for want of milk, suck her blood. *A Medea murdering her children*, by Timomachus, was likewise much cried up, as the ingenious artist contrived to express, at once, in her countenance, both the fury that hurried her on to the commission of so great a crime, and the tenderness of a mother that seemed to withhold her from it. Rubens attempted to express such a double effect in the face of Mary of Me-

dicis, still in pain from her past labour, and at the same time full of joy at the birth of a Dauphin. And in the countenance of Sancta Polonia, painted by Tiepolo for St Anthony's church at Padua, one may clearly read a mixture of pain from the wound given her by the executioner, and of pleasure from the prospect of paradise opened to her by it.

Few, to say the truth, are the examples of strong expression afforded by the Venetian, Flemish, or Lombard schools. Deprived of that great happiness, the happiness of being able to contemplate, at leisure, the works of the ancients, the purest sources of perfection in point of design, expression, and character; and having nothing but nature constantly before their eyes; they made strength of colouring, blooming complexions, and the grand effects of the chiaroscuro, their principal study: they aimed more at charming the senses than at captivating the understanding. The Venetians, in particular, seem to have placed their whole glory in setting off their pieces with all that rich variety of personages and dress, which their capital is continually receiving by means of its extensive commerce, and which attracts so much the eyes of all those who visit it. It is much to be doubted, if, in all the pictures of Paolo Veronese, there is to be found a bold and judicious expression, or one of those attitudes which, as Petrarch expresses it, speak without words; unless, perhaps, it be that remarkable one in his

*Marriage Feast of Cana of Galilee*. At one end of the table, and directly opposite to the bridegroom, whose eyes are fixed upon her, there appears a woman in red, holding up to him the skirt of her garment; as much as to say, we may suppose, that the wine miraculously produced was exactly of the colour with the stuff on her back. And in fact it is red wine we see in the cups and pitchers. But all this while the faces and attitudes of most of the company betray not the least sign of wonder at so extraordinary a miracle. They all, in a manner, appear intent upon nothing but eating, drinking, and making merry. Such, in general, is the style of the Venetian school. The Florentine, over which Michael Angelo presided, above all things curious of design, was most minutely and scrupulously exact in point of anatomy. On this he set her heart, and took singular pleasure in displaying it. Not only elegance of form, and nobleness of invention, but likewise strength of expression, triumph in the Roman school, nursed as it were amongst the works of the Greeks, and in the bosom of a city which had once been the seminary of learning and politeness. Here it was that Domenichino and Poussin, both great masters of expression, refined themselves, as appears more particularly by the *St Jerome* of the one, and the *Death of Germanicus*, or the *Slaughter of the Innocents*, by the other. Here it was that arose Raphael, the sovereign master of them all. One would imagine, that pictures, which are generally considered as the books of the ignorant, and of the ignorant only, he had undertaken to make the instructors even of the learned. One would imagine, that he intended, in some measure, to justify Quintilian\*, who affirms, that painting has more power over us than all the arts of rhetoric. There is not, indeed, a single picture of Raphael's, from the study of which those who are curious in point of expression may not reap great benefit; particularly his *Martyrdom of St*

*Felicitas*, his *Transfigurations*, his *Joseph explaining to Pharaoh his dream*, a piece so highly rated by Poussin. His *School of Athens*, in the Vatican, is, to all intents and purposes, a school of expression. Among the many miracles of art with which this piece abounds, we shall single out that of the four boys attending on a mathematician, who, stooping to the ground, his compasses in his hand, is giving them the demonstration of a theorem. One of the boys, recollecting within himself, keeps back, with all the appearance of profound attention to the reasoning of the master; another, by the briskness of his attitude, discovers a greater quickness of apprehension; while the third, who has already seized the conclusion, is endeavouring to beat it into the fourth, who, standing motionless, with open arms, a staring countenance, and an unspeakable air of stupidity in his looks, will never perhaps be able to make any thing of the matter. And it is probably from this very group that Albani, who studied Raphael so closely, drew the following precept of his: "That it behoves a painter to express more circumstances than one by every attitude; and so to employ his figures, that, by barely seeing what they are actually about, one may be able to guess, both what they have been already doing, and are next going to do." This is indeed a difficult precept; but it is only by a due observance of it that the eye and the mind can be made to hang in suspense on a painted piece of canvas. It is expression that a painter, ambitious to soar in his profession, must, above all things, labour to perfect himself in. It is the last goal of his art, as Xenoph. Memorab. l. iii. Socrates proves to Parrhasius. It is in expression that dumb poetry consists, and what the prince of our poets calls a visible language.

#### SECT. XI. Of proper Books for a Painter.

FROM what has been already said, it may be easily gathered, that a painter should be neither illiterate, nor unprovided with books. Many are apt to imagine, that the *Iconologia* of Ripa, or some such collection, is alone sufficient for this purpose; and that all the apparatus he stands in need of, may be reduced to a few casts of the remains of antiquity, or rather to what remnants used to call his *antiques*, being nothing more than coats of mail, turbans, sherds of stuff, and all manner of old household trumpery and wearing apparel. Such things, no doubt, are necessary to a painter, and, perhaps, enough for one who wants only to paint half-lengths, or is willing to confine himself to a few low subjects. But they are by no means sufficient for him who would soar higher; for a painter who would attempt the Universe, and represent it in all its parts, such as it would appear, had not matter proved refractory to the intentions of the sovereign Artist. Such a painter alone is a true, an universal, a perfect painter.—No mortal, indeed, must ever expect to rise to that sublimity; yet all should aspire to it, on pain of ever continuing at a very mortifying distance from it: as the orator, who wishes to make a figure in his profession, should propose to himself no less a pattern than that perfect orator described by Tully; nor the courtier, than that perfect courier delineated by Castiglione. It cannot, therefore, appear surprising if we insist on the propriety of reckoning a good collection

\* Instit.  
lib. xi.  
cap. 3.

selection of books as part of such a painter's implements. The Bible, the Greek and Roman historians, the works of Homer, that prince of painters, and of Virgil, are the most classical. To these let him add the *Metamorphoses* of Ovid, some of our best poets, the voyage of Paulanias, Vinci, Vasari, and others upon painting.

It will also be of considerable advantage to him to have a well-chosen collection of drawings by the best masters, in order to trace the progress and history of his art, and make himself acquainted with the various styles of painting, which have been, and now are, in the greatest vogue. The prince of the Roman school was not ashamed to hang up in his study the drawings of Albert Durer; and spared no pains or expence to acquire all the drawings he could meet with, that were taken from basso relievos; things, which the art of engraving has since rendered so common as to be in every one's hands. This art of multiplying drawings by means of the graver is of the same date, and boasts the same advantages, with the art of printing, by means of which the works of the mind are multiplied, as it were, at one stroke, and dispersed over the whole world.

The sight of fine subjects treated by able masters, and the different forms which the same subjects assume in different hands, cannot fail both of enlightening and enlaming the mind of the young painter. The same may be said of the perusal of good poets and historians, with the particulars and proofs of what they advance; not to mention those ideas and flights of invention, with which the former are wont to clothe, beautify, and exalt every thing they take in hand. Bouchardon, after reading Homer, conceived, to use his own words, that men were three times taller than before, and that the world was enlarged in every respect. It is very probable, that the beautiful thought of covering Agamemnon's face with the skirt of his mantle, at the sacrifice of Iphigenia, was suggested to Timantes by the tragedy of Euripides. And the sublime conceit of Raphael, who, in a *Creation* of his, represents God in the immense space, with one hand reaching to the sun and the other to the moon, may be considered as the child of the following words of the Psalmist: *The heavens declare the glory of God, and the firmament sheweth his handy-work.*

This thought of Raphael has been, indeed, censured by Mr Webb. "A God," says this gentleman, "extending one hand to the sun, and another to the moon, destroys that idea of immensity, which should accompany the work of creation, by reducing it to a world of a few inches." But the opinion of Count Algarotti is very different. "For my part," says that elegant critic, "I cannot discover, in this painting, a world of a few inches, but a world on a much greater scale; a world of millions and millions of miles: and yet this so immense a world, by means of that act of the Godhead, in which with one hand he reaches to the sun, and with the other to the moon, shrinks, in my imagination, to a mere nothing, in respect to the immensity of God himself; which is all that the powers of painting can pretend to. This invention is, though in a contrary sense, of the same kind with that of Timantes, who, to express the enormous size of a sleeping Polyphemus, placed round him some satires measuring the monster's thumb

with a thyrus. Hence Pliny, who relates the fact, takes occasion to tell us, that his works always imply more than they express; and that how great soever he may be in execution, he is still greater in invention: *Atque in omnibus ejus operibus intelligitur plus semper quam pingitur; et cum ars summa sit, ingenium tamen ultra artem est.*" Nat. Hist. lib. xxxv. c. x.

The perusal of good authors cannot but be very serviceable to a painter in another respect; as, among the great number of subjects afforded by history and poetry, he may expect to meet with many on which his talents may display themselves to the greatest advantage. A painter can never be too nice in the choice of his arguments; for on the beauty of them, that of his piece will greatly depend. How much to be pitied, therefore, were our first masters, in being so often obliged to receive their subjects from the hands of simple and illiterate persons! and what is worse, to spend all the riches of their art upon barren or unworthy subjects! Such are the representations of those saints, who, though they never had the least intercourse with each other, and perhaps even lived in different ages, are, notwithstanding, to be introduced, *tete a tete*, as it were, in the same picture. The mechanic of the art, may, indeed, display itself on these occasions; but by no means the ideal. The disposition may be good and praise-worthy, as in the works of Cortona and Lauffranc; but we are not to expect in them either invention or expression, which require for their basis the representation of some fact capable of producing such effects. Who does not, on the bare mention of this abuse, immediately recollect many sad instances of it? such as the famous St Cæcilia of Raphael, surrounded by St Paul, St Mary Magdalen, St John, and St Augustin; and the picture of Paolo Veronese, in the vestry of the Nuns of St Zachary at Venice, in which St Frances of Assisium, Saint Catharine, and St Jerome richly habited in his cardinal's robes, form a ring round the Virgin seated on a throne with the child Jesus in her arms; perhaps the most beautiful and picturesque of all the insipid and insignificant pieces with which Italy abounds. It is very shocking to think, that young painters should be obliged to study their art from such wretched compositions.

The subjects in which the pencil triumphs most, and with which a judicious painter may stock himself by the perusal of good books, are, no doubt, those which are most universally known, which afford the largest field for a display of the passions, and contain the greatest variety of incidents, all concurring, in the same point of time, to form one principal action. Of this the story of Coriolanus besieging Rome, as related by Livy, is a shining example. Nothing can be imagined more beautiful than the scene of action itself, which ought to take in the pretorium in the camp of the Volscians, the Tiber behind it, and the seven hills, among which the towering Capitol is, as it were, to lord it over the rest. It is impossible to conceive a greater variety, than what must appear in that crowd of soldiers, women, and children, all which are to enter the composition; unless, perhaps, it be that of the different passions with which they are severally agitated; some wishing that Coriolanus may raise the siege, others fearing it, others again suspecting it. But the

Painter's  
Balance.Painter's  
Balance.Liv. Dec. l.  
lib. 2.

the principal groupe forms the picturesque part of the piece. Coriolanus, hastily descending from his tribunal, and hurried on by love, to embrace his mother, stops short through shame, on her crying out to him, Hold! let me first know, if it is a son, or an enemy, I am going to embrace? Thus a painter may impart novelty to the most hackneyed subject by taking, for his guides those authors who possess the happy talent of adding grace and dignity, by their beautiful and sublime descriptions, even to the most common and trifling transactions.

SECT. XV. *Of the Painter's Balance.*

18. THE celebrated de Piles, who by his writings, has thrown so much light upon painting, in order to assist young painters in forming a right judgment of those masters who hold the first rank in the profession, and to reduce such judgment to the greater precision, bethought himself of a pictorial balance, by means of which a painter's merit may be weighed with the greatest exactness. This merit he divides into Composition, Design, Colouring, and Expression; and in each of these branches he has assigned every painter that share he thought him entitled to, according as he approached more or less the highest degree of excellence and summit of perfection; so that, by summing up the numbers which, standing against each master's name, express his share of merit in each of these branches, we have his total merit or value in the art, and may hence gather what rank one painter holds in regard to another. Several objections, it is true, have been started to this method of calculation, by a famous mathematician of our days, who, among other things, insists, that it is the product of the above numbers multiplied by each other, and not the sum of them, that gives the merit of the artist. But this is not a place to enter into such niceties, nor indeed would the doing it be of any service to the art. The only thing worth our notice is, whether the original numbers, standing for the painter's merit in the several branches of his art, are such as he is really intitled to, without suffering ourselves to be biased by any partiality, as de Piles has been, in favour of the prince of the Flemish school; the consequence of which, strange as it may appear, is, that in his balance Raphael and Rubens turn out exactly of the same weight.

Raphael is now universally allowed to have attained that degree of perfection, beyond which it is scarce lawful for mortals to aspire. Painting, in some measure, revived among us by the diligence of Cimabue, towards the decline of the 13th century, received no small improvements from the genius of Giotto, Masaccio, and others; inasmuch that, in less than 200 years, it began to blaze forth with great lustre in the works of Ghirlandai, Gian Bellino, Mantegna, Pietro Perugino, and Leonardo da Vinci, the best grounded of them all, a man of great learning, and the first who contrived to give relief to pictures. But whatever improvement the art might have received from these different masters in different parts of Italy, they still, to a man almost, servilely followed the same manner, and all partook more or less of that hardness and dryness, which, in an age still Gothic, painting received from the hands of its restorer Cimabue; till Raphael, at length, issuing from the Perugian school, and, study-

ing the works of the Greeks, without ever losing sight of nature, brought the art, in a manner, to the highest pitch of perfection. This great man has, if not entirely, at least in a great measure, attained those ends which a painter should always propose to himself, to deceive the eye, satisfy the understanding, and touch the heart. So excellent are his pieces, that the spectator, far from praising his pencil, seems sometimes entirely to forget that they are the feats of it which he has before him; solely intent upon, and as it were transported to, the scene of action, in which he almost fancies himself a party. Well, indeed, has he deserved the title of *divine*, by the beauty and comprehensiveness of his expression, the justness and nobleness of his compositions, the chastity of his designs, and the elegance of his forms, which always carry a natural ingenuity along with them; but above all, by that inexpressible gracefulness, more beautiful than beauty itself, with which he has contrived to season all his pieces. Carlo Maratti having engraved a piece, called the *School*, placed at the top of it the three Graces, with this verse under them,

*Seneca di noi ogni fatica è vana;*

"Without our aid, all labour is in vain."

Without their aid, in fact, the light of a picture is no better than darkness, every attitude is insipid, every motion awkward. It is they who impart to every thing that *Je ne sçai quoi*, that charm, which is as sure to conquer, as impossible to be defined. Maratti has placed the Graces on high, and, as it were, descending from heaven, in order to shew that they really are a celestial gift. Happy the artist on whose cradle they have smiled, whose vows and offerings they have not disdain'd! Maratti was not to be informed, that gracefulness, that jewel which adds such value to every thing, tho' not originally obtainable by all the gold of diligence and study, may yet be greatly heightened and polished by them.

Though Raphael might boast, like Apelles \* of old, \* *Quintil.* whom he resembled in so many other respects, that in *Justit. l. xii.* gracefulness he had no equal; yet Parmigiano and Correggio must be allowed to have come very near him. One of them has, however, often trespassed the just bounds of symmetry; and the other is not always chaste in his designs: both, besides, were too apt to be guilty of affectation. We ought perhaps to forgive Correggio every thing, for the sake of that uncommon greatness of manner, that life and soul, which he has infused into all his figures; for the sake of that inimitable ease and delicacy of pencil, which makes his pieces appear as if finished in a day, and seen in a glass. Of this we have a sufficient proof in the *Ancona* of St Jerome and the Magdalen on their knees before the child Jesus, which is in Parma; the finest picture, perhaps, that ever issued from mortal hands.

There are some glimpses of Correggio's style in the works of Barocci, though he studied at Rome. He never drew a figure that he did not borrow from nature; and, for fear of losing the masses, used to drape his models with very large folds. His pencil was exceedingly sweet, and his colouring equally harmonious. He indeed spoiled a little the natural tints by too free an use of reds and blues; and has now and then robbed things of their body, by shading them too much, and melting them, as it were, into one another.

Algarotti.

ther. In point of design, he was far more diligent than successful; and, in the air of his heads, affected the gracefulness of the Lombard school, rather than the elegance of the Greeks and his countryman Raphael.

Julio Romano, full of spirit, and of learning and uncommon conceits, seems to come nearer the manner of Michael Angelo than the elegantly natural one of Raphael, under whom he studied.

The Germans, by feverily following Michael Angelo, gave into those strange attitudes and clumsy forms which appear in the works of their greatest men, Spranger and Goltzius.

The Florentines copied him with greater judgment and discretion. We must, however, except Andrea del Sarto, who, though an observer of truth, is somewhat clumsy in his figures. But then he is easy in his draperies; sweet in his colours; and would have carried the palm among the Tuscans, had it not been ravished from him by Fra. Bartolomeo; to immortalise whom, his *St Mark* in the palace of Pitti would alone be sufficient; for there is not wanting in that piece any of the perfections necessary to constitute an excellent master.

Titian, whom Giorgione first imitated in the art, is an universal master. Upon every thing he took in hand, he has contrived to stamp its own proper nature. His pencil flows with juices that are truly vital. His figures breathe; and the blood circulates in their faces. And though some perhaps have surpassed him in design; not but that he is generally correct enough in the bodies of his women; and his children, on account of their form, have been studied by the greatest masters; he never had his equal in colouring, or in portrait and landscape painting. He most indefatigably studied truth, and never lost sight of her. He most indefatigably laboured to convert, if we may be allowed the expression, the colours of his pallet into flesh and blood. But what cost him most was, as he himself confesses, to cover and hide his fatigue: and in this he has succeeded so well, that his works seem rather born than made. His fortune equalled his merit. He was greatly honoured by Charles V. as the great Raphael had been, a few years before, by the Popes Julius II. and Leo X.

Jacopo Bassano distinguished himself, at the same time, by the strength of his colouring. Few have equalled him in the just dispensation of light reflected from one object to another, and in those happy contrasts by means of which painted objects become really transparent. He may boast his having deceived an Annibal Caracci, as Phariasio formerly deceived Zeuxes; and had the glory of Paolo Veronese's not being willing that his son Carletto should learn the principles of colouring from any other master.

Paolo Veronese was the creator, as it were, of a new manner. Though careless in point of design, and in point of costume extremely licentious, he was noble of fancy, and most fruitful of invention. One would imagine, that those who behold his magnificent pictures longed to be of the action represented by them; and it may be said of him with great justice, that even his faults are pleasing. He has had very great admirers in every age; and among them a Guido Reni, whose praise, no doubt, would have flattered him most.

Tintoret is no way inferior to any of the Venetians in those pieces which he drew by way of displaying his talents, and not improving them. This he has particularly shown in his *Martyrdom*, now in the school of St Mark; in which there is design, colouring, composition, effects of light, life, expression, and all carried to the highest pitch of perfection. Scarce had this picture made its appearance, when all mankind seemed to fall in love with it. Aretine himself, tho' so warm a friend to Titian, that, through mere jealousy he turned Tintoret out of his school, could not forbear crying it up to excess. He wrote himself to Tintoret, that this piece had extorted the applause of all those who saw it. The scene, adds he, appears rather true than feigned; and happy would you be, if, instead of being so expeditious, you could prevail on yourself to be a little more patient.

Next to these great artists, who had no guide but nature, or the most perfect copies of nature, the Greek statues, started up those other artists, whom we are not to consider as the disciples of nature, so much as of those masters who a little before had revived the art of painting, and restored it to its ancient honour and dignity. Such were the Caraccis, who undertook to unite in their manner the beauties of all the most famous Italian schools, and founded a new one, which did not yield to the Roman in elegance of forms, to the Florentine in correctness of design, nor to the Venetian or Lombard in beauty of colouring. These schools, if we may be allowed the expression, are the primitive metals of painting; and the Caraccis, by melting them down together, composed a Corinthian metal, noble indeed and beautiful to look at, but wanting the strength, ductility, and weight, possessed singly by the different metals which compose it. And indeed the greatest praise that can be bestowed on the works of the Caraccis, is not owing to any air of originality in them, or any perfect imitation of nature, but to the striking likeness in them to the manner of Titian, Raphael, Parmigianino and Correggio. As to the rest, the Caraccis did not neglect to provide their school with all those helps which learning could afford; from a conviction that the arts never succeed through mere good fortune or boldness of fancy, but are rather so many habits working according to the dictates of learning and right reason. In their school, the pupils were taught perspective, anatomy, in a word every thing necessary to lead them by the shortest and safest road. And it is to this that we are chiefly to attribute the school of Bologna's having produced a greater number of able masters than any other.

At the head of these masters stand Domenichino and Guido; one a most curious observer of nature, and most profound painter; the other the inventor of a certain noble and beautiful manner peculiar to himself, which shines especially in that sweetness and beauty he has contrived to give the faces of his women. Both these artists have been preferred to the Caraccis; and it must be owned, that the last did really excel them.

Francesco Barbieri, called *il Guercino*, studied first in this school; but he afterwards formed to himself a certain peculiar manner, entirely founded upon nature and truth. Quite careless in the choice of his forms, he produced a chiaroscuro that gives the greatest relief to objects, and renders them palpable. Caravaggio, the

Painter's  
Balance.

the Rembrants of Italy, was the real author of this manner; which, in these our days, has been again brought to light by Piazzetta and Crespi. He abused the saying of that Greek, who being asked, who was his master, pointed to the poplance; and such, indeed, was the magic of his chiaroscuro, that, as often as he undertook to copy nature in low and trivial subjects, he had the power of deceiving even a Domenichino and a Guido. The style of Caravaggio was followed by two famous Spaniards; Velezquez, the founder of a school among his countrymen; and il Ribera, who settled in Italy, and from whom afterwards the whimsical Salvator Rosa, and that most fertile genius Lucas Giordano, the Proteus and thunderbolt of painting, studied the first principles of the art.

Between the masters of the Bolognian and those of the other schools of Italy, we are to place Rubens, the prince of the Flemish school, and a man of the most elevated genius, who appeared, at once, as painter and ambassador in a country, which, in a few years after, saw one of its greatest poets secretary of state. Nature endowed him with great vivacity, and great ease is working; and he added learning to these natural gifts. He, too, studied our masters, Titian, Tintoret, Caravaggio and Paul; and borrowed a little from every one of them, so sparingly, however, that his own peculiar manner predominates. He was in his movements more moderate than Tintoret, more soft in his chiaroscuro than Caravaggio; but not so rich in his compositions, or light in his touches, as Paolo; and, in his carnations, always less true than Titian, and less delicate than his own scholar Vandyke. He contrived to give his colours the greatest transparency, and no less harmony, notwithstanding the extraordinary deepness of them; and he had a strength and grandeur of style entirely his own. He would have soared still higher, had nature afforded him finer objects in Flanders, or had he known how to create them anew, or correct them after the patterns left us by the Greek masters.

Poussin, the prince of French painters, had a particular fondness for the works of Rubens, at the same time that he fought for the art of design among the ancient marbles, in which, as an ingenious author expresses it, he fits as Queen to give law to the moderns. He spared no pains in the choice and composition of his subjects; and gave them life, learning, and dignity. He would have equalled Raphael himself, whose style he imitated; were gracefulness, ease, and vivacity, to be acquired by study. For, in fact, it was by mere dint of labour and fatigue, that he produced what in a manner cost Raphael nothing; inasmuch, that his figures may be said to mimic the natural actions of that great master.

## PART II. Of the Different CLASSES of PAINTING.

### SECT. I. General Enumeration.

21. **A**ll the objects in nature are susceptible of imitation by the pencil, the masters of this art have applied themselves to different subjects, each one as his talents, his taste, or inclination, may have led him. From whence have arisen the following classes.

### SECT. XVI. Of Imitation.

19. A painter ought attentively to consider, compare together, and weigh in the balance of reason and truth, all these different styles. But he ought likewise carefully to guard against too great a fondness for any one of them in particular that he may think proper to adopt; otherwise, to use the Danteque expression of a first-rate master †, instead of the child, he would become the grand-child, of nature.

Besides, his imitation must be of generals and not of particulars. Whatever a young painter's natural disposition may be, whether to paint boldly and freely like Tintoret and Rubens, or to labour his works like Titian or da Vinci, let him follow it. This kind of imitation is very commendable. It is thus that Dante, at the same time that he carefully avoided adopting the particular expressions of Virgil, endeavoured to seize his bold and free manner, and at last caught from him that elegance of style which has done him so much honour.

20. As to the rest, nothing should hinder an able master from making use now and then of any antique, or even modern figure, which he may find his account in employing. Sanzio, in a *St Paul at Lystra*, scrupled not to avail himself of an ancient sacrifice in basso-relievo; nor did Buonarroti himself disdain to use, in his paintings of the Sextine chapel, a figure taken from that famous cornelian which tradition tells us he wore on his fingers, and which is now in the possession of the most Christian King. Men like these avail themselves of the productions of others in such a manner as to make us apply to them, what La Bruyere said of Despreaux, that one would imagine the thoughts of other men had been of his own creation.

In general, a painter should have his eye constantly fixed on nature, that inexhaustible and varied source of every kind of beauty; and should study to imitate her in her most singular effects. As beauty scattered over the whole universe, shines brighter in some objects than in others, he should never be without his little book and crayon, in order to make drawings of every beautiful or uncommon object that may happen to present itself; and take sketches of every fine building, every situation, every effect of light, every flight of clouds, every flow of drapery, every attitude, every expression of the passions, that may happen to strike him. He may afterwards employ these things as occasions offer; and in the mean time will have the advantage of acquiring a grand taste. By uniting in a grand composition effects no less bold and beautiful than true and natural, he will acquire the same glory that orators acquire by the sublime, the glory of surprising, and in a manner exalting us above ourselves.

† Da Vinci  
on Painting.

II. *Rural history*; or the representation of a country life, of villages and hamlets, and their inhabitants. This is an inferior class; and in which Teniers, Brueghel, Watteau, &c. have great reputation, by rendering it at once pleasing and graceful.

III. *Portrait-painting*; which is an admirable branch of this art, and has engaged the attention of the greatest masters in all ages, as Apelles, Guido, Van Dyke, Rembrandt, Regauds, Pefne, Kneller, La Tour, &c.

IV. *Grotesque histories*: as the nocturnal meetings of witches; sorceries, and incantations; the operations of mountebanks, &c. A sort of painting in which the younger Brueghel, Teniers, and others, have exercised their talents with success.

V. *Battle-pieces*; by which Huchtemberg, Wouwerman, &c. have rendered themselves famous.

VI. *Landscapes*; a charming species of painting, that has been treated by masters of the greatest genius in every nation.

VII. *Landscapes diversified with waters*, as rivers, lakes, cataracts, &c.; which require a peculiar talent, to express the water sometimes smooth and transparent, and at others foaming and rushing furiously along.

VIII. *Sea-pieces*; in which are represented the ocean, harbours, and great rivers; and the vessels, boats, barges, &c. with which they are covered; sometimes in a calm, sometimes with a fresh breeze, and at others in a storm. In this class Backhuysen, Vandervelde, Blome, and many others, have acquired great reputation.

IX. *Night-pieces*; which represent all sorts of objects, either as illuminated by torches, by the flames of a conflagration, or by the light of the moon. Schalk, Vanderneer, Vanderpool, &c. have here excelled.

X. *Living Animals*: A more difficult branch of painting than is commonly imagined; and in which Rofa, Carré, Vandervelde, and many others, have succeeded marvellously well.

XI. *Birds of all kinds*; a very laborious species, and which requires extreme patience minutely to express the infinite variety and delicacy of their plumage.

XII. *Culinary pieces*; which represent all sorts of provisions, and animals without life, &c. A species much inferior to the rest, in which nature never appears to advantage, and which requires only a servile imitation of objects that are but little pleasing. The painting of fishes is naturally referred to this class.

XIII. *Fruit-pieces*, of every kind, imitated from nature.

XIV. *Flower-pieces*; a charming class of painting, where Art in the hands of Huyzum, P. Segers, Merian, &c. becomes the rival of Nature. *Plants and insects* are usually referred to the painters of flowers, who with them ornament their works.

XV. *Pieces of architecture*; a kind of painting in which the Italians excel all others. Under this class may be comprehended the representations of ruins, seaports, freets, and public places; such as are seen in the works of Caneletti, and other able masters.

XVI. *Instruments of music, pieces of furniture*, and other inanimate objects; a trifling species, and in which able painters only accidentally employ their talents.

XVII. *Imitations of bas-reliefs*; a very pleasing kind of painting, and which may be carried by an able hand to a high degree of excellence.

XVIII. *Hunting pieces*: these also require a peculiar talent, as they unite the painting of men, horses, dogs, and game, to that of landscapes.

It will not be expected that we should here give the rules that the painter is to observe in handling each particular subject. What has been said on historical painting (Part I. \*) may throw some light on the rest, and the particular rules must be learned from the study of the art itself. Good masters, academies of reputation, and a rational practice, are the sources from whence the young painter must derive the detail of his art. We shall however insert some rules and observations relative to *Landscape and Portrait*; these, with *History-painting* (already pretty fully treated), forming the principal branches of the art.

\* In the  
sections of  
Invention  
and Disposition.

## SECT. II. Of Landscape.

22. **LANDSCAPE-painting** includes every object that the country presents: And is distinguished into the *heroic*, and the *pastoral or rural*; of which indeed all other styles are but mixtures.

The *heroic style* is a composition of objects, which in their kinds draw both from art and nature every thing that is great and extraordinary in either. The situations are perfectly agreeable and surprising. The only buildings are temples, pyramids, ancient places of burial, altars consecrated to the divinities, pleasure-houses of regular architecture; and if nature appear not there as we every day casually see her, she is at least represented as we think the ought to be. This style is an agreeable illusion, and a sort of enchantment, when handled by a man of fine genius and a good understanding, as Poussin was, who has so happily expressed it. But if, in the course of this style, the painter has not talent enough to maintain the sublime, he is often in danger of falling into the childish manner.

The *rural style* is a representation of countries, rather abandoned to the caprice of nature, than cultivated: we there see nature simple, without ornament, and without artifice; but with all those graces wherewith she adorns herself much more when left to herself than when constrained by art.

In this style, situations bear all sorts of varieties: sometimes they are very extensive and open, to contain the flocks of the shepherds; at others very wild, for the retreat of solitary persons, and a cover for wild beasts.

It rarely happens that a painter has a genius extensive enough to embrace all the parts of painting: there is commonly some one part that pre-engages our choice, and so fills our mind, that we forget the pains that are due to the other parts; and we seldom fail to see, that those whose inclination leads them to the heroic style, think they have done all, when they have introduced into their compositions such noble objects as will raise the imagination, without ever giving themselves the trouble to study the effects of good colouring. Those, on the other hand, who practise the pastoral, apply closely to colouring, in order to represent truth more lively. Both these styles have their sectaries and partisans. Those who follow the heroic, supply by their imagination what it wants of truth, and they look no farther.

As a counterbalance to heroic landscape, it would be proper to put into the pastoral, besides a great character

Landscape. racter of truth, some affecting, extraordinary, but probable effect of nature, as was Titian's custom.

There is an infinity of pieces wherein both these styles happily meet; and which of the two has the ascendant, will appear from what we have been just observing of their respective properties. The chief parts of landscape are, their openings or situations, accidents, skies and clouds, off-skipps and mountains, verdure or turling, rocks, grounds or lands, terraces, fabrics, waters, fore-grounds, plants, figures and trees; of all which in their places.

23. *Of Openings or Situations.* The word *site*, or situation, signifies the "view, prospect, or opening of a country." It is derived from the Italian word *sito*; and our painters have brought it into use, either because they were used to it in Italy, or because, as we think, they found it to be very expressive.

Situations ought to be well put together; and so disengaged in their make, that the conjunction of grounds may not seem to be obstructed though we should see but a part of them.

Situations are various, and represented according to the country the painter is thinking of: as either open or close, mountainous or watery, tilled and inhabited, or wild and lonely; or, in fine, variegated by a prudent mixture of some of these. But if the painter be obliged to imitate nature in a flat and regular country, he must make it agreeable by a good disposition of the *claro-obscuro*, and such pleasing colouring as may make one soil unite with another.

It is certain, that extraordinary situations are very pleasing, and cheer the imagination by the novelty and beauty of their makes, even when the local colouring is but moderately performed: because, at work, such pictures are only looked on as unfinished, and wanting to be completed by some skilful hand in colouring; whereas common situations and objects require good colouring and absolute finishing, in order to please. It was only by these properties that Claud Lorrain has made amends for his insipid choice in most of his situations. But in whatever manner that part be executed, one of the best ways to make it valuable, and even to multiply and vary it without altering its form, is properly to imagine some ingenious accident in it.

24. *Of Accidents.* An accident in painting is an obstruction of the sun's light by the interposition of clouds, in such manner, that some parts of the earth shall be in light and others in shade, which, according to the notion of the clouds, succeed each other, and produce such wonderful effects and changes of the *claro-obscuro*, as seem to create so many new situations. This is daily observed in nature. And as this newness of situations is grounded only on the shapes of the clouds, and their motions, which are very inconstant and unequal, it follows, that these accidents are arbitrary; and a painter of genius may dispose them to his own advantage when he thinks fit to use them: For he is not absolutely obliged to do it; and there have been some able landscape-painters who have never praised it, either through fear or custom, as Claude Lorrain and some others.

25. *Of the Sky and Clouds.* The sky, in painters terms, is the ethereal part over our heads; but more particularly the air in which we breathe, and that where clouds and storms are engendered. Its colour is blue,

growing clearer as it approaches the earth, because of the interposition of vapours arising between the eye and the horizon; which, being penetrated by the light, communicates it to objects in a greater or lesser degree, as they are more or less remote.

But we must observe, that this light being either yellow or reddish in the evening, at sun-set, these same objects partake not only of the light, but of the colour: thus the yellow light mixing with the blue, which is the natural colour of the sky, alters it, and gives it a tint more or less greenish, as the yellowness of the light is more or less deep.

This observation is general and infallible: but there is an infinity of particular ones, which the painter must make upon the natural, with his pencil in his hand, when occasion offers; for there are very fine and singular effects appearing in the sky, which it is difficult to make one conceive by physical reasons. Who can tell, for example, why we see, in the bright part of some clouds, a fine red, when the source of the light which plays upon them is a most lively and distinguishing yellow? Who can account for the different reds seen in different clouds, at the very moment that these reds receive the light but in one place? for these colours and surprising appearances seem to have no relation to the rainbow, a phenomenon for which the philosophers pretend to give solid reasons.

These effects are all seen in the evening, when the weather is inclining to change, either before a storm, or after it, when it is not quite gone, but has left some remains of it to draw our attention.

The property of clouds is to be thin and airy, both in shape and colour: their shapes, though infinite, must be studied and chosen after nature, at such times as they appear fine. To make them look thin, we ought to make their grounds unite thinly with them, especially near their extremities, as if they were transparent: And if we would have them thick, their reflections must be so managed, as, without destroying their thinness, they may seem to wind and unite, if necessary, with the clouds that are next to them. Little clouds often discover a little manner, and seldom have a good effect, unless when, being near each other, they seem all together to make but one object.

In short, the character of the sky is to be luminous; and, as it is even the source of light, every thing that is upon the earth must yield to it in brightness: If however there is any thing that comes near it in light, it must be waters, and polished bodies which are susceptible of luminous reflections.

But, whilst the painter makes the sky luminous, he must not represent it always shining throughout.

On the contrary, he must contrive his light so, that the greatest part of it may fall only upon one place: and, to make it more apparent, he must take as much care as possible to put it in opposition to some terrestrial object, that may render it more lively by its dark colour; as a tree, tower, or some other building that is a little high.

This principal light might also be heightened, by a certain disposition of clouds having a supposed light, or a light ingeniously itself enclosed between clouds, whose sweet obscurity spreads itself by little and little on all hands. We have a great many examples of this in the Flemish school, which best understood landscape;

*Landscape.* as Paul Bril, Brûgel, Saveri: And the Sadlers and Merian's prints give a clear idea of it, and wonderfully awaken the genius of those who have the principles of the *clarescuro*.

26. *Of Offships and Mountains.* Offships have a near affinity with the sky; it is the sky which determines either the force or faintness of them. They are darkest when the sky is most loaded, and brightest when it is most clear. They sometimes intermix their shapes and lights; and there are times, and countries, where the clouds pass between the mountains, whose tops rise and appear above them. Mountains that are high, and covered with snow, are very proper to produce extraordinary effects in the offship, which are advantageous to the painter, and pleasing to the spectator.

The disposition of offships is arbitrary; let them only agree with the whole together of the picture, and the nature of the country we would represent. They are usually blue, because of the interposition of air between them and the eye: but they lose this colour by degrees, as they come nearer the eye, and so take that which is natural to the objects.

In distancing mountains, we must observe to join them insensibly by the roundings off, which the reflections make probable; and must, among other things, avoid a certain edginess in their extremities, which makes them appear in slices, as if cut with scissors, and stuck upon the cloth.

We must further observe, that the air, at the feet of mountains, being charged with vapours, is more susceptible of light than at their tops. In this case, we suppose the main light to be set reasonably high, and to enlighten the mountains equally, or that the clouds deprive them of the light of the sun. But if we suppose the main light to be very low, and to strike the mountains; then their tops will be strongly enlightened, as well as every thing else in the same degree of light.

Though the forms of things diminish in bigness, and colours lose their strength, in proportion as they recede from the first plan of the picture, to the most remote offship, as we observe in nature and common practice; yet this does not exclude the use of the accidents. These contribute greatly to the wonderful in landscape, when they are properly introduced, and when the artist has a just idea of their good effects.

27. *Of Verdure, or Turfing.* By turfing is meant the greenness with which the herbs colour the ground: This is done several ways; and the diversity proceeds not only from the nature of plants, which, for the most part, have their particular verdures, but also from the change of seasons, and the colour of the earth, when the herbs are but thin sown. By this variety, a painter may choose or unite, in the same tract of land, several sorts of greens, intermixed and blended together, which are often of great service to those who know how to use them; because this diversity of greens, as it is often found in nature, gives a character of truth to those parts, where it is properly used. There is a wonderful example of this part of landscape, in the view of Mechlin, by Rubens.

28. *Of Rocks.* Though rocks have all sorts of shapes, and participate of all colours, yet there are, in their diversity, certain characters which cannot be

well expressed without having recourse to nature, *Landscape.* Some are in banks, and set off with beds of shrubs; others in huge blocks, either projecting or falling back; others consist of large broken parts, contiguous to each other; and others, in short, of an enormous size, all in one stone, either naturally, as free-stone, or else through the injuries of time, which in the course of many ages has worn away their marks of separation. But, whatever their form be, they are usually set out with clefts, breaks, hollows, bushes, moss, and the stains of time; and these particulars, well managed, create a certain idea of truth.

Rocks are of themselves gloomy, and only proper for solitudes: but where accompanied with bushes, they inspire a fresh air; and, when they have waters, either proceeding from, or washing them, they give an infinite pleasure, and seem to have a soul which animates them, and makes them sociable.

29. *Of Grounds or Lands.* A ground or land, in painters terms, is a certain distinct piece of land, which is neither too woody nor hilly. Grounds contribute, more than any thing, to the gradation and distancing of landscape; because they follow one another, either in shape, or in the *claro-oscuro*, or in their variety of colouring, or by some insensible conjunction of one with another.

Multiplicity of grounds, though it be often contrary to grand manner, does not quite destroy it; for, besides the extent of country which it exhibits, and which, with good management, have a fine effect.

There is one nicety to be observed in grounds, which is, that in order to characterize them well, care must be taken, that the trees in them have a different verdure and different colours from those grounds; though this difference, withal, must not be too apparent.

30. *Of Terraces.* A terrace, in painting, is a piece of ground, either quite naked, or having very little herbage, like great roads and places often frequented. They are of use chiefly in the foregrounds of a picture, where they ought to be very spacious and open, and accompanied, if we think fit, with some accidental verdure, and also with some stones, which, if placed with judgment, give a terrace a greater air of probability.

31. *Of Buildings.* Painters mean by buildings any structures they generally represent, but chiefly such as are of a regular architecture, or at least are most conspicuous. Thus building is not so proper a name for the houses of country-people, or the cottages of shepherds, which are introduced into the rural taste, as for regular and showy edifices, which are always brought into the heroic.

Buildings in general are a great ornament in landscapes, even when they are Gothic, or appear partly inhabited and partly ruinous: they raise the imagination by the use they are thought to be designed for; as appears from ancient towers, which seem to have been the habitations of fairies, and are now retreats for shepherds and owls.

Poussin has very elegantly handled the Roman manner of architecture in his works, as Bonbon has done the Gothic; which, however Gothic, fails not to give a sublime air to his landscapes. Little Bernard has introduced

32. *Of Waters.* Much of the spirit of landscape is owing to the waters which are introduced in it. They appear in divers manners; sometimes impetuous, as when a storm makes them overflow their banks; at other times rebounding, as by the fall of a rock; at other times, through unusual pressure, gushing out and dividing into an infinity of silver streams, whose motion and murmuring agreeably deceive both the eye and ear; at other times calm and purling in a sandy bed; at other times fo still and standing, as to become a faithful looking-glass, which doubles all the objects that are opposite to it; and in this state they have more life than in the most violent agitation. Consult Bourdon's works, or at least his prints, on this subject: he is one of those who have treated of waters with the greatest spirit and best genius.

Waters are not proper for every situation: but to express them well, the artist ought to be perfect master of the exactness of watery reflexions; because they only make painted water appear as real: for practice alone, without exactness, destroys the effect, and abates the pleasure of the eye. The rule for these reflexions is very easy, and therefore the painter is the less pardonable for neglecting it.

But it must be observed, that though water be as a looking-glass, yet it does not faithfully represent objects but when it is still; for if it be in any motion, either in a natural course, or by the driving of the wind, its surface, becoming uneven, receives on its surges such lights and shades, as, mixing with the appearance of the objects, confound both their shapes and colours.

33. *Of the Foreground of a Picture.* As it is the part of the foreground to usher the eye into the piece, great care must be taken that the eye meet with good reception; sometimes by the opening of a fine terrace, whose design and workmanship may be equally curious; sometimes by a variety of well-distinguished plants, and those sometimes flowered; and at other times, by figures in a lively taste, or other objects, either admirable for their novelty, or introduced as by chance.

In a word, the artist cannot too much study his foreground objects, since they attract the eye, impress the first character of truth, and greatly contribute to make the artifice of a picture successful, and to anticipate our esteem for the whole work.

34. *Of Plants.* Plants are not always necessary in foregrounds, because, as we have observed, there are several ways of making those grounds agreeable. But if we resolve to draw plants there, we ought to paint them exactly after the life; or at least, among such as we paint practically, there ought to be some more finished than the rest, and whose kinds may be distinguished by the difference of design and colouring, to the end that, by a probable supposition, they may give the others a character of truth. What has been said here of plants, may be applied to the branches and barks of trees.

35. *Of Figures.* In composing landscape, the artist may have intended to give it a character agreeable to the subject he has chosen, and which his figures ought to represent. He may also, and it commonly happens, have only thought of his figures, after finishing his landscape. The truth is, the figures in most landscapes are made rather to accompany than to suit them.

It is true, there are landscapes so disposed and situated, as to require only passing figures; which several good masters, each in his style, have introduced, as Poussin in the heroic, and Fouquier in the rural, with all probability and grace. It is true also, that resting figures have been made to appear inwardly active. And these two different ways of treating figures are not to be blamed, because they act equally, tho' in a different manner. It is rather inaction that ought to be blamed in figures; for in this condition, which robs them of all connection with the landscape, they appear to be pacted on. But without obstructing the painter's liberty in this respect, undoubtedly the best way to make figures valuable is, to make them so to agree with the character of the landscape, that it may seem to have been made purely for the figures. We would not have them either insipid or indifferent, but to represent some little subject to awaken the spectator's attention, or else to give the picture a name of distinction among the curious.

Great care must be taken to proportion the size of the figures to the bigness of the trees, and other objects of the landscape. If they be too large, the picture will discover a little manner; and if too small, they will have the air of pigmies: which will destroy the worth of them, and make the landscape look enormous. There is, however, a greater inconvenience in making figures too large than too small; because the latter at least gives an air of greatness to all the rest. But as landscape figures are generally small, they must be touched with spirit, and such lively figures as will attract, and yet preserve probability and a general union. The artist must, in fine, remember, that as the figures chiefly give life to a landscape, they must be dispersed as conveniently as possible.

36. *Of Trees.* The beauty of trees is perhaps one of the greatest ornaments of landscape; on account of the variety of their kinds, and their freshness, but chiefly their lightness, which makes them seem, as being exposed to the air, to be always in motion.

Though diversity be pleasing in all the objects of landscape, it is chiefly in trees that it shews its greatest beauty. Landscape considers both their kinds and their forms. Their kinds require the painter's particular study and attention, in order to distinguish them from each other; for we must be able at first sight to discover which are oaks, elms, firs, fycamores, poplars, willows, pines, and other such trees, which, by a specific colour, or touching, are distinguishable from all other kinds. This study is too large to be acquired in all its extent; and, indeed, few painters have attained such a competent exactness in it as their art requires. But it is evident, that those who come nearest to perfection in it, will make their works infinitely pleasing, and gain a great name.

Besides the variety which is found in each kind of tree, there is in all trees a general variety. This is observed in the different manners in which their branches

are disposed by a sport of nature; which takes delight in making some very vigorous and thick, others more dry and thin; some more green, others more red or yellow. The excellence of practice lies in the mixture of these varieties: but if the artist can distinguish the sorts but indifferently, he ought at least to vary their makes and colours; because repetition in landscape is as tiresome to the eye, as monotony in discourse is to the ear.

The variety of their makes is so great, that the painter would be inexorable not to put it in practice upon occasion, especially when he finds it necessary to awaken the spectator's attention; for, among trees, we discover the young and the old, the open and close, tapering, and squat, bending upwards and downwards, flopping and shooting: in short, the variety is rather to be conceived than expressed. For instance, the character of young trees is, to have long slender branches, few in number, but well set out; boughs well divided, and the foliage vigorous and well shaped: whereas, in old trees, the branches are short, stocky, thick, and numerous; the tufts blunt, and the foliage unequal and ill shaped: but a little observation and genius will make us perfectly sensible of these particulars.

In the various makes of trees, there must also be a distribution of branches, that has a just relation to, and probable connection with, the boughs or tufts, so as mutually to assist each other in giving the tree an appearance of thickness and of truth. But, whatever their natures or manners of branching be, let it be remembered, that the handling must be lively and thin, in order to preserve the spirit of their characters.

Trees likewise vary in their barks, which are commonly grey; but this grey, which in thick air, and low and marshy places, looks blackish, appears lighter in a clear air: and it often happens, in dry places, that the bark gathers a thin moss, which makes it look quite yellow; so that, to make the bark of a tree apparent, the painter may suppose it to be light upon a dark ground, and dark on a light one.

The observation of the different barks merits a particular attention; for it will appear, that, in hard woods, age chaps them, and thereby gives them a sort of embroidery; and that, in proportion as they grow old, these chaps grow more deep. And other accidents in barks may arise either from moisture, or dryness, or green mosses, or white stains of several trees.

The barks of white woods will also afford much matter for practice, if their diversity be duly studied: and this consideration leads us to say something of the study of landscape.

37. *Of the study of Landscape.* The study of landscape may be considered either with respect to beginners, or to those who have made some advances in it.

Beginners will find, in practice, that the chief trouble of landscape lies in handling trees; and it is not only in practice, but also in speculation, that trees are the most difficult part of landscape, as they are its greatest ornament. But it is only proposed here, to give beginners an idea of trees in general, and to shew them how to express them well. It would be needless to point out to them the common effects of trees and plants, because they are obvious to every one;

yet there are some things, which, though not unknown, deserve our reflection. We know, for instance, that all trees require air, some more, some less, as the chief cause of their vegetation and production; and for this reason, all trees (except the cypress, and some others of the same kind) separate in their growth from one another and from other strange bodies as much as possible, and their branches and foliage do the same: wherefore, to give them that air and thinness, which is their principal character, the branches, boughs, and foliage, must appear to fly from each other, to proceed from opposite parts, and be well divided. And all this without order; as if chance aided nature in the fanciful diversity. But to say particularly how these trunks, branches, and foliages, ought to be distributed, would be needless, and only a description of the works of great masters: a little reflection on nature will be of more service than all that can be said on this head. By great masters, we mean, such as have published prints; for those will give better ideas to young copyists, than even the paintings themselves.

Among the many great masters of all schools, Du Pile prefers Titian's wooden prints, where the trees are well-shaped; and those which Cornelius Cort, and Agostino Carracche, have engraved. And he asserts, that beginners can do no better than contract, above all things, an habit of imitating the touches of these great masters, and of considering, at the same time, the perspective of the branches and foliages, and observing how they appear, either when rising and seen from below, or when sinking and seen from above, or when fronting and viewed from a point, or when they appear in profile; and, in a word, when set in the various views in which nature presents them, without altering their characters.

After having studied and copied, with the pen or crayon, first the prints, and then the designs of Titian and Carracche, the student should imitate with the pencil those touches which they have most distinctly specified, if their paintings can be procured: but since they are scarce, others should be got which have a good character for their touching; as those of Fouquier, who is a most excellent model: Paul Bril, Breugel, and Bourdon, are also very good; their touching is neat, lively, and thin.

After having duly weighed the nature of trees, their spread and order, and the disposition of their branches, the artist must get a lively idea of them, in order to keep up the spirit of them throughout, either by making them apparent and distinct in the foregrounds, or obscure and confused in proportion to their distance.

After having thus gained some knowledge in good manner, it will next be proper to study after nature, and to choose and rectify it according to the idea which the aforesaid great masters had of it. As to perfection, it can only be expected from long practice and perseverance. This, we think, is what concerns those, who, having an inclination for landscape, would take the proper methods for beginning it well.

As for those who have made some advances in this part of painting, it is proper they should collect the necessary materials for their further improvement, and study

**Landscape.** study those objects at least, which they shall have most frequent occasion to represent.

Painters usually comprize, under the word *study*, any thing whatever, which they either design or paint separately, after the life; whether figures, heads, feet, hands, draperies, animals, mountains, trees, plants, flowers, fruits, or whatever may confirm them in the just imitation of nature: the drawing of these things is what they call *study*; whether they be for instruction in design, or only to assure them of the truth, and to perfect their work. In fact, this word *study* is the more properly used by painters, as in the diversity of nature they are daily making new discoveries, and confirming themselves in what they already know.

As the landscape-painter need only study such objects as are to be met with in the country, we would recommend to him some order, that his drawings may be always at hand when he wants them. For instance, he should copy after nature, on separate papers, the different effects of trees in general, and the different effects of each kind in particular, with their trunks, foliage, and colours. He should also take the same method with some sorts of plants; because their variety is a great ornament to terraces on fore-grounds. He ought likewise to study the effects of the sky in the several times of the day, and seasons of the year, in the various dispositions of clouds, both in serene, thundering, and stormy weather; and in the off-skip, the several sorts of rocks, waters, and other principal objects.

These drawings, which may be made at times, should be collected together; and all that relate to one matter be put into a book, to which the artist may have recourse at any time for what he wants.

Now, if the fine effects of nature, whether in shape or colour, whether for an entire picture or a part of one, be the artist's study; and if the difficulty lies in choosing those effects well, he must for this purpose be born with good sense, good taste, and a fine genius; and this genius must be cultivated by the observations which ought to be made on the works of the best masters, how they choose nature, and how, while they corrected her, according to their art, they preferred her character. With these advantages, derived from nature, and perfected by art, the painter cannot fail to make a good choice; and, by distinguishing between the good and the bad, must needs find great instruction, even from the most common things.

To improve themselves in this kind of studies, painters have taken several methods.

There are some artists who have designed after nature, and in the open fields; and have there quite finished those parts which they had chosen, but without adding any colour to them.

Others have drawn, in oil-colours, in a middle-tint, on strong paper; and found this method convenient, because, the colours sinking, they could put colour on colour, though different from each other. For this purpose they took with them a flat box, which commodiously held their pallet, pencils, oil, and colours. This method, which indeed requires several implements, is doubtless the best for drawing nature more particularly, and with greater exactness, especially if, after the work be dry and varnished, the artist return

to the place where he drew, and retouch the principal things after nature.

Others have only drawn the out-lines of objects, and slightly washed them in colours near the life, for the ease of their memory. Others have attentively observed such parts as they had a mind to retain, and contented themselves with committing them to their memory, which upon occasion gave them a faithful account of them. Others have made drawings in pastel and wash together. Others, with more curiosity and patience, have gone several times to the places which were to their taste: the first time they only made choice of the parts, and drew them correctly; and the other times were spent in observing the variety of colouring, and its alterations through change of light.

Now these several methods are very good, and each may be practised as best suits the student and his temper: but they require the necessities of painting, as colours, pencils, pastels, and leisure. Nature, however, at certain times, presents extraordinary, but transient beauties, and such as can be of no service to the artist who has not as much time as is necessary to imitate what he admires. The best way, perhaps, to make advantage of such momentary occasions, is this:

The painter being provided with a quire of paper, and a black-lead pencil, let him quickly, but slightly, design what he sees extraordinary; and, to remember the colouring, let him mark the principal parts with characters, which he may explain at the bottom of the paper, as far as is necessary for himself to understand them: a cloud, for instance, may be marked A, another cloud B, a light C, a mountain D, a terrace E, and so on. And having repeated these letters at the bottom of the paper, let him write against each, that it is of such or such a colour; or for greater brevity, only *blue, red, violet, grey,* &c. or any other shorter abbreviation. After this, he must go to painting as soon as possible; otherwise most of what he has observed well, in a little time, slip out of his memory. This method is the more useful, as it not only prevents our losing an infinity of sudden and transitory beauties, but also helps, by means of the aforesaid marks and characters, to perfect the other methods we have mentioned.

If it be asked, Which is the properest time for these studies? the answer is, That nature should be studied at all times, because she is to be represented at all seasons; but autumn yields the most plentiful harvest for her fine effects: the mildness of that season, the beauty of the sky, the richness of the earth, and the variety of objects, are powerful inducements with the painter to make the proper inquiries for improving his genius and perfecting his art.

But as we cannot see or observe every thing, it is very commendable to make use of other men's studies, and to look upon them as if they were our own. Raphael sent some young men into Greece to design such things as he thought would be of service to him, and accordingly made use of them to as good purpose as if he himself had designed them on the spot: for this, Raphael is so far from deserving censure, that he ought, on the contrary, to be commended; as an example, that painters ought to leave no way untried for improving in their professions. The landscape painter

may, accordingly, make use of the works of all those who have excelled in any kind, in order to acquire a good manner; like the bees, which gather their variety of honey from different flowers.

38. *General remarks on Landscapes.* As the general rules of painting are the basis of all the several kinds of it, we must refer the landscape painter to them, or rather suppose him to be well acquainted with them. We shall here only make some general remarks on this kind of painting.

I. Landscape supposes the knowledge and practice of the principal rules in *perspective*, in order to maintain probability.

II. The higher the leaves of trees are to the earth, the larger they are, and the greener; as being aptest to receive, in abundance, the sap which nourishes them; and the upper branches begin first to take the redness or yellowness which colours them in autumn. But it is otherwise in plants; for their stalks renew all the year round, and their leaves succeed one another, at a considerable distance of time, inasmuch that nature, employed in producing new leaves to adorn the stock as it rises, does by degrees desert the under ones; which, having first performed their office, are the first that die: but this effect is more visible in some than in others.

III. The under parts of all leaves are of a brighter green than the upper, and almost always incline to the silveryish; and those which are wind-shaken are known from others by that colour: but if we view them from beneath, when penetrated by the sun's rays, they discover such a fine and lively green as is far beyond all comparison.

IV. There are five principal things which give spirit to landscape, *viz.* figures, animals, waters, wind-shaken trees, and thinness of pencilling; to which add smoke, when there is occasion to introduce it.

V. When one colour predominates throughout a landscape, as one green in spring, or one red in autumn, the piece will look either as of one colour, or else as unfinished. We have seen many of Bourdon's landscapes, which, by handling the corn one way throughout, have lost much of their beauty, though the situations and waters were very pleasant. The ingenious painter must endeavour to correct, and, as they say, redeem the harsh unlightly colouring of winter and spring by means of figures, waters, and buildings; for summer and autumn subjects are of themselves capable of great variety.

VI. Titian and Carrache are the best models for inspiring good taste, and leading the painter into a good track, with regard to forms and colours. He must use all his efforts to gain a just idea of the principles which those great men have left us in their works; and to have his imagination filled with them, if he would advance by degrees towards that perfection which the artist should always have in view.

VII. The landscapes of these two masters teach us a great many things, of which discourse can give us no exact idea, nor any general principle. Which way, for example, can the measures of trees in general be determined, as we determine those of the human body? The tree has no settled proportions; most of its beauty lies in the contrast of its branches, an unequal distribution of boughs, and, in short, a kind of whim-

fical variety, which nature delights in, and of which the painter becomes a judge when he has thoroughly relished the works of the two masters aforesaid. But we must say, in Titian's praise, that the path he struck out is the surest; because he has exactly imitated nature in its variety with an exquisite taste, and fine colouring: whereas Carrache, though an able artist, has not, more than others, been free from manner in his landscapes.

VIII. One of the greatest perfections of landscape, in the variety it represents, is a faithful imitation of each particular character: as its greatest fault is, a licentious practice, which brings us to do things by rote.

IX. Among those things which are painted practically, we ought to intermix some done after nature, to induce the spectator to believe that all are so.

X. As there are styles of thought, so there are also styles of execution. We have handled the two relating to thought, *viz.* the heroic and pastoral; and find that there are two also with regard to execution, *viz.* the firm style, and the polished; these two concern the pencil, and the more or less ingenious way of conducting it. The firm style gives life to work, and excuse for bad choice; and the polished finishes and brightens every thing; it leaves no employment for the spectator's imagination, which pleases itself in discovering and finishing things which it ascribes to the artist, though, in fact, they proceed only from itself. The polished style degenerates into the soft and dull, if not supported by a good opening or situation; but when those two characters meet, the picture is fine.

### SECT. III. Of Portraiture.

39. If painting be an imitation of nature, it is doubly so in a portrait; which not only represents a man in general, but such an one as may be distinguished from all others. And as the greatest perfection of a portrait is extreme likeness, so the greatest of its faults is to resemble a person for whom it was not made; since there are not in the world two persons quite like one another. But before we proceed to the particulars which let us into the knowledge of this imitation, it is necessary, for shortening this part of our subject, to attend to some general propositions.

I. Imitation is the essence of painting: and good choice is to this essence what the virtues are to a man; they raise the value of it. For this reason, it is extremely the painter's interest to choose none but good heads, or favourable moments for drawing them, and such positions as may supply the want of a fine natural.

II. There are views of the natural, more or less advantageous; all depends upon turning it well, and taking it in the favourable moment.

III. There is not a single person in the world who has not a peculiar character, both in body and face.

IV. Simple and genuine nature is more proper for imitation; and is a better choice than nature much formed, and embellished too artificially.

V. To adorn nature too much, is doing it a violence; and the action which attends it can never be free, when its ornaments are not easy. In short, in proportion as we adorn nature, we make it degenerate from itself, and

Portraiture. and bring it down to art.

VI. Some means are more advantageous than others, to come at the same end.

VII. We must not only imitate what we do see in nature, but also what we may possibly see that is advantageous in art.

VIII. Things are valuable by comparison; and it is only by this we are enabled to make a right judgment of them.

IX. Painters easily accustom themselves to their own tints, and the manner of their masters: and after this habit is rooted in them, they view nature, not as she really is, but as they are used to paint her.

X. It is very difficult to make a picture, the figures of which are as big as the life, to have its effect near, as at a distance. A learned picture pleases the ignorant only when it is at some distance; but judges will admire its artifice near, and its effect at a distance.

XI. Knowledge makes work pleasant and easy. The traveller who knows his road, comes to his journey's end with more speed and certainty than he who inquires and gropes it out.

XII. It is proper, before we begin a work, to meditate upon it, and to make a nice coloured sketch of it, for our own satisfaction, and an help to the memory.

We cannot too much reflect on these propositions; and it is necessary to be well acquainted with them, that they may present themselves to our mind, of their own accord, without our being at the trouble to recal them to our memory, when we are at work.

There are four things necessary to make a portrait perfect; *air, colouring, attitude, and dress.*

40. *Of Air.* The air respects the lines of the face, the head-attire, and the size.

The lines of the face depend upon exactness of draught, and agreement of the parts; which all together must represent the physiognomy of the person painted in such a manner, that the picture of his body may seem to be also that of his mind.

It is not exactness of design in portraits that gives spirit and true air, so much as the agreement of the parts at the very moment when the disposition and temperament of the sitter are to be hit off. We see several portraits which, though correctly designed, have a cold, languishing, and stupid air; whilst others, less correct in design, strike us however, at first sight, with the sitter's character.

Few painters have been careful enough to put the parts well together: Sometimes the mouth is smiling, and the eyes are sad; at other times, the eyes are cheerful, and the cheeks lank: by which means their work has a false air, and looks unnatural. We ought therefore to mind, that, when the sitter puts on a smiling air, the eyes close, the corners of the mouth draw up towards the nostrils, the cheeks swell, and the eye-brows widen: but in a melancholy air, these parts have a contrary effect.

The eye-brows, being raised, give a grave and noble air; but if arched, an air of astonishment.

Of all the parts of the face, that which contributes most to likeness is the nose; it is therefore of great moment to set and draw it well.

Though the hair of the head seems to be part of the dress, which is capable of various forms, without altering the air of the face; yet the head-attire which one has been most accustomed to creates such a likeness, that we scarce know a familiar acquaintance on his putting on a periwig somewhat different from that which he used to wear. It is necessary therefore, as far as possible, to take the air of the head-ornament, and make it accompany and set off that of the face, if there be no reason to the contrary.

As to the stature, it contributes so much to likeness, that we very often know people without seeing their face: It is therefore extremely proper to draw the size after the sitter himself, and in such an attitude as we think fit; which was Vandyke's method. Here let us remark, that, in sitting, the person appears to be of a less free make, through the heaving of his shoulders; wherefore, to adjust his size, it is proper to make him stand for a small time, swaying in the posture we would give him, and then make our observation. But here occurs a difficulty, which we shall endeavour to examine: "Whether it is proper, in portraiture, to correct the defects of nature?"

Likeness being the essence of portraiture, it would seem that we ought to imitate defects as well as beauties, since by this means the imitation will be more complete: It would be even hard to prove the contrary to one who would undertake the defence of this position. But ladies and gentlemen do not much approve of those painters who entertain such sentiments, and put them in practice. It is certain that some complaisance in this respect is due to them; and there is little doubt but their pictures may be made to resemble, without displeasing them: for the effectual likeness is a just agreement of the parts that are painted with those of nature; so that we may be at no loss to know the air of the face, and the temper of the person, whose picture is before us. All deformities, therefore, when the air and temper may be discovered without them, ought to be either corrected or omitted in women and young men's portraits. A nose somewhat awry may be helped, or a shrivelled neck, or high shoulders, adapted to good air, without going from one extreme to another. But this must be done with great discretion: for, by endeavouring to correct nature too much, we insensibly fall into a method of giving a general air to all our portraits; just as, by confining ourselves too much to the defects and littleness of nature, we are in danger of falling into the low and tasteless manner.

But in the faces of heroes and men of rank, distinguished either by dignities, virtues, or great qualities, we cannot be too exact, whether the parts be beautiful or not: for portraits of such persons are to be standing monuments to posterity; in which case, every thing in a picture is precious that is faithful. But after whatever manner the painter acquits himself in this point, let him never forget good air nor grace; and that there are, in the natural, advantageous moments for hitting them off.

41. *Of Colouring.*—Colouring, in portraiture, is an effusion of nature, discovering the true tempers of persons; and the temper being essential to likeness, it ought to be handled as exactly as the design. This part is the more valuable, as it is rare and difficult to hit. A great many painters have come to a likeness by strokes and outlines;

*Portraiture.* outlines; but certainly they are few who have shewn in colours the tempers of persons.

Two points are necessary in colouring; exactness of tints, and the art of setting them off. The former is acquired by practice, in examining and comparing the colours we see in life with those by which we would imitate it: and the art of those tints consists in knowing what one colour will produce when set by another, and in making good what either distance or time may abate of the glow and freshness of the colours.

A painter who does nothing more than what he sees, will never arrive at a perfect imitation; for though his work may seem, on the easel, to be good to him, it may not appear so to others, and perhaps even to himself, at a distance. A tint which, near, appears disjoined, and of one colour, may look of another at a distance, and be confounded in the mass it belongs to. If you would have your work, therefore, to produce a good effect in the place where it is to hang, both the colours and lights must be a little loaded; but learnedly, and with discretion. In this point consult Titian, Rubens, Vandyke, and Rembrandt's methods; for indeed their art is wonderful.

The tints usually require three times of observation. The first is at the person's first sitting down, when he has more spirit and colour than ordinary; and this is to be noted in the first hour of his sitting. The second is when, being composed, his look is as usual; which is to be observed in the second hour. And the third is when, through tiredness, by sitting in one posture, his colour alters to what weariness usually creates. On which account, it is best to keep to the sitter's usual tint, a little improved. He may also rise, and take some turns about the room, to gain fresh spirits, and shake off or prevent tiredness.

In *draperies*, all sorts of colours do not suit all sorts of persons. In mens portraits, we need only observe great truth, and great force: but in womens there must also be charms; whatever beauty they have must appear in a fine light, and their blemishes must by some means or other be softened. For this reason, a white, lively, and bright tint, ought never to be set off by a fine yellow, which would make it look like plaster; but rather by colours inclining to green, blue, or grey, or such others as, by their opposition, may make the tint appear more fleshy than usual in fair women. Vandyke often made a fillemot-coloured curtain for his ground; but that colour is soft and brown. Brown women, on the other hand, who have yellow enough in their tints to support the character of fleshiness, may very well have yellowish draperies, in order to bring down the yellow of their tints, and make them look the fresher; and, near very high-coloured and lively carnations, linen does wonders.

In *grounds*, two things are observable; the tone and the colour. The colour is to be considered in the same manner as those of draperies, with respect to the head. The tone must be always different from the mass it supports, and of which it is the ground, that the objects coming upon it may not seem transparent, but solid and raised. The colour of the hair of the head usually determines the tone of the ground; and when the former is a bright chestnut, we are often embarrassed, unless helped by means of a curtain, or some accident of the *claro obscuro*, supposed to be behind, or

unless the ground is a sky.

We must further observe, that where a ground is neither curtain nor landscape, or such like, but is plain and like a wall, it ought to very much party-coloured, with almost imperceptible patches or stains; for, besides its being so in nature, the picture will look the more grand.

42. *Of Attitude, or Posture.* Attitudes ought to suit the ages and qualities of persons and their tempers. In old men and women, they should be grave, majestic, and sometimes bold: and generally, in women, they ought to have a noble simplicity and modest cheerfulness; for modesty ought to be the character of women; a charm infinitely beyond coquetry! and indeed coquettes themselves care not to be painted such.

Attitudes are of two kinds; one in motion, the other at rest. Those at rest may suit every person: but those in motion are proper for young people only, and are hard to be expressed; because a great part of the hair and drapery must be moved by the air; motion, in painting, being never better expressed than by such agitations. The attitudes at rest must not appear so much at rest as to seem to represent an inactive person, and one who sits for no other purpose but to be a copy. And though the figure that is represented be at rest, yet the painter, if he thinks fit, may give it a flying drapery, provided the scene or ground be not a chamber or close place.

It is above all things necessary that the figures which are not employed should appear to satisfy the spectator's curiosity; and for this purpose shew themselves in such an action as suits their tempers and conditions, as if they would inform him what they really were: and as most people pretend to sincerity, honesty, and greatness of mind, we must avoid, in attitudes, all manner of affectation; every thing there must appear easy and natural, and discover more or less spirit, nobleness, and majesty, in proportion to the person's character and dignity. In a word, the attitudes are the language of portraits; and the skilful painter ought to give great attention to them.

But the best attitudes are such as induce the spectator to think that the sitter took a favourable opportunity of being seen to advantage, and without affectation. There is only one thing to be observed with regard to womens portraits, in whatever attitude they are placed; which is, that they sway in such a manner as to give their face but little shade; and that we carefully examine whether the lady appear most beautiful in a smiling or in a serious air, and conduct ourselves accordingly. Let us now proceed to the next article.

43. *Of Practice in Portraiture.* According to De Piles, portraiture requires three different sittings and operations; to wit, dead-colouring, second-colouring, and retouching or finishing. Before the painter dead-colour, he must attentively consider what aspect will best suit the sitter, by putting him in different positions, if we have not any settled design before us: and when we have determined this, it is of the last consequence to put the parts well together, by comparing always one part with another; for not only the portrait acquires a greater likeness when well designed, but it is troublesome to make alterations at the second sitting, when the artist must only think of painting, that

*Portraiture.*

Portraiture, that is, of disposing and uniting his colours.

Experience tells us, that the dead-colouring ought to be clean, because of the slope and transparency of the colours, especially in the shades: and when the parts are well put together, and become clammy, they must be judiciously sweetened and melted into each other; yet without taking away the air of the picture, that the painter may have the pleasure of finishing it, in proportion as he draws. But if fiery genies do not like this method of scumbling, let them only mark the parts slightly, and so far as is necessary, for giving an air.

In dead-colouring, it is proper to put in rather too little than too much hair about the forehead; that, in finishing, we may be at liberty to place it where we please, and to paint it with all possible softness and delicacy. If, on the contrary, you sketch upon the forehead a lock which may appear to be of a good taste, and becoming the work, you may be puzzled in finishing it, and not find the life exactly in the same position as you would paint it. But this observation is not meant for men of skill and consummate experience, who have nature in their heads, and make her submit to their ideas.

The business of the second sitting is, to put the colours well in their places, and to paint them in a manner that is suitable to the fitter and to the effect we propose: But before they are made clammy, we ought to examine afresh whether the parts are rightly placed, and here and there to give some touches towards likenesses, that, when we are assured of it, the work may go on with greater satisfaction. If the painter understands what he is about, and the portrait be justly designed, he ought as much as possible to work quick; the fitter will be better pleased, and the work will by this means have the more spirit and life. But this readiness is only the effect of long study and experience; for we may well be allowed a considerable time to find out a road that is easy, and such as we must often travel in.

Before we retouch or finish, it is proper to terminate the hair, that, on finishing the carnations, we may be able to judge of the effect of the whole head.

If, at the second sitting, we cannot do all we intended, which often happens, the third makes up the loss, and gives both spirit, physiognomy, and character.

If we would paint a portrait at once, we must load the colouring; but neither sweeten, nor drive, nor very much oil it: and if we dip the pencil in varnish as the work advances, this will readily enable us to put colour on colour, and to mix them without driving.

The use and sight of good pictures give greater light into things than words can express: What hits one artist's understanding and temper may be disagreeable to another's; and almost all painters have taken different ways, though their principles were often the same.

We are told that a friend of Vandyke's having observed to him how little time he bestowed on his portraits, Vandyke answered, "That at first he worked hard, and took great pains, to acquire a reputation, and also to get a swift hand, against the time he should work for his kitchen." Vandyke's custom is said to have been this: He appointed both the day and hour

for the person's sitting, and worked not above an hour on any portrait, either in rubbing in or finishing; so that as soon as his clock informed him that the hour was out, he rose up, and made a bow to the fitter, to signify, that he had done enough for that day, and then appointed another hour some other day; whereupon his servant came to clean his pencils, and brought a fresh pallet, whilst he was receiving another fitter, whose day and hour he had before appointed. By this method he worked on several pictures the same day, with extraordinary expedition.

After having lightly dead-coloured the face, he put the fitter into some attitude which he had before contrived; and on a grey paper, with white and black crayons, he designed, in a quarter of an hour, his shape and drapery, which he disposed in a grand manner and an exquisite taste. After this, he gave the drawing to the skilful people he had about him, to paint after the fitter's own cloaths, which, at Vandyke's request, were sent to him for that purpose. When his disciples had done what they could to these draperies, he lightly went over them again; and so, in a little time, by his great knowledge, displayed the art and truth which we at this day admire in them. As for hands, he had in his house people of both sexes, whom he paid, and who served as models.

This conduct of Vandyke, however, is mentioned rather to gratify the reader's curiosity, than to excite his imitation; he may choose as much of it as he pleases and as suits his own genius, and leave the rest.

We must observe by the way, that there is nothing so rare as fine hands, either in the design or colouring. It is therefore convenient to cultivate, if we can, a friendship with some women who will take pleasure in serving for a copy: The way to win them is, to praise their beauty exceedingly. But if an opportunity serves of copying hands after Vandyke, it must not be let slip; for he drew them with a surprising delicacy, and an admirable colouring.

It is of great service to copy after the manners which come nearest to nature; as are those of Titian and Vandyke. We must, at such times, believe them to be nature itself; and, at some distance, consider them as such, and say to ourselves—*What colour and tint shall I use for such a part?* And then, coming near the picture, we ought to examine, whether we are right, or not; and to make a fixed rule of what we have discovered, and did not practise before without uncertainty.

It is recommended, before we begin colouring, to catch the very first moments, which are commonly the most agreeable and most advantageous, and to keep them in our memory for use when we are finishing: for the fitter, growing tired with being long in the same place, loses those spirits, which, at his first sitting down, gave beauty to the parts, and conveyed to the tint more lively blood, and a fresher colour. In short, we must join to truth a probable and advantageous possibility, which, far from abating likeness, serves rather to set it off. For this end, we ought to begin with observing the ground of a tint, as well what it is in lights as in shades; for the shades are only beautiful as they are proportioned to the light. We must observe if the tint be very lively; whether it partake of yellowness, and where that yellowness is placed;

Decorations  
&c.

placed; because usually, towards the end of the sitting, fatigue diffuses a general yellowness, which makes us forget what parts were of this colour, and what were not, unless we had taken due notice of it before. For this reason, at the second sitting, the colours must be every where readily clapped in, and such as appear at the first sitting down; for these are always the finest.

The surest way to judge of colours is by comparison; and to know a tint, nothing is better than to compare it with linen placed next it, or else placed next to the natural object, if there is occasion. We say this only to those who have little practised nature.

The portrait being now supposed to be as much finished as you are able, nothing remains, but, at some reasonable distance, to view both the picture and sitter together, in order to determine with certainty, whether there is any thing still wanting to perfect the work.

#### SECT. IV. *Of Theatric Decorations; the Designs for Furniture, Embroidery, Carriages, &c.*

46. *Of Theatrical Decorations.* This is a particular art which unites several of the general parts of painting with the knowledge of architecture, perspective, &c. They who apply themselves to it, would do well to design their decorations by day, and to colour them by candle-light, as they will be much better able to judge of the effect of a painting intended to be viewed by that light. It is proper also to caution the young painter to avoid, as much as possible, the uniting the imitations of nature with nature itself; that is, he should not introduce with his decorations living horses, or other animals, real fountains or cascades, trees, or statues, &c. For such combinations are the effect of ignorance and a bad taste; they are the resource of painters of little ability; they discover a sterility of invention, and produce great inconvenience in the representation. Those pieces which they call moving pictures, where the painted landscape remains immovable, and the figures move by means of springs, form a part of these decorations; and there are some of them, as those of Antwerp and Ghent, that have a pleasing effect.

47. The designs for *furniture, carriages, porcelain*, and other branches of manufacture, form also a very important article of painting in general, and of academy painting in particular. This is a distinct branch of the art; and without doubt not the least useful of its parts, as it concurs so essentially to the success of manufactures, and consequently to the prosperity of a

state; and it is an art, to which it were much to be wished that youth of ability and invention would apply themselves. See the articles *JAPANNING* and *PORCELAIN*. Materials,  
&c.

#### SECT. V. *Enumeration of the different Methods of Painting, or the different Means and Materials that painters make use of to imitate all visible objects on a plane superficies.*

48. THOSE now in practice are,

1. *Painting in oil*; which is preferable to all other other methods, as it is more susceptible of all sorts of expressions, of more perfect gradations of colours, and is at the same time more durable.

2. *MOSAIC painting*; an invention truly wonderful; it is composed of a great number of small pieces of marble of different colours, joined together with stucco. The works of this kind are made principally at Rome, where this art has been carried so far as to resemble the paintings of the greatest masters; and of these are made monuments for the latest posterity.

Paintings in *FRESCO*; which is by drawing, with colours diluted with water, on a wall newly plastered, and with which they so incorporate, that they perish only with the stucco itself. This is principally used on ceilings.

4. *Painting in WATER-COLOURS*; that is, with colours mixed with water and gum, or paste, &c.

5. *MINIATURE painting*; which differs from the preceding only as it represents objects in the least discernible magnitudes; and is consequently vastly more delicate, seeing it is performed by the smallest strokes possible; whereas the others have the full scope of the pencil.

6. *Painting in CRAYONS*; for which purpose colours, either simple or compound, are mixed with gum, and made into a kind of hard paste like chalk, and with which they draw on paper or parchment.

7. *Painting in ENAMEL*; which is done on copper or gold, with mineral colours that are dried by fire, and become very durable. The paintings on the *PORCELAIN* of China and Europe, on Delph ware, &c. are so many sorts of enamel.

8. *Painting in WAX, or ENCAUSTIC painting*: This is a new invention, and in which there are in France performances highly pleasing. It is done with wax mixed with varnish and colours.

9. *Painting on GLASS*; of which there are various kinds.

See all the articles here enumerated, explained in the order of the alphabet.

## P A I

**PAIR**; two of a sort, a couple.

**PAIRING**, the uniting or joining in couples.

The instinct of pairing is bestowed on every species of animals to which it is necessary for rearing their young; and on no other species. All wild birds pair; but with a remarkable difference between such as place their nests on trees, and such as place them on the ground. The young of the former, being hatched blind, and without feathers, require the nursing care of both parents till they be able to fly. The male feeds his mate on the nest, and cheers her with a song.

## P A I

As soon as the young are hatched, singing yields to a more necessary occupation, that of providing food for a numerous issue; a task that requires both parents.

Eagles and other birds of prey build on trees, or on other inaccessible spots. They not only pair, but continue in pairs all the year round; and the same pair procreates year after year. This at least is the case of eagles: the male and female hunt together, unless during incubation, during which time the female is fed by the male. A greater number than a single pair are never seen in company.

Gre-

Pairing.

Paired.

Gregarious birds pair, in order probably to prevent discord in a society confined to a narrow space. This is the case particularly of pigeons and rooks. The male and female sit on the eggs alternately, and divide the care of feeding their young.

Partridges, plovers, pheasants, sea-fowl, grouse, and other kinds that place their nests on the ground, have the instinct of pairing; but differ from such as build on trees in the following particular, that after the female is impregnated, she completes her task without needing any help from the male. Retiring from him, she chooses a safe spot for her nest, where she can find plenty of worms and grubs-feed at hand; and her young, as soon as hatched, take foot, and seek food for themselves. The only remaining duty incumbent on the dam is, to lead them to proper places for food, and to call them together when danger impends. Some males, provoked at the desertion of their mates, break the eggs if they stumble on them. Eider ducks pair like other birds that place their nests on the ground; and the female finishes her nest with down plucked from her own breast. If the nest be destroyed for the down, which is remarkably warm and elastic, she makes another nest as before. If she is robbed a second time, she makes a third nest; but the male furnishes the down. A lady of spirit observed, that the eider duck may give a lesson to many a married woman, who is more disposed to pluck her husband than herself. The black game never pair: in spring, the cock on an eminence crows, and claps his wings; and all the females within hearing instantly resort to him.

Pairing birds, excepting those of prey, flock together in February, in order to choose their mates. They soon disperse; and are not seen afterward but in pairs.

Pairing is unknown to quadrupeds that feed on grubs. To such it would be useless; as the female gives suck to her young while she herself is feeding. If M. Buffon deserves credit, the roe-deer are an exception. They pair, though they feed on grubs, and have but one litter in a year.

Beasts of prey, such as lions, tigers, wolves, pair not. The female is left to shift for herself and for her young; which is a laborious task, and often so unsuccessful as to shorten the life of many of them. Pairing is essential to birds of prey, because incubation leaves the female no sufficient time to hunt for food. Pairing is not necessary to beasts of prey, because their young can bear a long fast. Add another reason, that they would multiply so fast by pairing, as to prove troublesome neighbours to the human race.

Among animals that pair not, males fight desperately about a female. Such a battle among horned cattle is finely described by Lucretius. Nor is it unusual for seven or eight lions to wage bloody war for a single female.

The same reason that makes pairing necessary for gregarious birds, obtains with respect to gregarious quadrupeds; those especially who store up food for winter, and during that season live in common. Discord among such would be attended with worse consequences than even among lions and bulls, who are not confined to one place. The beavers, with respect to pairing, resemble birds that place their nests on the ground. As soon as the young are produced, the

males abandon their flock of food to their mates, and live at large; but return frequently to visit them while they are suckling their young.

Hedgehogs pair as well as several of the monkey-kind. We are not well acquainted with the natural history of these animals; but it would appear that the young require the nursing care of both parents.

Seals have a singular economy. Polygamy seems to be a law of nature among them, as a male associates with several females. The sea-turtle has no occasion to pair, as the female concludes her task by laying her eggs in the sand. The young are hatched by the sun, and immediately crawl to the sea.

PAISLEY, a town of Renfrewshire, in Scotland, situated about six miles west of Glasgow, on the river White-Cart, over which there are two stone-bridges of two arches each, and one which consists of three arches. The town is very ancient; but was of much less consequence formerly than it is at present. The old part of it runs from east to west upon the south slope of a ridge of hills, from which there is a fine prospect of the city of Glasgow and the adjacent country; but to the southward, the view terminates in a ridge of green hills, about two miles distant. Including the late buildings and suburbs, it is fully a mile long, and nearly as much in breadth. On the east side of the river Cart, stand the abbey and new town; which last was lately seceded off by the Earl of Abercorn, and already consists of a number of handsome buildings. The streets are here laid off in a regular manner, but (rather unfortunately for the convenience and elegance of some of the houses) not in right angles. Here the Earl of Abercorn has built, at his own expence, one of the largest, most commodious, and most elegant inns in Scotland. In the vicinity of this his Lordship is likewise to build several convenient and necessary market-places. A little way south of the inn stands the abbey-church, the only one which Paisley, before the year 1735, required. This church, when entire, has been a most noble building, and consisted of several distinct and separate places of worship: what now remains of this magnificent Gothic structure is not yet unworthy the notice of the curious in antiquities. The next church, called the *Laigh-Church*, is built in form of a Greek cross, very well laid out, and capable of containing a great number of people. The one called the *High-Church*, is a very fine building; and as it stands on the top of a hill, its lofty spire is visible at a great distance. This church is an oblong square of 82 feet by 62 within the walls, built of free-stone well smoothed, having rustic corners and an elegant stone cornice at the top. In the construction of the roof (which is a pavilion covered with slate, having a platform covered with lead on the top), there is something very curious, and it is admired by every person of taste. The Middle or New Church is a very neat building, on much the same model with the High Church, but not quite so large. Besides these, there are also two Seceding Meeting-houses and a Church of Relief. The town-house is a very handsome building of cut stone, with a tall spire and a clock. The flesh-market has a genteel front of cut stone, and is one of the neatest and most commodious of this kind in Britain. Butchers'-meat, butter, cheese, fish, wool, and several other articles, are sold here by what they call the

*Paisley.* tron-pound, of 22 English ounces and an half.

The poor-house is a large building, very well laid out; and stands opposite to the quay, in a fine free air. It is supported by a small tax laid upon the inhabitants quarterly.

Close by the Abbey-Church is the Earl of Abercorn's burial-place, the greatest curiosity in Paisley. It is a vaulted Gothic chapel, without pulpit, pew, or any other ornament, but has the finest *echo* perhaps in the world. When the end door (the only one it has) is shut, the noise is equal to a loud and not very distant clap of thunder. If you strike a single note of music, you hear the sound gradually ascending, with a great number of repetitions, till it dies away as if at an immense distance, and all the while diffusing itself through the circumambient air. If a good voice sings, or a musical instrument is well played upon, the effect is inexpressibly agreeable. The *deepest*, as well as the most *acute tones*, are distinctly reverberated, and these in regular intervals of time. When a musical instrument is sounded, it has the effect of a number of instruments of a like size and kind playing in concert. When a number of different instruments in unison sounds the same note, a good ear is able to distinguish the variety of sound produced by each. A single instrument sounding a particular note, and then instantly its fifth, or any other concordant note, the two sounds can be heard, as it were, running into and uniting with each other in a manner peculiarly agreeable. But the effect of a variety of instruments playing in concert, is particularly charming, and must excite such emotions in the soul as it is impossible to describe. In this chapel is the monument of Marjory Bruce; she was daughter of Robert Bruce, and wife of Walter, great steward of Scotland, and mother of Robert II. In this same chapel were interred *Elizabeth Muir* and *Euphemia Ross*, both consorts to Robert II. In 1160, a fine monastery was founded by Walter, great steward of Scotland; but of this there are scarce any vestiges now remaining. The vestiges of the Roman camp and *prætorium*, at the west end of the town, are at present almost annihilated. It was supposed to be vaulted underneath.

The inhabitants of Paisley, in 1746, were computed at no more than 4000: but from a very accurate survey which has just been made, the number of families in Paisley and suburbs is found to be 3723; and allowing 4½ persons to each family, the number of inhabitants will be 16,753.

Paisley is now the first manufacturing town in Scotland, and is greatly celebrated on account of some of its branches. The manufactory of silk gauze, in this respect, first claims our notice. This branch is brought here to the utmost perfection, and is wrought to an amazing variety of patterns. It has been just computed, that there have been no less than 5000 weavers employed in Paisley and in the country adjacent, in this branch, last year (1781); and the number of winders, warpers, clippers, and others necessary in other parts of the silk-manufacture, has been likewise computed to be no less than 5000. Each loom will produce in average value 70*l.* yearly; the whole will then be 350,000 *l.*

The linen branch is likewise carried on here to a very considerable amount, particularly the manufac-

ture of lawns; and vast quantities of foreign yarn are annually imported from France, Germany, &c. for this branch, besides what is made of our home-manufactured yarn. It appears from the stamp-master's books, that from 1st November 1780 to 1st November 1781, there were stamped at Paisley no less than 1,248,843 yards, value 105,930 *l.* 19 *s.* 10½. The making of white stitching thread was introduced into this town about 50 or 60 years ago. A gentleman in this place lately discovered the method of making what is called *glazed white-thread*, to as great perfection as that made by Mr Leland and Son, London. The value of this branch is computed at about 60,000 *l.* annually. There are also several manufactures of a more local nature. There are three of hard-soap and tallow-candles, and one of black-soap. The candles, especially the moulded ones, are reckoned the best and most elegant that have been made in Scotland; and great quantities is sent into England, to America, and to the West Indies. The annual amount of these last branches are estimated at nearly 20,000 *l.* There are also two or three tan-works, and a porter brewery, in town; and in the neighbourhood there is a copras work, a callico printing work, and two works for the cotton spinning manufactory.

The river on which Paisley stands runs from south to north; and falls into Clyde, after it has joined the conflux of the rivers Grief and Black-Cart at Inchinnan bridge, about three miles below the town. At spring-tides, vessels of 40 tons burthen come up to the quay. The communication by water is of great importance to the inhabitants: for in this way they are frequently served with fish of different kinds, and can send their goods and manufactures to Port-Glasgow and Greenock, and to Glasgow likewise; and now, when the canal is finished, they have also a communication with the frith of Forth.

Paisley was created a burgh of barony in the year 1488; and the affairs of the community are managed by three bailies, of which the eldest is commonly in the commission of the peace, a treasurer, a town-clerk, and 17 counsellors, who are annually elected upon the first Monday after Michaelmas. It gives the title of baron to the earls of Abercorn; the first of whom was a younger son of the Duc de Chatellerault. The *black-book of Paisley*, frequently mentioned in Scottish history, was a chronicle of the public affairs and remarkable events, kept by the monks who resided in the monastery already mentioned. It agreed in every material fact with the *Scoti-chronicon* of Fordun; and is by many thought to be the same performance.

PAITA, a sea-port of America, in Peru, and in the audience of Quito. The town consists of about 200 houses but one story high; and the walls are made of split cane and mud, and the roofs only a covering of leaves. The only defence of Paita is a fort without either ditch or out-work; but it is surrounded by a brick wall of little or no strength, on which are mounted eight pieces of cannon. Commodore Anson got possession of this fort in 1741; and took and burnt the town, because the governor refused to ransom it. W. Long. 80. 5. S. Lat. 5. 5.

PALACE, PALATIUM, a name generally given to the dwelling-houses of kings, princes, and other great personages; and taking different epithets, according to the

*Paisley Palace.*

Palace  
 Palace.  
 Palace.

the quality of the inhabitants, as *imperial palace*, *royal palace*, *pontifical palace*, *cardinal palace*, *ducal palace*, *episcopal palace*, &c.

**PALACE-Court.** See MARSHALSEA.

**PALÆMON**, or **MELICERTES**, in fabulous history, a marine god, was the son of Athamas, king of Thebes and Ino. The latter, fearing the rage of the king her husband, took Melicertes in her arms, and leaped with him into the sea, when they were both changed into marine deities; the mother under the name *Leucothea*, supposed by some to be the same with Aurora; and her son under that of *Palæmon*, or *Portunus*, a god who presided over sea-ports. Paulanias says, that Melicertes was saved on the back of a dolphin, and his dead body thrown on the isthmus of Corinthus, where Sisyphus, his uncle, who reigned in that city, instituted to his honour the Isthmian games.

**PALÆMON** (Q. Rhemmius), a Latin grammarian, born at Vicenza, was the son of slave. He taught at Rome with great applause under Tiberius and Claudius, and Juvenal mentions him with praises. We have only two fragments of his works.

**PALEPAPHOS**, (Strabo, Virgil, Pliny), a town of Cyprus, where stood a temple of Venus; and an adjoining town called *Nea Paphos*; where St Paul struck Elymas blind, and converted the proconsul Sergius Paulus.

**PALESTRA**, in Grecian antiquity, a public building, where the youth exercised themselves in wrestling, running, playing at quoits, &c.

**PALESTROPHYLAX**, was the director of the palestra, and the exercises performed there.

**PALAMEDIA**, in ornithology, a genus belonging to the order of grallæ. The bill is conical, the superior mandible being crooked; and the feet have three divided toes. There are two species, both natives of Brazil.

**PALARIA**, among the Romans, a kind of exercise performed at a stake by the soldiers. The stake being fixed in the ground, and six feet high above it, the young undisciplined soldiers advanced against it, armed with a hurdle and cudgel, instead of a sword and shield, and went through all the rules of attack and defence, as if actually engaged with an adversary. Sometimes they stood at a distance, and attacked with missile weapons; at the same time using all the requisite motions for defending themselves, and warding off what might be thrown against them.

**PALATE**, in anatomy, the flesh that composes the roof, or the upper and inner part, of the mouth.

The palate has much the same structure with the gums; but it has also a great number of glands, discovered so early as the time of Fallopius: these are principally situated in the hinder part near the uvula, where it is pendulous, in the manner of a curtain, which part is called the *velum*, or *claustrum*, of the palate. The glands situated particularly in this part, secrete a mucous fluid, serving to lubricate the mouth and throat, and to facilitate deglutition: they have a great number of apertures there for the discharge of this humour into the mouth.

The great uses of this membrane are to defend the bones of the palate from corrupting; and for preventing, by its claustrum or velum, the things to be swallowed from getting up into the nostrils.

**PALATINATE**, a province or signiory, possessed by a palatine.

**PALATINATE** of the Rhine, a province of Germany, divided into two parts by the Rhine, called the *Upper* and *Lower Palatinate*. The former lies in the circle of Bavaria, and belongs to the elector thereof; but the latter, in the circle we are now treating, belongs to the elector Palatine. The latter part is bounded to the east by the county of Katzenellbogen, the archbishopric of Mentz, the bishopric of Worms, and part of the territory of the Teutonic order in Franconia; to the west, by Alsace, the duchy of Deuxponts, the county of Sponheim, the duchy of Simmern, and certain districts of the electorate of Mentz; to the south, by the duchy of Wurtemberg and the bishopric of Spire; and to the north, by a part of archbishopric of Mentz and the county of Katzenellbogen. It contains 41 towns, besides several boroughs; and its greatest extent is about 80 miles. The air is healthful, and the soil fruitful in corn, pasturage, wine, tobacco, and all sorts of pulse and fruits, particularly walnuts, chestnuts, and almonds. This country also breeds abundance of cattle, and is well watered by the Neckar, the Nahe, and the Rhine. In the last of these, near Germersheim and Selz, is found gold; the exclusive right of searching for which is farmed out by the elector. The state of religion hath varied greatly here since the Reformation, Lutheranism and Calvinism having been uppermost by turns, till the electorate devolved to the Popish branches of the family, when Popery, with all its superstition and mummery, was established anew: so that the Protestant religion is now on a very precarious footing in the Palatinate, though most of the natives are still of that persuasion: but the two sects of Protestants, namely, the Lutherans and Calvinists, have greatly contributed to their own ruin, by their mutual jealousy and animosity, being no less rancorous against one another than against their common adversaries the Papists. The Lutherans reckon themselves 50,000 strong, and are possessed of about 85 churches; but not one half of their preachers and schoolmasters have a competent maintenance. The number of Calvinist clergy here is estimated at 500, and that of the Roman Catholics at 400. Besides schools and Jesuits colleges in this country, there is one university, namely, that of Heidelberg; but there is very little trade in it except in wine. Authors are divided about the origin of the name *Palatine*, or *Palzgraves*, as the Germans call them; but it seems most likely to be derived from the *palatia*, or palaces, which the old Frankish and German kings and Roman emperors were possessed of in different parts of the country, and over which they appointed supreme stewards or judges, who were called *Palatines* or *Palzgraves*. The countries where these Palatines kept their courts were, from them, called *Palatinates*; which name came at last to be appropriated, by way of eminence, to this country, as being the most considerable of them. The ancient electoral line failing in 1685, the electorate devolved to Philip-William Duke of Neuburg; and upon the death of his second son Charles-Philip, to the prince of Sulzbach. This elector has the title of arch-treasurer of the empire, as well as the elector of Brunswick-Luneburgh, and is the fifth in rank among the secular electors. He is

Palatinate

Palatine. also one of the vicars of the empire alternately with the elector of Bavaria, and enjoys many other prerogatives. In his own dominions, he disposes of all vacant benefices; but allows the ecclesiastical council, composed of two clergymen and two laymen, to present two candidates, of which he chooses one. He is also master of all the tithes in his dominions; but he either grants them to the clergy, or salaries in lieu of them, out of the revenues of the church. His title is Palzgrave of the Rhine; archtreasurer and elector of the holy Roman empire; duke in Bavaria, Juliers, Cleve, and Berg; prince of Mora; marquis of Bergen-op-Zoom; count of Veldeus, Sponheim, the Mark, and Ravensberg; and lord of Ravenstein. His quota to the army of the empire is 30 horse, and 138 foot, or 914 florins monthly. To the chamber of Wetzlar he contributes, each term, 404 rix-dollars, 82 kruiters. There is an order of knighthood in this country, viz. that of St Hubert; the badge of which is a quadrangular cross pendant to a red ribbon, with a star on the breast. The whole of the elector's revenue, arising from the Palatinate, the duchies of Berg and Juliers, the feigniory of Ravenstein, and the duchies of Neuburg and Sultzbach, hath been estimated at about 300,000 l. *per annum*. The military establishment consists of several regiments of horse and foot, besides the horse and Swiss life-guards. All the different courts and councils, usual in other countries for the different departments of government, are also to be found here.

PALATINE, or COUNT PALATINE, a title anciently given to all persons who had any office or employment in the prince's palace; but afterwards conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the Lords as had a palace, that is, a court of justice, in their own houses.

Counties-PALATINE in England.—Chester, Durham, and Lancaster, are called *counties palatine*. The two former are such by prescription, or immemorial custom; or, at least as old as the Norman conquest: the latter was created by king Edward III. in favour of Henry Plantagenet, first earl and then duke of Lancaster; whose heirs being married to John of Gaunt the king's son, the franchise was greatly greatly enlarged and confirmed in parliament, to honour John of Gaunt himself, whom, on the death of his father-in-law, the king had also created duke of Lancaster. Counties-palatine are so called *à palatio*; because the owners thereof, the earl of Chester, the bishop of Durham, and the duke of Lancaster, had in those counties *jura regalia*, as fully as the king hath in his palace; *regalem potestatem in omnibus*, as Bracton expresses it. They might pardon treasons, murders, and felonies; they appointed all judges and justices of the peace; all writs and indictments ran in their names, as in other counties in the king's; and all offences were said to be done against their peace, and not, as in other places, *contra pacem domini regis*. And indeed by the ancient law, in all peculiar jurisdictions, offences were said to be done against his peace in whose court they were tried: in a court-leet, *contra pacem domini*; in the court of a corporation, *contra pacem ballivorum*; in the sheriff's court or tourn, *contra pacem vicecomitis*. These palatine privileges (so similar to the

regal independent jurisdictions usurped by the great barons on the continent during the weak and infant state of the first feudal kingdoms in Europe), were in all probability originally granted to the counties of Chester and Durham, because they bordered upon enemies countries, Wales and Scotland: in order that the owners, being encouraged by so large an authority, might be the more watchful in its defence; and that the inhabitants, having justice administered at home, might not be obliged to go out of the county, and leave it open to the enemy's incursions. And upon this account also there were formerly two other counties palatine, Pembrokeshire and Hexhamshire, the latter now united with Northumberland: but these were abolished by parliament, the former in 27 Hen. VIII. the latter in 14 Eliz. And in 27 Hen. VIII. likewise, the powers before mentioned of owners of counties-palatine were abridged; the reason for their continuance in a manner ceasing: though still all writs are witnessed in their names, and all forfeitures for treason by the common law accrue to them.

Of these three, the county of Durham is now the only one remaining in the hands of a subject. For the earldom of Chester, as Camden testifies, was united to the crown by Hen. III. and has ever since given title to the king's eldest son. And the county palatine, or duchy, of Lancaster was the property of Henry of Bolingbroke, the son of John of Gaunt, at the time when he wrested the crown from king Richard II. and assumed the title of Hen. IV. But he was too prudent to suffer this to be united to the crown; left, if he lost one, he should lose the other also. For, as Plowden and Sir Edward Coke observe, "he knew he had the duchy of Lancaster by sure and indefeasible title, but that his title to the crown was not so assured: for that after the decease of Richard II. the right of the crown was in the heir of Lionel duke of Clarence, second son of Edward III.; John of Gaunt, father to this Henry IV. being but the fourth son." And therefore he procured an act of parliament, in the first year of his reign, ordaining that the duchy of Lancaster, and all other his hereditary estates, with all their royalties and franchises, should remain to him and his heirs for ever; and should remain, descend, be administered, and governed, in like manner as if he never had attained the regal dignity: and thus they descended to his son and grandson, Henry V. and Henry VI.; many new territories and privileges being annexed to the duchy by the former. Henry VI. being attainted in 1 Edward IV. this duchy was declared in parliament to have become forfeited to the crown, and at the same time an act was made to incorporate the duchy of Lancaster, to continue the county palatine (which might otherwise have determined by the attainder), and to make the same parcel of the duchy: and, farther, to vest the whole in king Edward IV. and his heirs, kings of England, for ever; but under a separate guiding and governance from the other inheritances of the crown. And in 1 Hen. VII. another act was made, to resume such part of the duchy lands as had been dismembered from it in the reign of Edward IV. and to vest the inheritance of the whole in the king and his heirs for ever, as amply and largely, and in like manner, form, and condition, separate from the crown of Eng-  
land

Palætrius.

land and possession of the same, as the three Henries and Edward IV. or any of them, had and held the same.

The Isle of Ely is not a county-palatine, though sometimes erroneously called so, but only a royal franchise: the bishop having, by grant of king Henry the first, *jura regalia* within the Isle of Ely; whereby he exercises a jurisdiction over all causes, as well criminal as civil.

**PALATINE Games**, in Roman antiquity, games instituted in honour of Augustus by his wife Livia, after he had been enrolled among the gods. They were celebrated in the palace, and were confirmed by the succeeding emperors.

**PALATINUS MOUNTS**, or *Palatium*, the first mountain of Rome occupied by Romulus, and where he fixed his residence and kept his court, as did Tullus Hostilius, Augustus, and all the succeeding emperors: and hence it is that the residence of princes is called *palatium*. The reason of the name is variously assigned. To the east it has the Mons Coelius, to the south the Aventine, to the west the Capitoline, and to the north the Forum.—*Palatinus*, the surname of Apollo from this place; where Augustus built a temple to that god, adorned with porticos and a library, (Horace).

**PALATIUM**, (anc. geog.) a place in the territory of Reate, distant from it 25 stadia. Dionysius Halicarnassensis reckons it one of the first towns of the Aborigines, and from it Varro accounts for the name of the *Mons Palatinus*; namely, that a colony from Palatium settled there.

**PALATIUM** (Pliny), *Pallantium* (Pausanias), *Palanteum* (Livy); *Pallanteum* (Solinus). This last is the true writing; the great grandfather of Evander, from whom it took its name, being called *Pallar*, not *Palas*: A town of Arcadia, which concurred to form Megalopolis (Pausanias). From it the *Palatium*, or *Mons Palatinus*, takes also its name, according to Virgil and Pliny.

**PALATIUM Dioclesiani**; the villa of Dioclesian, near Salonæ, where he died, (Eusebius). Afterwards called *Spalatium*; which rose to a considerable city from the ruins of Salonæ; situate in Dalmatia on the Adriatic. Now *Spalatto*, or *Spalatro*.

**PALATIUM Luculli**, (Plutarch), or *Villa Luculli*; a place between Misenum and Baiæ in Campania, of wonderful structure. Now in ruins, and called *Piscina Mirabile*.

**PALATO-SALPINGÆUS**, } See ANATOMY, Table  
**PALATO-Staphylinus**, } of the Muscles.

**PALE**, a little pointed stake or piece of wood used in making inclosures, separations, &c. The *pale* was an instrument of punishment and execution among the ancient Romans, and still continues so among the Turks. Hence empaling, the passing a sharp pale up the fundament through the body.

**PALE**, in heraldry. See HERALDRY, p. 4839.

**PALEARIUS** (Aonius), was a man of the greatest probity, and one of the best writers of the 16th century. He gained the esteem of the men of wit and learning of his time by a noble poem on the immortality of the soul. He was appointed professor of poetry literature at Sienna; where his tranquillity was disturbed by contests with an envious colleague, and by

the malicious aspersions of his enemies; against which, however, his eloquence proved always a sufficient defence. At last he left Sienna, and accepted the invitation of the magistrates of Lucca, who gave him several marks of their esteem, and settled a considerable stipend upon him. Some years after, he removed to Milan; where he was seized by order of Pope Pius V. and carried to Rome. He was convicted of having spoken in favour of the Lutherans, and against the inquisition; and therefore was condemned to be burnt. This sentence was executed in 1566. He wrote several pieces in verse and prose; of which the one above-mentioned is the most esteemed.

**PALENCIA**, a town of Spain, in the kingdom of Leon, with a rich archbishop's see. It had an university, but it was removed to Salamanca. It is seated in a fertile soil on the river Carion on the frontiers of Castile, in W. Long. 3. 7. N. Lat. 42. 10.

**PALERMO**, an ancient, large, populous, rich, and handsome city of Sicily in the Val-di-mazara, with an archbishop's see and a harbour. It was the seat of the ancient kings, and is four miles in circumference. It is a place of great trade; the houses are handsome and superb; it is also well fortified, and very populous. The public buildings, squares, churches, and fountains, are extremely fine. The fountain in the great square is thought to be the finest in all Italy. The number of the inhabitants is above 200,000; and the harbour is very large, having a mole 1300 geometrical paces in length; but the vessels that ride therein are not always very safe. There is a magnificent castle built near the sea-side, wherein the viceroy resides six months in the year; and his presence draws a great number of nobility to this place. This city has suffered greatly by earthquakes, particularly in 1693; and it was greatly damaged by a fire in 1730, when a magazine of powder was blown up, containing 400 tons. It stands in a pleasant fruitful country on the north-east coast of the island, and at the bottom of the gulph of the same name. E. Lon. 33. 40. N. Lat. 38. 10.

**PALES**, in Pagan worship, the goddesses of the shepherds; to whom they offered milk and honey, in order that the might deliver them and their flocks from wild beasts and infectious diseases. This goddess is represented as an old woman.

**PALESTINE**, a part of Asiatic Turkey, situated between 36 and 38 degrees of E. Long. and between 31 and 34 of N. Lat. It is bounded by Mount Libanus, which divides it from Syria, on the north; by Mount Hermon, which separates it from Arabia Deserta, on the east; by the mountains of Seir and the deserts of Arabia Petrea, on the south; and by the Mediterranean Sea on the west.

This once fertile and happy spot was first called the land of *Canaan*, or *Chanaan*, from Noah's grandson. In scripture, however, it is frequently distinguished by other names; such as the *land of promise*, the *land of God*, the *land of Israel*, &c. It received the name of *Palestine* from the *Palestines*, or *Philistines*, who possessed a great part of it; and it had the name of *Jurdea*, or *Judea-Palestina*, from *Judab*, the most considerable of the twelve sons of Jacob. The Christians have denominated it the *Holy Land*; partly on account of the many singular blessings it received from the divine

Palengia  
||  
Palestina.

*Palestine.* vine providence, and partly on account of its metropolis being made the centre of God's worship and his peculiar habitation; but much more for its being the place of our Saviour's birth, the scene of his preaching, and manifold miracles; especially the place in which he accomplished the great work of our redemption. As to the name of *Judea*, it did not begin to receive that till after the return of the Jews from the Babylonish captivity, though it had been styled long before the *kingdom of Judah*, in opposition to that of *Israel*, which revolted from it under Jeroboam, in the reign of Rehoboam the son of Solomon. But after the return, the tribe of Judah, the only one that made any figure, settling at Jerusalem, and in the countries adjacent, quickly gave its name to the whole territory. By profane authors it was called by many different names; such as Syria, Palestina Syria, Cælesyria, Iduma, Idumæa, and Phœnicia or Phœnice; but these are supposed only to have been given out of contempt to the Jewish nation, whom they looked upon as unworthy of any other name than what distinguished the most obscure parts of the neighbouring provinces.

That part of the country which was properly called the *Land of Promise*, was inclosed on the west by the Mediterranean; on the east by the lake Asphaltites, the Jordan, and the sea of Tiberias or of Galilee, and the Samachonite lake; to the north it had the mountains of Libanus, or rather of Antilibanus, or the province of Phœnicia; and to the south, that of Edom or Idumæa, from which it was likewise parted by another ridge of high mountains. The boundaries of the other part, which belonged to the two tribes and an half beyond the river Jordan, are not so easily defined, as well as those of the conquests made by the more prosperous kings of the Jews. All that can be said with any probability is, that the river Arnon was the first northern boundary on that side; and with respect to those on this side the Jordan, there is a considerable disagreement between the Hebrew and Samaritan versions of the Pentateuch.

The extent of this country is likewise variously settled by geographers; some giving it no more than 170 or 180 miles from north to south, and 140 in breadth where broadest, though not much above half that breadth where narrowest. But from the latest and most accurate maps, it appears to extend near 200 miles in length, and about 80 in breadth about the middle, and about 10 or 15 more or less, where it widens or shrinks. It reaches from 31. 30. to 33. 30. N. Lat. and from 34. 50. to 37. 15. E. Long. the longest day being about 14 hours 15 minutes.

These limits are so small, considering that the country is likewise intersected by high ridges or mountains, woods, deserts, &c. that many learned men have been induced to question what we read of its fertility and populousness in former times. It must be owned, indeed, that when we compare its ancient and flourishing state, when it was cultivated with the utmost diligence by persons well skilled in every branch of agriculture, with what it hath been since the total extirpation of the Jews out of it, and more especially since it fell into the hands of the Turks, the contrast is amazingly great: but when we consider the many evident causes which have contributed to effect this change, and even yet consider the nature of the country itself, we find not

the least reason to doubt the truth of what the sacred historians have related. Moses describes the richness of it in the strongest terms, even before the Israelites got possession of it. It even exceeded the land of Egypt, so much celebrated by ancient historians; especially in the vast numbers of cattle which it produced; in the quantity and excellence of its wine, oil, and fruits. With respect to the oil and fruits, it is plain, that the olives and oil of Canaan exceeded in goodness those of Egypt, since the tribes sent them thither from thence; and as for vines, Herodotus tells us, that the Egyptians had none at all, but supplied the want of them by a liquor brewed from barley. The presents which Jacob sent to his son Joseph, of honey, spices, myrrh, almonds, and other fruits of Palestine, shew that they must have been much better in the land of Judea than in Egypt. The wines of Gaza, Ascalon, and Sarepta, were famous among the most remote nations; though it is allowed, that the wine which was made at and in the neighbourhood of Bethlehem, in great quantities, was equal at least, if not superior, to any of the rest: and that of Libanus, mentioned by the prophet Hosea, was no less celebrated for its excellent flavour.

Several circumstances contributed to this wonderful fecundity: such as, the excellent temperature of the air, which was never subject to excessive heats or colds; the regularity of its seasons, especially the former and latter rain; and the natural fatness and fertility of its soil, which required neither dunging nor manuring, and could be ploughed with a single yoke of oxen and a small kind of plough; for the soil was, and is still, so shallow, that to have gone deep into it, would rather endanger, than improve, the crop. With respect to the excellency of its corn, we are told, that the bread of Jerusalem was preferred above all other; and the tribe of Asher produced the best of both, and in greater quantity than any other tribe: and such plenty was there of it, that, besides what sufficed the inhabitants, who made it their chief sustenance, Solomon, we read, could afford to send 20,000 cors, or measures, of it, and as many of oil, yearly, to Hiram king of Tyre; besides what they exported into other countries. And we find, even so late as king Herod surnamed Agrippa, the countries of Tyre and Sidon received most of their sustenance from his tetrarchy.

As to their fruits, the grapes were delicious, finely flavoured, and very large. The palm tree and its dates were in no less request; and the plain of Jericho, among other places, was famed for the great plenty and excellence of that fruit; inasmuch, that the metropolis of that territory was emphatically styled *the city of palm-trees*. But what both this plain, and other parts of Palestine, were most celebrated for, was, the balsam shrub, whose balm was esteemed so precious a drug among the Greeks, Romans, Egyptians, and other nations, and is still to this day under the name of *balm of Gilead*. They had likewise the greatest variety of other fruit-trees in the highest perfection; and which might be, in some sense, styled *perpetual*, because they were not only covered with a constant verdure, but because the new buds always appeared on the same boughs before the old fruit was ripe; and of those buds, which were

Palestine. in too great quantities to be allowed to come to maturity, they gathered enough to make very delightful pickles and sweatmeats, especially of their citrons, oranges, and apples of paradise, which last commonly hung by hundreds in a cluster, and as big as hens eggs, and of an excellent taste and flavour. Their vines yielded grapes twice, and sometimes three times, a-year, great quantities of which were dried up, and preserved for use, as well as their figs, plums, and other fruits. They had plenty of honey; the very trees distilled it; and the rocks yielded it in great quantities: but whether that of the latter kind were there deposited by the industrious bees, or produced some other way, is much disputed by travellers and naturalists. They likewise cultivated sugar-canes in great abundance; and the cotton, hemp, and flax, were mostly of their own growth and manufacture, except some of a finer sort, that were brought to them from Egypt, and worn by those of the higher rank. Their vicinity to Libanus made the cedars, cypresses, and other stately fragrant trees, very common in most parts of the land, but more especially in Jerusalem. Cattle, both large and small, they fed in vast quantities; and the hilly countries not only afforded them variety and plenty of pasture, but also of water, which descended thence into the valleys and lowlands, and fertilized them to the degree we have seen; besides several other rivers and brooks, some of the most remarkable of which we shall speak of in their proper places. But the most fertile pasture-grounds were those on each side the river Jordan; besides those of Sharon, or Sarona, the plains of Lydda, Jamnia, and some others then justly famed for their fecundity. As for fish, the rivers above-mentioned, the lake of Tiberias, and the Mediterranean Sea, afforded, as they do to this day, great plenty and variety. Vast quantities were brought to Jerusalem, on which the inhabitants mostly subsisted; and hence one of the gates of that metropolis was, according to St Jerome, called *the fish-gate*. The lake Asphaltites yielded salt in abundance, wherewith to season and preserve their fish, which Galen affirms to have been preferable to any other for wholesomeness, digestion, and extenuation. In short, the Scripture is so pregnant with proofs of the extraordinary richness and fecundity of this once happy land, and the vast number of people that lived in it, almost wholly upon its product, to say nothing of the vast exports of its corn, wine, oil, raisins, and other fruits, &c. that a man must have taken a strange warp to infidelity, that can call it in question, merely on account of the melancholy and quite opposite figure it now makes under its present tyrannical government.

But it ought to be considered, that it was then inhabited by an industrious people, who knew how to improve every inch of their land, and had made even the most desert and barren places to yield some kind of productions, by proper care and manure: so that the very rocks, which now appear quite bare and naked, were made to produce corn, pulse, or pasture; being, by the industry of the old inhabitants, covered with mould, which, through the laziness of the succeeding proprietors, has been since washed off with rains and storms. We may add, that the kings themselves were not above encouraging all kind of agriculture, both by precept and example; and, above all,

that they had the divine blessing promised to their honest endeavours and industry: whereas it is now, and hath been long since, inhabited by a poor, lazy, indolent people, groaning under an intolerable servitude and all manner of discouragements; by which their aversion to labour and agriculture, farther than what barely serves to supply their present wants, is become, in a manner, natural and invincible. We may farther observe, after the judicious Mr Maundrell, that there is no forming an idea of its ancient flourishing state, when under the influence of heaven, from what it is now under a visible curse. And, if we had not several concurring testimonies from profane authors, who have extolled the fecundity of Palestine, that single one of Julian the apostate, a sworn enemy to Jews and Christians, as well as to all the sacred writings, would be more than sufficient to prove it; who frequently makes mention, in his epistles, of the perpetuity, as well as excellence and great abundance, of its fruits and product. The visible effects of God's anger, which this country has felt, not only under Titus Vespasian (when myriads of inhabitants were either slain, or perished by the most severe famine, pestilence, and other calamities; and the rest sold for slaves, into all lands; and new colonies sent to re-people it; who found it in such a desolate state, as quite discouraged them from restoring it to its pristine fruitfulness); but much more since that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and destructive Christians during the holy war; and in the oppression it now feels under the Turkish yoke; may be easily owned to be more than sufficient to have wrought the dismal change we are speaking of, and to have reduced the far greater part into a mere desert.

Nevertheless, if we may credit those who have viewed it in this doleful condition, they will tell us, there are still such visible signs of its natural richness and fertility, as plainly shew, that the bare want of culture is the main, if not the only cause of its present poverty and barrenness. We shall hint, as a further proof of this, what a learned traveller hath lately written of it from his own observations.

"The Holy Land," says Dr Shaw, "were it as well peopled and cultivated as in former times, would still be more fruitful than the very best part of the coast of Syria and Phœnice; for the soil is generally much richer, and, all things considered, yields a more preferable crop. Thus the cotton that is gathered in the plains of Ramah, Edsraelon, and Zabulon, is in greater esteem than what is cultivated near Sidon and Tripoli. Neither is it possible for pulse, wheat, or any sort of grain, to be more excellent than what is sold at Jerusalem. The barrenness, or scarcity rather, which some authors may, either ignorantly or maliciously, complain of, doth not proceed from the incapacity or natural unfruitfulness of the country, but from the want of inhabitants, and the great aversion there is to labour and industry in those few who possess it. There are, besides, such perpetual discords and depredations among the petty princes who share this fine country, that, allowing it was better peopled, yet there would be small encouragement to sow, when it was uncertain who should gather in the harvest. Otherwise, the land is a good land, and still

**Palestina** still capable of affording its neighbours the like supplies of corn and oil which it is known to have done in the time of Solomon.

**Palingenius**

**PALESTRINA**, a town of Italy, in the Campagna di Roma, with a bishop's see. It is the capital of a principality of the same name, and the bishop is one of the six cardinals. It was anciently famous for the temple of Fortune, being then called *Præneste*, and seated on the top of a mountain, the ruins of which may yet be seen. E. Long. 12. 55. N. Lat. 41. 51.

**PALESTRINA**, is one of the largest and most populous of the islands called the *Lagunes*, near Venice, and where the most considerable of the noblemen have houses of pleasure. It is 15,000 paces in length, and 400 in breadth; the principal harbour has also the same name.

**PALFIN** (John), an eminent surgeon, anatomist, and reader in surgery at Ghent, the place of his birth; acquired great reputation by his learning and works. The principal of these are, 1. A treatise on Osteology, in 12mo, Paris 1731. 2. Anatomy of the human body, in 2 vols 8vo, Paris 1734. He died at Ghent at a great age, in 1730.

**PALFREY**, is one of the better sort of horses used by noblemen or others for state; and sometimes of old taken for a horse fit for a woman to ride. Camden says, that William Fauconberge held the manor of Cokeny, in the county of Nottingham, in fergeantry, by the service of shoeing the king's palfrey when the king should come to Mansfield.

**PALICATE**, a sea-port town of India, on this side of the Ganges. It is seated on the coast of Comorandel, in the kingdom of Carnate, 70 miles north of Fort St George. Here the dutch have a factory, and fort called the *Fort of Guelderland*. E. Long. 80. 1. N. Lat. 13. 34.

**PALINURI PROMONTORIUM**, (Virgil, Velleius,) with a cognominal port, was situated at the south extremity of the Sinus Pæstanus, on the coast of Lucania; so called from Palinurus, Æneas's steersman, who there perished. (Mela, Dionysius Halicarnassæus.)

**PALINDROMUS**, a verse or sentence which runs the same when read either backwards or forwards. Such is the verse,

*Roma tibi subito motibus ibi amor.*

Some people of leisure have refined upon the Palindromus, and composed verses, each word of which is the same backwards as forwards; for instance, that of Camden:

*Odo tenet mulum, madidam nappam tenet Anna.*

*Anna tenet nappam madidam, nulum tenet Odo.*

**PALINGENESIA**, among divines, the same with regeneration. Among chemists, it denotes the producing of a body from its principles.

**PALINGENIUS** (Marcellus), well known by a poem divided into 12 books, and intitled *Zodiacus Vitæ*, which he was several years of composing, and dedicated to Hercules II. of Este, duke of Ferrara. Some say he was physician to the prince: others rank him among the learned Lutherans to whom the dukes of Ferrara gave a reception in her court and honoured with her protection. His *Zodiac* contains good things, and is a philosophical satire against immorality and false prejudices. Though this poem has borne a

multitude of impressions, the author's life is but little known. He died some time between the years 1537 and 1543.

**PALINODY**, a discourse contrary to a preceding one: hence the phrase of *palinodiam canere* was taken for a recantation.

**PALISADES**, in fortification, stakes made of strong split wood, about nine feet long, six or seven inches square, three feet deep in the ground, in rows about two and an half or three inches asunder, placed in the covert way, at three feet from, and parallel to, the parapet or side of the glacies, to secure it from surprise. They are also used to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, and in general all posts liable to surprise. They are usually fixed perpendicularly, though some make an angle inclining towards the ground next the enemy, that the ropes cast over them to tear them up may slip off.

**Turning PALISADES**; an invention of Mr Coehorn, in order to preserve the palisades of the covert way from the besiegers' shot. They are so ordered, that as many of them as stand in the length of a rod, or about ten feet, turn up and down like traps, so as not to be in sight of the enemy till they just bring on their attack; and yet are always ready to do the proper service of palisades.

**PALISSE**, in heraldry, a bearing like a range of palisades before a fortification, represented on a fesse, rising up a considerable height, and pointed a-top, with the field appearing between them.

**PALIURUS**, in botany. See *RHAMNUS*.

**PALL**, in heraldry, a figure like a Greek  $\pi$ , about the breadth of a pallet; it is by some heralds called a *cross-pall*, on account of its being looked upon as an archiepiscopal bearing.

**PALLA**, in Roman antiquity, a mantle which women wore over the gown called *stola*. It was borne on the left shoulder; whence passing to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare.

**PALLADIO** (Andrea), a celebrated Italian architect of the 16th century, was a native of Vicenza in Lombardy, and the disciple of Trissin. He made exact drawings of the principal works of antiquity to be met with at Rome, adding commentaries to them, which went through several impressions. But this, though a very useful work, was greatly exceeded by the Treatise of Architecture in four books, which he published in 1570. Inigo Jones wrote some excellent remarks on it; which were included in an edition of Palladio, published by Leoni, in 2 vols folio, 1742.

**PALLADIUM**, in antiquity, a statue of the goddess Pallas, supposed to have dropped down from heaven, preserved in Troy, whereon the fate of that city is said to have depended. It is said that there was anciently a statue of Pallas preserved at Rome, in the temple of Vesta, which some pretended to be the true palladium of Troy, brought into Italy by Æneas: it was kept among the sacred things of the temple, and only known to the priests and vestals. It was esteemed the destiny of Rome; and there were several others made perfectly like it to secure it from being stolen,

**Palinody**

**Palladium**

Pallet  
||  
Palm.

as was that at Troy, which the oracle of Apollo declared should never be taken so long as the palladium was found within its walls: this occasioned Diomedes and Ulysses, in the time of the Trojan war, to undertake the stealing of it.

**PALLET**, among painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which, the painters place the several colours they have occasion for, to be ready for the pencil. The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but, instead thereof, a hole at one end to put the thumb through to hold it.

**PALLET**, among potters, crucible-makers, &c. a wooden instrument, almost the only one they use, for forming, heating, and rounding their works. They have several kinds: the largest are oval, with a handle; others are round, or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off whatever is superfluous on the moulds of their work.

**PALLET**, in gilding, an instrument made of a squirrel's tail, to take up the gold leaves from the pillow, and to apply and extend them on the matter to be gilt. See **GILDING**.

**PALLET**, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

**PALLET**, is also a part belonging to the balance of a watch or movement. See the article **WATCH**.

**PALLIATION**, or a **PALLIATIVE Cure**, in medicine, is when, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain or some other urgent symptoms, as in ulcerated cancers, or cancerous fistulas, and the like.

**PALLIUM**, a word often mentioned in our old historians. Durandus tells us, that it is a garment made of white wool, after the following manner, viz. The nuns of St Agnes, every year, on the feast-day of their saint, offer two white lambs on the altar of their church, during the time they sing *Agnus Dei*, in a solemn mass; which lambs are afterwards taken by two of the canons of the Lateran church, and by them given to the Pope's subdeacons, who send them to pasture till shearing time, and then they are shorn, and the pall is made of their wool mixed with other white wool. The pall being thus made, is carried to the Lateran church, and there placed on the high altar, by the deacons of that church, on the bodies of St Peter and St Paul; and after an usual watching, it is carried away in the night, and delivered to the subdeacons, who lay it up safe. And because it was taken from the body of St Peter, it signifies the plenitude of ecclesiastical power: and therefore it was the prerogative of popes, who pretend to be the immediate successors of that saint, to invest other prelates with it; which at first was done nowhere but at Rome, tho' afterwards at other places.

**PALM-SUNDAY**, in the Christian church, the Sunday next before Easter; being so called in memory of our Saviour's triumphal entry into Jerusalem, when the multitude that attended him threw branches on his way.

VOL. VIII.

Palm  
||  
Palmyra.

**PALM-Tree**, in botany. See **PHOENIX**.

**PALMA**, or **PALMA Noca**, a very strong town of Italy, in the territory of Venice, and in Friuli. It is a very important place, for the defence of the Venetians against the Austrians and Turks; and was built in 1593, for that very purpose. They have cut a canal near this place, which is very advantageous. It is seated on the sea-side, 10 miles south-east of Udino, and 55 north-east of Venice. E. Long. 13. 25. N. Lat. 46. 2.

**PALMA**, an island in the Atlantic Ocean, and one of the Canaries, 36 miles north-west of Gomera, and about 75 in circumference. It abounds in wine and sugar; and has a handsome town of the same name, which carries on a trade in wine to the West Indies and other parts. Their best vines grow in a soil called the *Brenia*, where they make 12,000 butts of wine every year, which is well known by the name of *palm-wine*. There is plenty of cattle, and all sorts of fruits. In 1625 a volcano broke out in this island, with a most violent earthquake; the flame was seen for six weeks together, and a great quantity of ashes were thrown as far as Teneriff. It was conquered by the Spaniards in 1460.

**PALMARIS MUSCLE**, in anatomy. See there, *Table of the muscles*.

**PALMATED**, something resembling the shape of the hand: thus we say, palmated leaves, roots, stones, &c.

**PALMPIEDES**, among ornithologists, the same with web-footed birds. See **ORNITHOLOGY**.

**PALMISTRY**, a kind of divination, or rather a deceitful art practised by gypsies, who pretend to foretell events by looking upon the lines and marks of the hand.

**PALMYRA**, or **TADMOR**, a noble city of ancient Syria, now in ruins, the origin of whose name is uncertain. Neither is it well known by whom this city was built; for though, from the identity of the names, it is thought by many to have been the *Tadmor in the wilderness* built by Solomon, this point is much controverted by many learned men. Nor have we any authentic history of it till after the captivity of the Roman emperor, Valerian, by the Persians. At that time it was become an opulent city, to which its situation in the vicinity of the Roman and Parthian empires greatly contributed; as the caravans, in going to or returning from the East, frequented the place, and thus rendered it a considerable seat of merchandise. It enjoyed an independency till the time of Trajan; who, having made himself master of almost all the Parthian empire, reduced Palmyra likewise, and it was afterwards accounted part of the Roman dominions. But when the defeat and captivity of Valerian had so much weakened the empire, that the Persians seemed to be in a fair way of becoming masters of all the eastern provinces, the Palmyrenians began to entertain thoughts of recovering their liberty. Odenathus, prince of Palmyra, sent a very respectful letter to Sapor on his return, accompanied with considerable presents; but by that haughty conqueror his letter and embassy were treated with the most provoking contempt. The presents were thrown into the Euphrates: and to his letter Sapor replied, That his insolence in presuming to write to his lord was inexcusable; but if he could

atone for it in any way, it would be by presenting himself before the throne bound hand and foot, in token of a consciousness of his crime, and the punishment he deserved. With this injurious treatment Odenathus was so provoked, that he swore either to bring down the pride of the haughty conqueror, or die in the attempt. Accordingly, having assembled what forces he could, he fell upon the Persians, destroyed a number of them, took a great part of their baggage, and some of the king's concubines. Of the war of Odenathus with the Persians, however, we know very little: only that though the latter were often vanquished, and the independency of Palmyra established for the present; yet Valerian was never released from his captivity, tho' Odenathus earnestly wished to have the honour of refusing him from his enemies.

Odenathus enjoyed his sovereignty but a very short time; being murdered by his nephew, who was soon after put to death by Zenobia the wife of Odenathus. This lady is said to have been possessed of very extraordinary endowments both of body and mind, being, according to Mr Gibbon, almost the only Asiatic woman who is recorded to have overcome the obstacles arising from the confined situation of the fair sex in that part of the world. Immediately on taking vengeance for the murder of her husband, she assumed the government, and soon strengthened herself so much, that she resolved to submit neither to the Roman nor Persian power. The neighbouring states of Arabia, Armenia, and Persia, dreaded her enmity, and solicited her alliance. To the dominions of Odenathus, which extended from the Euphrates to the frontiers of Bithynia, his widow added the inheritance of her ancestors, the populous and fertile kingdom of Egypt. The emperor Claudius acknowledged her merit, and was content, that, while he pursued the Gothic war, she should assert the dignity of the empire in the east. The conduct, however, of Zenobia, was attended with some ambiguity; nor is it unlikely that she had conceived the design of erecting an independent and hostile monarchy. She blended with the popular manners of Roman princes the stately pomp of the courts of Asia, and exacted from her subjects the same adoration that was paid to the successors of Cyrus. She bestowed on her three sons a Latin education, and often shewed them to the troops adorned with the imperial purple. For herself she reserved the diadem, with the splendid but doubtful title of *Queen of the East*.

When Aurelian passed over into Asia, against an adversary whose sex alone could render her an object of contempt, his presence restored obedience to the province of Bithynia, already shaken by the arms and intrigues of Zenobia. Advancing at the head of his legions, he accepted the submission of Ancyra; and was admitted into Tyana, after an obstinate siege, by the help of a perfidious citizen. The generous, tho' fierce temper of Aurelian, abandoned the traitor to the rage of the soldiers; a superstitious reverence induced him to treat with lenity the countrymen of Apollonius the philosopher. Antioch was deserted on his approach; till the emperor, by his salutary edicts, recalled the fugitives, and granted a general pardon to all who, from necessity rather than choice, had been engaged in the service of the Palmyrenian queen. The unexpected mildness of such a conduct reconciled the minds of the

Syrians, and, as far as the gates of Emesa, the wishes of the people seconded the terror of his arms.

Zenobia would have ill deserved her reputation, had she indolently permitted the emperor of the West to approach within 100 miles of her capital. The fate of the East was decided in two great battles; so similar in almost every circumstance, that we can scarcely distinguish them from each other, except by observing that the first was fought near Antioch, and the second near Emesa. In both, the queen of Palmyra animated the armies by her presence, and devolved the execution of her orders on Zabdus, who had already signalized his military talents by the conquest of Egypt. The numerous forces of Zenobia, consisted for the most part of light archers, and of heavy cavalry clothed in complete steel. The Moorish and Illyrian horse of Aurelian were unable to sustain the ponderous charge of their antagonists. They fled in real or affected disorder, engaged the Palmyrenians in a laborious pursuit, harassed them by a desultory combat, and at length discomfited this impenetrable but unweildy body of cavalry. The light infantry, in the mean time, when they had exhausted their quivers, remaining without protection against a closer onset, exposed their naked sides to the swords of the legions. Aurelian had chosen these veteran troops, who were usually stationed on the Upper Danube, and whose valour had been severely tried in the Allemannic war. After the defeat of Emesa, Zenobia found it impossible to collect a third army. As far as the frontier of Egypt, the nations subject to her empire had joined the standard of the conqueror; who detached Probus, the bravest of his generals, to possess himself of the Egyptian provinces. Palmyra was the last resource of the widow of Odenathus. She retired within the walls of her capital; made every preparation for a vigorous resistance; and declared with the intrepidity of a heroine, that the last moment of her reign and of her life should be the same.

In his march over the sandy desert, between Emesa and Palmyra, the emperor Aurelian was perpetually harassed by the Arabs; nor could he always defend his army, and especially his baggage, from those flying troops of active and daring robbers, who watched the moment of surprise, and directed the slow pursuit of the legions. The siege of Palmyra was an object far more difficult and important; and the emperor, who with incessant vigour pressed the attacks in person, was himself wounded with a dart. "The Roman people," (says Aurelian, in an original letter), speak with contempt of the war which I am waging against a woman. They are ignorant both of the character and of the power of Zenobia. It is impossible to enumerate her warlike preparations, of stones, of arrows, and of every species of missile weapons. Every part of the walls is provided with two or three ballistæ, and artificial fires are thrown from her military engines. The fear of punishment has armed her with a desperate courage. Yet I trust still in the protecting deities of Rome, who have hitherto been favourable to all my undertakings." Doubtful, however, of the protection of the gods, and of the event of the siege, Aurelian judged it more prudent to offer terms of an advantageous capitulation: to the queen, a splendid retreat; to the citizens, their ancient privileges. His proposals were obstinately rejected,

jected, and the refusal was accompanied with insult. The firmness of Zenobia was supported by the hope, that in a very short time famine would compel the Roman army to repass the desert; and by the reasonable expectation that the kings of the East, and particularly the Persian monarch, would arm in the defence of their most natural ally. But fortune, and the perseverance of Aurelian, overcame every obstacle. The death of Sapor, which happened about this time, distracted the councils of Persia; and the inconsiderable succours that attempted to relieve Palmyra, were easily intercepted either by the arms or the liberality of the emperor. From every part of Syria a regular succession of convoys safely arrived in the camp, which was increased by the return of Probus with his victorious troops from the conquest of Egypt. It was then that Zenobia resolved to fly. She mounted the fleetest of her dromedaries; and had already reached the banks of the Euphrates, about 60 miles from Palmyra, when she was overtaken by the pursuit of Aurelian's light-horse, seized, and brought back a captive to the feet of the emperor. Her capital soon after surrendered, and was treated with unexpected lenity. The arms, horses, and camels, with an immense treasure of gold, silver, silk, and precious stones, were all delivered to the conqueror; who, leaving only a garrison of 600 archers, returned to Emesa, and employed some time in the distribution of rewards and punishments at the end of so memorable a war, which restored to the obedience of Rome those provinces that had renounced their allegiance since the captivity of Valerian.

When the Syrian queen was brought into the presence of Aurelian, he sternly asked her, How she had presumed to rise in arms against the emperors of Rome? The answer of Zenobia was a prudent mixture of respect and firmness: "Because I disdained to confide as Roman emperors, an Aurelius or a Galienus. You alone I acknowledge as my conqueror and my sovereign." But as female fortitude is commonly artificial, so it is seldom steady or consistent. The courage of Zenobia deserted her in the hour of trial; she trembled at the angry clamours of the soldiers, who called aloud for her immediate execution; forgot the generous despair of Cleopatra, which she had proposed as her model; and ignominiously purchased life by the sacrifice of her fame and her friends. It was to their counsels which governed the weakness of her sex, that she imputed the guilt of her obstinate resistance; it was on their heads that she directed the vengeance of the cruel Aurelian. The fame of Longinus, who was included among the numerous and perhaps innocent victims of her fear, will survive that of the queen who betrayed, or the tyrant who condemned him. Genius and learning were incapable of moving a fierce unlettered soldier, but they had served to elevate and harmonise the soul of Longinus. Without uttering a complaint, he calmly followed the executioner, pitying his unhappy mistress, and bestowing comfort on his afflicted friends.

Returning from the conquest of the East, Aurelian had already crossed the streights which divide Europe from Asia; when he was provoked by the intelligence that the Palmyrenians had massacred the governor and garrison which he had left among them, and again

erected the standard of revolt. Without a moment's deliberation, he once more turned his face towards Syria. Antioch was alarmed by his rapid approach, and the helpless city of Palmyra felt the irresistible weight of his resentment. We have a letter of Aurelian himself, in which he acknowledges, that old men, women, children, and peasants, had been involved in that dreadful execution, which should have been confined to armed rebellion: and although his principal concern seems directed to the re-establishment of a temple of the Sun, he discovers some pity for the remnant of the Palmyrenians, to whom he grants the permission of rebuilding and inhabiting their city. But it is easier to destroy than to restore. The seat of commerce, of arts, and of Zenobia, gradually sunk into an obscure town, a trifling fortress, and at length a miserable village. The ruins of its temples, palaces, and porticos of Grecian architecture, lie scattered over an extent of several miles. These magnificent remains were accidentally discovered by some English travellers from Aleppo about a century ago; and most splendid views have since been given of them by Messrs Wood and Dawkins, to whose work the curious reader is referred.

PALPABLE, something perceivable by the senses, particularly that of feeling.

PALPITATION of the Heart. See MEDICINE, n° 206. 395.

PALSY. Ibid. n° 190. 377—380. & p. 4870.

PALUDAMENTUM, in Roman antiquity, a habit that differed but little from the chlamys, except that his last belonged chiefly to the lower class of people.

PALUS MEOTIS, the ancient name of a gulph between Europe and Asia, to the north of the Black Sea, now called the *sea of Zabach*, or *Asoph*.

PALY, or PALE, in heraldry, is when the shield is divided into four or more equal parts, by perpendicular lines falling from the top to the bottom.

PALY Bende, is when the escutcheon is divided by perpendicular lines, which is *paly*; and also by diagonals, which is called *bendy*.

PAMPELUNA, the capital of the kingdom of Navarre in Spain, with a very strong citadel and rich bishopric. It is handsome and populous, and carries on a great trade, seated in a very fertile plain, in E. Long. 1. 25. N. Lat. 42. 42.

PAMPELUNA, a town of New Granada in South America, famous for its gold mines and numerous flocks of sheep. W. Long. 68. 30. N. Lat. 6. 30.

PAMPHYLLIA, the ancient name of a country of Natolia in Asia, now called *Carmania* and *Cay-bay*, between Lycia and Cilicia, on the south coast, to the north of the Mediterranean sea.

PAN, in Pagan worship, the son of Mercury and Penelope (the wife of Ulysses), who was ravished by that god in the form of a white goat, while he was keeping her father's flocks. He was educated on Mount Menelaus, in Arcadia, by Sinoe, and the other nymphs, whom he attracted by his music. He afterwards distinguished himself in the war with the giants, when he entangled Typhon in his nets. He attended Bacchus in his Indian expedition; and when the Gauls were about to pillage the temple of Delphos, he struck them with such a sudden conformation by night, that they fled,

Pan.

though none pursued them. He had a contest with Cupid; but was conquered by the little god, who punished him, by inspiring him with a passion for the nymph Syrinx, who treated him with disdain; but he closely pursuing her, overtook her by the river Ladon, when, invoking the Naiads, she was changed into a tuft of reeds, which the disappointed lover grasped in his arms; but observing, that as they trembled with the wind, they formed a murmuring sound, he made of them the pipe for which he became so famous. He charmed Luna in the shape of a beautiful ram, and had several other amours.

Pan is represented with a smiling ruddy face, a thick beard, with the horns, legs, feet, and tail of a goat; holding a shepherd's crook in one hand, and his pipe of unequal reeds in the other.

The abbe Banier remarks, that if ever the Greeks corrupted ancient history, it was in fabricating the fable of Pan. According to them, says Herodotus, Hercules Dionysius, or Bacchus, and Pan, were the last of all the gods; however, in the opinion of the Egyptians, Pan was one of the eight great divinities that formed the first class in their theology, which were the most powerful and the most ancient of all.

Diodorus makes him one of the attendants upon Osiris, in his Indian expedition. "Osiris," says this author, "took with him Pan, a person much respected throughout his dominions: for he had not only his statue afterwards placed in all the temples, but a city was built in the Thebaid; which, in honour of Pan, was called *Chennis*, or *Channio*, a word that signifies in the Egyptian language the city of Pan."

The same author, however, tells us, that he was the leader of a troop of fauns and satyrs, or wild and rustic men, much addicted to singing, dancing, and feats of activity, who were presented to Osiris in Ethiopia, and with whom that prince was so much pleased, that he retained them in his service.

Pan was regarded by the Egyptians, after his apotheosis, as the god who presided over the whole universe, as *Pan, omne*, implies. He represented nature and fertility; and was god of the woods and fields, wholly taken up with the pleasures of a country life; dancing constantly with the fauns and satyrs; and running after the nymphs, to whom he was such a terror, that it is supposed the word *panic* is derived from *Panici terrores*, with which those who were said to have seen him were seized. Apuleius, however, gives an agreeable description of him. "By chance the god Pan happened to be seated on a little eminence near a river; and, always constant in his love to the nymph Syrinx, transformed into a reed, he taught her to produce all kinds of agreeable sounds, while his goats were skipping round him, and feeding on the banks."

Lucian describes him as the companion, minister, and counsellor of Bacchus. He was a kind of Scrub, a drudge fit for all work, having been occasionally employed in the capacity of shepherd, musician, dancer, huntsman, and soldier. In short, he served not only as *maestro di capello*, in directing the Bacchanals, but was so expert in playing upon flutes, and was such an excellent piper on the fiddle, that Bacchus was never happy without him.

He was particularly honoured in Arcadia, where the shepherds offered him milk and honey in wooden

bowls: when successful in hunting, they gave him a part of the spoils; but if they caught nothing, they shewed their repentment by whipping his image.

The Romans adopted him amongst their deities under the names of *Lupercus* and *Lycæus*.

PANACEA, among physicians, denotes an universal medicine, or a remedy for all diseases; a thing impossible to be obtained.

PANADA, a diet consisting of bread boiled in water to the consistence of pulp, and sweetened with a little sugar.

PANAMA, the capital city of the province of Darien in South America, where the treasures of gold and silver, and the other rich merchandises of Peru, are lodged in magazines till they are sent to Europe. W. Long. 82. o. N. Lat. 9. o.

This town, which had been the gate through which an entrance was gained into Peru, had risen to great prosperity, when, in 1670, it was pillaged and burnt by pirates. It was rebuilt on a more advantageous spot, at the distance of four or five miles from the first. Its harbour, called *Perico*, is very secure. It is formed by an archipelago, consisting of 48 small islands, and is capable of containing the largest fleets.

This place, a little while after it was founded, became the capital of the kingdom of Terra Firma. Some hopes were at first entertained from the three provinces of Panama, Darien, and Veragua, which composed it; but this prosperity vanished instantaneously. The savages of Darien recovered their independence; and the mines of the two other provinces were found to be neither sufficiently abundant, nor of an alloy good enough to make it worth while to work them. Five or six small boroughs, in which are seen some Europeans quite naked, and a very small number of Indians, who have come to reside there, form the whole of this state, which the Spaniards are not ashamed of honouring with the great name of kingdom. It is in general barren and unwholesome, and contributes nothing to trade but pearls.

The pearl fishery is carried on in the islands of the gulph. The greatest part of the inhabitants employ such of their negroes in it as are good swimmers. These slaves plunge and replunge in the sea in search of pearls, till this exercise has exhausted their strength or their spirits.

Every negro is obliged to deliver a certain number of oysters. Those in which there are no pearls, or in which the pearl is not entirely formed, are not reckoned. What he is able to find beyond the stipulated obligation, is considered as his indisputable property: he may sell it to whom he pleases; but commonly he cedes it to his master at a moderate price.

Sea monsters, which abound more about the islands where pearls are found than on the neighbouring coasts, render this fishing dangerous. Some of these devour the divers in an instant. The manta fish, which derives its name from its figure, surrounds them, rolls them under its body, and suffocates them. In order to defend themselves against such enemies, every diver is armed with a poinard: the moment he perceives any of these voracious fish, he attacks them with precaution, wounds them, and drives them away. Notwithstanding this, there are always some fishermen destroyed, and a great number crippled.

Panacea

Panama.

Panari  
Panak.

The pearls of Panama are commonly of a very fine water. Some of them are even remarkable for their size and figure: these were formerly sold in Europe. Since art has imitated them, and the passion for diamonds has entirely superseded or prodigiously diminished the use of them, they have found a new mart more advantageous than the first. They are carried to Peru, where they are in great estimation.

This branch of trade has, however, infinitely less contributed to give reputation to Panama, than the advantage which it hath long enjoyed of being the mart of all the productions of the country of the Incas, that are destined for the old world. These riches, which are brought hither by a small fleet, were carried, some on mules, others by the river Chagre, to Porto Bello, that is situated on the northern coast of the isthmus which separates the two seas.

PANARI, one of the Lipari islands lying in the Tuscan Sea. It is only five miles in circumference, and the soil is barren. E. Long. 15. o. N. Lat. 39. o.

PANARO, a river of Italy, which rises in the Appennines, crosses the valley of Frignano; and running on the confines of the Modenese and Bolognese, waters Fenal, and falls into the Po at Bondeno, ten miles above Ferrara.

PANATHENÆA, in Grecian antiquity an ancient Athenian festival, in honour of Minerva the protectress of Athens, and called *Athenæa*. There were two festivals under this denomination, the greater and the lesser. The greater panathenæa were exhibited every five years; the lesser every three, or, according to some writers, annually. Though the celebration of neither, at first, employed more than one day; yet in after-times they were protracted for the space of many days, and solemnized with greater preparations and magnificence than at their first institution.

Prizes were established there for three different kinds of combat: the first consisted of foot and horse races; the second, of athletic exercises; and the third, of poetical and musical contests. These last are said to have been instituted by Pericles. Singers of the first class, accompanied by performers on the flute and cithara, exercised their talents here, upon subjects prescribed by the directors of these exhibitions. And while the Athenian state was free and independent, the noble and generous actions of Harmodius and Aristogiton, who had opposed the power of the Pisistratids, and of Aristobulus, who had delivered the Athenians from the oppression of the thirty tyrants imposed upon them by the Lacedæmonians, were celebrated in these songs.

PANAX, GINSENG, a genus of the dioecia order, belonging to the polygamia class of plants. There are two species, the quinquefolium and trifolium. Both these are natives of North America. The former is generally believed to be the same with the Tartarian ginseng; the figures and descriptions of that plant which have been sent to Europe by the missionaries, agreeing perfectly with the American Plant. This hath a jointed, fleshy, and taper root, as large as a man's finger, frequently divided into two smaller fibres downwards. The stalks rises near a foot and an half high, and is naked at the top, where it gene-

rally divides into three smaller foot-stalks, each sustaining a leaf composed of five spear-shaped lobes, sawed on their edges: they are of a pale green, and a little hairy. The flowers grow on a slender foot-stalk, just at the division of the foot-stalks which sustain the leaves, and are formed into a small umbel at the top; they are of an herbaceous yellow colour, composed of small yellow petals, which are recurved. These appear the beginning of June; and are succeeded by compressed, heart-shaped berries, which are first green, but afterwards turn red; inclosing two hard, compressed, heart-shaped seeds, which ripen in the beginning of August. The second sort grows naturally in the same countries: but Mr Miller never saw more than one plant, which was sent to him from Maryland, and did not live beyond the first year; being planted in a dry soil, in a very dry season. The stalk was single, and did not rise more than five inches in height, dividing into three foot-stalks, each sustaining a trifoliate leaf, whose lobes were longer, narrower, and deeper indented on their edges, than the former. The flower-stalk rose from the divisions of the foot-stalk of the leaves; but before the flowers opened, the plant decayed.

*Properties.* The root of this plant is used in medicine. It is two or three inches long, taper, about the thickness of the little finger, often forked at the bottom, which gives it a distant resemblance of a man, whence it is called *gingeng*; it is elegantly striated with circular wrinkles; it is of a brownish yellow colour on the outside, and whitish or of a pale yellow within; on the top are commonly one or more little knots, which are the remains of the stalks of the preceding years, and from the number of which the age of the root is judged of. Those roots which are brought from China are somewhat paler than those from America, but in no other respect is any difference found.

The Chinese esteem the ginseng root as a general restorative and corroborant: to the taste it is mucilaginous, and sweet like liquorice; yet accompanied with a degree of bitterness and a slight aromatic warmth, with little or no smell: the sweet matter of these roots is preserved in the watery as well as in the spirituous extract, and so is their aroma; the spirituous extract is a pleasant warm bitterish sweet.

A dram of the ginseng root may be sliced and boiled in a quarter of a pint of water to about two ounces; then a little sugar being added, it may be drank as soon as it is cool enough: the dose must be repeated morning and evening; but the second dose may be prepared from the same portion of root which was used at first, for it may always be twice boiled. The plant has been introduced into the British gardens, and will thrive in those places where it hath a light soil and shady situation, and will produce flowers and seeds; but the latter, though in appearance ripe and perfect, will not produce any new plants, as Mr Miller says he has repeatedly made the experiment, and waited for them three years without disturbing the ground.

PANAY, an island of Asia, and one of the Philippines, lying between those of Paragoa and Negro. It is 250 miles in circumference, and is the most populous and fertile of them all. It is watered by a great

Panari,  
Panay.

**Panacarpus** great number of rivers and brooks, and produces a great quantity of rice.

**Pandora.**

**PANACARPUS**, in Roman antiquity, a kind of shew which the Roman emperors frequently exhibited to the people. In this spectacle, the Circus being all fet over with large trees, represented a forest, into which the beasts being let from the dens underground, the people, at a sign given by the emperor, pursued, shot, and killed all they could lay hold of, which they afterwards carried away, to regale upon at home. The beasts usually given on these occasions were boars, deers oxen, and sheep.

**PANCIROLLUS** (Guy), a famous lawyer of Rhegium, was a person of an excellent genius, which he cultivated with the greatest care in the principal universities of Italy; and was afterwards ordinary professor of law at Padua. Philibert Emanuel, duke of Savoy, invited him to his university in 1571, where he composed his ingenious treatise *De rebus inventis et deperditis*. But the air of Turin not agreeing with him, he there lost an eye; and, for fear of losing the other, returned to Padua, where he died in 1591.

**PANCREAS**, in anatomy. See there, n° 356.

**PANDATARIA**, (Suetonius, Pliny, Strabo); *Pandateria*, (Mela, Tacitus): An island in the Tuscan sea; a place of banishment for the more illustrious exiles. Hither Julia, the daughter of Augustus, was banished for her incontinence. To this island Tiberius banished Agrippina, his daughter-in-law, (Suetonius). It was the place of confinement of Octavia, the daughter of Claudius, married to Nero; a sight that affected every eye, (Tacitus). Now *Santa Maria*, situate between Pontia and Ichia, (Hollenius).

**PANDECTS**, **PANDECTÆ**, in jurisprudence, the digest, or collection, made by Justinian's order, of 529 decisions or judgments of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by the epistle prefixed to them.—The word is Greek, *Πανδectes*, compounded of *παν*, "all," and *δικομαι*, *capio*, "I take;" *q. d.* a compilation, or a book containing all things.—Though others, as Bartoli, will have it formed from *παν*, and *δικομαι*, as if these books contained the whole doctrine of the law.

The pandects consist of 50 books, and make the first part of the body of the civil law.

They were denoted by two *¶¶*; but the copists taking those *¶¶* for *ff*, the custom arose of quoting them by *ff*.

The *Florentine pandects*, are those printed from a famous ancient manuscript at Florence.

Papias extends the denomination of *pandects*, to the Old and New Testament.

There are also *Pandecta Medicinæ*, "Pandects of Medicine;" a kind of dictionary of things relating to medicine, compiled by Mat. Sylvaticus of Mantua, who lived about the year 1297. Leunclavius has published *Pandects of Turkey*; and bishop Beveridge, *Pandecta canonum*.

**PANDICULATION**, a stretching; or that violent and tense motion of the solids, which usually accompanies the act of yawning.

**PANDORA**, in fabulous history, a woman formed by Prometheus, to whom each of the gods gave some

perfection. Venus bestowed upon her beauty; Pallas, wisdom; Juno, riches; Apollo, music; and Mercury, eloquence; but Jupiter being displeased at Prometheus for having stolen fire from heaven to animate the mass he had formed, gave Pandora a box, which she was ordered not to open; and then sent her to the earth with this box, in which were inclosed age, diseases, pestilence, war, famine, envy, discord, and all the evils and vices that could afflict mankind. This fatal box was opened by Epimetheus, Prometheus's brother, when instantly all the diseases and mischiefs with which it was filled spread over the earth, and Hope alone remained at the bottom.

**PANDOURS**, are Hungarian infantry: they wear a loose garment fixed tight to their bodies by a girdle, with great sleeves, and large breeches hanging down to their ancles. They use fire-arms, and are excellent marksmen: they also use a kind of sabre near four feet long, which they use with great dexterity.

**PANDOSIA**, (Livy, Justin, Strabo), an inland town of the Brutii, and a place of strength, on the river Acheron, where Alexander of Epirus, deceived by the oracle of Dodona, met his fate and perished. Now *Mendicino*, (Hollenius). Another of Epirus, (Strabo); situate on the river Acheron, (Livy); which Alexander of Epirus was advised to avoid as fatal, but which he met with in Italy. This last is said to have been the residence of the Oenotrian kings, (Strabo.)

**PANEAS**, (Pliny, Josephus); the apparent spring from which the Jordan rises, on the extremity of the west side of the Trachonitis, (Pliny).

**PANEAS**, (Coins, Pliny, Josephus), the name of a district adjoining to the spring *Paneas*, with a cognominal town, either enlarged and adorned, or originally built, by Philip son of Herod, and called *Cæsarea*, by Josephus; and in St Matthew, *Cæsarea of Philip*; with a temple erected to Augustus his benefactor, who conferred the Trachonitis upon him, (coin). It was afterwards called *Neronias*, in honour of Nero, (Josephus).

**PANEGYRIC**, an oration in praise of some extraordinary thing, person, or virtue.

The name is Greek, *πανηγυρις*; formed of *παν*, "all," and *αγορα*, "I assemble;" because anciently held in public and solemn assemblies of the Greeks, either at their games, their feasts, fairs, or religious meetings.

**PANEGYRICUM**, in church-history, an ecclesiastical book, used by the Greek church, containing the panegyric orations of various authors, on the solemnities of Jesus Christ and the saints.

Among the principal authors of this work are Athanasius, Cyrill, Basil, Chrysostom, &c.

**PANEL**, (*Panella*, *Panellum*), according to Sir Edw. Coke, denotes a little part; but the learned Spelman says, that it signifies *schedula vel pagina*, a "schedule or roll;" as a panel of parchment, or a counterpane of an indenture: but it is used more particularly for a schedule or roll, containing the names of such jurors as the sheriff returns to pass upon any trial. And the *impanelling* a jury is the entering their names in a panel, or little schedule of parchment.

**PANEL**, in Scots law, signifies the prisoner at the bar, or person who takes his trial before the court of judicatory for some crime.

**Pangonia** PANAGONIA, in natural history, the name of a genus of crystals, consisting of such as are composed of many angles.

**Pantheon.**

**PANIC**, denotes an ill-grounded terror or fright. See PAN.

**PANICLE**, in botany, denotes a soft woolly beard, on which the seeds of some plants, as millet, reeds, and hay.

**PANNELS of a SADDLE**, are two cushions or bolsters, filled with cows, deer, or horse's hair, and placed under the saddle, on each side, to prevent the bows and bands from galling the horse.

**PANNICULUS CARNOSUS**, in comparative anatomy, a robust fleshy tunic, situated in beasts between the skin and the fat; by means of which they can move their skin in whole or in part. It is altogether wanting in mankind.

**PANNONIA**, (Pliny, Strabo, Dio), an extensive country of Europe, having the Danube on the north, Dalmatia on the south, Noricum on the west, and Moesia on the east. It is divided in *superior* and *inferior*, (Ptolemy, Dio). The common boundary between both were the river Arabo and mount Cetus, having the superior to the west, and the inferior on the east side. This division is thought to be no older than the times of the Antonines. *Pannonicus* the epithet, (Martial).

**PANORMUS**, (Polybius, Pausanias), a town of Achaia, in Peloponnesus, near the promontory Rhium. —Another, (Ptolemy, Pliny), a town on the north side of Crete. —A third, (Ptolemy), in Macedonia, on the Egean sea, near mount Athos. —A fourth, of Samos, (Livy). —A fifth, of Sicily; an ancient city, built by the Phœnicians, (Thucydides); a principal town of the Carthaginians, (Polybius); situate between Lilybæus and Pelorus, (Mela) a Roman colony. Now *Palermo*, capital of the island, on the north side. E. Long. 13. N. Lat. 38. 30. —A sixth Panormus of the Thracia Chersonesus, placed by Pliny on the west side of the peninsula, and mentioned by no other writer.

**PANORMUS**, (Ptolemy), a port of Attica; its name denoting it to be capacious. —Another, of Epirus, (Strabo, Ptolemy); a large harbour in the heart of the Montes Cerauni, below the citadel Chimæra. —A third, of Ionia, (Strabo); near Ephesus, with the temple of the Ephesian Diana.

**PANORPA**, the SCORPION-FLY, in zoology, a genus of insects belonging to the order of neuroptera. The rostrum is horny and cylindrical; there are two pappi, and three stemonata; the feelers are longer than the thorax; and the tail of the male is furnished with a forceps. There are four species, distinguished by the colour and shape of their wings. They skip, and are found in meadows.

**PANTALARIA**, an island in the Mediterranean Sea, between Sicily and the main land of Africa, about 17 miles in circumference. It is near the coast of Tunis, and abounds in cotton, fruits, and wine; but the inhabitants are obliged to bring all their corn to Sicily, as it belongs to the king of the two Sicilies. E. Long. 12. 25. N. Lat. 36. 55.

**PANTALOON**, a sort of garment consisting of breeches and stockings all of one piece; said to have been first introduced by the Venetians.

**PANTHEON**, a beautiful edifice at Rome, anci-

ently a temple, dedicated to all the gods; but now converted into a church, and dedicated to the Virgin and all the martyrs.

This edifice is generally thought to have been built by Agrippa son-in-law to Augustus, because it has the following inscription on the frieze of the portico:

M. AGRIPPA L. F. COS. TERTIUM FECIT.

Several antiquarians and artists, however, have supposed that the pantheon existed in the times of the commonwealth; and that it was only embellished by Agrippa, who added the portico. Be this as it will, however, the pantheon when perfected by Agrippa was an exceedingly magnificent building; the form of whose body is round or cylindrical, and its roof or dome is spherical: it is 144 feet diameter within; and the height of it, from the pavement to the grand aperture on its top, through which it receives the light, is just as much. It is of the Corinthian order. The inner circumference is divided into seven grand niches, wrought in the thickness of the wall: six of which are flat at the top; but the seventh, opposite to the entrance, is arched. Before each niche are two columns of antique yellow marble fluted, and of one entire block, making in all 14, the finest in Rome. The whole wall of the temple, as high as the grand cornice inclusive, is cased with divers sorts of precious marble in compartments. The frieze is entirely of porphyry. Above the grand cornice arises an attic, in which were wrought, at equal distances, 14 oblong square niches: between each niche were four marble pilasters, and between the pilasters marble tables of various kinds. This attic had a complete entablature; but the cornice projected less than that of the grand order below. Immediately from the cornice springs the spherical roof, divided by bands, which cross each other like the meridians and parallels of an artificial terrestrial globe. The spaces between the bands decrease in size as they approach the top of the roof; to which, however, they do not reach, there being a considerable plain space between them and the great opening. That so bold a roof might be as light as possible, the architect formed the substance of the spaces between the bands, of nothing but lime and pumice stones. The walls below were decorated with lead and brass, and works of carved silver over them; and the roof was covered on the outside with plates of gilded bronze. There was an ascent from the springing of the roof to the very summit by a flight of seven flights; yet that it was difficult to judge of their merit, upon account of their elevated situation." The portico is composed of 16 columns of granite, four feet in diameter, eight of which stand in front, with an equal intercolumniation all along, contrary to the rule of Vitruvius, who is for having the space answering to the door of a temple, wider than the rest. On these columns is a pediment, whose tympanum, or flat, was ornamented with bas-reliefs in brass; the cross beams which formed the ceiling of the portico were covered with the same metal, and so were the doors. The ascent up to the portico was by eight or nine steps.

Such was the pantheon; the richness of which induced

Pantheon. eed Pliny to rank it among the wonders of the world.

The eruption of Vesuvius, in the reign of Tiberius, damaged the pantheon very considerably; it was repaired by Domitian, which occasioned some writers to mention that prince as the founder of the building. The emperor Adrian also did something to it. But it appears, that the pantheon is more indebted to Septimius Severus, than to any one since its erection. The most, perhaps, that any of his predecessors had done, was the adding some ornament to it: Septimius bestowed essential reparations upon it. The following inscription appears upon the architrave:

IMP. CAES. SEPTIMIUS. SEVERVS.  
PIVS PERTINAX.  
ARABICVS. PARTHICVS. PONTIF.  
MAX. TRIB. POT.  
XI. COS. III. P. P. ET. IMP. CAES.  
MARCVS.  
AVRELIVS. ANTONINVS. PIVS.  
FELIX. AVG. TRIB.  
POT. V. COS. PROCOS. PANTHEVM.  
VETVSTATI.  
OBRYPTVM. CVM. OMNI. CVLTV.  
RESTITVERVNT.

It is really a manner of alms-giving, that a structure, which, granting it to have been built by Agrippa, was not more than 200 years old, should have fallen into decay through age. This single consideration seems sufficient to confirm the opinion of those who believe it to have stood in the time of the commonwealth.

The temple subsisted in all its grandeur, till the incursion of Alaric in the time of Honorius. Zozyms relates, that the Romans having engaged to furnish this barbarian prince with 3000 pounds weight of gold, and 5000 pounds weight of silver, upon condition that he should depart from their walls; and it proving impossible to raise those sums either out of the public treasury or private purses, they were obliged to strip the temples of their statues and ornaments of gold and silver. It is probable that the pantheon supplied a good part, as that of Jupiter Capitolinus was the only one in Rome that could vie with it for riches.

Alaric carried off nothing from the Romans besides their precious metals. Thirty-nine years after this, Genseric king of the Vandals took away part of their marbles; and whether from a greediness of plunder, or from a relish of the productions of art, loaded one of his ships with statues. It cannot be questioned, but that on this occasion the pantheon was forced to part with more of its ornaments, and that the inestimable works of Diogenes became the prey of this Barbarian.

Before these unwelcome visits of the Goths and Vandals, the Christian emperors had issued edicts for demolishing the pagan temples. But the Romans, whatever were their motives, spared the pantheon, which is known to have suffered no damage from the zeal of the pontiffs, or the indignation of the saints, before the first siege of Rome by Alaric. It remained so rich till about the year 655, as to excite the avarice of Constantine II. who came from Constantinople to pillage the pantheon, and executed his purpose so far as to strip it both of its inside and outside brazen coverings, which he transported to Syracuse, where they soon after fell into the hands of the Saracens.

About 50 years before this, pope Boniface IV. had

obtained the pantheon of the emperor Phocas, to make a church of it. The artists of those days were totally ignorant of the excellence of the Greek and Roman architecture, and spoiled every thing they laid their hands upon. To this period, certain alterations are to be referred, of which we shall speak by and by.

After the devastations of the barbarians, Rome was contracted within a narrow compass: the seven hills were abandoned; and the Campus Martius, being an even plain, and near the Tyber, became the ground-plat of the whole city. The pantheon, happening to stand at the entrance of the Campus Martius, was presently surrounded with houses, which spoiled the fine prospect of it; and it was yet more deplorably disgraced by some of them which stood close to its walls. Pedlars shades were built even within its portico, and the intercolumniations were bricked up, to the irreparable damage of the matchless pillars, of which some lost part of their capitals, some of their bases, and others were chiseled out six or seven inches deep, and as many feet high, to let in posts. Which excavations are to this day half filled up with brick and mortar; a sad monument of the licentiousness of the vulgar, and of the stupid avarice of those who sold them the privilege to ruin the noblest piece of art in the world!

This disorder continued till the pontificate of Eugene IV. whose zeal for the decency of a consecrated place, prevailed upon him to have all the houses cleared away that incumbered the pantheon, and so the miserable barracks in the portico were knocked down.

From the time Constantius carried off the brass plating of the external roof, that part was exposed to the injuries of the weather, or at best was but slightly tiled in, till Benedict II. covered it with lead, which Nicholas V. renewed in a better style.

It does not appear that from this time to Urban VIII. any pope did any thing remarkable to the pantheon.

Raphael Urban, who had no equal as a painter, and who as an architect had no superior, left a considerable sum by his will for the reparation of the pantheon, where his tomb is placed. Perino de la Vague, Jacomo Udino, Annibale Carracci, Flamingo Vacca, and the celebrated Archangelo Corelli, did the same. All the ornaments within, that have any claim to be called good, are of the latter times; the paintings merit esteem; and the statues, though not master-pieces, do honour to sculpture, which alone is a proof that they are posterior to the 15th century.

But, with all the respect due to a pontiff, who was otherwise a protector, and even a praeficer of the arts, it were much to be wished that Urban VIII. had not known that the pantheon existed. The inscriptions cut at the side of the door inform us, that he repaired it; yet, at the same time that he built up with one hand, he pulled down with the other. He caused two bell-fries of a wretched taste to be erected on the ancient front work; and he diverted the portico of all the remains of its ancient grandeur, viz. the brazen covering of the cross beams, which amounted to such a prodigious quantity, that not only the vast baldachin, or canopy, of the confessional in St Peter's, was cast out of it, but likewise a great number of cannon for the castle of St Angelo. This pope, who was of the family of Barbarini, presented also as much of this metal to his nephew, as was sufficient for the decoration

Pantheon of his new palace; on which occasion this remarkable  
 Pantheum ||  
 Panthome pasquinade was stuck up,

*Quod non fecerunt Barbari fecere Barbarini.*

If ever gingle added force to wit, it was certainly in this instance.

It is surprising, that whilst all these operations were carrying on in the portico, he never once thought of repairing the damages which time had wrought in it! Of the 16 pillars which supported this magnificent pile, there were no more than 13 left; the three next the temple of Minerva had disappeared; with these the entablature and an angle of the front had tumbled down. There were not wanting in Rome fragments enough of antique columns that might have been put together and set up, to have prevented the downfall of a pile which deserved to stand as long as the world endured.

Alexander VII. did what Urban VIII. had neglected to do. At the same time that Bernini was constructing the colonnade of St Peter, this pontiff ordered search to be made for pillars to match those of the portico of the pantheon; and some were found not far from the French church of St Lewis, of the very same model. They were granite of the life of Ilva, and those of the portico were Egyptian granite; the colour, however, was the same, so that the effect was equal. The pope's zeal did not stop here; he caused all the old houses before the portico to be pulled down, and the soil and rubbish to be cleared away, which covered the steps, and even the bases of some of the pillars. He began covering the roof with marble, and raised a lantern over the aperture, to keep out rain; but death took him off before his project was completed. Clement IX. his successor, inclosed the portico within iron rails. Several later popes have added to its decorations, which were all in the taste of the times they were done in, and the body of the edifice and its architecture gained nothing from them. The main object of their holiness's liberality was the embellishment of the grand altar. One gave purple curtains, another beflowed silver tabernacles; others again vases, and superb dresses, suited to the solemn ceremonies of religion. All these might be called rich; but they had in no sense a tendency to retrieve the ancient majesty or original splendour of the temple. The true gusto of the ornaments was a little imitated at the revival of the arts. Good statues took place of the skeletons and squat figures that ridiculously disgraced the altars for the space of eight centuries. The paintings of Perugino, Cozza, and Gressi, covered the dull mosaics with which the Greeks of Constantinople had loaded the walls of most of the churches in Rome. The porphyry and the green and yellow antique, found among the old ruins, were employed to much advantage.

PANTHER, in zoology. See LEO.

PANTOMIME, Παντομιμος, among the ancients, a person who could imitate all kind of actions and characters by signs and gestures, without speaking.

The pantomimes made a part in the theatrical entertainments of the ancients; their chief employment was to express, in gestures and action, whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied. They were very ancient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato's time. In Rome

VOL. VIII.

1

it was so late as the time of Augustus before they made their appearance. As to their dress, it was various, being always suited as near as possible to that of the person they were to imitate. The crocata was much used among the Roman pantomimes, in which and other female dresses they personated women.

PANUCO, a town and province of North America, in New Spain, lying to the north of Mexico, with a bishop's see. There are veins of gold, and salt-works, which are the principal revenue of the inhabitants. It is seated near the mouth of a river of the same name, at a small distance from the Gulph of Mexico. W. Long. 100 5. N. Lat. 24. 0.

PAPA, a small but strong town of Lower Hungary, in the county of Vespri. It was taken from the Turks in 1683, after raising the siege of Vienna, and is subject to the house of Austria. It is seated on a mountain, near the river Marchaez, in E. Long. 18. 10. N. Lat. 47. 20.

PAPAYER, the Poppy; a genus of the monogynia order, belonging to the polyandria class of plants.

*Species.* 1. The somniferum, or somniferous common garden-poppy, rises with an upright smooth stalk, dividing or branching a yard or more high; garnished with large, deeply jagged, amplexicaule, smooth leaves; and terminated by large, spreading, dark-purple, and other coloured flowers, in the varieties, having smooth cups and capsules, flowering in June and July. There are a great many varieties, some of them extremely beautiful. The white officinal poppy is one of the varieties of this sort. It grows often to the height of five or six feet, having large flowers both singles and doubles, succeeded by capsules or heads as large as oranges, each containing about 8000 seeds. 2. The rheas, or wild globular-headed poppy, rises with an upright, hairy, multiflorous stalk branching a foot and an half high; garnished with long, pinnatifid, deeply cut, hairy leaves; the stalk terminated by many red and other coloured flowers in the varieties, succeeded by globular smooth capsules. The flowers appear in June. 3. The Cambricum, or Welsh poppy, has a perennial root, pinnated cut leaves, smooth, upright, multiflorous stalks a foot and an half high; garnished with small pinnated leaves, and terminated by many large yellow flowers, succeeded by smooth capsules. The flowers appear in June. 4. The orientalis, or oriental poppy, hath a large, thick, perennial root; long, pinnated, sawed leaves; upright, rough, uniflorous stalks, terminated by one deep red flower, succeeded by oval, smooth, capsules. The flowers appearing in May.

*Propagation.* All the kinds are hardy, and will prosper any where. The two first species being annual, are to be propagated only by seeds; but the two last by parting the roots as well as the seeds.

*Uses.* The somniferous quality of the white poppy is well known. This quality resides in the milky juice of the capsule containing the seeds, nor is it evaporated by drying the juice; hence the dried capsules are preserved in the shops for making the syrup. The inspissated juice itself is a kind of opium; and for an account of its virtues see the article OPIUM. The seeds also make a very agreeable emulsion, but have no soporific virtue.

PAPAW, or PAPA-TREE. See CARICA.—This tree

33 A

is

Pannico  
 ||  
 Papaw.

is male and female upon different roots: the flowers of the former are white, and of the latter yellowish. The tender buds of these last are preferred into sweetmeats; and the long mango-popo, which is said to be little inferior to an East India mango, into pickles. When nearly ripe, the fruits are likewise boiled and eaten with any kind of flesh-meat, care being taken previously to cleanse them of the milky corrosive juice contained in them, which is of so penetrating a nature, says Hughes, that if the unripe fruit, when unpeeled, is boiled with the toughest old salt meat, it will soon make it soft and tender; and, if hogs are for any considerable time fed with the raw fruit, it wears off all the mucous slimy matter which covers the inside of the guts; and would in time, if not prevented by a change of food, entirely lacerate them. This juice, according to Linnæus, is sometimes made use of to cure ring-worms and such cutaneous eruptions. It must be expelled by the medium of salt-water before the fruit is fit for use. It is remarkable, that the stalk of this plant is herbaceous and hollow; which last attribute has passed into a proverb in Barbadoes and other West India islands, where it is common to characterise a dissembler, by saying, that he is as hollow as a popo.

PAPER, sheets of a thin matter, made of some vegetable substance.

The materials on which mankind have, in different ages, contrived to write their sentiments, have been extremely various; in the early ages they made use of stones, and tablets of wood, wax, ivory, &c. See Book.

Paper, with regard to the manner of making it, and the materials employed therein, is reducible to several kinds; as Egyptian paper, made of the rush papyrus; bark-paper, made of the inner rind of several trees; cotton-paper; incombustible paper; and European paper, made of linen rags.

Egyptian paper was principally used among the ancients; being made of the papyrus, or biblus, a species of rush which grew on the bank of the Nile. In making it into paper, they began with lopping off the two extremes of the plant, the head and the root; the remaining part, which was the stem, they cut lengthwise into two nearly equal parts, and from each of these they stripped the scaly pellicles of which it consisted. The innermost of these pellicles were looked on as the best, and that nearest the rind as the worst: they were therefore kept apart, and made to constitute two different sorts of paper. As the pellicles were taken off, they extended them on a table, laying them over each other transversely, so as that the fibres made right angles: in this state they were glued together by the muddy waters of the Nile; or, when those were not to be had, with paste made of the finest wheat-flour, mixed with hot water and a sprinkling of vinegar. The pellicles were next pressed to get out the water, then dried, and lastly flattened and smoothed by beating them with a mallet: this was the Egyptian paper, which was sometimes farther polished by rubbing it with a glass-ball, or the like.

Bark-paper was only the inner whitish rind, inclosed between the bark and the wood of several trees, as the maple, plane, beech, and elm; but especially the tilia, or linden-tree, which was that mostly used for

this purpose. On this stripped off, flattened, and dried, the ancients wrote books, several of which are said to be still extant.

Chinese paper is of various kinds. Some is made of the rinds or barks of trees, especially the mulberry-tree and elm, but chiefly of the bamboo and cotton-tree. In fact, almost each province has its several paper. The preparations of paper made of the barks of trees, may be inflamed in that of the bamboo, which is a tree of the cane or reed kind. The second skin of the bark, which is soft and white, is ordinarily made use of for paper: this is beat in fair water to a pulp, which they take up in large moulds, so that some sheets are above twelve feet in length; they are completed, by dipping them sheet by sheet in alum-water; which serves instead of the size among us, and not only hinders the paper from imbibing the ink, but makes it look as if varnished over. This paper is white, soft, and close, without the least roughness; though it cracks more easily than European paper, is very subject to be eaten by the worms, and its thinness makes it liable to be soon worn out.

Cotton-paper is a sort of paper which has been in use upwards of 600 years. In the French king's library are manuscripts on this paper, which appear to be of the 10th century; and from the 12th century, cotton manuscripts are more frequent than parchment ones. Cotton-paper is still made in the East Indies, by beating cotton-rags to a pulp.

Linen or European paper appears to have been first introduced among us towards the beginning of the 14th century; but by whom this valuable commodity was invented, is not known. The method of making paper of linen or hempen rags, is as follows: The linen-rags being carried to the mill, are first sorted, then washed very clean in puncheons, whose sides are grated with strong wires, and the bottoms bored full of holes. After this they are fermented, by laying them in heaps close covered with sack, till they sweat and rot, which is commonly done in four or five days. When duly fermented, they are twisted into handfuls, cut small, and thrown into oval mortars, made of well-seasoned oak, about half a yard deep, with an iron-plate at bottom, an inch thick, eight inches broad, and thirty long; in the middle is a washing-block, grooved, with five holes in it, and a piece of hair-sieve fastened on the inside; this keeps the hammers from touching it, and prevents any thing going out except foul water. These mortars are continually supplied with water, by little troughs from a cistern, fed by buckets fixed to the several floats of a great wheel, which raises the wooden hammers for pounding the rags in the mortars. When the rags are beaten to a certain degree, called the *first stuff*, the pulp is removed into boxes, made like corn-chandlers bins, with the bottom-board aslant, and a little separation on the front for the water to drain away. The pulp of the rags being in, they take away as many of the front-boards as are needful, and press the mass hard down with their hands; the next day they put on another board, and add more pulp, till the box is full; and here it remains mellowing a week, more or less, according to the weather. After this, the stuff is again put into clean mortars, and is beaten afresh, and removed into boxes, as before; in which state it is called the

the second stuff. The mafs is beat a third time, till fome of it being mixed with fair water, and brewed to and fro, appears like flour and water, without any lumps in it: it is then fit for the pit-mortar, where it is perfectly diffolved, and is then carried to the vat, to be formed into sheets of paper. But lately, instead of pounding the rags to a pulp with large hammers, as above, they make use of an engine, which performs the work in much less time. This engine consists of a round solid piece of wood, into which are fastened several long pieces of steel, ground very sharp. This is placed in a large trough with the rags, and a sufficient quantity of water. At the bottom of the trough is a plate with steel bars, ground sharp like the former; and the engine being carried round with prodigious velocity, reduces the rags to a pulp in a very short time. It must be observed, that the motion of the engine causes the water in the trough to circulate, and by that means constantly returns the stuff to the engine. The trough is constantly fed with clean water at one end, while the dirty water from the rags is carried off at the other, through a hole, defended with wire gratings, in order to hinder the pulp from going out with the dirty water.

When the stuff is sufficiently prepared as above, it is carried to the vat, and mixed with a proper quantity of water, which they call *priming the vat*. The vat is rightly primed, when the liquor has such a proportion of the pulp, as that the mould, on being dipped into it, will just take up enough to make a sheet of paper of the thickness required. The mould is a kind of sieve exactly of the size of the paper to be made, and about an inch deep, the bottom being formed of fine brass wire, guarded underneath with sticks, to prevent it bagging down, and to keep it horizontal; and further, to strengthen the bottom, there are large wires placed in parallel lines, at equal distances, which form those lines visible in all white paper when held up to the light: the mark of the paper is also made in this bottom, by interweaving a large wire in any particular form. This mould the maker dips into the liquor, and gives it a shake as he takes it out, to clear the water from the pulp. He then slides it along a groove to the coucher, who turns out the sheet upon a felt laid on a plank, and lays another felt on it; and returns the mould to the maker, who by this time has prepared a second sheet in another mould: and thus they proceed, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a *post*; and this they do with such swiftness, that, in many sorts of paper, two men make 20 posts and more in a day. A post of paper being made, either the maker or coucher whistles; on which four or five men advance, one of whom draws it under the press, and the rest press it with great force, till all the water is squeezed from it; after which it is separated sheet by sheet from the felts, and laid regularly one sheet upon another; and having undergone a second pressing, it is hung up to dry. When sufficiently dried, it is taken off the lines, rubbed smooth with the hands, and laid by till sized; which is the next operation. For this they choose a fine temperate day; and having boiled a proper quantity of clean parchment, or vellum-shavings, in water, till it comes to a size, they prepare a fine cloth, on which they strew a due proportion of white vitriol and

roch alum finely powdered, and strain the size through it into a large tub; in which they dip as much paper at once as they can conveniently hold, and with a quick motion give every sheet its share of the size, which must be as hot as the hand can well bear it. After this, the paper is pressed, hung up sheet by sheet to dry; and being taken down is sorted, and what is only fit for outside-quires laid by themselves: it is then told into quires, which are folded and pressed. The broken sheets are commonly put together, and two of the worst quires are placed on the outside of every ream or bundle: and being tied up in wrappers, made of the felling of the vat, it is fit for sale.

Paper is of various kinds, and used for various purposes: with regard to colour, it is principally distinguished into white, blue, and brown; and with regard to its dimensions, into atlas, elephant, imperial, super-royal, royal, medium, demy, crown, fools-cape, and pot-paper.

Mr Guettard of the Royal Academy of Sciences in France has given an account of a number of experiments on materials for making paper; with a view, if possible, to procure this useful substance from such others as are always to be had in greater plenty than rags can be got; of which there is sometimes a considerable scarcity. Mr Reaumur has observed, that wasps have a method of preparing bits of rotten wood whereby they build their nests, in such a manner, that it looks like strong paper or pasteboard. Seba, in the first volume of his *Natural History*, proposes the *algæ marina*. "This country (says he) does not seem to want trees fit for making paper, if people would give themselves the necessary trouble and expence. *Algæ marina*, for example, which is composed of long, strong, viscous filaments, might it not be proper for this purpose, as well as the mats of Muscovy, if they were prepared as the Japanese make their paper? The curious may at least try the experiment." P. du Halde, in the first volume of his *History of China*, pretends, that the Chinese make paper of the second bark of bamboo, of the bark of different trees, particularly the mulberry, of straw, rue, and hemp. Other authors mention its having been made of mallows, and several different kinds of herbs. All Mr Guettard's trials, however, proved unsuccessful, and flax, cotton, hemp, and silk, seem to be the only materials of which it is possible to make this valuable commodity. The reason of these failures was, that the abovementioned substances only seem capable of being reduced to fibres indefinitely fine, and which at the same time preserve a considerable degree of toughness; all others being very coarse in the fibre itself, and soon reducible to their ultimate fineness; and what is worse, the fibres are brittle, so that the paper when made has no cohesion. Our author, however, has found, that paper may be made from flax, hemp, and silk, without the trouble of manufacturing them into cloth; and therefore he recommends the dressings of the two former, which are sometimes in such abundance as to be thrown away; but if we consider the great trouble which must be necessary to bring those materials to a proper colour, and the great diminution of them which must necessarily ensue during the tedious operation, it is not probable that any advantage could be gained in this way.

*Preparation of PAPER for durable writing.* For this purpose Dr Lewis recommends the impregnation of it with astringent materials. "It is observable (says he) that writings first begin to fade or change their colour on the back of the paper, where the larger flocks have sunk in, or are visible through it; as if part of the irony matter of the vitriol was in a more subtle or dissolved state than the rest, and sunk further, on account of its not being fully disengaged from the acid, or sufficiently combined with the astringent matter of the galls. Hence, it should seem probable, that if the paper was impregnated with astringent matter, the colour of the ink would be more durable. To see how far this notion was well founded, I dipped some paper in an infusion of galls; and, when dry, repeated the dipping a second and third time. On the paper thus prepared, and some that was unprepared, I wrote with different inks; several of which, that the effects might be more sensible, had an over-proportion of vitriol. The writings being exposed to the weather till the best of the inks on the unprepared paper had faded and changed their colour, those on the prepared paper were all found to retain their blackness. It is therefore recommended to the consideration of the paper-makers, whether a particular kind of paper might not be prepared for those uses where the long duration of the writing is of principal importance, by impregnating it with galls or other astringents, in some of the operations it passes through before it receives the glazing; as for instance, by using an astringent infusion, instead of common water, in the last operation, when the matter is reduced into a pulp for being formed into sheets. The brownish hue which the paper receives from the galling, would not perhaps be any great obstacle to its use; and, if the proposal should be thought worthy of being carried into execution, further inquiries may possibly discover the means of obviating the imperfection, and communicating astringency without colour.

*Staining or Colouring of PAPER.* The colours proper for paper are not different from those used for other substances, and are enumerated under the article *Colour-Making*. They are applied with soft brushes, after being tempered to a due degree with size or gum water. If the paper on which they are to be laid is soft, so that the colours are apt to go through, it must also be sized before they are laid on, or a proportionably larger quantity must be used along with the colours themselves. If a considerable extent of the paper is to be done over with one colour, it must receive several coatings, as thin as possible, letting each coat dry before another is put on, otherwise the colour will be unequal.

*To gild PAPER.* Take yellow oker, grind it with rain-water, and lay a ground with it upon the paper all over; when dry, take the white of eggs, beat it clear with white sugar-candy, and strike it all over: then lay on the leaf-gold; and, when dry, polish it with a tooth. Some take saffron, boil it in water, and dissolve a little gum with it; then they strike it over the paper, lay on the gold; and, when dry, they polish it.

*To flower PAPER, after the Chinese manner, without silver.* Take two scruples of clear glue made of neat leather, one scruple of white allum, and half a pint

of clear water; simmer the whole over a slow fire, till the water is consumed, or the steam ceases: Then, your sheets of paper being laid on a smooth table, you dip a pretty large pencil into that glue, and daub it over as even as you can, repeating this two or three times: then sift the powder of talc through a fine sieve, made of horse-hair or gauze, over it; and then hang it up to dry; and, when dry, rub off the superfluous talc, which serves again for the same purpose. The talc you prepare in the following manner: Take fine white transparent Muscovy talc; boil it in clear water for four hours; then take it off the fire, and let it stand so for two days: then take it out, wash it well, and put it into a linen-rag, and beat it to pieces with a mallet: to ten pounds of talc add 3 pounds of white allum, and grind them together in a little hand-mill; sift it through a gauze-sieve; and being thus reduced to a powder, put it into water, and just boil it up: then let it sink to the bottom, pour off the water from it, place the powder in the sun to dry, and it will become a hard confluence. This beat in a mortar to an impalpable powder, and keep it, for the use above-mentioned, free from dust.

*PAPER-Hangings*, furniture now greatly used, and generally approved, as it is at once airy and cheap.

The paper manufactured for hangings is of several kinds, some being made in representation of stucco work, for the covering ceilings or the sides of halls, stair-cases, passages, &c. and others in imitation of velvet, damask, brocades, chints, or other such silks and stuffs as are employed for hanging rooms. The principal difference in the manufacture lies, however, in the grounds: some of which are laid in varnish, and others in the common vehicles for water-colours; and in the raising a kind of coloured embossment by chapt cloth, which is called *flock-paper*.

*Unwrought PAPER proper for Hangings.*—The kind of paper employed for making the paper-hangings is a sort of coarse cartoon manufactured for this purpose; and there being a particular duty on paper-hangings, it is required, under considerable penalties, to be stamped before it be painted or otherwise decorated for this purpose. There is no occasion, however, to be more particular in explaining the qualities of this kind of unwrought paper; because it is to be had of all the great dealers in paper, manufactured in a proper manner.

*White and coloured Grounds for PAPER-Hangings.*—The common grounds laid in water are made by mixing whiting with the common gloves size, and laying it on the paper with a proper brush in the most even manner. This is all that is required, where the ground is to be left white; and the paper being then hung on a proper frame, till it be dry, is fit to be painted. When coloured grounds are required, the same method must be pursued, and the ground of whiting first laid; except in pale colours, such as straw-colours or pink, where a second coating may sometimes be spared, by mixing some strong colour with the whiting.

*Manner of painting the PAPER-Hangings.*—There are three methods by which paper-hangings are painted: the first by *printing* on the colours; the second by using the *stencil*; and the third by laying them on with a *pencil*, as in other kinds of painting.

When.

Paper.

Paper.

When the colours are laid on by printing, the impression is made by wooden prints; which are cut in such manner, that the figure to be expressed is made to project from the surface by cutting away all the other part; and this, being charged with the colours tempered with their proper vehicle, by letting it gently down on a block on which the colour is previously spread, conveys it from thence to the ground of the paper, on which it is made to fall more forcibly by means of its weight, and the effort of the arm of the person who uses the print. It is easy to conclude, that there must be as many separate prints as there are colours to be printed. But where there are more than one, great care must be taken, after the first, to let the print fall exactly in the same part of the paper as that which went before; otherwise the figure of the design would be brought into irregularity and confusion. In common paper of low price, it is usual, therefore, to print only the outlines, and lay on the rest of the colours by stencilling; which both saves the expence of cutting more prints, and can be practised by common workmen, not requiring the great care and dexterity necessary to the using several prints.

The manner of *stencilling* the colours is this. The figure, which all the parts of any particular colour make in the design to be painted, is to be cut out, in a piece of thin leather or oil-cloth, which pieces of leather or oil-cloth, are called *stencils*; and being laid flat on the sheets of paper to be printed, spread on a table or floor, are to be rubbed over with the colour, properly tempered, by means of a large brush. The colour passing over the whole is consequently spread on those parts of the paper where the cloth or leather is cut away, and give the same effect as if laid on by a print. This is nevertheless only practicable in parts where there are only detached masses or spots of colours: for where there are small continued lines, or parts that run one into another, it is difficult to preserve the connection or continuity of the parts of the cloth, or to keep the smaller corners close down to the paper; and therefore, in such cases, prints are preferable. Stencilling is indeed a cheaper method of ridding coarse work than printing: but, without such extraordinary attention and trouble as render it equally difficult with printing, it is far less beautiful and exact in the effect. For the outline of the spots of colour want that sharpness and regularity that are given by prints, besides the frequent extralinations, or deviations from the just figure, which happens by the original misplacing of the stencils, or the shifting the place of them during the operation.

*Pencilling* is only used in the case of nicer work, such as the better imitations of the India paper. It is performed in the same manner as other paintings in water or varnish. It is sometimes used only to fill the outlines already formed by printing, where the price of the colour, or the exactness of the manner in which it is required to be laid on, render the stencilling or printing it less proper; at other times, it is used for forming or delineating some parts of the design, where a spirit of freedom and variety, not to be had in printed outlines, are desired to be had in the work.

*Management of the Flock PAPER.*—The paper designed for receiving the flock is first prepared with a varnish-ground with some proper colour, or by that of the

paper itself. It is frequently practised to print some Mosaic, or other small running figure in colours, on the ground, before the flock be laid on; and it may be done with any pigment of the colour desired, tempered with varnish, and laid on by a print cut correspondently to that end.

The method of laying on the flock is this. A wooden print being cut, as is above described, for laying on the colour in such manner, that the part of the design which is intended for the flock may project beyond the rest of the surface, the varnish is put on a block covered with leather or oil-cloth, and the print is to be used also in the same manner, to lay the varnish on all the parts where the flock is to be fixed. The sheet, thus prepared by the varnished impression, is then to be removed to another block or table; and to be strewn over with flock; which is afterwards to be gently compressed by a board, or some other flat body, to make the varnish take the better hold of it: and then the sheet is to be hung on a frame till the varnish be perfectly dry; at which time the superfluous part of flock is to be brushed off by a soft camel's-hair brush; and the proper flock will be found to adhere in a very strong manner.

The method of preparing the flock is, by cutting woollen-rags, or pieces of cloth with the hand, by means of a large bill or chopping knife; or by means of a machine worked by a horse-mill.

There is a kind of counterfeit flock-paper, which, when well managed, has very much the same effect to the eye as the real, though done with less expence. The manner of making this sort is, by laying a ground of varnish on the paper; and having afterwards printed the design of the flock in varnish, in the same manner as for the true; instead of the flock, some pigment, or dry colour, of the same hue with the flock required by the design, but somewhat of a darker shade, being well powdered, is strewn on the printed varnish; and produces nearly the same appearance.

*PAPER-Money*, is a term frequently made use of for bank-bills, which pass currently in trade instead of gold and silver.

Concerning this species of currency, the national utility of which has been controverted by some, we have the following observations in Dr Smith's Treatise on the Wealth of Nations: "The substitution of paper in the room of gold and silver money replaces a very expensive instrument of commerce with one much less costly, and sometimes equally convenient. Circulation comes to be carried on by a new wheel, which it costs less both to erect and maintain than the old one.

"When the people of any particular country have such confidence in the fortune, probity, and prudence of a particular banker, as to believe that he is always ready to pay upon demand such of his promissory notes as are likely at any time to be presented to him, those notes come to have the same currency as gold and silver money, from the confidence that such money can at any time be had for them.

"A particular banker lends among his customers his own promissory notes, to the amount, we shall suppose, of 100,000 l. As those notes serve all the purposes of money, his debtors pay him the same interest as if he had lent them so much money. This interest is the source of his gain. Though some of those notes

are:

Paper.

are continually coming back upon him for payment, part of them continue to circulate for months and years together. Though he has generally in circulation, therefore, notes to the amount of 100,000 l. 20,000 l. in gold and silver may frequently be a sufficient provision for answering occasional demands. By this operation, therefore, 20,000 l. in gold and silver perform all the functions which 100,000 l. could otherwise have performed. Eighty thousand pounds of gold and silver can therefore, in this manner, be spared from the circulation of the country; and if different operations of the same kind should, at the same time, be carried on by many different banks and bankers, the whole circulation may be thus conducted with a fifth part only of the gold and silver.

"Let us suppose, for example, that the whole circulating money of some particular country amounted, at a particular time, to 1,000,000 sterling, that sum being then sufficient for circulating the whole annual produce of their land and labour. Let us suppose too, that, some time thereafter, different banks and bankers issued promissory notes, payable to the bearer, to the extent of 1,000,000, reserving in their different coffers 200,000 l. for answering occasional demands. There would remain, therefore, in circulation 800,000 l. in gold and silver, and 1,000,000 of bank-notes, or 1,800,000 l. of paper and money together. But the annual produce of the land and labour of the country had before required only 1,000,000 to circulate and distribute it to its proper consumers, and that annual produce cannot be immediately augmented by those operations of banking. One million, therefore, will be sufficient to circulate it after them. The goods to be bought and sold being precisely the same as before, the same quantity of money will be sufficient for buying and selling them. The channel of circulation, if I may be allowed such an expression, will remain precisely the same as before. One million we have supposed sufficient to fill that channel. Whatever, therefore, is poured into it beyond this sum, cannot run in it, but must overflow. One million eight hundred thousand pounds are poured into it. Eight hundred thousand pounds, therefore, must overflow, that sum being over and above what can be employed in the circulation of the country. But though this sum cannot be employed at home, it is too valuable to be allowed to lie idle. It will therefore be sent abroad, in order to seek that profitable employment which it cannot find at home. But the paper cannot go abroad; because, at a distance from the banks which issue it, and from the country in which payment of it can be exacted by law, it will not be received in common payments. Gold and silver, therefore, to the amount of 800,000 l. will be sent abroad, and the channel of home circulation will remain filled with 1,000,000 of paper, instead of 1,000,000 of those metals which filled it before.

"But though so great a quantity of gold and silver is thus sent abroad, we must not imagine that it is sent abroad for nothing, or that its proprietors make a present of it to foreign nations. They will exchange it for foreign goods of some kind or another, in order to supply the consumption either of some other foreign country or of their own.

"If they employ it in purchasing goods in one fo-

reign country in order to supply the consumption of another, or in what is called the *carrying trade*, whatever profit they make will be an addition to the neat revenue of their own country. It is like a new fund, created for carrying on a new trade; domestic business being now transferred by paper, and the gold and silver being converted into a fund for this new trade.

"If they employ it in purchasing foreign goods for home-consumption, they may either first purchase such goods as are likely to be consumed by idle people who produce nothing, such as foreign wines, foreign silks, &c.; or, secondly, they may purchase an additional stock of materials, tools, and provisions, in order to employ an additional number of industrious people, who re-produce, with a profit, the value of their annual consumption.

"So far as it is employed in the first way, it promotes prodigality, increases expence and consumption, without increasing production, or establishing any permanent fund for supporting that expence, and is in every respect hurtful to the society.

"So far as it is employed in the second way, it promotes industry; and though it increases the consumption of the society, it provides a permanent fund for supporting that consumption, the people who consume, re-producing, with a profit, the whole value of their annual consumption. The gross revenue of the society, the annual produce of their land and labour, is increased by the whole value which the labour of those workmen adds to the materials upon which they are employed; and their neat revenue by what remains of this value, after deducting what is necessary for supporting the tools and instruments of their trade.
